Introdução/Fundamentos: Cardiac amyloidosis (CA) is an infiltrative cardiomyopathy caused by a deficiency of misfolded amyloid proteins in the myocardium, resulting in diastolic dysfunction, arrhythmias, and heart failure. While AI-enhanced echocardiography offers transformative potential for early detection, the existing literature is characterized by significant methodological heterogeneity and fragmented evidence. Objetivos: To perform a systematic review and diagnostic meta-analysis evaluating AI-enhanced echocardiography performance in CA detection, and an epistemic synthesis to characterize methodological patterns and propose a standardized framework for robust model development. Métodos: A systematic review and meta-analysis were conducted following PRISMA guidelines. PubMed, Web of Science, and Embase were searched (Feb/2026) for AI models in echocardiographic CA detection. Meta-analysis was performed in R using a general inverse variance random-effects model to pool AUC (area under the receiver operating characteristic curve) , sensitivity, specificity, and DOR (diagnostic odds ratio) with 95% CIs. Prespecified subgroup analyses included clinical context, AI architecture, and amyloid subtype. An integrative epistemic meta-analysis characterized methodological patterns across predefined domains—clinical intent, input data (radiomics vs. raw images), and validation strategies (internal vs. external)—to identify drivers of performance beyond quantitative synthesis. Resultados e Conclusões: A total of 15 studies (2018–2026) were included in the final synthesis. AI-enhanced models demonstrated high overall diagnostic accuracy for CA with a pooled AUC of 0.907 (95% CI 0.879–0.935) and a DOR of 105.75. Subgroup analyses revealed superior performance in screening/detection scenarios (AUC 0.978) compared to differential diagnosis (AUC 0.882). No significant differences were found between deep learning (AUC 0.914) and machine learning (AUC 0.901, p=0.65), or between echocardiography-only and multimodal models (p=0.50). Epistemic analysis showed that performance was primarily driven by input data representation: deep learning models using raw images/videos consistently outperformed those based on structured parameters (AUC 0.90 vs. 0.80–0.85). External validation emerged as a critical but inconsistently applied factor for generalizability. AI models for echocardiography show excellent performance for CA. Standardization and prospective validation are necessary for their integration into clinical practice.

Introdução/Fundamentos: Heart Failure (HF) is a prevalent condition associated with high morbidity and mortality, requiring accurate and accessible patient education. Artificial Intelligence Models (AIMs) are increasingly used as sources of health information; however, concerns remain regarding the quality, transparency, and readability of their outputs. Evaluating these aspects is essential to determine their reliability for disseminating HF information. Objetivos: To compare the quality, transparency, and readability of HF related information generated by AIMs. Métodos: This observational cross-sectional study evaluated responses from 11 free AIMs (ChatGPT 5.1T, ChatGPT 5.1I, ChatGPT 5.2T, ChatGPT 5.2I, ChatGPT 5.2A, ChatGPT 4.1, Gemini 3 Pro, Gemini Rapid, Gemini Reasoning, Perplexity, and Copilot) to 30 HF related questions. Quality, transparency, and readability were assessed using the DISCERN instrument, JAMA criteria, and ALT software, respectively. Two blinded reviewers performed the evaluations, with inter-rater reliability assessed by ICC. Descriptive statistics, repeated-measures ANOVA (ω^2), Friedman test (Kendall's W), post hoc pairwise comparisons, and Spearman's correlation (ρ) were applied, with $p < 0.05$ considered statistically significant. The questions were adapted from a previously published study. Resultados e Conclusões: A total of 330 responses were analyzed. ChatGPT 5.2T achieved the highest DISCERN mean score, 45.47 (± 6.46), followed by Gemini 3 Pro, 44.40 (± 6.31), and Perplexity, 41.33 (± 5.35), while Copilot showed the lowest performance, 15.50 (± 8.80). Differences among AIMs were significant (repeated-measures ANOVA and Friedman test, $p < 0.001$; Kendall's W = 0.60). For the JAMA criteria, the highest scores were observed for Gemini 3 Pro, 1.30 (± 0.47), and ChatGPT 5.2T, 1.27 (± 0.45), while Copilot presented the lowest value, 1.10 (± 0.31) ($p < 0.001$). ALT readability scores were similar across AIMs, ranging from 23.50 (± 3.88) for Copilot to 24.20 (± 4.10) for Gemini 3 Pro, with no significant differences ($p > 0.05$). Significant positive correlations between DISCERN and readability were identified, with Spearman's ρ ranging from 0.51 to 0.60 (all $p < 0.001$). AIMs showed significant variability in the quality of HF related information, with low adherence to transparency criteria and similar readability across systems. These findings underscore the need for cautious use of AI in disseminating information.

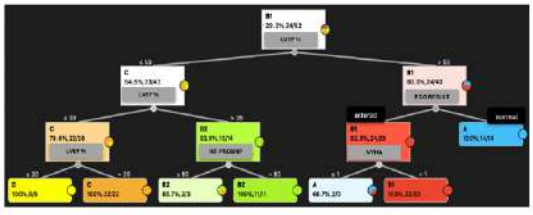
DEVELOPMENT AND EVALUATION OF A MACHINE LEARNING MODEL FOR CLASSIFICATION OF THE EVOLUTIONARY STAGES OF CHRONIC CHAGAS DISEASE

MAYRA DOMINGUES CARDOSO1; ANA JULIA TORRES BONFIM ROCHA1; JENIFFER EDUARDA FIRMINO ALMEIDA SILVA1; DÉBORA NATÁLIA MENEZES ALMEIDA1; MATHAUS HENRIQUE REIS SILVA1; MARIA CECÍLIA MARQUES DA SILVA1; DANIELLE FERNANDA SANTOS SERPA1; LEIDE DAIANA SILVEIRA CARDOSO2; LUCIANO FREITAS FERNANDES2; ARIELA MOTA FERREIRA1; RENATO SOBRAL MONTEIRO-JUNIOR3; DESIRÉE SANT'ANA HAIKAL1;

(1) UNIVERSIDADE ESTADUAL DE MONTES CLAROS - MONTES CLAROS - MG - BRASIL; (2) IRMANDADE NOSSA SENHORA DAS MERCÊS- HOSPITAL SANTA CASA DE MONTES CLAROS, MONTES CLAROS, MINAS GERAIS, BRASIL - MONTES CLAROS - MG - BRASIL; (3) CENTRO DE PESQUISA EM SAÚDE DA SANTA CASA MONTES CLAROS, MONTES CLAROS, MG, BRASIL. - MONTES CLAROS - MG - BRASIL;



Introdução/Fundamentos: Chronic Chagasic cardiomyopathy (CCC), resulting from Chagas disease (CD), develops in approximately 30% to 40% of infected individuals and may lead to cardiac arrhythmias, dilated cardiomyopathy, and heart failure (Marin-Neto et al., 2002). The new guideline from the Brazilian Society of Cardiology (BSC) describes the classification of chronic CD into evolutionary stages: A (indeterminate form, without cardiac damage), B1 and B2 (structural cardiac damage with or without impaired ventricular function), and C and D (severe heart failure with worsening ventricular dysfunction) (Marin-Neto et al., 2023). In this context, machine learning emerges as a promising strategy to support the classification of such a neglected disease. Objetivos: This study aimed to develop and evaluate machine learning models for classifying the evolutionary stages of chronic CD. Métodos: This is an observational, analytical study based on a database of 116 patients treated at a specialized outpatient clinic in northern Minas Gerais, Brazil. Preprocessing included the selection of clinically relevant variables and random imputation of missing data. The target variable was classification into stages A, B1, B2, C, and D. Resultados e Conclusões: Three supervised algorithms were applied (kNN, Random Forest, and Decision Tree), with 20-fold cross-validation. Among the tested algorithms, the Decision Tree showed the best performance (AUC = 0.967; accuracy = 0.915; sensitivity = 0.915; specificity = 0.974) (Table 1). The confusion matrix demonstrated high agreement between predicted and actual values, with accuracy above 90% in most classes and 100% in class D (Table 2) The Decision Tree showed high interpretability, allowing patient classification based on a reduced set of clinical variables, such as ejection fraction, electrocardiographic changes, functional class (NYHA), and NT-proBNP levels. These variables were hierarchically organized, reflecting the progression of cardiac dysfunction and enabling differentiation among stages (Figure 3). Thus, the model demonstrated the ability to reproduce, in a structured manner, the clinical reasoning used in practice for this classification. As a neglected disease, this model shows potential to simplify stage classification even in the absence of specialized tests, contributing to a more accessible approach.

Table 1: Performance Metrics of the Algorithms

Model	AUC	CA	F1	PREC	RECALL	MCC	SPEC
kNN	0.679	0.512	0.493	0.485	0.512	0.352	0.836
Constant	0.173	0.134	0.086	0.064	0.134	-0.263	0.650
Random Forest	0.970	0.793	0.772	0.794	0.793	0.731	0.930
Tree	0.967	0.915	0.915	0.918	0.915	0.889	0.974

DIAGNOSTIC ACCURACY OF ARTIFICIAL INTELLIGENCE FOR ARRHYTHMIA DETECTION USING THE 12-LEAD ELECTROCARDIOGRAM: A SYSTEMATIC REVIEW AND META-ANALYSIS

LUIZ FILIPE TORRES DE ALENCAR1; MARINA DE ANDRADE NORÕES BEZERRA1; GABRIEL FONTENELE XIMENES1; LEONARDO BRITO DE SOUZA1; PEDRO JORGE PIRES VIANA1; NICOLE AIRES PERAZOLO1; JOÃO PEDRO TEIXEIRA BENTES MONTEIRO1; MATEUS PAIVA MARQUES FEITOSA1; JEFFERSON LUÍS VIEIRA2; SHAAN KHURSHID3;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (2) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL; (3) MASSACHUSETTS GENERAL HOSPITAL - UNITED STATES;

Introdução/Fundamentos: Artificial intelligence (AI) has emerged as a promising tool for interpreting 12-lead electrocardiograms (ECGs), with the potential to enhance diagnostic accuracy for arrhythmia detection. However, published studies vary widely in methodology and validation strategy, warranting a quantitative synthesis of diagnostic performance. Objetivos: To synthesize the diagnostic test characteristics of AI for 12-lead ECG arrhythmia analysis. Métodos: A systematic review and meta-analysis were conducted in accordance with the PRISMA-DTA 2018 guidelines and registered in PROSPERO (CRD420251027264). Searches were performed in MEDLINE, Embase, and Cochrane Library through September 2025 without language restrictions. Studies evaluating AI algorithms for arrhythmia detection using 12-lead ECGs were included. Data on sensitivity, specificity, and area under the curve (AUC) were extracted. Pooled estimates were generated using a bivariate random-effects model. Risk of bias was assessed with QUADAS-2, and the certainty of evidence was quantified using GRADE. Resultados e Conclusões: 20 studies were included in the meta-analysis, encompassing over 5.5 million ECGs. The pooled sensitivity, specificity, and AUC for AI-based arrhythmia detectionwere 94.0% (95% CI 90.8–96.2; I² = 96.9%), 98.7% (95% CI 97.3–99.3; I² = 98.3%), and 0.982 (95% CI 0.965–0.986), respectively. Detection of atrial fibrillation (AF) yielded a sensitivity of 92.6% (95% CI 86.4–96), a specificity of 99.1% (95% CI 98.4–99.5), and an AUC of 0.988. Convolutional neural networks (CNNs) demonstrated a sensitivity of 97.6%, a specificity of 98.7%, and an AUC of 0.982 for overall arrhythmia detection. When limited to external validation (n=6), the sensitivity was 96.9% (95% CI89.2–99.1), specificity was 95.6% (95% CI 77.6–99.3), and AUC was 0.983. No significant publication bias was detected, and the overall certainty of evidence was rated as high. In our meta-analysis, we concluded that AI models applied to 12-lead ECGs demonstrate excellent diagnostic performance for arrhythmia detection. Findings support potential integration into clinical workflows, particularly in settings with limited cardiology expertise. Given substantial heterogeneity, standardized datasets and multicenter prospective validation are essential to ensure effective and equitable implementation.

Introdução/Fundamentos: The management of patients with functional mitral regurgitation (MR) and atrial fibrillation (AF) involves rate or rhythm control strategies, whose indication depends on clinical and cardiac structural characteristics. However, the superiority of machine learning–based predictive models over logistic regression in this population has not yet been established. Objetivos: To compare the performance of a Random Forest model with multivariate logistic regression in predicting rhythm control in patients with functional MR and AF. Métodos: Cross-sectional study including 117 patients with functional MR. The primary outcome was the adoption of a rhythm control strategy (cardioversion or catheter ablation) within 24 months. Continuous variables were compared using the Mann–Whitney test, and categorical variables using Fisher's exact test. A Random Forest model was developed with recursive feature elimination, stratified 5-fold cross-validation, and a 70/30 train–test split. A multivariate logistic regression model was also built for comparison. Discriminative ability was assessed by AUCs and compared using the DeLong test. Resultados e Conclusões: Patients undergoing intervention had lower left atrial volume (52 [49.8–61.2] vs 64 [51–73]; p = 0.03) and higher ejection fraction (50% [35–62] vs 35% [27–56]; p = 0.05) compared to the rate control group. The final Random Forest model, with seven variables, achieved an AUC of 0.926. In the test set, it maintained high performance, with an AUC of 0.925 (95% CI: 0.832–1.000), accuracy of 91.2%, sensitivity of 91.7%, and specificity of 90.0%. The main predictors were presence of AF, heart rate, left atrial volume, and TAPSE. The multivariate logistic regression model showed an AUC of 0.896 (95% CI: 0.782–1.000), sensitivity of 70.0%, specificity of 91.7%, and accuracy of 88.0%. In logistic regression, neoplasm (p = 0.0428) and anticoagulant use (p = 0.0191) were associated with the outcome. Comparison of ROC curves using the DeLong test showed no difference between models (Z = -0.52; p = 0.60). Random Forest and logistic regression showed similar discriminative performance in predicting rhythm control in patients with functional mitral regurgitation.

19094

EVALUATION OF THE QUALITY AND READABILITY OF ECHOCARDIOGRAPHY INFORMATION PROVIDED BY GENERATIVE ARTIFICIAL INTELLIGENCE MODELS: A CROSS-SECTIONAL COMPARATIVE STUDY

ANA BEATRIZ BOMFIM DE ALMEIDA1; MARINA DE OLIVEIRA SOUSA1; FREDERICO AUGUSTO TRAVI SQUIZZATO1; FELIPE PIMENTEL RODRIGUES DA SILVA1; LUIZ GUSTAVO ALBUQUERQUE MELLO DE OLIVEIRA1; ALEXANDRE SILVA MAIA1; HELOÍSA BULHÕES OLIVEIRA1; JOÃO PEDRO MOURA DE FREITAS1; LARISSA SOUSA DA SILVA1; SOFIA FREITAS DIAS1; GABRIEL SCHNITMAN1; ANDRÉ GUSMÃO CUNHA1;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Echocardiographic complexities prompt users to seek clarification via artificial intelligence models (AIMs). Despite rapid access, establishing their clinical reliability is essential for informed decision making and patient safety. Objetivos: To evaluate and compare the quality and readability of echocardiography-related information provided by different AIMs. Métodos: This observational cross-sectional study assessed responses from free AIMs (ChatGPT 5.1, ChatGPT 5.2, Gemini 3 Fast, Gemini 3 Pro, Gemini Reasoning, and Perplexity) to 30 echocardiography-related questions. Responses were obtained in independent sessions, considering only the first output without reprompting. Quality was evaluated using the DISCERN instrument and JAMA criteria, while readability was assessed using ALT software. Two independent, blinded reviewers performed the evaluations. Descriptive analyses (mean and standard deviation) were conducted, adopting $p < 0.05$. Questions were adapted from a previously published study. Resultados e Conclusões: A total of 180 responses were analyzed. Perplexity achieved the highest DISCERN mean score, 38.47 (± 3.10), followed by ChatGPT 5.1, 38.27 (± 2.57), Gemini Reasoning, 37.17 (± 4.25), and Gemini 3 Pro, 37.10 (± 3.99). Gemini 3 Fast had a mean of 36.27 (± 3.99), while the lowest performance was observed for ChatGPT 5.2, 34.97 (± 3.22). Minimum values ranged from 33 to 35, and maximum values from 43 to 52. The Shapiro–Wilk test indicated partial violation of normality ($p < 0.05$). There was a statistically significant difference among models (repeated measures ANOVA, $p < 0.001$), confirmed by nonparametric analysis ($p < 0.001$), with moderate agreement among rankings (Kendall's W = 0.351). In the JAMA criteria, adherence was low, with mean scores near zero; Perplexity showed the highest score, 1.03 (± 0.18), with significant differences among models ($p < 0.001$). Regarding readability (ALT), mean scores ranged from 23.50 (± 3.88) to 24.07 (± 3.37), with no significant difference ($p = 0.79$). A moderate correlation between quality and readability was observed ($\rho = 0.525$), with high inter-rater agreement (ICC = 0.89). Models showed differences in the quality of echocardiography-related information, with consistent ranking and good reproducibility. These findings highlight the need for cautious use of AI models as sources of health information.

INCREASING ACCESS TO THROMBOLYTIC TREATMENT FOR ST-ELEVATION MYOCARDIAL INFARCTION USING THE LOCATION-ALLOCATION MODEL IN A LOW-INCOME STATE IN BRAZIL

FERNANDO LUCAS GOMES MOTA LIMA1; ROMULLO JOSÉ COSTA ATAIDES2; TIAGO CORDEIRO MEDEIROS1; JOÃO PAULO NASCIMENTO MIRANDA3; GUILHERME ARAUJO RAYOL1; LUCIANA ALBUQUERQUE DE OLIVEIRA4; MARCOS ADRIANO GARCIA CAMPOS1;

(1) UNIVERSIDADE FEDERAL DO MARANHAO - SÃO LUIS - MA - BRASIL; (2) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (3) UNICAMP - CAMPINAS - MT - BRASIL; (4) UFMA - CAMPUS SAO LUIS - SÃO LUÍS - MA - BRASIL;

Introdução/Fundamentos: Around 400,000 people die annually from cardiovascular diseases in Brazil. The state of Maranhao, which has an area of similar size to Italy, has one of the highest mortality from ST-elevation myocardial infarction (STEMI). Only the state capital offers percutaneous coronary intervention, and no other city has a thrombolysis protocol, leaving 7 million people without assistance. Objetivos: We propose a strategic model to allocate STEMI thrombolysis services in high-demand areas of Maranhao state. Métodos: Ecological study using the LAM and the following parameters: population density and distribution (demand), location of health facilities (supply), and transportation network (mobility). The demand was estimated by dasymetric gridding from WorldPop, corresponding to 5,072,506 people in Maranhao. The supply points corresponded to the coordinates of the emergency public hospitals that are candidates to implement thrombolysis services, totaling 362 services across the state. The mobility was set with the roads available on OpenStreetMap. We used ArcGIS Pro 2.9 with the Maximize Attendance algorithm to set a 30-minute cutoff time for demand to reach the facilities using the mobility network. The optimal number of chosen facilities was defined as the plateau point at which additional facilities yield no significant increase in population coverage. Resultados e Conclusões: The plateau point was 45 health facilities allocated in the regions of Maranhao with the highest population demand. Together, these hospitals could cover 94.56% of the population (about 4.8 million people) to perform thrombolysis in 30 minutes in the case of STEMI. We used the Location-Allocation Model (LAM) as an automated tool to decide the best allocation of resources and optimize the distribution of thrombolysis services for STEMI in a low-resource region with the highest mortality rate from cardiovascular diseases in Brazil. This project can support future evidence that aims to reduce the time to access treatment for cardiovascular diseases in low- and middle-income countries, where choosing the best health facilities is based on population demand using open-source data to perform the analyses. This automated, low-cost approach indicates that more strategic hospitals in low-resource settings are needed to improve timely access to acute care for STEMI, decentralize acute treatment for STEMI, and reduce cardiovascular disease mortality.

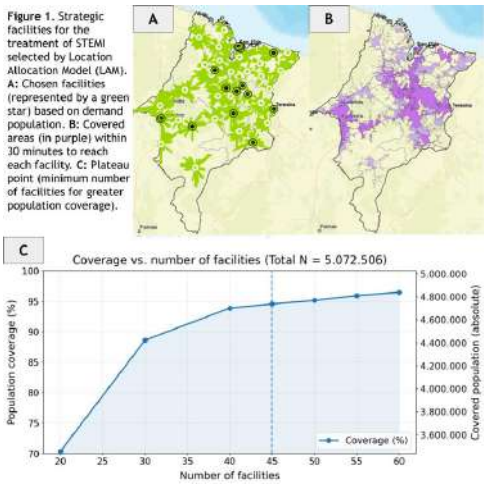

Figure 1. Strategic facilities for the treatment of STEMI selected by Location Allocation Model (LAM). **A:** Chosen facilities (represented by a green star) based on demand population. **B:** Covered areas (in purple) within 30 minutes to reach each facility. **C:** Plateau point (minimum number of facilities for greater population coverage).

INTERPRETABLE DEEP LEARNING PREDICTS MORTALITY FOLLOWING ACUTE MYOCARDIAL INFARCTION USIGN SINGLE TIME-POINT ECG

RICCARDO CAVARRA1; SHAHEIM OGBOMO-HARMITT1; SHAHID AZIZ2; ADELAIDE DE VECCHI1; ANDREW KING1; OLEG ASLANIDI1;

(1) KING'S COLLEGE LONDON - UNITED KINGDOM; (2) NORTH BRISTOL NHS TRUST - UNITED KINGDOM;

Introdução/Fundamentos: Acute myocardial infarction (AMI) is a leading cause of death and long-term morbidity, affecting the quality of life of millions of people. Despite reperfusion therapy, AMI remains associated with a one-year mortality rate of around 10%. Early identification of high-risk individuals is therefore essential to support timely intervention and management. Comorbidity-based models such as the GRACE risk score can be used to predict in-hospital mortality, but their performance in predicting long-term outcomes after AMI remains suboptimal. Integrating ECG data with deep learning, which has already shown strong performance in other cardiology applications, may improve mortality risk assessment in AMI. Objetivos: This study applies interpretable deep learning to predict mortality in AMI patients from the MIMIC-IV database using single time-point 12-lead ECG data, and to identify ECG biomarkers associated with mortality. Métodos: Twelve-lead ECG data from 8,499 AMI patients were extracted from the MIMIC-IV database. Among these patients, 3,097 died during follow-up. Single time-point ECGs recorded during the first hospitalisation were used to train a convolutional neural network (CNN) to predict all-cause mortality at different time points following AMI. The CNN model was validated using the area under the receiver operating characteristic curve (AUC) on unseen data using cross-validation, and Grad-CAM was used to highlight the ECG regions that contributed most strongly to the model's predictions. Resultados e Conclusões: The CNN accurately predicted in-hospital mortality in patients from the unseen set (AUC 0.92). The same model also predicted one-year (AUC 0.86) and long-term (AUC 0.80) all-cause mortality following AMI. Qualitative Grad-CAM results (Figure 1) showed that the ST segment and T wave, which are associated with AMI, were the most influential predictors of mortality after AMI. Thus, this study highlights the potential of deep learning to predict mortality in AMI patients using single time-point ECG data. Interpretable ECG features provide valuable insight into post-AMI risk and should therefore be considered in patient stratification.

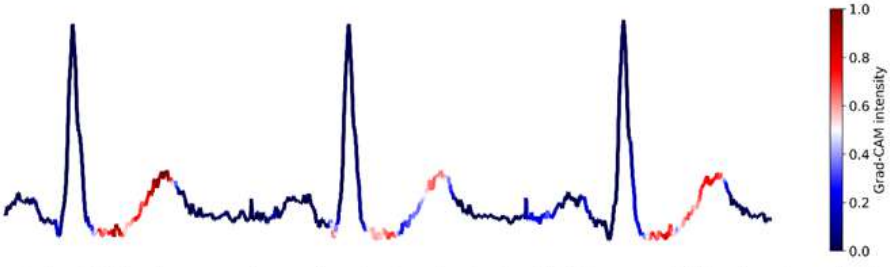

Figure 1: Grad-CAM saliency map of a sample patient overlayed on lead II ECG segment. ECG regions shown in red contributed most strongly to the model's predictions.

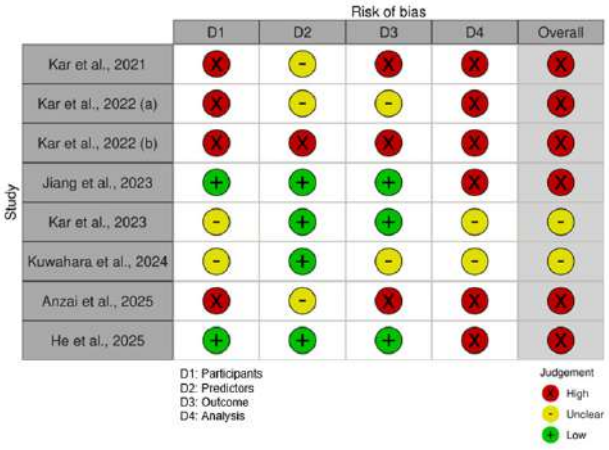
MACHINE LEARNING AND THE PREDICTION OF ARRHYTHMOGENIC RIGHT VENTRICULAR CARDIOMYOPATHY: A SYSTEMATIC REVIEW.

LUIZA HELENA CARDOSO PLATILHA1; LUCAS SILVA CABEÇA1; MARIANA BRAGA ALMEIDA1; JEFFERSON PEREIRA CORRÊA1; LOUI DE OLIVEIRA NERY1; LISIO EDUARDO FERREIRA HERMES1; ROBERTO ALVES BRAGA NETO1; MARIA EDUARDA AMARAL FIDALGO1; VICTOR ENJI OSHIKIRI1; BRUNA GIOVANNA BASTOS AGUIAR1; THIAGO DA SILVA PAULO2; ROBERTO MÁRCIO DE OLIVEIRA JÚNIOR1;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (2) FUNDACAO HOSPITAL DE CLINICAS GASPAR VIANNA PA - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Arrhythmogenic Right Ventricular Cardiomyopathy is a genetic cardiomyopathy marked by fibrofatty myocardial changes and high arrhythmic risk. To overcome challenging, expert-dependent diagnostics, machine learning models are increasingly utilized to streamline ARVC detection and risk stratification Objetivos: To systematically evaluate the eficacy, diagnostic accuracy, and clinical utility of machine learning and transfer learning algorithms in the prediction and risk stratification of patients with ARVC. Métodos: A systematic review and meta-analysis was conducted in accordance with the PRISMA guidelines and registered in PROSPERO (CRD420261368429). The databases searched included Embase (136 results), Scopus (36 results), PubMed (16 results), and Web of Science (8 results), using search terms such as “Arrhythmogenic Right Ventricular Dysplasia,” “Arrhythmogenic Right Ventricular Cardiomyopathy,” “Machine Learning,” and “Transfer Learning.” Studies evaluating ML models for ARVC prediction and reporting outcomes on diagnostic accuracy, area under the curve (AUC), and arrhythmic risk were included. Heterogeneity was assessed using the I^2 statistic, and a random-efects model was applied to pool the performance metrics. Following the screening process, 6 studies were selected for the systematic review and meta-analysis. Resultados e Conclusões: We analyzed 6 studies on ARVC using ML algorithms like Random Survival Forests, Gradient Boosted Trees, and Neural Networks. ML models showed high diagnostic performance with a pooled Area Under the Cover (AUC) of 0.92 (95% CI 0.88–0.95; p<0.0001). Compared to traditional diagnostic pathways and clinical scoring, ML models yielded a higher pooled sensitivity of 0.86 (95% CI 0.81–0.90; p<0.01) and specificity of 0.89 (95% CI 0.84–0.93; p<0.01). For risk stratification, ML techniques utilizing multimodal data (ECG, clinical history, and cardiovascular radiomics) significantly improved the prediction of malignant ventricular arrhythmias and all-cause mortality (HR 2.45; 95% CI 1.80–3.34; p<0.001) over standard clinical risk scores alone. These findings suggest that machine learning provides a highly accurate, scalable, and standardized approach for the early prediction and risk stratification of ARVC. Ensemble methods and deep learning models efectively integrate complex multimodal data, reducing reliance on subjective expert interpretation and supporting targeted clinical decision-making.



17675

MACHINE LEARNING IN MYOCARDIAL STRAIN ANALYSIS FOR EARLY DETECTION OF CARDIOTOXICITY IN ONCOLOGICAL PATIENTS: A SYSTEMATIC REVIEW

ANDRÉ CARVALHO1; KEVENI HAGATA PINHO LEAL2; SOPHIA GOUVEIA DAMASCENO2; SOFIA MENEZES ALVES1; PRISCILA SABINO DOS SANTOS1; FLÁVIA SOEIRO SALGADO1; GIORDANA TEIXEIRA DA SILVA PROFETI3; ISABELA DE CASTRO FROTA LIMA1; EDSON GABRIEL SANTOS NASCIMENTO1; LETHYCIA SANTANA DE ARAÚJO CASTRO2; GIOVANNA BARCELOS FONTENELE PEREIRA3;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (3) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Advancements in cancer treatment have increased cure rates significantly. Although chemotherapy plays a fundamental role in disease remission, its administration leads to side effects, including cardiotoxicity. In this scenario, the use of Artificial Intelligence (AI) through Machine Learning (ML) proves to be a game-changer in the rapid detection of patterns in imaging exams to predict the risk of specific complications early on. Objetivos: To evaluate the efficacy of ML models applied to myocardial strain analysis for the early detection of cardiotoxicity in oncological patients, comparing their diagnostic performance with conventional methods (LVEF, conventional echocardiography, and clinical assessment). Métodos: A systematic review was conducted in accordance with the PRISMA guidelines across the PubMed, Virtual Health Library, and Web of Science databases, encompassing original studies published between 2021 and 2026. Utilizing the PECO strategy, the search focused on Machine Learning (ML) and myocardial deformation in humans undergoing antineoplastic therapy. Observational studies were included and identified through independent screening, followed by a risk of bias assessment via the PROBAST tool. Analyzed outcomes included sensitivity, specificity, and AUC for the prediction of ventricular dysfunction. Resultados e Conclusões: From an initial total of 443 references, 8 original studies were included in the final analysis. Automated models demonstrated high accuracy (up to 97%) and strong correlation with reference methods (p(rho): 0.74; p-value <0.01). AI outperformed manual analysis in inter-observer reproducibility (0.82 vs. 0.68), mitigating the technical variability inherent to the method. In prospective analyses, Global Longitudinal Strain (GLS) via Cardiac Magnetic Resonance established itself as an independent predictor of cardiotoxicity (HR=2.0; p=0.01), allowing the identification of subclinical reductions weeks before the drop in Left Ventricular Ejection Fraction. However, the PROBAST tool indicated that some studies carry a high risk of bias in Statistical Analysis (D4) due to the lack of external validation and small sample sizes, suggesting potential overfitting. It is concluded that ML applied to GLS is effective and reproducible for early cardiotoxicity detection, surpassing conventional methods. Prospective, multicentric studies are required to validate the generalizability of these algorithms before their integration into cardio-oncology monitoring protocols.

19843

MACHINE LEARNING PREDICTION OF EARLY MORTALITY AFTER ACUTE MYOCARDIAL INFARCTION: AN ECOLOGICAL STUDY FROM THE SOUTHERN REGION OF BRAZIL

FELIPE YUJI SASAZAKI1; GABRIEL CARUSO NOVAES TUDELLA1; ISABELLA KELNHAR1; DIEGO CHEMELLO1; JULIANA DA ROSA WENDT1; DANIEL OLIVEIRA QUEIROZ1; DANIEL OLIVEIRA QUEIROZ1;

(1) UNIVERSIDADE FEDERAL DE SANTA MARIA - SANTA MARIA - RS - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases remain the leading cause of death in Brazil, with acute myocardial infarction (AMI) standing out prominently. Recent evidence indicates an increase in the occurrence of AMI among younger age groups, resulting in a rise in premature mortality. In this context, the application of machine learning techniques to large population-based datasets enables the identification of patterns associated with early mortality, despite the limited literature on this topic. Objetivos: To develop and evaluate machine learning models for predicting early mortality due to AMI in Rio Grande do Sul. Métodos: This retrospective ecological study used secondary data from the Mortality Information System (SIM/DATASUS) from 2014 to 2024. Deaths due to AMI (ICD-10 I21/I22) were included. Early mortality was defined by sex-specific thresholds (<55 years for men, <65 for women). Sociodemographic and healthcare variables were analyzed, excluding chronological age. Data were split into training and testing sets. Supervised learning models (Random Forest, Gradient Boosting Machine, and Naive Bayes) were evaluated using AUC, sensitivity, and specificity. Resultados e Conclusões: The best performance was achieved by the GBM model, with an AUC of 0.837. After adjusting the cutoff point, the model showed an accuracy of 71.6%, sensitivity of 82.6%, and specificity of 71.0%, indicating a good balance between detecting early cases and correctly classifying non-early cases. Variable analysis demonstrated that healthcare-related and sociodemographic factors had the greatest impact on prediction. The main predictors were lack of medical assistance, occurrence of death outside the hospital setting, and lower educational level. These findings suggest that early mortality from AMI is associated with inequalities in access to and quality of healthcare. In conclusion, machine learning models showed adequate performance in predicting early mortality due to AMI, despite limitations from the restricted number of variables. Additionally, educational level does not directly influence premature deaths but reflects associated lifestyle factors. This approach may help identify vulnerable groups and guide public health policies for cardiovascular prevention, although limitations remain.

REGULATORY FRAMEWORKS, GOVERNANCE, AND CLINICAL INTEGRATION STRATEGIES FOR CARDIOVASCULAR ARTIFICIAL INTELLIGENCE AND WEARABLE TECHNOLOGIES: A SYSTEMATIC REVIEW

BEATRIZ DE LIMA VITORIO FERREIRA1; FLAVIA BEATRIZ DO CARMO MOREIRA2; MARCOS AURELIO FONSECA MEDEIROS1; EVELIN GABRIELLY DE VARGAS2; MARISOL LACERDA CORONADO3; JOSIANE DE SOUZA BEZERRA2; MICHELE GONÇALVES DA SILVA2; BIANCA RIBEIRO CORREIA LIMA4; ANNE KAROLLYNE ALVARES SANTOS2;

(1) UNIFACISA - CAMPINA GRANDE - PB - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (3) UNIVERSIDADE DO OESTE PAULISTA - UNOESTE - PRESIDENTE PRUDENTE - SP - BRASIL; (4) CENTRO UNIVERSITARIO MAURICIO DE NASSAU - RECIFE - PE - BRASIL;

Introdução/Fundamentos: The expansion of wearable devices and artificial intelligence (AI) in cardiology has occurred without standardized regulatory frameworks or validated clinical integration pathways. Heterogeneity across jurisdictions and limited clinical evidence hinder safe incorporation of these technologies into practice Objetivos: To systematically analyze the regulatory landscape for cardiovascular AI and wearables, governance frameworks proposed by scientific societies, and strategies for integration. Métodos: Systematic review according to PRISMA guidelines. Documents addressing regulation (FDA, EU AI Act/MDR, ANVISA/LGPD), scientific statements (AHA, HRS, EHRA, JACC), and implementation studies were included. After eligibility criteria were applied, 12 documents were analyzed. Data were synthesized qualitatively, focusing on jurisdictions, governance frameworks, and clinical integration models. Resultados e Conclusões: In the United States, AI devices were approved through pathways requiring limited clinical evidence, with 97% cleared via the 510(k) process among 950 approved devices. Only 3.2% of cardiovascular AI devices are supported by clinical trials. In the European Union, classification of AI-based devices as high-risk under the AI Act adds requirements to those established by the MDR, reflecting a more restrictive approach. In Brazil, no specific framework for AI/ML in healthcare has been established, with the LGPD serving as the primary data protection regulation. Governance frameworks converge on domains including accuracy, clinical benefit, interoperability, and data governance. Additional principles emphasize continuous oversight, transparency, and reduction of overdiagnosis. Regarding clinical integration, the “alert-driven” model reduced unnecessary evaluations by 75% in implantable devices, although applicability to consumer wearables remains unvalidated. Additional strategies include new professional roles to facilitate digital health integration. Findings demonstrate a misalignment between technological innovation and the maturity of regulatory and clinical validation frameworks. Persistent gaps across jurisdictions, limited requirements for high-quality evidence, and absence of standardized clinical integration pathways remain major barriers. Adoption of cardiovascular AI and wearables depends on technological advances on regulatory and healthcare structures capable of ensuring safety, effectiveness, and real-world applicability.

STANDARDIZING Z-SCORE EQUATIONS IN FETAL ECHOCARDIOGRAPHY: A DIGITAL PLATFORM BASED ON BRAZILIAN POPULATION DATA

IGOR ALEXANDRE MAKOTO ONO SOUSA1; DAVID RIBEIRO GOMES1; JULIA CASTRO RODRIGUES2; MANUELA RIBEIRO DE QUEIROZ2; LUCIANE ALVES DA ROCHA AMORIM3;

(1) UNIVERSIDADE DO ESTADO DO AMAZONAS - MANAUS - AM - BRASIL; (2) UNIVERSIDADE FEDERAL DO AMAZONAS - MANAUS - AM - BRASIL; (3) HOSPITAL UNIVERSITÁRIO GETÚLIO VARGAS - UFAM - MANAUS - AM - BRASIL;

Introdução/Fundamentos: Z-scores are a valuable tool for assessing fetal cardiac structures, enabling standardized comparisons across gestational ages. Despite their clinical utility, routine use remains inconsistent, largely because the available equations are scattered across the literature, derived from heterogeneous populations, and rarely organized in a way that makes them easy to apply at the bedside. In Brazil, population-specific reference data have been produced over the past decade across multiple centers, yet no unified resource existed to bring these equations together. Objetivos: To compile and digitize Brazilian population-based Z-score equations for fetal cardiac measurements for clinical and research use. Métodos: We reviewed Z-score equations for fetal echocardiographic measurements from Brazilian cohorts, covering biometry, myocardial thickness, function, conduction, and atrial wall volumes. Key data (structure, variables, modeling, gestational range) was extracted, standardized, and integrated into a web-based platform for automated, consistent calculation and interpretation. Resultados e Conclusões: A total of 37 equations were identified and integrated, derived from five original Brazilian studies encompassing more than 3,000 fetal echocardiograms. Structural coverage included 19 cardiac biometry parameters (mitral, tricuspid, aortic and pulmonary valve annuli; ventricular dimensions and areas; cardiac circumference and area; ascending aorta, aortic isthmus, main, right and left pulmonary arteries, and ductus arteriosus), four myocardial thickness measurements (right and left ventricular lateral walls and interventricular septum in two planes), 11 functional parameters (biventricular cardiac output, atrioventricular valve inflow, pulmonary vein and inferior vena cava flows), the atrioventricular conduction interval, and atrial wall volumes by 3D ultrasound. Source studies varied significantly in gestational age ranges, independent variable selection, and modeling. The resulting digital platform standardizes these Z-score equations with consistent inputs and automated outputs, simplifying calculations and enabling direct measurement comparison. This platform unifies Brazilian Z-score equations for fetal echocardiography, spanning structural, functional, and electromechanical parameters into a one accessible tool, streamlining clinical application of reference data. It aims to improve measurement consistency, support research, and promote population-appropriate fetal cardiology care in Brazil.

UNINTENDED CONSEQUENCES OF CONSUMER CARDIAC WEARABLES: A SYSTEMATIC REVIEW OF PSYCHOLOGICAL, CLINICAL, DERMATOLOGICAL, AND PRIVACY-RELATED HARMS

BEATRIZ DE LIMA VITORIO FERREIRA1; FLAVIA BEATRIZ DO CARMO MOREIRA2; MARCOS AURELIO FONSECA MEDEIROS1; EVELIN EVELIN VARGAS2; MARISOL LACERDA CORONADO3; JOSIANE DE SOUZA BEZERRA2; MICHELE GONÇALVES DA SILVA2; BIANCA RIBEIRO CORREIA LIMA4; ANNE KAROLLYNE ALVARES SANTOS2;

(1) UNIFACISA - CAMPINA GRANDE - PB - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (3) UNIVERSIDADE DO OESTE PAULISTA - UNOESTE - PRESIDENTE PRUDENTE - SP - BRASIL; (4) CENTRO UNIVERSITARIO MAURICIO DE NASSAU - RECIFE - PE - BRASIL;

Introdução/Fundamentos: Cardiac monitoring wearable devices have been increasingly incorporated into preventive care; however, their large-scale adoption is associated with potential adverse effects that remain insufficiently systematized. Emerging evidence indicates psychological, clinical, dermatological, sleep-related, and data privacy impacts. Objetivos: To systematically identify categories of adverse effects associated with prolonged use of cardiac monitoring wearables and estimate the magnitude of these outcomes when possible. Métodos: A systematic review was conducted in accordance with PRISMA guidelines. A structured search was performed in PubMed, Embase, and Scopus, including studies reporting psychological, clinical, dermatological, sleep-related, privacy-related, or operational adverse effects associated with cardiac monitoring wearable devices. Fifteen studies were included, comprising clinical cohorts, qualitative studies, systematic reviews, and scientif society reports. Data were synthesized qualitatively due to heterogeneity across study designs. Resultados e Conclusões: Five main categories of adverse effects were identified. Psychological: compulsive monitoring and responses to device alerts were associated with increased anxiety, particularly in low-risk individuals. Diagnostic cascade: among 264 patients seeking care after device alerts, 11.4% had actionable diagnoses, while 59.8% underwent ECG and 29.2% Holter monitoring. Dermatological: contact dermatitis related to metals and occlusive materials, with nickel sensitization prevalence up to 16.2%. Sleep: device-emitted light exposure was associated with melatonin suppression and impaired sleep quality in part of the studies. Privacy: substantial variability in data transparency, with a significant proportion of manufacturers classified as high risk. Additionally, device abandonment rates reached up to 71% within 90 days. The use of cardiac monitoring wearable devices is associated with measurable and multidimensional adverse effects, including psychological, clinical, dermatological, sleep-related, and data privacy impacts. These findings highlight the need for stricter criteria for indication, alert interpretation, and user guidance, particularly in low-risk populations.

Unlocking legacy ECG archives for AI-based reanalysis: class-stratified validation of an image-to-signal pipeline (N=6,400)

GUILHERME CESAR FERNANDES DE OLIVEIRA DA COSTA1; GIULIA FERNANDES DE OLIVEIRA DA COSTA2; JOSE GREGORIO VALERO RODRIGUEZ1; EVANDRO TINOCO MESQUITA1; ERIVELTON ALESSANDRO DO NASCIMENTO1;

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (2) FACULDADE DE CIENCIAS MEDICAS DE MARICA - MARICÁ - RJ - BRASIL;

Introdução/Fundamentos: Many institutions retain large archives of paper or scanned 12-lead electrocardiograms (ECGs). These records cannot be processed by signal-based artificial intelligence (AI) tools used for cardiac diagnosis support. Reliable image-to-signal digitisation could open these archives for retrospective screening, rare-event research, and AI triage. Published validations have been limited to small samples and to overall figures that do not separate diagnostic classes. Objetivos: To quantify the accuracy of a new developed image-to-signal ECG pipeline against a reproducible digital ground truth, with results stratified by diagnostic class. Métodos: A stratified sample of 6,400 records (1,280 per class) was drawn from a large-scale, publicly available 12-lead ECGs dataset covering five diagnostic categories: normal, myocardial infarction, ST/T changes, conduction disturbance, and hypertrophy. Each record was rendered as a 12-lead image at 16 px/mm and processed through the pipeline at 1 kHz, without manual correction. The recovered signal was compared with the original waveform using Pearson correlation, root mean square error (RMSE), and morphological metrics (heart rate, PR, QRS, QT). The same delineator was applied to both signals, so the comparison reflects digitisation error in isolation. Bland-Altman analysis used signed differences. Resultados e Conclusões: Across 76,800 lead-level pairs, median Pearson r was 0.967, with median absolute differences of 8 ms in QRS, 8 ms in QT and 1.9 bpm in heart rate. Performance was consistent across the five classes (median Pearson 0.958-0.976). Signed Bland-Altman analysis disclosed a small positive QRS bias of +8.4 ms, reproducible across classes and lead groups; this offset is a property of the delineation algorithm rather than of the digitisation step. 1.84% (118 of 6,400) of records had at least one failed lead, predominantly in the hypertrophy class (61% of failures); the failure mode traces to layout detection, not amplitude clipping. Throughput on a single workstation was 0.66 s/record for the pipeline core and 2.51 s end-to-end. Across all five classes, the pipeline reproduces 12-lead ECG morphology at error magnitudes comparable to inter-reader variability, with a small bounded QRS offset attributable to the delineation algorithm. At this throughput, archives of tens of thousands of records can be digitised in hours on a single machine. This may enable retrospective deployment of modern AI models in hospitals where only paper ECG archives are available.

RECOGNITION AND MANAGEMENT OF OCCLUSION MI AMONG STUDENTS AND YOUNG PHYSICIANS: A CROSS-SECTIONAL STUDY FROM BRAZIL

JOÃO VITOR GARDELLI TRINDADE1; GUILHERME VIEIRA GONÇALVES1; DANIEL BRANCO DE ARAUJO2; CARLOS GUN2; JOSÉ NUNES DE ALENAR2;

(1) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL; (2) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Acute coronary occlusion (ACO) triage remains anchored to ST-elevation (STE) criteria, although a substantial fraction of acute occlusions present without classical STE. Objetivos: We quantified recognition and management of occlusion-myocardial-infarction (OMI) ECG patterns among Brazilian medical students and early-career physicians, and evaluated the psychometric properties of a 13-item instrument. Métodos: Cross-sectional assessment of 406 consenting students and physicians in São Paulo, Brazil. The 13-item instrument comprised an anchor on ST measurement (Q1), five immediate-management vignettes (Q2–Q6), two guideline statements (Q7–Q8), and five ECG recognition items (Q9–Q13: classical STE, Aslanger, de Winter, normal, hyperacute T). The primary outcome was per-response accuracy on OMI-recognition items (Q10, Q11, Q13), analyzed by mixed-effects logistic regression with random intercepts for participant and item, and fixed effects for training level, sex, age band, and routine ACS care. Secondary outcomes were subscale accuracies and a pre-specified safety-critical composite (failed OMI-management AND failed serial ECG). Psychometrics included per-subscale KR-20 with bootstrap 95% CI, 2-parameter-logistic IRT (2PL vs. Rasch by LRT), and Mantel–Haenszel / logistic DIF. Four sensitivity filters were applied. Resultados e Conclusões: STEMI recognition was 76.4% (95% CI 72.0–80.2), but mean OMI-equivalent recognition was 28.2% — Aslanger 15.3%, de Winter 25.1%, hyperacute T 44.1%. The adjusted OR for students vs. physicians on OMI recognition was 1.05 (99% CI 0.64–1.72); sex, age band, and ACS exposure were likewise non-significant, and estimates were stable across all four sensitivity scenarios (OR 0.95–1.20). Serial-ECG behavior was near-floor (Q3 correct 11.8%, Q6 13.3%), with “troponin” the modal distractor in both. The pre-specified safety-critical composite (missed OMI-management AND failed serial ECG) occurred in 74.6% (99% CI 68.7–79.8). Internal consistency was low per-subscale (Recognition KR-20 = 0.37, 95% CI 0.26–0.46; Management 0.07) and the 13-item total (KR-20 = 0.30) did not behave as a unidimensional construct. A 2PL IRT model outperformed Rasch (p = 0.049); Q13 was the most discriminating item (a = 1.30). Students and early-career physicians recognize classical STEMI, yet most OMI-equivalents are missed, and a troponin-first heuristic replaces serial ECG monitoring. Training should emphasize OMI patterns and structured serial ECG protocols for early recognition and reperfusion

ABBREVIATED ANTITHROMBOTIC STRATEGIES IN ELDERLY PATIENTS AFTER PCI: A SYSTEMATIC REVIEW OF RCTS

GIOVANNA BARCELOS FONTENELE PEREIRA1; GIOVANNA NOBRE FARIAS2; RAYANE ARAUJO BARROS2; RAISSA FERREIRA VALLE2; MARIA CLARA LIMA PEREIRA2; GUSTAVO MIRANDA DE AZEVEDO FERREIRA1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Elderly patients undergoing percutaneous coronary intervention (PCI) face a high concomitant risk of bleeding and ischemic events, making it challenging to define the optimal antithrombotic strategy. Abbreviated dual antiplatelet therapy (DAPT) strategies have emerged as alternatives to conventional prolonged therapy. However, their clinical impacts remain uncertain. Objetivos: To analyze the efficacy and safety of standard antiplatelet therapy compared to abbreviated therapy in the elderly population undergoing PCI. Métodos: published between 2021 and 2026 were included, featuring patients who underwent PCI with stenting, comparing standard DAPT with abbreviated strategies in predominantly older populations (>60 years). Searches were performed in PubMed, Embase, Cochrane, MEDLINE, and Scopus. After removing duplicates, 335 articles were screened; 19 underwent full-text review by two independent reviewers. Risk of bias was assessed using RoB 2. Protocol registered in PROSPERO prior to data collection. Resultados e Conclusões: Fourteen studies were included, comprising 10 RCTs and 4 sub-analyses. Regarding risk of bias, 12 studies presented 'some concerns' and 2 were classified as 'low risk.' Abbreviated strategies involving P2Y12 inhibitor monotherapy reduced bleeding events compared to conventional DAPT, without a significant increase in ischemic events. However, early aspirin withdrawal (<30 days) was associated with a higher risk of stent thrombosis. Abbreviated antiplatelet therapies may benefit elderly patients undergoing PCI, provided they are individualized according to age, bleeding risk, and ischemic risk.

CARDIAC RESYNCHRONIZATION THERAPY AS A MARKER OF IMPROVED QUALITY OF LIFE IN OLDER ADULTS WITH HEART FAILURE WITH REDUCED EJECTION FRACTION: A SYSTEMATIC REVIEW

LETÍCIA NISTI CALCIOLARI1; ANA CAROLINA YAMAGUTI MONTEIRO1; IRVING GABRIEL ARAÚJO BISPO1;

(1) UNIVERSIDADE MUNICIPAL DE SAO CAETANO DO SUL - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Heart failure with reduced ejection fraction (HFrEF) is a syndrome that significantly impairs quality of life, especially in older adults, due to the higher prevalence of comorbidities, lower functional performance and greater management complexity. Cardiac resynchronization therapy (CRT) has emerged as an important therapeutic strategy, potentially improving cardiac function and symptoms. However, its impact on quality of life in older adults remains incompletely understood. Objetivos: To evaluate the impact of CRT on quality of life in older adults with HFrEF. Métodos: A systematic review was conducted using PubMed, Cochrane Library, BVS and LILACS databases with the descriptors "Cardiac Resynchronization Therapy", "Heart Failure", "Quality of Life", and "Aged". Data collection occurred from January to March 2026. Articles in Portuguese and English from the last 5 years were included. 209 studies were identified according to the PRISMA flow diagram. Ultimately, 4 studies met inclusion criteria: original studies of patients over 60 years with HFrEF undergoing CRT and quality of life outcomes. Resultados e Conclusões: The studies included 2,607 participants with a mean age of 65-72 years and minimum follow-up of 6 months. Quality of life was assessed using validated instruments with similar core domains, such as symptoms, functional status and psychosocial aspects, allowing an integrated analysis. Findings demonstrated an improvement in quality of life after CRT, reflected by patient-reported outcomes, such as EQ-5D-3L (0.685 to 0.837) and KCCQ-12 (43.4 to 57.5), and by objective functional measures, including the 6-minute walk test (269.7 to 312.1 meters). Some studies suggest that benefits vary according to clinical profile, with greater results in patients over 75 years old and those with BMI <30 kg/m². Although CRT improves ventricular function, the association between left ventricular ejection fraction (LVEF) and quality of life does not appear to be linear. Initially, baseline LVEF ranged between 23.8% and 31.1%. After CRT, there was an absolute increase of 8.6% to 9.5%. The NYHA functional class, used to assess the impact of symptoms on daily activities and considered an indirect marker of quality of life, showed consistent improvement across studies. Overall, CRT is associated with consistent improvements in quality of life and functional capacity in older adults with HFrEF, however, the response varies according to the clinical profile.

CARDIOVASCULAR OUTCOMES OF GLP-1 RECEPTOR AGONISTS IN OLDER ADULTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

THEODORA CRISTINA CRUZ DE ASSIS1; LUÍS GUSTAVO SEDENHO PRADO2; LOUISE BUONALUMI TÁCITO YUGAR2; MARÍLIA PAIVA MARTINS2; ANA RAQUEL FILIPO WHITAKER3; DANIEL CAMPOS JESUS4; ANDREI CARVALHO SPOSITO2;

(1) UNICAMP - CAMPINAS - SP - BRASIL; (2) UNICAMP - CAMPINAS - MT - BRASIL; (3) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL; (4) PONTIFICIA UNIVERSIDADE CATOLICA DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Aging is accompanied by progressive physiological changes in body characterized by sarcopenia, as well as by metabolic and inflammatory mechanisms that increase the clinical vulnerability of older adults. In this context, a comprehensive synthesis of the use of glucagon-like peptide-1 (GLP-1) receptor agonists in elderly adults remains lacking beyond the pivotal clinical studies. Objetivos: To assess the use of GLP-1 receptor agonists in older populations compared with younger adults in terms of cardiovascular (CV) and safety outcomes. Métodos: PubMed, Embase, and Cochrane databases were searched through December 2025. Hazard ratios (HRs) and 95% confidence intervals (CIs) were extracted. The generic inverse variance method was applied, incorporating the standard errors of the HRs. Primary outcomes included 3-point major adverse CV events (3P-MACE: CV death, non-fatal myocardial infarction, and non-fatal stroke), CV death, all-cause mortality, myocardial infarction (MI), stroke, and hospitalization for heart failure (HHF). Secondary outcomes comprised adverse events (AEs), including gastrointestinal, hypoglycemia, and treatment discontinuation due to AEs. Subgroup analysis was performed to compare outcomes between older adults (≥60 years) and younger adults (≤66 years). Resultados e Conclusões: Ten randomized controlled trials, comprising 82.239 participants (68.3% male), were included. GLP-1 receptor agonists reduced the risk of 3P-MACE events (HR 0.84; 95% CI 0.79–0.90; p < 0.00001; I^2 = 46%), CV death (HR 0.85; 95% CI 0.77–0.93; p < 0.0003; I^2 = 7%), all-cause mortality (HR 0.85; 95% CI 0.79–0.92; p < 0.00001; I^2 = 13%), MI (HR 0.85; 95% CI 0.75–0.97; p = 0.01; I^2 = 37%), and stroke (HR 0.88; 95% CI 0.77–1.00; p = 0.04; I^2 = 27%), with no significant differences between age groups, as indicated by non-significant tests for subgroup differences. HHF (HR 0.94; 95% CI 0.83–1.06; p = 0.29; I^2 = 0%) and gastrointestinal AEs (HR 1.85; 95% CI 0.93–3.67; p = 0.08; I^2 = 91%) did not reach statistical significance. Hypoglycemia was less frequent among GLP-1 users (HR 0.74; 95% CI 0.57–0.97; p = 0.03; I^2 = 0%), with no statistically significant difference between older and younger adults. GLP-1 users had a 38% higher risk of treatment discontinuation due to AEs (HR 1.38; 95% CI 1.25–1.53; p < 0.00001; I^2 = 0%), with a consistent, but not statistically significant, effect across subgroups. GLP-1 reduced the risk of CV outcomes, and increased the risk of some AEs, without significant differences between the ages.

19568

CARDIOVASCULAR PROFILE ANALYSIS OF OLDER ADULTS FROM AN COGNITION AND AGING BRAZILIAN COHORT WITH LOW EDUCATIONAL ATTAINMENT

ANA CAROLINA OLIVEIRA SINZATO1; LEONARDO RYUITI KIMOTO1; GIOVANNA CORREIA PEREIRA MORO1; JOÃO VITOR DA SILVA VIANA1; PEDRO HENRIQUE NARDACI CORREIA1; PEDRO VITOR ARAUJO VALADARES1; THAISE VALLESCA QUEIROZ1; GABRIELA TOMÉ OLIVEIRA ENGELMANN1; BERNARDO DE MATTOS VIANA1; MARIA APARECIDA CAMARGOS BICALHO1; JOICE COUTINHO DE ALVARENGA1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases and dementia are among the leading global causes of mortality and impose a substantial economic burden worldwide. Objetivos: The present study aimed to characterize the cardiovascular profile and electrocardiographic (EKG) findings of a Brazilian cognitive aging cohort followed longitudinally over 12 years. Métodos: We analyzed 122 participants from a Brazilian cognitive aging cohort. All participants underwent a comprehensive geriatric and neuropsychological protocol to determine cognitive diagnosis. Additionally, they underwent specialized clinical evaluation for the assessment of hypertension (HTN), orthostatic hypotension (OH), diabetes mellitus (DM), dyslipidemia, coronary artery disease (CAD), metabolic syndrome (MS), cardiovascular risk, and polypharmacy (>5). Evaluated EKG variables included baseline rhythm, corrected QT interval (QTc), QRS voltage abnormalities, right and left bundle branch blocks (RBBB and LBBB), atrioventricular block (AVB), cardiac axis deviation, heart rate (HR), and signs of left ventricular hypertrophy (LVH). Resultados e Conclusões: The mean age of participants was 76.8 years, and 75.4% were female. Overall, 22.13% were classified as cognitively unimpaired , 45.90% as having mild cognitive impairment , and 30.32% as having dementia. Notably, 61.47% of participants were classified as having high cardiovascular risk. The most prevalent cardiovascular comorbidities were HTN (66.39%), dyslipidemia (48.36%), DM (28.68%), and CAD (17.21%). Polypharmacy was observed in 39.34% of participants, while OH was identified in 6.55%. EKG abnormalities included cardiac axis deviation (18.03%), RBBB (11.47%), AVB (9.83%), LVH (9.83%), low QRS voltage (5.73%), non-sinus rhythm (5.73%), LBBB (4.09%), and prolonged corrected QT interval (QTc) (3.27%). Additionally, the Mann-Whitney test revealed no statistically significant differences between patients with and without dementia regarding PR interval, QRS duration, QTc interval, HR, polypharmacy , systolic and diastolic blood pressure, as shown in table 2. In contrast, chi-square analysis identified significant differences between the groups only for ventricular overload (p=0.035) and CAD (p=0.019). This sample exhibited a high prevalence of cardiovascular risk factors and ECG abnormalities. These findings highlight the importance of comprehensive cardiovascular assessment in this population to improve risk stratification and guide preventive strategies.

CHRONIC PAIN AND CARDIOVASCULAR RISK IN OLDER ADULTS: A SYSTEMATIC REVIEW OF EPIDEMIOLOGICAL AND TREATMENT-RELATED EVIDENCE

MATHEUS LOPES BITAR MESQUITA1; FABIO AUGUSTO LOBO SANTOS2; LUCIANA MOTA SILVA2;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Chronic pain is highly prevalent in older adults and may increase cardiovascular risk through autonomic, inflammatory, behavioral, and treatment-related pathways. However, evidence linking pain, analgesic exposure, and cardiovascular outcomes remains fragmented. Objetivos: To review epidemiological and treatment-related evidence on chronic pain and cardiovascular risk in older adults. Métodos: We conducted a PRISMA 2020-compliant systematic review of PubMed/MEDLINE, Embase, Cochrane CENTRAL, and Scopus from January 2015 to March 2026, without language restrictions. Eligible studies included adults aged ≥60 years, studies with mean or median age ≥60 years, or age-stratified older-adult data, assessing chronic pain or pain treatments in relation to cardiovascular outcomes. Two reviewers independently screened studies, extracted data, and assessed risk of bias. Owing to heterogeneity in definitions, exposures, endpoints, and designs, findings were synthesized narratively. Resultados e Conclusões: Of 5,412 records, 20 primary studies were included, covering epidemiological, pharmacological, non-pharmacological, genetic, and mechanistic evidence. Older-adult cohorts showed consistent associations between chronic pain and cardiovascular risk: chronic pain was associated with acute coronary syndrome in a nationwide Taiwanese cohort (adjusted sHR 1.18; 95% CI 1.07-1.30), and each 1-point increase in a composite pain scale was associated with higher incident CVD (HR 1.21; 95% CI 1.03-1.42). Increasing or persistent pain trajectories were linked to higher CVD risk, whereas decreasing trajectories were not. Treatment-related evidence indicated that systemic NSAIDs increased blood pressure and heart failure risk, with approximately 41% of the osteoarthritis-CVD association mediated by NSAID use. Opioids, gabapentinoids, and corticosteroids were associated with higher cardiovascular or thrombotic risk in observational studies; pregabalin showed higher heart failure incidence than gabapentin in Medicare beneficiaries aged 65-89 years. Acetaminophen appeared safer for short-term use, although chronic use may affect blood pressure. Evidence for non-pharmacological strategies was limited but favored exercise interventions. Overall, chronic pain appears to be an underrecognized cardiovascular risk marker, while several analgesic strategies may compound this risk. Prospective studies should disentangle pain-related from treatment-related cardiovascular risk.

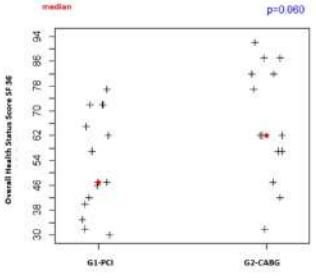
COMPARATIVE ANALYSIS OF QUALITY OF LIFE IN ELDERLY PATIENTS UNDERGOING MYOCARDIAL REVASCULARIZATION PROCEDURES IN SECONDARY CARE

VICTORIA LUQUE DE BARROS COBRA1; GABRIELA TAIRA MORENO1; LARISSA HIROMI YAMAMOTO1; PEDRO HENRIQUE NOVOA FERREIRA1; IRVING GABRIEL ARAUJO BISPO1;



(1) UNIVERSIDADE MUNICIPAL DE SAO CAETANO DO SUL - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Coronary Artery Disease (CAD) may be associated with several unfavorable outcomes, including angina, reduced exercise capacity, depression, rehospitalizations, recurrent myocardial infarction, and stroke, significantly impacting patients' quality of life. Several studies have demonstrated that myocardial revascularization, whether through percutaneous coronary angioplasty (PCI) or coronary artery bypass grafting (CABG), is effective in relieving symptoms, reducing the need for antianginal medications, and improving patients' quality of life. A valuable instrument for assessing quality of life is the SF-36 questionnaire. Objetivos: To compare the quality of life of elderly patients with CAD who underwent myocardial revascularization procedures in secondary care using the SF-36 questionnaire. Métodos: It was a cross-sectional study combining qualitative and quantitative elements.The SF-36 questionnaire was applied, which evaluates eight domains (ranging from functional capacity to mental health) and establishes a score ranging from 0 to 100 points; the higher the score, the better the quality of life. Inferential analyses were performed to further examine these data, including Fisher's exact test or its extension, the Mann–Whitney test, and Student's t-test for independent samples, as well as the nonparametric Mann–Whitney and Kruskal–Wallis tests, according to the variables analyzed. A significance level (alpha) of 5% was adopted for all inferential analyses. Resultados e Conclusões: A total of 29 patients were evaluated and distributed into two groups: coronary angioplasty (G1–PCI; n=15) and coronary artery bypass grafting (G2–CABG; n=14). The mean age was 69.7 years, with 69% of the participants being male; 55% of the sample had Diabetes Mellitus. Regarding echocardiographic data, a difference was observed in the left ventricular end-diastolic diameter: G1 :50.53 ± 2.23 mm vs. G2 :53.00 ± 3.01 mm (p = 0.02). In the social functioning domain, no significant difference was found: G1 : 83.3 ± 18.1 vs. G2 : 80.4 ± 22.8 (p = 0.855). The overall SF-36 assessment did not reveal significant differences, with similar mean scores: G1 : 62.9 ± 16.7 vs. G2 : 68.6 ± 16.6 (p = 0.315). The SF-36 questionnaire domains and the overall mean score also did not show significant differences. These patients presented a reasonable quality of life in the late evaluation after revascularization procedures.

Table 1. SF-36 questionnaire domains and mean score between groups G1-PCI and G2-CABG.

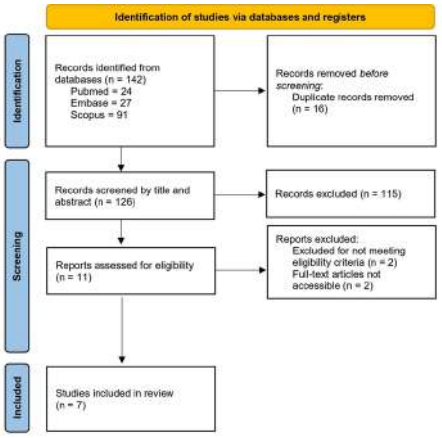
DEPRESSION AND CARDIOVASCULAR DISEASES IN OLDER ADULTS: A SYSTEMATIC REVIEW OF THE BIDIRECTIONAL RELATIONSHIP AND ITS PROGNOSTIC IMPACTS

RENAN MORETTI COELHO1; BRENO AUGUSTO RAMOS DE FRANÇA1; THAYLLA ARIANY DE SOUZA OLIVEIRA1; ARTHUR SANTANA AMORIM SILVA1; ANNA GABRIELLE CAVALINI BIZARELLO1; ISABELLA CAROLINA BESSA ROCHA1; JOÃO PEDRO COSTA ARAÚJO1; LETICIA ZEN1; ERNANDES SOBREIRA1;

(1) UNIVERSIDADE DO ESTADO DE MATO GROSSO - CÁCERES - MT - BRASIL;



Introdução/Fundamentos: The coexistence of Depression and Cardiovascular Diseases (CVD) in aging constitutes a bidirectional pathway integrated with biological, clinical, and social factors. Moreover, persistent psychiatric underdiagnosis limits the available evidence, highlighting a gap in understanding the mind–body axis in cardiovascular prognosis. Objetivos: To analyze the bidirectional relationship between Depression and CVD in older adults, characterizing associated risk factors, pathophysiological mechanisms, and impacts on clinical outcomes. Métodos: A systematic review (2020–2025) was conducted using PubMed, BVS, and Scopus databases. The search strategy included the terms: "Depression" AND "Cardiovascular Diseases" AND "Aged" AND "Risk Factors." Inclusion criteria comprised human studies published in English and Spanish, followed by duplicate removal and screening for qualitative analysis. Resultados e Conclusões: A total of 32 studies were included, encompassing 2,051,683 individuals (predominantly middle-aged and older adults). The analysis demonstrated directional consistency of the association, identifying depression as an independent predictive risk factor for cardiometabolic multimorbidity (HR = 1.64). Additionally, a dose–response effect was observed, with risk increasing to HR = 2.65 in more severe clinical presentations. Within this framework, severe depression increased the likelihood of heart failure by 3.19-fold, while chronicity of the disorder raised CVD risk by 65%. The mind–heart axis was further supported by evidence of coronary anatomical damage (Gensini score, p = 0.01) and systemic inflammation (RDW-CV OR = 2.16) across most studies. Notably, a critical vulnerability was observed among women, who—even in the absence of traditional risk factors (SMuRF-less)—had a doubled risk of stroke (HR = 2.08). Furthermore, social determinants and physical frailty increased mortality by up to 2.31-fold, according to the reviewed literature. Therefore, this study demonstrates that depression acts as a potent modulator of cardiovascular morbidity in older adults. However, a significant clinical challenge remains: although the true prevalence in cardiology outpatient settings reaches 61.4%, formal diagnosis occurs in only 6% (notably among very high-risk preoperative patients), underscoring the need for systematic psychiatric screening within cardiology to improve cardiovascular survival.

Study	Sample	Home-Based Cardiac Rehabilitation Protocol	Outcomes
Lundgren et al. (2025)	n = 61	High-intensity interval training (60-min sessions), with intervals at 85–95% of HRmax, targeting large muscle groups	Physical function and quality of life: no statistically significant difference between groups
Rawstorn et al. (2022)	n = 30	Aerobic, resistance, and flexibility exercises (30–40 min/session, 2–5×/week) at moderate intensity	Physical function: significant improvement in the intervention group (6MWT, p < 0.001). Quality of life: no statistically significant difference between groups
Anderson et al. (2017)	n = 50	Progressive aerobic exercise (~3×/week) with individualized intensity and gradual progression	Physical function: no statistically significant difference between groups. Quality of life: trend toward improvement in the intervention group (−11.5 points; 95% CI −22.8 to 0.3)
Taylor et al. (2019)	n = 216	Progressive aerobic exercise (~3×/week) with individualized intensity and gradual progression	Physical function: no statistically significant difference between groups. Quality of life: significant improvement in the intervention group (−5.7 points; 95% CI −10.6 to −0.7; p = 0.025)
Huang et al. (2018)	n = 75	Aerobic exercise (30 min/session, ≥3×/week) at moderate intensity	Physical function: significant improvement in the intervention group (VO_2peak, p = 0.02; 6MWT, p = 0.03). Quality of life: significant improvement in the intervention group (MLHFQ, p < 0.01)
Maddison et al. (2017)	53	Aerobic and resistance exercises (60 min/session, 2×/week), at light-to-moderate intensity with individualized progression	Physical function and quality of life: no statistically significant difference between groups.
Chen Y, et al. (2018)	n = 98	Aerobic and resistance exercises (20–30 min/session, 3–5×/week), combined with educational and psychological support	Physical function and quality of life: significant improvement in the intervention group (p < 0.05)

Introdução/Fundamentos: Heart Failure (HF) represents one of the leading causes of morbidity and hospitalization among the aging population. In this context, there is an intensified search for strategies that expand access and adherence to therapies such as exercise-based cardiac rehabilitation, given its role in improving cardiovascular function and functional capacity.T herefore, investigating the efficacy of home-based cardiac rehabilitation is particularly relevant, especially considering its potential to improve functional autonomy and quality of life in older and vulnerable populations. Objetivos: To evaluate the efficacy of home-based cardiac rehabilitation on the physical function and quality of life of patients with HF, focusing on the older adult population. Métodos: A systematic review of randomized controlled trials (RCTs) published between 2016 and 2026 was conducted. These trials investigated the efficacy of home-based cardiac rehabilitation on physical function and quality of life in HF patients compared to standard care. Only studies with a mean sample age of ≥60 years were included, characterizing a population of older adults and the elderly. The search was performed across PubMed, Embase, and Scopus databases using DeCS/MeSH descriptors and free-text terms, such as "Home Care Services", "Aged", "Cardiac Rehabilitation", and "Heart Failure". Resultados e Conclusões: From 142 studies identified in the databases, seven RCTs were included (n = 583), in which home-based rehabilitation was primarily conducted through telerehabilitation strategies, such as videoconference monitoring, wearable devices, and telephone contact. Regarding physical function, three out of the seven studies demonstrated significant improvement in the intervention group (6MWT, p < 0.05). Concerning quality of life, four RCTs showed significant improvement in scores assessed by validated instruments (KCCQ or MLHFQ, p < 0.05). Therefore, home-based rehabilitation was not inferior to standard care and yielded favorable results in quality of life. These findings indicate that this modality can expand access to rehabilitation for older adults with HF, especially given the limitations in adherence to center-based programs.

FRAILTY AND RISK OF MAJOR CARDIOVASCULAR EVENTS IN OLDER ADULTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

LUCAS MARINHO REIS DA CUNHA SILVA1; RAFAEL ALVES DE OLIVEIRA1; POLIANA MARCELINO JOIA1; THIAGO VITTOR SILVA FREITAS1; TAYNARA TAVARES DOS SANTOS1; BRUNO DE FREITAS SILVA1; GIOVANA CASAGRANDE DE ALENCAR1; AMANDA OLIVA SPAZIANI1;

(1) UNIVERSIDADE BRASIL - FERNANDÓPOLIS - SP - BRASIL;

Introdução/Fundamentos: Frailty is a geriatric syndrome characterized by reduced physiological reserve and increased vulnerability to stressors, being associated with worse clinical outcomes. Evidence suggests its relationship with increased cardiovascular risk; however, the magnitude of this association still requires consolidation through systematic analysis. Objetivos: To evaluate the association between frailty and the risk of major cardiovascular events in older adults. Métodos: A systematic review was conducted in accordance with PRISMA guidelines, with a structured search in PubMed, Embase, and the Cochrane Library up to January 2026. Prospective studies assessing frailty using validated scales (such as Fried or the Clinical Frailty Scale) and its relationship with cardiovascular events were included. The primary outcome was major adverse cardiovascular events (MACE). The meta-analysis was performed using a random-effects model, with calculation of relative risk (RR) and 95% confidence intervals (95% CI). Heterogeneity was assessed using the I^2 statistic. Resultados e Conclusões: A total of 11 studies were included, comprising 62,418 participants. Frailty was associated with a significant increase in the risk of major cardiovascular events (RR = 1.69; 95% CI: 1.48–1.93; $p < 0.001$). An increase in mortality was also observed. Heterogeneity was moderate ($I^2 = 36\%$). Frailty is associated with a significant increase in cardiovascular risk in older adults, reinforcing the importance of its assessment in clinical practice and risk stratification

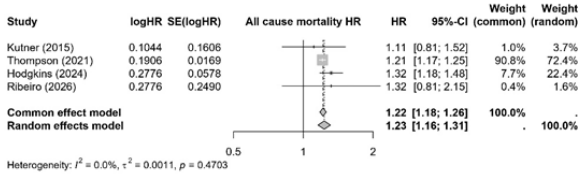
20995

FRAILTY IN HEART FAILURE AND ITS IMPACT ON LIFE EXPECTANCY

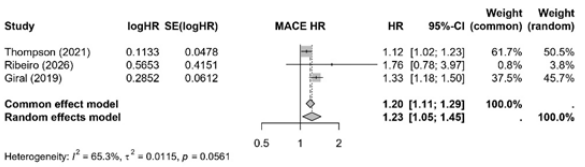
GABRIELA FISS SEITZ1; ÁLVARO CESAR CATTANI1; BEATRICCE ISABELLE GOEDERT FARINON2; LÍVIA MARIA BARBIERI1; KATLIN GABRIELE WOLLMER1; MARIA FERNANDA HAAS TONIAL1; RAYSSA MARINI REIS1;

(1) AFYA CENTRO UNIVERSITÁRIO DE PATO BRANCO - PATO BRANCO - PR - BRASIL; (2) AFYA CENTRO UNIVERSITARIO DE PATO BRANCO - PATO BRANCO - PR - BRASIL;

Introdução/Fundamentos: Frailty has emerged as a relevant prognostic marker in heart failure, being associated with higher mortality, rehospitalization, and functional decline. Characterized by reduced physiological reserve and lower capacity to respond to stressors, this syndrome directly affects clinical outcomes, therapeutic tolerance, and medical decision-making, making its identification essential in heart failure management. Objetivos: To evaluate, through a systematic literature review, the impact of frailty on mortality and life expectancy in patients with heart failure. Métodos: A systematic review was conducted according to PRISMA recommendations. The search in the PubMed database, using MeSH descriptors and Boolean operators, identified 1,256 studies, of which 93 were screened after application of the eligibility criteria. Original studies published within the last 10 years, with validated frailty assessment and analysis of prognostic outcomes, were included. After analysis of titles, abstracts, and full texts, 8 studies composed the final qualitative synthesis. Resultados e Conclusões: The studies demonstrated a high prevalence of frailty in patients with heart failure, ranging between 30% and 50%, depending on the population and assessment tool used. Frail patients presented a significantly higher risk of mortality, with an increase of approximately 1.5 to 2.5 times compared to non-frail patients, in addition to higher hospitalization and rehospitalization rates. Worse functional capacity was also observed, evidenced by reduced gait speed and handgrip strength, as well as longer hospital stays. Frailty was also associated with a higher prevalence of comorbidities, especially chronic kidney disease and diabetes mellitus. Beyond the prognostic impact, greater therapeutic complexity and lower utilization of guideline-recommended therapies were observed, reinforcing the influence of frailty on treatment individualization. Frailty is associated with worse prognosis in heart failure, including higher mortality, hospitalization, and therapeutic complexity. Early identification may contribute to better risk stratification and treatment individualization.



19443

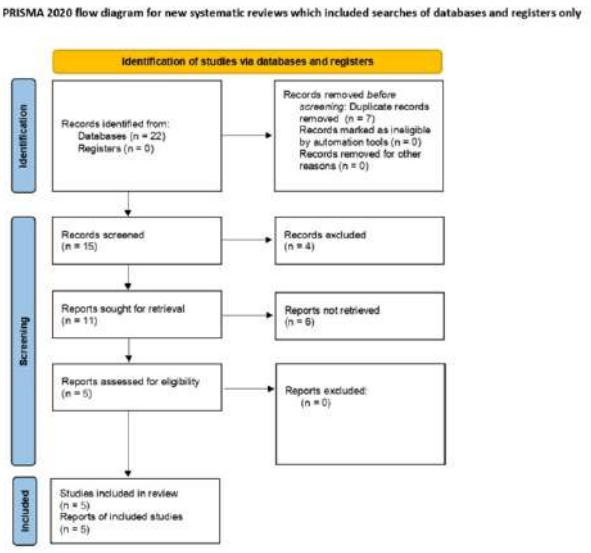


IMPACT OF STATIN DISCONTINUATION ON LONG-TERM MORTALITY AND CARDIOVASCULAR EVENTS IN PATIENTS AGED 70 YEARS AND OLDER: A META-ANALYSIS OF ADJUSTED DATA

JOSÉ RICARDO PIRES PEREIRA1; LETICIA FONSECA SILVA1; SADRAK LYON DANTAS PONTES1; JOÃO GUILHERME GOMES PEDROSA1; FELIZARDO JOSÉ LEANDRO PEREIRA1; KAROLINA AZEVEDO BRINGEL1; MARIA EDUARDA FRANCO LONDRES GOMES1; MARCELO DANTAS TAVARES DE MELO1;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL;

Introdução/Fundamentos: The clinical benefit of continuing statin therapy in the elderly remains a subject of intense debate, particularly in primary prevention. As life expectancy increases, understanding the risks associated with statin deprescribing in patients aged 70 years and older is essential for clinical decision-making. Objetivos: To evaluate the impact of statin discontinuation on all-cause mortality (ACM) and major adverse cardiovascular events (MACE) in individuals aged ≥ 70 years using adjusted effect estimates. Métodos: Systematic review and meta-analysis conducted following PRISMA guidelines. The study included observational registries providing adjusted Hazard Ratios (HR) for ACM and MACE following statin discontinuation. Statistical analysis was performed using the natural logarithm of the HR (logHR) and its corresponding Standard Error (SE). Random-effects models (REML) were used to synthesize results, and heterogeneity was assessed by I². Resultados e Conclusões: Seven study estimates were analyzed (k=4 for ACM; k =3 for MACE), including registries such as Thompson (2021) and Ribeiro (2026). Statin discontinuation was associated with a significant increase in all-cause mortality in the random-effects model (HR 1.23; 95% CI: 1.16-1.31; p < 0.0001$), with negligible heterogeneity (I² = 0.0%). Regarding MACE, discontinuation also presented a significant risk (HR 1.23; 95% CI: 1.05-1.45; p = 0.012), with moderate heterogeneity (I² = 65.3%). In conclusion, statin discontinuation in patients aged 70 and older is associated with a 23% increase in the risk of death and major cardiovascular events. These findings suggest that statin therapy should not be routinely discontinued based solely on age, reinforcing the importance of individualized cardiovascular prevention in the elderly population.



19976

IMPACT OF TRANSCATHETER IMPLANTATION ON MITRAL ANNULUS CALCIFICATION IN HIGH-RISK ELDERLY PATIENTS: A SYSTEMATIC REVIEW.

MARIA EDUARDA VIANA RIBEIRO1; ISABELLA FERNANDES BELLISSIMO1; CAMILA LOPES CARREIRO MACHADO DA SILVA1; CARLA FABIANA BATISTA1; PEDRO HENRIQUE NOVOA FERREIRA1; GUSTAVO MARTINS JATUBA1; MANUELA RODRIGUES DE LIMA1; IRVING GABRIEL ARAUJO BISPO1; GIOVANNA HONORIO1;

(1) UNIVERSIDADE MUNICIPAL DE SAO CAETANO DO SUL - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Mitral annular calcification (MAC) is a prevalent degenerative condition in the elderly and is frequently associated with mitral stenosis or insufficiency in patients at high surgical risk. Conventional mitral valve replacement is technically complex and has high morbidity and mortality, mainly due to the risk of complications such as atrioventricular dissociation and paravalvular leaks. Therefore, transcatheter implantation in the mitral position in the presence of significant annular calcification (TVMR) has become established as a therapeutic alternative for elderly patients at very high risk. Objetivos: A systematic review was conducted to analyze the most recent studies on the impact of transcatheter implantation on mitral annular calcification in elderly patients. Métodos: The review followed the PRISMA flowchart recommendations, encompassing the steps of study identification, screening, eligibility, and inclusion. The search was performed in the PubMed and LILACS databases using the descriptors: “transcatheter valve”, “mitral annular calcification”, “outcomes”, and “elderly” combined using the Boolean operators AND and OR. Inclusion criteria were articles in English and Portuguese published in the last 5 years. Exclusion criteria were case reports, narrative reviews, and studies that did not analyze major cardiovascular outcomes. Resultados e Conclusões: Twenty-two articles were found in the databases; after analysis, five articles were included in this review. The number of patients per study varied widely, from series with 15 to 30 individuals to multicenter registries with more than 300 patients. The analyzed population was mostly composed of elderly patients (mean age between 72 and 82 years), with high surgical risk.Praz et al. studied transatrial TMVR in 26 patients with MAC and reported 100% technical success.37 Furthermore, there was considerable improvement in NYHA functional class. It was found that valve-in-MAC is possible in selected patients, with higher technical success rates when performed with strategies to prevent paravalvular leak, prosthetic migration, and, mainly, left ventricular outflow tract (LVOT) obstruction. TMVR is a promising strategy, even though the progress in this field has been slow. Careful and thorough imaging is essential to identify the risk of LVOT obstruction and other procedural complications.

21472

TRENDS IN HOSPITALIZATION AND IN-HOSPITAL MORTALITY DUE TO HEART FAILURE IN BRAZIL AMONG PATIENTS AGED 80 YEARS OR OLDER: ANALYSIS OF THE LAST 15 YEARS WITH EMPHASIS ON REGIONAL DISPARITIES (2011–2025)

LAÍS VASQUES BERTONCINI1; PAULO KOJI HARA SONODA2; JOSÉ AUGUSTO MANTOVANI RESENDE3;

(1) UNIVERSIDADE FEDERAL DO TRIANGULO MINEIRO - UBERABA - GO - BRASIL; (2) FACULDADE DE MEDICINA DE SÃO JOSÉ DO RIO PRETO - SÃO JOSÉ DO RIO PRETO - SP - BRASIL; (3) UNIVERSIDADE FEDERAL DO TRIANGULO MINEIRO - UBERABA - MG - BRASIL;

Introdução/Fundamentos: Heart failure (HF) is a major public health problem, associated with reduced quality of life and a significant impact on hospital expenditures. The occurrence of the disease increases substantially with advancing age and, in octogenarians, represents a growing clinical challenge due to a higher burden of comorbidities, worse outcomes, and undertreatment compared to younger patients. In Brazil, population aging and regional inequalities further amplify this challenge. Objetivos: To analyze temporal trends in hospitalization and in-hospital mortality due to HF in the population aged ≥ 80 years in Brazil between 2011 and 2025, with emphasis on disparities among geographic regions. Métodos: This was a descriptive, retrospective ecological study using data from the Hospital Information System of the Brazilian Unified Health System (SIH/SUS). All hospitalizations due to HF in individuals aged 80 years or older were included and stratified by region of residence from 2011 to 2025. Variables of interest included volume of hospitalizations, in-hospital deaths, case-fatality rate, and annual distribution. Data were tabulated and analyzed using Microsoft Excel. As the study utilized publicly available secondary data, review by the Research Ethics Committee was waived. Resultados e Conclusões: During the study period, there were 702.315 hospitalizations for HF in individuals aged ≥ 80 years, 116.776 in-hospital deaths, and an overall case-fatality rate of 16.63%. There was a 10.32% reduction in hospitalizations (from 55.027 in 2011 to 49.348 in 2025). However, there was a 12.99% increase in deaths (from 7.739 to 8.744) and in case-fatality rate (from 14.06% to 17.72%). The Southeast region accounted for 42.5% of cases, followed by the South (24.1%) and the Northeast (22.5%). The highest case-fatality rates were observed in the Southeast (18.56%), followed by the North (15.98%) and Northeast (15.58%). The Midwest and South regions presented the lowest rates, with mean case-fatality rates of 15.03% and 14.73%, respectively. Despite a modest reduction in hospitalizations, the increase in deaths and case-fatality rate reveals regional inequalities in HF care among octogenarians, particularly in the North and Northeast regions, underscoring the need to improve care for this population. These findings should be interpreted with caution, considering possible underreporting, absence of detailed clinical data, and the impossibility of inferring individual causality in an ecological study based on aggregated data.

20892

VASCULAR AGING AND INTRINSIC CAPACITY: ANALYSIS OF ELDERLY PATIENTS STRATIFIED BY PULSE WAVE VELOCITY QUARTILES.

MIRIAN PEREIRA DE OLIVEIRA1; JACK EDUARDA ANTUNES BATISTA1; MAELLY GIL PEREIRA1; IZABEL SOUZA SILVA1; IGOR ANTONIO CARVALHO-RIBEIRO1; DANIEL HENRIQUE MOREIRA QUIRINO2; KAMILA ANDRADE DE SOUSA2; ANA KAROLINA LIMA SOUZA1; ISIDORO JOSÉ DE SOUTO DANTAS3; TIAGO ABREU VELLOSO1; MARIA DA GLORIA RODRIGUES MACHADO1; LEANI SOUZA MÁXIMO PEREIRA1;

(1) FACULDADE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) UNIVERSIDADE FEDERAL DO AMAZONAS - MANAUS - AM - BRASIL;

Introdução/Fundamentos: Pulse wave velocity (PWV), considered a biomarker of vascular aging and an independent predictor of major cardiovascular events, has been associated with functional decline in older adults. However, the relationship between different PWV quartis and the domains of Intrinsic Capacity (IC) remains poorly explored. IC is defined as the composite of all physical and mental capacities of an individual. Objetivos: To compare the demographic, cardiovascular, and IC characteristics, specifically the locomotion and cognition domains, among older adults classified according to different PWV quartis. Métodos: A cross-sectional analytical study was conducted using a randomized sample of 115 older adults enrolled in the Integrated Care for Older People (ICOPE Brazil/Feasibility) study. Participants were stratified into three groups according to PWV quartis: PWV<25% (n=28), PWV25-75% (n=59), and PWV>75% (n=28). Sociodemographic data and cardiovascular parameters were assessed using the oscillometric brachial device Mobil-O-Graph. Comorbidity burden was evaluated using the Charlson Comorbidity Index (CCI). Locomotion was assessed by 4-meter gait speed using the Short Physical Performance Battery (SPPB). Cognition was assessed using the Mini-Mental State Examination (MMSE). Resultados e Conclusões: The PWV >75% group was significantly older (77.25±4.80 years) than the PWV 25-75% and PWV<25% groups (67.02±3.48 and 63.36±2.46 years, respectively). The CCI score in the PWV>75% group (5.0±1.8) was significantly higher than in the PWV24-75% and PWV<25% groups (3.78±2.02 and 3.07±1.18, respectively). Educational level was lower in the group with greater arterial stiffness (5.42±5.27 years) compared with the PWV<25% group. The 4-meter gait speed of the SPPB was significantly lower in the PWV >75% group (0.87±0.36 m/s) compared with the PWV 50% group (1.12±0.57 m/s). MMSE scores in the PWV >75% group did not differ from the PWV25-75% group but were significantly higher than in the PWV<25% group. Hypertension was the most prevalent comorbidity across all groups. CONCLUSION: Older individuals with a higher burden of comorbidities and poorer cognitive and 4-meter gait speed performance exhibited higher PWV levels, demonstrating the applicability of PWV as a noninvasive tool for the early identification of vascular aging. These data contribute to screening strategies, functional monitoring, and prevention of cardiovascular and functional outcomes in clinical and geriatric practice.

A BAYESIAN EVIDENCE OF THE OPTIMAL DURATION OF DUAL ANTIPLATELET THERAPY AFTER CTO-PCI

RICARDO FONSECA OLIVEIRA SURUAGY-MOTTA1; LEONARDO DEXHEIMER DA SILVA2; GABRIEL REZENDE NEVES3; CARLOS ALEXANDRE FARIAS4; LEONARDO GALVÃO DE OLIVEIRA OLDRA5; MARIA ISABELE CARNEIRO PESSOA DE SANTANA1; FRANCISCO MONTEIRO PINHEIRO6; ALEXANDRE ABIZAID7; BRUNNA PILEGGI7; EVANDRO MARTINS FILHO8; CHARLES MICHAEL GIBSON7; DANIEL CHAMIÉ9;

(1) CENTRO UNIVERSITARIO CESMAC - MACEIO - AL - BRASIL; (2) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (3) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (4) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (5) UNIVERSIDADE ANHEMBI MORUMBI - SÃO PAULO - SP - BRASIL; (6) CENTRO UNIVERSITARIO DE MACEIO - UNIMA / AFYA - MACEIO - AL - BRASIL; (7) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (8) SANTA CASA DE MISERICORDIA DE MACEIO - MACEIÓ - AL - BRASIL; (9) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Optimal dual antiplatelet therapy (DAPT) duration after complex percutaneous coronary intervention (PCI) remains controversial. Chronic total occlusions (CTO) represent the most complex lesion subset, characterized by high atherosclerotic burden and long stent lengths, potentially requiring extended DAPT. We sought to synthesize evidence comparing short-term (≤12 months) vs. long-term (>12 months) DAPT specifically in the CTO-PCI population. Objetivos: We sought to synthesize evidence comparing short-term vs. long-term DAPT specifically in the CTO-PCI population Métodos: Following PRISMA guidelines, we systematically searched PubMed, Scopus, Embase, and Web of Science through August 2025. We included studies comparing DAPT durations in CTO-PCI using contemporary drug-eluting stents. The primary outcome was all-cause death. Secondary outcomes included cardiovascular (CV) death, MI, stroke, target lesion revascularization (TLR), and bleeding (BARC ≥2). Bayesian random-effects meta-analyses were performed to estimate pooled odds ratios (OR) and 95% credible intervals (CrI). We calculated the posterior probability (P) of one strategy being superior to the other. Resultados e Conclusões: Results: Four observational studies (n=4,205; Short-DAPT: 1,986; Long-DAPT: 2,219) were included. The weighted mean follow-up was 45.5 months. Bayesian analysis revealed that long-term DAPT was associated with significantly lower odds of all-cause mortality (OR 2.83 for short-DAPT; 95% CrI 1.07–7.36; P[Long-DAPT < Short-DAPT] = 98.3%) and CV death (OR 5.38; 95% CrI 2.00–14.28; P[Long-DAPT < Short-DAPT] = 100%). No significant differences were observed for MI (OR 1.14; 95% CrI 0.65–2.00), stroke (OR 1.00; 95% CrI 0.49–2.03), or TLR (OR 0.94; 95% CrI 0.57–1.56). Bleeding rates were lower in the short-term group but did not reach statistical significance in the primary analysis (OR 0.55; 95% CrI 0.28–1.08; P[Short-DAPT < Long-DAPT] = 95.8%). Sensitivity analysis confirmed the robustness of the mortality benefit. Conclusion: In patients undergoing CTO-PCI, long-term DAPT is associated with a significant reduction in all-cause and cardiovascular mortality compared to short-term DAPT, without a statistically significant increase in major bleeding. These findings suggest that the high-complexity nature of CTO lesions may benefit from prolonged antiplatelet protection. Final confirmation through randomized controlled trials is warranted.

ASPIRIN DISCONTINUATION WITHIN ONE MONTH IN PATIENTS WITH ACUTE CORONARY SYNDROME FOLLOWING PERCUTANEOUS CORONARY INTERVENTION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

LUIZ FILIPE TORRES DE ALENCAR1; CAUÃ PIMENTEL MARTINS FERNANDES1; DAVI PONTE PIERRE1; ISRAEL NASCIMENTO COUTINHO SOUZA1; ANTÔNIO ARAGÃO XEREZ JÚNIOR1; LEONARDO BRITO DE SOUZA1; VANESSA ARAUJO PINHEIRO1; MARINA DE ANDRADE NORÕES BEZERRA1; JOÃO MACEDO COELHO NETO1; MATEUS PAIVA MARQUES FEITOSA1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Dual antiplatelet therapy (DAPT) with aspirin and a P2Y12 inhibitor for 12 months is the standard antithrombotic treatment for patients with acute coronary syndromes undergoing percutaneous coronary intervention (PCI). Recent randomized controlled trials (RCTs) support the ultrashort (≤1 month) withdrawal of aspirin, showing non-inferiority in ischemic events and reduction in bleeding, which can improve patient prognosis. Objetivos: This study aims to evaluate the security and benefit of the discontinuation of aspirin within one month, followed by P2Y12 inhibitor monotherapy. Métodos: A systematic review and meta-analysis were conducted in accordance with PRISMA guidelines. 277 records were screened. We included RCTs enrolling patients with acute coronary syndrome undergoing PCI. The RCTs compared early aspirin discontinuation within one month followed by P2Y12 inhibitor monotherapy with 12-month DAPT. Data were synthesized using random-effects models. Risk of bias was assessed through ROBINS-2. The study is registered in PROSPERO under the protocol CRD420261355098. Resultados e Conclusões: A total of 6 randomized controlled trials were included, comprising 19,745 patients, with 9877 in the 1 month DAPT group and 9868 in the 12 month DAPT group. The mean age was approximately 62 years, and 76% were male. 59% of the patients had hypertension, 27% diabetes mellitus and 61% had dyslipidemia. Current smoking was present in 35%. Previous MI occurred in 11%, previous PCI in 15%, and previous CABG in 2%. Prior stroke was observed in 4%, and CKD in 9%. STEMI accounted for 41% of the cases, NSTEMI for 38%, and unstable angina for 21%. Multivessel disease was present in 53% of patients. The overall publication bias was low. There was no statistically significant difference between groups in all-cause mortality (HR 1.02, 95% CI 0.89–1.17; p = 0.78), myocardial infarction (HR 0.98, 95% CI 0.87–1.11; p = 0.74), stent thrombosis (HR 1.05, 95% CI 0.78–1.41; p = 0.74), stroke (HR 0.95, 95% CI 0.78–1.16; p = 0.62), and target vessel revascularization (HR 1.01, 95% CI 0.91–1.13; p = 0.79). However, major bleeding (BARC 3–5) was significantly reduced with early aspirin withdrawal (HR 0.68, 95% CI 0.55–0.83; p < 0.001). This reduction remained consistent across analyses stratified by P2Y12 inhibitor type. We concluded that the ultrashort discontinuation of aspirin is non-inferior to 12-month DAPT in mortality and ischemic outcomes, while showing significant benefit in the reduction of major bleeding.

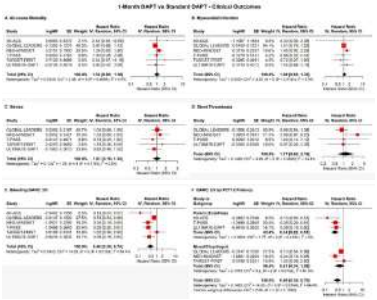

Table 01: Baseline characteristics of the included studies

Study	N (I/C)	Age (years)	Female (%)	BMI (kg/m²)	Hypertension (%)	Diabetes (%)	Dyslipidemia (%)	Current smoker (%)	Median duration of DAPT (days)	STEMI (%)	Previous PCI (%)	Multivessel disease (%)

DOACS VERSUS DAPT AFTER LAAO: LOWER THROMBOTIC AND BLEEDING EVENTS IN AN UPDATED META-ANALYSIS

ALEX RIBEIRO ROMERO1; VITÓRIA PIFFERO JUNGES OLIVEIRA2; JOÃO OLIVEIRA DE LIMA NETO1; FABRICIUS MIGUEL STORCK1; KENZO KAWAKAMI1; LUCAS FIRMIANO LOPES DE SOUZA3; FERNANDA SANTINONI COUTO4; MIRELA PARISSA BONDAN MISAGHI5; FERNANDO JOSÉ PEREZ DA SILVA GRAÇA2;

(1) UFMT - CUIABÁ - MT - BRASIL; (2) UNIVERSIDADE FEDERAL DE RORAIMA - BOA VISTA - RR - BRASIL; (3) UNIVERSIDADE ESTADUAL DE RORAIMA - BOA VISTA - RR - BRASIL; (4) FACULDADE DE MEDICINA DE MARILIA - MARÍLIA - SP - BRASIL; (5) UNIVERSIDADE DA REGIAO DE JOINVILLE - JOINVILLE - SC - BRASIL;

Introdução/Fundamentos: Left atrial appendage occlusion (LAAO) reduces thromboembolic risk in patients with atrial fibrillation who are unsuitable for long-term anticoagulation. However, the early post-implantation period remains highly thrombogenic due to incomplete endothelialization, increasing the risk of device-related thrombosis (DRT). Despite widespread use of dual antiplatelet therapy (DAPT), its effectiveness in preventing DRT remains debated. Objetivos: To compare the efficacy and safety of direct oral anticoagulants (DOACs) versus DAPT following LAAO. Métodos: A systematic review and meta-analysis were conducted according to PRISMA guidelines. PubMed, Embase, and Scopus were searched through April 2026 for randomized and comparative observational studies evaluating DOACs versus DAPT after LAAO. Given the limited number of randomized trials, high-quality observational studies were included to enhance external validity. Primary efficacy outcomes included DRT and thromboembolic events (stroke, transient ischemic attack, and systemic embolism). Major bleeding was the primary safety outcome. Pooled relative risks (RR) and 95% confidence intervals (CI) were estimated using a random-effects model. Heterogeneity was assessed using the I² statistic. Resultados e Conclusões: Eleven studies including 34,499 patients (mean age 69–78 years) were analyzed. DOAC therapy was associated with a lower risk of DRT compared with DAPT (RR 0.53, 95% CI 0.35–0.82; I²=28%). Thromboembolic events were also reduced (RR 0.66, 95% CI 0.48–0.90; I²=0%), with consistent findings across thrombotic endpoints. No significant difference was observed in all-cause mortality (RR 0.94, 95% CI 0.56–1.57; I²=5.6%). DOACs were associated with a lower risk of major bleeding compared with DAPT (RR 0.68, 95% CI 0.51-0.92), despite moderate heterogeneity (I²=61.2%). Collectively, these findings support reconsideration of routine antiplatelet-based strategies after LAAO, favoring anticoagulation-based approaches during the early post-implantation period. While the predominance of observational data and residual heterogeneity warrant cautious interpretation, these results reinforce DOACs as a consistent and clinically relevant alternative in this setting.

EARLY VERSUS PERIPROCEDURAL HEPARIN ADMINISTRATION IN ST-ELEVATION MYOCARDIAL INFARCTION REGARDING INFARCT-RELATED ARTERY OUTCOMES: A SYSTEMATIC REVIEW AND META-ANALYSIS

ARTHUR MENDES BENEVIDES MEDEIROS1; PAULO GONDIM GONÇALVES2; CAIO TEOTONIO OLIVEIRA1; HEITOR GONDIM BRAGA1; ANNA JÚLIA ANDRINO SCHNEIDER1; REBECA MOURA ALVES1; MÁRIO SERRANO BARBOSA FILHO1; JOÃO RAFAEL SÁ NOGUEIRA2; DUSTIN ANDREI MESQUITA BARBOSA1; MATEUS PAIVA MARQUES FEITOSA2;

(1) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Intravenous administration of unfractionated heparin (UFH) in patients with ST-elevation myocardial infarction (STEMI) referred to primary percutaneous coronary intervention (PPCI) is well-established clinically. However, the benefits and safety of the pretreatment with UFH at the first medical contact in patients with STEMI is still contentious. Therefore, we aimed to perform a meta-analysis to determine the optimal timing of UFH administration in patients with STEMI undergoing PPCI regarding infarct- related artery (IRA) outcomes. Objetivos: We analyzed reperfusion of the IRA, measured by TIMI 3 flow (complete coronary perfusion), from randomized controlled trials comparing UFH at first medical contact versus administration at the catheterization laboratory for STEMI patients undergoing PPCI. Métodos: This systematic review and meta-analysis was performed in accordance with the PRISMA guidelines. We searched PubMed, Embase and Cochrane databases for randomized controlled trials that investigated the impact of UFH administration timing on reperfusion and all-cause mortality outcomes. Statistical analysis was executed using Review Manager (Cochrane Collaboration). Heterogeneity was assessed with i2 statistics. Resultados e Conclusões: We included 3 RCTs with 1.761patients from Slovenia, China and Iran. UFH administration at the first medical contact was used to increase IRA patency in 895 (50.1%) patients. Follow-up ranged from 40 days to 12 months. The mean age was 60.1±2,9 years, with 79% male patients and 20.1% patients with diabetes mellitus. The rate of pre-PCI time on TIMI 3 flow in the IRA (RR 1.44; 95% CI 1.17-1.76; p= 0.0005; i2= 0%) was significantly higher in patients with STEMI who received UFH at the FMC compared with those receiving only in the catheterization laboratory . There were no statistically significant differences in all-cause mortality at 30 days (RR 0.79; 95% CI 0.42-1.48; p=0.46; i2= 0%) or in the rate of post-PCI TIMI 3 flow in the IRA (RR 1.00; 95% CI 0.98- 1.03; p=0.29; i2= 0%). These findings suggest that early administration of UFH at the first medical contact is associated with improved reperfusion of the IRA with no differences in all-cause mortality in patients with STEMI assigned to PPCI.

FIRST 814 TAVI PROCEDURES IN BRAZIL'S UNIFIED HEALTH SYSTEM: FAVORABLE MORTALITY BUT MARKED REGIONAL DISPARITIES AND 71% UNMET DEMAND (2024–2025)

GUSTAVO SKONETZKY1; AMANDA TEIXEIRA WATERMANN1; KETLYN CAROLINE BONI1; LAURA CARBOLIN1; MARINA TOCHETTO ZIMMERMANN1; SIMONE TUCHTENHAGEN1; ISADORA BIGOLIN1; TIAGO VENDRUSCOLO1;

(1) UNIVERSIDADE REGIONAL INTEGRADA DO ALTO URUGUAI E DAS MISSÕES (URI) - ERECHIM - RS - BRASIL;

Introdução/Fundamentos: Aortic stenosis (AS) is highly prevalent among older adults and is associated with high morbidity and mortality, as well as increased surgical risk in this population. Current Brazilian guidelines recommend Transcatheter Aortic Valve Implantation (TAVI) as a Class I indication for patients aged ≥75 years across all surgical risk profiles. However, Brazil's public health system (SUS) restricts TAVI to high or prohibitive surgical risk, aged ≥75, via transfemoral access only, following its operational inclusion in 2024. However, gaps remain regarding its implementation and equity of access. Objetivos: To analyze the patient profile, in-hospital mortality, temporal trends, regional disparities, and estimated unmet demand for TAVI during the first 21 months of implementation in the SUS. Métodos: Ecological population-based study using Hospital Information System (SIH-SUS) microdata for all TAVI admissions from April 2024 to December 2025. Population estimates (≥75 years) were obtained from the national statistics agency (IBGE) projections. Inequality in access was assessed using the Gini index and Lorenz curve. Survival was analyzed via Kaplan-Meier curves and Cox regression. Unmet demand was estimated based on international incidence benchmarks. Data were publicly available and de-identified, ethics approval was waived per Resolution CNS 510/2016. Resultados e Conclusões: A total of 814 TAVI procedures were performed in 23 centers across 14 of 27 states (48% of states had zero procedures, including the entire North region - 7 states). Patients were 53.8% male, median age 81 years (IQR 78–85), and 94.3% had isolated AS. In-hospital mortality was 4.9% (40/814), with 70% of deaths occurring within the first 7 days. Monthly volume increased 8.2%/month (IRR= 1.082; 95%CI 1.069–1.095). The Gini index for access was 0.473, reflecting significant inequality. The national utilization rate was 5.0/100,000 inhabitants ≥75 years, ranging from 0.1 (1 state) to 19.2 (2 states). Only 29% of estimated demand was met nationally. Specialized post-procedure care was associated with lower mortality risk (HR= 0.22; 95%CI 0.11–0.44; p< 0.001). Initial TAVI implementation in Brazil's SUS demonstrated clinical safety, with mortality rates comparable to international registries. However, the program covers less than one-third of the estimated demand and is marked by severe geographic concentration. The complete absence in the North region highlights a critical equity gap that necessitates the urgent expansion of accredited centers.

HIGH THROMBUS BURDEN IS ASSOCIATED WITH WORSE INITIAL ANGIOGRAPHIC PROFILE IN PRIMARY PCI: A SINGLE-CENTER REGISTRY OF 379 PATIENTS

MATEUS SANTANA GUSMÃO1; BRENDA ALMEIDA DA SILVA2; THAMIRES SOUZA PIRES2; GABRIEL SANTOS GOMES2; VINICIUS RICARDO CARDOSO REIS2; SERGIO FIGUEIREDO CAMARA3; THAÍS CHANG VALENTE3; ADRIANO OSSUNA TAMAZATO3;

(1) CENTRO UNIVERSITARIO UNIDOMPEDRO - SALVADOR - BA - BRASIL; (2) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL; (3) HOSPITAL ANA NERY - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: High intracoronary thrombus burden is associated with greater angiographic complexity and worse outcomes in patients undergoing primary percutaneous coronary intervention (PCI) in the setting of ST-segment elevation myocardial infarction (STEMI). Studies demonstrate an association between high thrombus burden, increased distal embolization, no-reflow phenomenon, lower myocardial reperfusion, and worse clinical outcomes. Despite advances in antithrombotic strategies and reperfusion techniques, contemporary data regarding the impact of high thrombus burden on immediate primary PCI outcomes in high-complexity Brazilian centers remain limited. Objetivos: To evaluate the association between high thrombus burden and angiographic success of primary PCI in patients with STEMI undergoing angioplasty at a Brazilian tertiary center. Métodos: Retrospective observational study based on an institutional registry of patients with STEMI undergoing primary PCI at a tertiary cardiology center in Salvador, Bahia, from March 2020 to August 2023. Patients with complete data regarding thrombus burden, angiographic success, and in-hospital outcomes were included. Thrombus burden was classified according to the TIMI thrombus grade scale and categorized as low/intermediate (grades 0–3) or high (grades 4–5). The primary endpoint was PCI success, defined as final TIMI 3 flow associated with residual stenosis <20%. Initial coronary flow TIMI 0–1 and final TIMI 0–2 flow were evaluated as secondary endpoints. Resultados e Conclusões: A total of 379 patients were included, of whom 291 (76.8%) presented high thrombus burden. PCI success occurred in 90.7% of patients with high thrombus burden compared with 94.3% in the low/intermediate burden group (p=0.208). Initial TIMI 0–1 coronary flow was more frequent in the high-burden group (81.8% vs 14.8%; p<0.001), and a higher frequency of final TIMI flow 0–2 was also observed in these patients (12.0% versus 5.7%; p=0.145). In this consecutive cohort of patients undergoing primary PCI, high thrombus burden was associated with worse final coronary flow, characterized by a higher frequency of post-procedural TIMI flow 0–2, in addition to lower absolute rates of angiographic success. These findings reinforce the role of high thrombus burden as a marker of potentially worse coronary reperfusion in the setting of STEMI.

In-hospital outcomes after TAVI: a multicenter analysis in two tertiary centers in Southern Brazil.

LUCAS HENRIQUE SILVA DE FARIA1; ANA CAROLINA BUZZI MORAIS1; LUIZ EDUARDO KOENIG SAO THIAGO2; RICARDO ZANELLA ANTONIOLLI2;

(1) UNIVERSIDADE DO SUL DE SANTA CATARINA - PALHOÇA - SC - Brasil; (2) HOSPITAL SOS CARDIO + INSTITUTO DE CARDIOLOGIA DE SANTA CATARINA - FLORIANÓPOLIS - SC - Brasil;

Introdução/Fundamentos: Aortic stenosis is the most clinically significant valvular heart disease, particularly in the elderly. Transcatheter aortic valve implantation (TAVI) has emerged as a less invasive alternative to surgical aortic valve replacement (SAVR), with expanding indications. Studies show that TAVI is associated with reductions in all-cause mortality and stroke, regardless of baseline surgical risk or prosthesis type. Furthermore, technique refinement, driven by technological advances and greater operator experience, has contributed to improved survival and lower long-term complication rates. Evaluation of real-world in-hospital outcomes is essential for monitoring safety and effectiveness. Objetivos: This study aims to evaluate the in-hospital outcomes of patients undergoing TAVI in two tertiary centers in Southern Brazil. Métodos: This is a multicenter, retrospective observational study including 319 patients who underwent TAVI between 2018 and 2026 in two tertiary centers in Southern Brazil. Having a mean age of 81.82 years and 54.24% of the patients were male. Data were extracted from institutional databases. The following endpoints were assessed up to hospital discharge: procedural success, in-hospital mortality, stroke and new permanent pacemaker (PPM) implantation after TAVI. Resultados e Conclusões: Discussion: TAVI demonstrated high post-procedural success rates (97.20%), associated with low in-hospital mortality (2.5%), similar to values reported in the literature, reinforcing the short-term safety of the procedure. The incidence of stroke was 1.57%, comparable to studies reporting rates around 3% at 30 days, with higher occurrence within the first 48 hours after the procedure. The need for PPM implantation remained one of the main complications associated with the procedure, with a rate of 9.72%, similar to that reported in the literature (approximately 10.8%), which has not shown significant reduction over time. Conclusion: The results were consistent with the literature, showing high success rates and low mortality, likely associated with advancements in TAVI. Stroke and the need for permanent pacemaker implantation were the most frequent complications, highlighting the need for further studies. Nevertheless, the findings support the safety and effectiveness of TAVI in real-world clinical practice.

Outcomes after TAVI

OUTCOME	NUMBER	PERCENTAGE
Procedure success	310	97,20%
Death	8	2,50%
New permanent pacemaker after TAVI	31	9,72%
Stroke	5	1,57%

INTRAVASCULAR LITHOTRIPSY VERSUS BALLOON-BASED AND ATHERECTOMY LESION PREPARATION FOR CALCIFIED CORONARY PCI: A BAYESIAN META-ANALYSIS OF RANDOMIZED TRIALS

BARBARA REIS SILVA1; AUGUSTO MONTEIRO CASTRO XAVIER CARVALHO2; JUAN PERES OLIVEIRA3; VICENTE CASTOR BRITO4; PEDRO GOMES BATISTA5; IGOR RAFAEL SANTANDER6; JULIANA GIORGI7; CAROLINE OLIVEIRA FISCHER-BACCA3;

(1) PONTIFICIA UNIVERSIDADE CATOLICA DE GOIAS - GOIÂNIA - GO - BRASIL; (2) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (3) UNIDAVI - CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL; (4) UNIVERSIDADE FEDERAL DE CAMPINA GRANDE - UFCG - CAMPINA GRANDE - PB - BRASIL; (5) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (6) CARDIO LOGICA PB - JOÃO PESSOA - PB - BRASIL; (7) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Coronary artery calcification impairs lesion preparation and stent deployment during percutaneous coronary intervention (PCI). Intravascular lithotripsy (IVL) has emerged as a novel calcium-modifying strategy and represents a less aggressive alternative to balloon-based preparation and rotational atherectomy (RA), although comparative randomized evidence remains limited. Objetivos: To compare IVL with balloon-based preparation and RA for calcified coronary PCI using Bayesian meta-analysis, providing posterior probability estimates for clinically relevant thresholds. Métodos: A systematic search of PubMed, Embase, and Cochrane databases identified randomized trials (RCTs) comparing IVL with balloon-based strategies or RA before drug-eluting stent implantation in calcified coronary lesions. Bayesian random-effects models were fitted using vague priors for the overall effect and empirical or weakly-informative priors for between-study heterogeneity. Outcomes included minimal stent area (MSA), stent expansion, and major adverse cardiovascular events (MACE). Effect sizes were reported as mean differences (MD) or odds ratios (OR). Posterior means with 95% credible intervals (CrIs), prediction intervals, and threshold probabilities were computed. Sensitivity and leave-one-out analyses assessed robustness. Resultados e Conclusões: Compared with balloon-based PCI, IVL demonstrated a 92.6% posterior probability of benefit for MSA (MD, 0.91 mm²; 95% CrI, 0.13 to 1.70) and an 86.1% probability of improved stent expansion (MD, 3.17%; 95% CrI, −1.68 to 8.03), although no clear difference was observed for MACE (OR, 0.93; 95% CrI, 0.32 to 2.67). Compared with RA, IVL yielded comparable results across MSA (MD, -0.28 mm²; 95% CrI, -0.94 to 0.39), stent expansion (MD, -0.89%; 95% CrI, -4.55 to 2.76), and MACE (OR, 3.03; 95% CrI, 0.65 to 14.11). Likewise, no credible superiority was observed versus pooled PCI strategies. Findings remained robust across sensitivity and leave-one-out analyses. Conclusions: In patients undergoing PCI for calcified coronary lesions, IVL was associated with a favorable posterior estimate for MSA compared with balloon-based strategies, while showing broadly comparable results to RA across procedural and clinical outcomes. These probabilistic findings suggest that IVL may represent a feasible alternative for calcium modification, although larger randomized studies are required to clarify its relative clinical benefit.

INTRAVASCULAR LITHOTRIPSY VERSUS ROTATIONAL ATHERECTOMY IN SEVERELY CALCIFIED CORONARY LESIONS: A BAYESIAN META-ANALYSIS OF RANDOMIZED TRIALS

ANISIO UCHOA LEITE SANTANA1; RAFAEL NUNES DAHER1; CLARA UCHOA LEITE SANTANA2; LUCAS DE QUEIROZ MENEZES2; ICARO HEICKMEN TAVEIRA EGÍDIO DE MELO2; TIAGO JOSÉ NOGUES DE ALMEIDA2; ANDRÉ ALMEIDA JORGE NOGUES DE ALMEIDA2; MIGUEL CHAVES LENZI3; MARCILIO DE OLIVEIRA FILHO4; DEBORA DE QUEIROZ MENEZES5; RODRIGO DIÓGENES MARTINS1; HENRIQUE TROMBINI PINESI6;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) UFRN - NATAL - RN - BRASIL; (3) UNIVERSIDADE ESTADUAL DO RIO GRANDE DO NORTE - MOSSORÓ - RN - BRASIL; (4) FACULDADE DE MEDICINA DE BARBACENA - BARBACENA - MG - BRASIL; (5) FACULDADE DE MEDICINA DE OLINDA - OLINDA - PE - BRASIL; (6) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Percutaneous coronary intervention of severely calcified lesions remains technically demanding due to the high risk of stent underexpansion. While rotational atherectomy (RA) is an established strategy for robust plaque modification, intravascular lithotripsy (IVL) has emerged as a modern alternative utilizing acoustic waves to fracture calcium. Objetivos: To evaluate the anatomical efficacy and clinical outcomes of IVL compared with RA in patients with severely calcified coronary lesions undergoing Randomized Controlled Trials (RCTs). Métodos: We systematically searched Pubmed, Embase, Cochrane, and ClinicalTrials.gov through March 2026 for Randomized Controlled Trials (RCTs). A Bayesian hierarchical model was fitted in Stan using Hamiltonian Monte Carlo with the No-U-Turn Sampler. Treatment effects were expressed as mean differences (MD) for continuous anatomical outcomes and odds ratios (OR) for clinical endpoints, alongside 95% credible intervals (CrI). We calculated the posterior probability of IVL superiority for anatomical [Pr(MD>0)] and clinical [Pr(OR<1)] outcomes, along with predictive probabilities for future studies. Statistical analysis was performed using the brms package in R. Resultados e Conclusões: We included 372 patients across 4 RCTs. For minimum stent area (MSA), IVL and RA demonstrated strict equivalence (MD 0.00; 95% CrI -1.88–1.77), with a coin-flip 50.2% posterior probability of favoring IVL [Pr(MD>0)] and only a 14.3% probability of achieving a more substantial anatomical benefit (MD > 0.5). For clinical endpoints, IVL was associated with a trend toward higher adverse events, albeit with wide uncertainty. TVR (OR 1.57; 95% CrI 0.54–4.55) demonstrated only a 20.2% probability of IVL superiority [Pr(OR<1)], with a 23.6% predictive probability that a future study will demonstrate clinical benefit. Similarly, MACE (OR 1.36; 95% CrI 0.47–3.84) showed only a 29.1% probability of IVL superiority, and a 31.6% predictive probability of future benefit. In conclusion, while IVL provides anatomical stent expansion strictly comparable to RA, its clinical profile shows no advantage, with posterior probabilities suggesting a trend toward higher MACE and TVR, ultimately favoring RA as the strategy with a better prognostic clinical profile.

INTRAVASCULAR ULTRASOUND-GUIDED VERSUS ANGIOGRAPHY-GUIDED PERCUTANEOUS CORONARY INTERVENTION IN ADVANCED CORONARY LESION SUBSETS: AN UPDATED SYSTEMATIC REVIEW OF RANDOMIZED CONTROLLED TRIALS

THIAGO CERVEIRA DIOGENES1; MARINA MARIA RODRIGUES AGUIAR1; GIULIA OLIVEIRA RAMALHO1; EDER OLIVEIRA COSTA1; MARIANA LANDIM VIANA1; RODRIGO GOUVEIA AZEVEDO BORGES1; JULIA BARBOSA SALES DE LIMA1; RODRIGO ALVES DE SOUZA GALVÃO2;

(1) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL; (2) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Coronary Artery Disease is a major cause of cardiovascular morbidity and mortality worldwide. In complex coronary lesions, intravascular ultrasound (IVUS)-guided percutaneous coronary intervention (PCI) may optimize stent implantation and improve clinical outcomes compared with conventional angiography-guided PCI. Although IVUS-guided PCI has emerged as an important strategy, its impact on clinical outcomes in advanced coronary lesions remains uncertain. Objetivos: This systematic review aims to synthesize the evidences from randomized controlled trials (RCT) comparing intravascular ultrasound (IVUS)-guided versus angiography-guided percutaneous coronary intervention (PCI) in patients with advanced coronary lesion subsets, focusing on cardiovascular and clinical outcomes. Métodos: This review was conducted following the PRISMA 2020 guidelines, using a strategy based on the PICOTT model. The study protocol was registered in the PROSPERO database under the number CRD420261388792. The search was conducted in PubMed, Embase, Scopus and Cochrane using search terms related to “Intravascular Ultrasound-Guided”, “IVUS”, “Angiography-Guided”, “Coronary Lesion”, and “PCI”. Studies included were published in English between 2018 and 2026 that compared IVUS-guided versus angiography-guided PCI in patients with advanced coronary lesions. Two independent reviewers, in a double-blind process, screened 1248 records imported from title/abstract and full-text sources; a third reviewer resolved disagreements. After applying the inclusion and exclusion criteria, 6 RCTs were selected for this systematic review. Resultados e Conclusões: Across six randomized controlled trials comprising 6,649 patients, IVUS/imaging-guided PCI was associated with lower rates of adverse cardiovascular outcomes compared with angiography-guided PCI, particularly for composite ischemic endpoints and repeat revascularization. Significant reductions in target vessel failure or major adverse cardiovascular events were observed in DKCRUSH VIII (6.1% vs. 14.7%; HR 0.40, 95% CI 0.23–0.71), RENOVATE-COMPLEX-PCI (10.5% vs. 14.9%; HR 0.68, 95% CI 0.51–0.91), and ULTIMATE (2.9% vs. 5.4%; HR 0.53, 95% CI 0.31–0.90). IVUS guidance also reduced clinically driven revascularization and stent thrombosis in several studies. However, OPTIMAL and IVUS-CHIP did not demonstrate superiority of IVUS guidance for their primary endpoints. Overall, benefits were more pronounced in anatomically complex and high-risk PCI lesions,

KIDNEY INJURY RISK IN INTERVENTIONAL CARDIOLOGY (KIRIC) SCORE: DEVELOPMENT OF A PREDICTION MODEL FOR CONTRAST-ASSOCIATED ACUTE KIDNEY INJURY

THIAGO MARTINS DE SOUSA1; FRANCISCO ARIEL SANTOS DA COSTA2; VIRNA RIBEIRO FEITOSA CESTARI1; THEREZA MARIA MAGALHÃES MOREIRA1; SUZANNE FREDERICKS3; VERA LÚCIA MENDES DE PAULA PESSOA1;

(1) UNIVERSIDADE ESTADUAL DO CEARÁ - UECE - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE ESTADUAL DO CEARÁ - UECE - BRASIL - CE - BRASIL; (3) TORONTO METROPOLITAN UNIVERSITY - TMU - CANADA;

Introdução/Fundamentos: Contrast-associated acute kidney injury (CA-AKI) remains a relevant complication after interventional cardiology procedures, particularly in structural settings such as transcatheter aortic valve implantation (TAVI), in which traditional risk scores have limited applicability. This study aimed to develop a risk score to predict CA-AKI in patients undergoing interventional cardiovascular procedures and to assess its performance. Objetivos: To develop and evaluate the Kidney Injury Risk in Interventional Cardiology (KIRIC) Score. Métodos: This retrospective observational cohort included 1,191 adult patients undergoing TAVI, percutaneous coronary intervention, or diagnostic coronary procedures with iodinated contrast. The primary outcome was CA-AKI, defined according to KDIGO criteria as an absolute increase in serum creatinine ≥0.5 mg/dL within 24–48 hours after the procedure or a relative increase ≥25% from baseline. Binary logistic regression was used to estimate odds ratios and ln(OR). Variables with p<0.05 were retained in the final model, and coefficients were rounded to the nearest 0.5 to generate a cumulative point score. This study complied with Resolution No. 466/2012 for research involving human subjects and was approved by the Research Ethics Committee, Fortaleza, Ceará, Brazil, under opinion No. 6,298,583. Resultados e Conclusões: The final model included seven predictors: TAVI, age >65 years, hypertension, female sex, diabetes mellitus, estimated glomerular filtration rate <30 mL/min/1.73 m², and contrast volume >300 mL. The KIRIC Score ranged from 0 to 9.5 points and stratified patients into low- (0–2.5), intermediate- (3.0–5.5), and high-risk (6.0–9.5) groups. Discriminatory performance was good, with an AUC of 0.796. Among the evaluated cutoff points, the threshold of 0.15 provided the best clinical balance, with a sensitivity of 61.4%, specificity of 83.3%, and overall accuracy of 81.6%. The KIRIC Score showed good predictive performance and may support renal risk stratification and clinical decision-making in interventional cardiology.

Figure 1 – Receiver Operating Characteristic (ROC) curve of the predictive model for identifying the risk of Contrast-Induced Nephropathy (CIN) in patients undergoing interventional cardiology procedures (n = 1,191). Fortaleza, Brazil, 2026.

LEFT ATRIAL APPENDAGE CLOSURE VS ORAL ANTICOAGULATION IN PATIENTS WITH ATRIAL FIBRILLATION AND END-STAGE RENAL DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

ANA CÂNDIDA MARQUES NOGUEIRA COÊLHO1; GABRIEL CARUSO NOVAES TUDELLA2; GIOVANA MENEGUCCI2; LETÍCIA BEATRIZ COUTINHO ALVES1; LUIS FELIPE VIEIRA NUNES PORTO1; MARIA EDUARDA FREITAS DE BITTENCOURT SILVA2; GUILHERME OLIVEIRA GOMES1; ANTÔNIO JOSÉ MARQUES NOGUEIRA COÊLHO3; FRANCISCO RAFAEL GOMES LIMA1; CARLOS EDUARDO BATISTA DE LIMA4; MAURÍCIO BATISTA PAES LANDIM4;

(1) UNIVERSIDADE FEDERAL DO PIAUI - PIAUÍ - PI - BRASIL; (2) UNIVERSIDADE FEDERAL DE SANTA MARIA - SANTA MARIA - RS - BRASIL; (3) CENTRO UNIVERSITARIO UNINOVAFAPI - TERESINA - PI - BRASIL; (4) HOSPITAL UNIVERSITARIO DA UNIVERSIDADE FEDERAL DO PIAUI - TERESINA - PI - BRASIL;

Introdução/Fundamentos: Atrial fibrillation (AF) is common in patients with end-stage renal disease (ESRD) on dialysis and carries a high risk of stroke and thromboembolism. Oral anticoagulation (OAC) is challenging due to increased bleeding risk. Percutaneous left atrial appendage occlusion (LAAO) offers a non-pharmacological option by permanently sealing the left atrial appendage,the primary site of thrombus formation in AF, potentially reducing thromboembolic events while minimizing long-term anticoagulation needs. Objetivos: This study aimed to evaluate the efficacy and safety of percutaneous LAAO compared with anticoagulation in patients with AF and ESRD undergoing hemodialysis or peritoneal dialysis. Métodos: PubMed, Embase, Cochrane Library and Web of Science were systematically searched up to February 2026 following PRISMA guidelines. It was included observational studies comparing percutaneous left atrial appendage occlusion (LAAO) versus oral anticoagulation in patients with atrial fibrillation (AF) and end-stage renal disease (ESRD) undergoing hemodialysis or peritoneal dialysis. The primary outcomes were Major Bleeding, Mortality, Systemic Embolism, Intracranial hemorrhage and gastrointestinal bleeding. Resultados e Conclusões: Across 3 included studies, a total of 8,497 patients were analyzed. The CHA2DS2-VASc score ranged from 3.94 to 4, and age ranged from 65 to 76 years. Overall, 5,075 participants were male. Hypertension was reported in 8,016 patients, while heart failure was present in 4,849 patients. Prior ischemic stroke or TIA was observed in 2,612 individuals. For gastrointestinal bleeding, pooling of two studies demonstrated a significantly higher risk associated with OAC compared to LAOO (pooled HR = 2.61; 95% CI: 2.18–3.13; p < 0.01; I² = 22.3%). Regarding major bleeding, three studies were included, and the effect remained significant (pooled HR = 1.61; 95% CI: 1.36–1.90; p < 0.01; I² = 53.3%) favoring LAOO. Exclusion of Genovesi 2021 reduced heterogeneity (I² = 21.7%) without materially changing the effect estimate. For intracranial hemorrhage, mortality, and systemic embolism, no significant differences were observed between groups.In patients with atrial fibrillation and ESRD on dialysis, OAC was associated with higher rates of gastrointestinal and major bleeding compared with LAAO. These findings suggest that LAAO may be associated with bleeding events and should be considered after careful patient selection and further investigation.

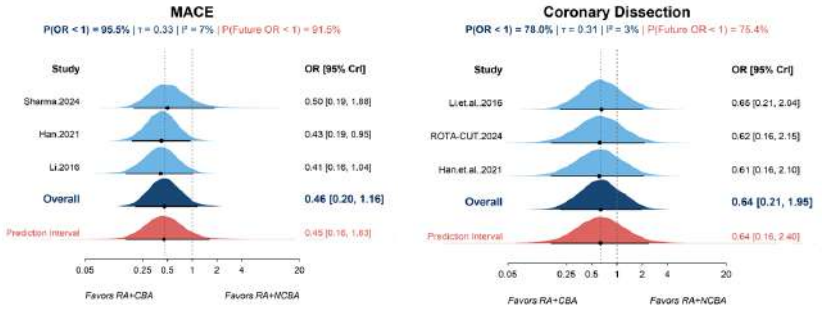
PROGNOSTIC IMPACT OF NUTRITIONAL INDICES ON MORTALITY AFTER TRANSCATHETER AORTIC VALVE REPLACEMENT: A TIME-TO-EVENT META-ANALYSIS

FELIZARDO JOSÉ LEANDRO PEREIRA1; JOÃO GUILHERME GOMES PEDROSA1; ANDRE TELIS DE VILELA ARÁUJO1; SADRAK LYON DANTAS PONTES1; MARIA EDUARDA FRANCO LONDRES GOMES1; KAROLINA AZEVEDO BRINGEL1; JOSÉ RICARDO PIRES PEREIRA1; LETÍCIA FONSECA SILVA1;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL;



Introdução/Fundamentos: Aortic stenosis is among the most prevalent cardiovascular disorders in the aging population. Over years, transcatheter aortic valve replacement (TAVR) has become a widely accepted standard therapy for elderly patients with severe disease. In this setting, frailty is a key determinant of prognosis, and within its spectrum, nutritional status has emerged as a crucial tool for risk stratification. These considerations highlight the need for improved identification and assessment of factors that may influence long-term clinical outcomes. Objetivos: To evaluate the prognostic value of nutritional indices in predicting all-cause mortality in patients undergoing TAVR. Métodos: A systematic review was conducted following PRISMA guidelines, we searched in PubMed, Embase, Web of Science, and Cochrane Library using descriptors and variations for the terms: TAVR, nutritional status, and mortality. Study selection was performed independently by two reviewers using the Rayyan platform. Studies that evaluated nutritional indices for predicting mortality were included. Hazard ratios (HR) were standardized to ensure consistency in the direction of effect. Statistical analysis was performed at RStudio. A random-effects meta-analysis was conducted based on log(HR) and standard errors. Resultados e Conclusões: A total of 20 studies including 14,121 patients were analyzed. GNRI was reported in 12 studies (n = 11,714) and was associated with increased mortality (HR 2.14, 95% CI 1.51–3.05). CONUT was evaluated in 4 studies (n = 2,066) and showed a higher risk (HR 3.70, 95% CI 1.47–9.29). The Naples score, reported in 3 studies (n = 965), demonstrated a strong association with mortality (HR 7.06, 95% CI 5.27–9.46). In contrast, PNI, evaluated in 4 studies (n = 1,551), did not show a statistically significant association (HR 1.71, 95% CI 0.82–3.58). Subgroup analyses were performed for GNRI, studies using a cutoff of 98 showed a HR of 2.28 (95% CI 1.48–3.51), while those using others demonstrated HR of 1.98 (95% CI 1.07–3.69). Stratified by geographic region, GNRI was associated with mortality in Western (HR 1.80, 95% CI 1.11–2.93) and Eastern populations (HR 2.57, 95% CI 1.52–4.36). Malnutrition is significantly associated with increased mortality after TAVR, particularly when assessed using comprehensive indices such as CONUT and the Naples. GNRI demonstrated consistent prognostic role. These findings support the role of nutritional assessment as an important component of risk stratification in patients undergoing TAVR

ROTATIONAL ATHERECTOMY FOLLOWED BY CUTTING VERSUS NON-CUTTING BALLOON ANGIOPLASTY IN SEVERELY CALCIFIED CORONARY LESIONS: A BAYESIAN META-ANALYSIS OF RANDOMIZED TRIALS

ANISIO UCHOA LEITE SANTANA1; ALFREDO ROGÉRIO DIAS DALCOMUNI1; GABRIEL ERZINGER2; LUCAS DE QUEIROZ MENEZES3; TIAGO JOSÉ NOGUES DE ALMEIDA3; ANDRÉ JORGE NOGUES DE ALMEIDA3; MARINA UCHÔA DE ARAÚJO3; DEBORA DE QUEIROZ MENEZES4; MIGUEL CHAVES LENZI5; MARCILIO DE OLIVEIRA FILHO6; AMANDA LIRA GONÇALVES DE MEDEIROS3; HENRIQUE TROMBINI PINESI7;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE DA REGIAO DE JOINVILLE - JOINVILLE - SC - BRASIL; (3) UFRN - NATAL - RN - BRASIL; (4) FACULDADE DE MEDICINA DE OLINDA - OLINDA - PE - BRASIL; (5) UNIVERSIDADE ESTADUAL DO RIO GRANDE DO NORTE - MOSSORÓ - RN - BRASIL; (6) FACULDADE DE MEDICINA DE BARBACENA - BARBACENA - MG - BRASIL; (7) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Percutaneous coronary intervention of severely calcified lesions often requires aggressive lesion preparation. While rotational atherectomy (RA) effectively ablates superficial calcium, subsequent balloon dilation is crucial to facilitate optimal stent delivery and expansion. The adjunctive use of cutting balloon angioplasty (CBA) following RA has emerged as a promising strategy to further modify calcific plaques compared to standard non-cutting balloon angioplasty (NCBA). Objetivos: To evaluate the periprocedural safety and long-term clinical outcomes of RA+CBA compared with RA+NCBA in patients with severely calcified coronary lesions undergoing Randomized Controlled Trials (RCTs). Métodos: We systematically searched Pubmed, Embase, and Cochrane through March 2026 for Randomized Controlled Trials (RCTs). A Bayesian hierarchical model was fitted in Stan using Hamiltonian Monte Carlo with the No-U-Turn Sampler. Treatment effects were expressed as odds ratios (OR) for clinical and safety endpoints, alongside 95% credible intervals (CrI). We calculated the posterior probability of RA+CBA superiority [Pr(OR<1)], along with predictive probabilities for future studies. Statistical analysis was performed using the brms package in R. Resultados e Conclusões: We included 251 patients across 3 RCTs. For periprocedural safety, RA+CBA demonstrated a protective trend against coronary dissection (OR 0.64; 95% CrI 0.21–1.95), with a 78.0% posterior probability of benefit [Pr(OR<1)] and a 75.4% predictive probability that a future study will demonstrate benefit. For long-term efficacy, the use of CBA indicated a strong trend toward reducing target vessel revascularization (TVR) (OR 0.48; 95% CrI 0.15–1.57), driven by an 89.2% probability of superiority and an 86.2% predictive probability of future benefit. For major adverse cardiovascular events (MACE), RA+CBA was associated with a high probable risk reduction (OR 0.46; 95% CrI 0.20–1.16) with a 95.5% posterior probability favoring RA+CBA, alongside a 91.5% predictive probability of future clinical benefit. In conclusion, the adjunctive use of cutting balloons following rotational atherectomy provides a highly probable clinical advantage over non-cutting balloons, suggesting reduction in MACE and a trend toward lower TVR and dissection rates, ultimately favoring RA+CBA with a better prognostic clinical profile.

ROUTINE PERCUTANEOUS CORONARY INTERVENTION PRIOR TO TRANSCATHETER AORTIC VALVE IMPLANTATION: A BAYESIAN META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

PEDRO GOMES BATISTA1; RAILLA RAQUEL ALBINO DOS SANTOS SILVA2; MUSHRIN MALIK3; GIULIA CALDEIRA GAELZER4; MARCELA VASCONCELOS MONTENEGRO5; CAROLINE O. FISCHER BACCA6; JULIANA GIORGI7;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (2) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL; (3) BETH ISRAEL DEACONESS MEDICAL CENTER - UNITED STATES; (4) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (5) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL; (6) CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL; (7) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: The optimal management of concomitant coronary artery disease (CAD) during transcatheter aortic valve implantation (TAVI) remains controversial due to conflicting data from randomized controlled trials (RCTs). Objetivos: To evaluate routine percutaneous coronary intervention (PCI) versus conservative management in TAVI patients with CAD using a Bayesian meta-analysis. Métodos: A systematic review and Bayesian meta-analysis of RCTs (through April 2026) compared routine percutaneous coronary intervention (PCI) versus conservative management in TAVI patients with CAD. Treatment effects were estimated as risk ratios (RRs) with 95% credible intervals (CrIs) using a Bayesian random-effects model, with posterior probabilities calculated to assess the likelihood of a protective effect (RR ≤ 1.00), a substantial reduction in risk (RR ≤ 0.75), or harm (RR > 1.00). Resultados e Conclusões: Three RCTs (N = 1,156) were included, of whom 579 patients (50%) underwent prior PCI. Routine PCI significantly reduced the risk of subsequent revascularization (RR, 0.27; 95% CrI, 0.11 to 0.66; 99.3% probability of benefit). Point estimates favored PCI for cardiovascular death (RR, 0.74; 95% CrI, 0.44 to 1.24), stroke (RR, 0.71; 95% CrI, 0.42 to 1.20), myocardial infarction (RR, 0.83; 95% CrI, 0.44 to 1.60), and all-cause mortality (RR, 0.92; 95% CrI, 0.62 to 1.35); however, a substantial proportion of the posterior distribution lay above RR = 1, indicating a meaningful probability of harm and overall uncertainty. Conversely, PCI was associated with an increased risk of major bleeding (RR, 1.57; 95% CrI, 0.96 to 2.57; 96.8% probability of harm). Routine PCI before TAVI in patients with concomitant CAD reduces subsequent revascularization and may lower cardiovascular death and stroke, but increases bleeding without clear benefit for all-cause mortality. These findings support an individualized, patient-centered balance between ischemic and bleeding risks.

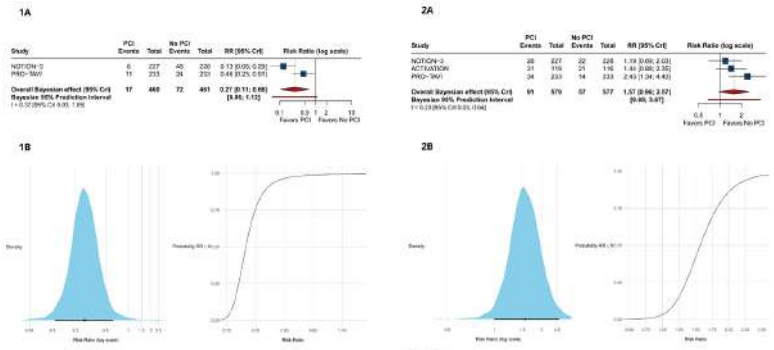

Figure 1.
(A) Bayesian forest plots showing the relative risk (RR) of routine percutaneous coronary intervention (PCI) versus conservative management prior to transcatheter aortic valve implantation (TAVI) for any revascularization outcome. (B) Marginal posterior density distribution of the overall RR, along with the corresponding cumulative probability curve.

Figure 2.
(A) Bayesian forest plots showing the relative risk (RR) of routine percutaneous coronary intervention (PCI) versus conservative management prior to transcatheter aortic valve implantation (TAVI) for major bleeding outcome. (B) Marginal posterior density distribution of the overall RR, along with the corresponding cumulative probability curve.

TRANSCATHETER EDGE-TO-EDGE REPAIR FOR ATRIAL VS VENTRICULAR FUNCTIONAL MITRAL REGURGITATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

RICARDO FONSECA OLIVEIRA SURUAGY-MOTTA1; JUAN PINILLA1; BEATRIZ MELO MIRANDA PAES1; TAREK CASTRO FAYYAT2; ZARAITH COY1; EVANDRO MARTINS FILHO3; ALEXANDRE ABIZAID4; BRUNNA PILEGGI4; ALBERTO COLELLA CERVONE5; LUCA CRISTIN4; LIONEL TASTET4; GREGG W STONE4;

(1) CENTRO UNIVERSITARIO CESMAC - MACEIO - AL - BRASIL; (2) UNIVERISADE POSITIVO - CURTIBA - PR - BRASIL; (3) SANTA CASA DE MISERICORDIA DE MACEIO - MACEIÓ - AL - BRASIL; (4) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (5) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Functional mitral regurgitation (FMR) may be categorized into atrial (aFMR) and ventricular (vFMR) phenotypes. While transcatheter edge-to-edge repair (TEER) is established for vFMR, whether clinical outcomes are as favorable for aFMR remains unclear. Objetivos: This systematic review and meta-analysis aims to compare the long-term clinical efficacy of transcatheter edge-to-edge repair (TEER) in patients with atrial functional mitral regurgitation (aFMR) versus ventricular functional mitral regurgitation (vFMR). Métodos: We systematically searched PubMed, Cochrane, Web of Science, Scopus, and Embase through November 2025 for studies comparing outcomes of TEER after treatment in patients with aFMR versus vFMR. The primary endpoints of interest were 2-year all-cause mortality and heart failure hospitalizations (HFH), analyzed using reconstructed individual patient data (IPD) from Kaplan–Meier curves in mixed-effects Cox proportional hazards models. Secondary outcomes included procedural success in reducing MR, early procedural safety, follow-up MR grade, and mid-term functional status (NYHA class I/II), analyzed using random-effects meta-analysis. Resultados e Conclusões: Seven studies involving 4,166 patients (aFMR: 662; vFMR: 3,504) were included. aFMR patients were older, had a higher prevalence of atrial fibrillation and preserved left ventricular ejection fraction (LVEF), whereas vFMR patients had larger ventricular diameters and lower LVEF. IPD meta-analysis (n=4,124) demonstrated lower 2-year mortality in TEER-treated aFMR compared with vFMR patients (HR 0.73; 95% CI 0.59–0.90; p=0.003). Procedural success, early procedural complications (mortality, stroke, bleeding), MR grade during follow-up, mid-term functional improvement to NYHA class I/II and rates of HFH after TEER were comparable between groups. In patients undergoing TEER, the aFMR phenotype is associated with better 2-year survival compared with vFMR. Both groups derive similar symptomatic benefits from the procedure, supporting TEER as an effective therapy for aFMR as well as vFMR.

A SILENT CARDIOVASCULAR WAVE: FORECASTING THE BURDEN AND ECONOMIC IMPACT OF CHAGAS CARDIOMYOPATHY IN THE BRAZILIAN AMAZON (2007–2033)

JOSE LUCAS PIRES REBELO DA GAMA1; ANDREA SILVESTRE SOUZA1; IGOR COSTA COSTERMANI1; FELIPE DIR LONG HSING1; ANNA TEREZA PIZZOLANTE SECCO1; RONIR RAGGIO LUIZ1; RENATA MOLL BERNARDES1; JOSÉ CARLOS PIZZOLANTE SECCO1; ALINE SILVA DE MEDEIROS1; ADRIANA MACINTYRE INNOCENZI1; JESSICA PRONESTINO DE LIMA MOREIRA1; MARIANA PÓVOA CORRÊA1;

(1) IDOR - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: The Brazilian Amazon, particularly Pará, concentrates most acute Chagas disease notifications in the country, accounting for over 80% of reported cases. Sustained transmission, largely driven by oral outbreaks, is generating cohorts at risk of chronic disease. Around 30% of infected individuals may develop cardiomyopathy, creating a silent and cumulative cardiovascular burden with potential impact on heart failure, arrhythmias, and premature mortality. Objetivos: To estimate the expected burden of chronic Chagas disease and cardiomyopathy and its economic impact in Pará from 2007 to 2033. Métodos: Retrospective and predictive study using SINAN data on acute cases. Projections were performed using Poisson regression, assuming a 4.6% annual transition rate from acute infection to chronic disease (MARTINS-MELO et al., 2014). The expected burden of chronic disease and cardiomyopathy was estimated using established progression rates. Economic impact was calculated using lifetime societal cost parameters from The Lancet Regional Health – Americas (2025). Resultados e Conclusões: Between 2007 and 2023, 3,858 acute cases were reported in Pará, indicating sustained transmission. Projections estimate 3,030 cumulative chronic cases by 2033. Applying known progression rates, a substantial proportion is expected to develop cardiomyopathy, contributing to future heart failure and other cardiovascular complications. In settings with limited diagnostic capacity, part of this burden may remain unrecognized within routine cardiovascular care. Considering a lifetime societal cost of R$ 225,270 per chronic patient (THE LANCET, 2025), the economic impact is estimated to exceed R$ 682 million over the next decade, with the most significant part of the costs attributable to cardiomyopathy (60.3 million yearly). These findings indicate an epidemiological transition toward a growing cardiovascular burden. If unaddressed, today's acute infections will become tomorrow's heart failure cases, silently reshaping the cardiovascular landscape of the Amazon.

CARDIOVASCULAR OUTCOMES IN PEDIATRIC RHEUMATIC HEART DISEASE: A PRISMA-BASED SYSTEMATIC REVIEW

ANA LAURA FERNANDES FERREIRA1; JÚLIA GURGEL BERNARDO1; MARIA LAURA LIMERES1; CLAUDIA MACHADO SIQUEIRA1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: Rheumatic heart disease (RHD) remains a major cause of cardiovascular morbidity and mortality in children, particularly in low- and middle-income countries, with significant long-term clinical impact. Objetivos: To evaluate the main cardiovascular outcomes associated with pediatric RHD, focusing on clinical severity, progression, and major complications. Métodos: A systematic review was conducted according to PRISMA guidelines. A total of 396 records were identified, with 32 duplicates removed and 364 studies screened. After title/abstract and full-text assessment, 18 studies were included. Eligible studies involved pediatric populations with RHD and reported cardiovascular outcomes. A qualitative synthesis was performed. Resultados e Conclusões: Data from clinical trials, observational cohorts, and screening programs conducted in endemic regions—including Ethiopia, Egypt, India, and Thailand—involving over 20,000 children across 18 publications were analyzed. RHD predominantly affected late childhood and early adolescence (mean 11–15 years), a peak that reflects a pattern of cumulative valvular damage resulting from recurrent streptococcal infections and failures in secondary prophylaxis. Valvular dysfunction was the most frequent manifestation, particularly mitral regurgitation, reported in up to 93.8% of cases. A high burden of severe disease at diagnosis was observed, with heart failure present in up to 61.4% of patients in low-resource settings. Pulmonary hypertension (up to 59.3%) and atrial fibrillation (up to 9.1%) were also reported. Long-term outcomes revealed substantial morbidity, including a significant decline in survival rates over time (up to 40% mortality at 8 years in high-risk groups) and a frequent need for valve surgery, reported in approximately 13.8% of cases in middle-income cohorts. Screening studies identified subclinical disease with progression rates of 12.5% within 2 years. Overall, pediatric RHD is associated with early-onset, severe cardiovascular complications and significant long-term burden. These findings highlight critical gaps in early diagnosis, implementation of secondary prevention, and access to specialized care in high-burden regions.

Introdução/Fundamentos: Sustained parasitological clearance is the primary objective of chronic Chagas disease treatment. However, the standard 60-day benznidazole regimen is limited by high toxicity and treatment discontinuation rates. Objetivos: We aimed to evaluate the comparative efficacy and safety profile of different antitrypanosomal drugs and reduced-duration dosage regimens in adult patients with chronic Chagas disease. Métodos: We systematically searched PubMed, Embase, and Cochrane to identify randomized clinical trials (RCTs) evaluating antitrypanosomal therapy in chronic Chagas disease. The primary efficacy endpoint was sustained parasitological clearance (negative qPCR at 12 months). Safety endpoints included treatment discontinuation due to adverse events (AE) and serious adverse events (SAE). A frequentist network meta-analysis was performed using a random-effects model to synthesize direct and indirect evidence. Treatment effects were estimated as odds ratios (OR) with 95% confidence intervals (CI). Treatment hierarchy was established utilizing P-scores. A bivariate scatter plot was generated to analyze the benefit-risk trade-off between efficacy and safety endpoints. Resultados e Conclusões: We included 3 RCTs comprising 675 patients. We evaluated diverse regimens of benznidazole, E1224, and fosravuconazole combinations. For sustained parasitological clearance (negative qPCR at 12 months), all benznidazole-containing regimens were superior to placebo. Benznidazole 300 mg/30 days ranked highest for efficacy (P-score = 0.85; OR vs. placebo = 129.23, 95% CI 22.92-728.73), followed by benznidazole 150 mg/60 days (P-score = 0.75; OR = 86.36, 95% CI 24.06-309.99). The standard regimen (benznidazole 300 mg/60 days) ranked seventh (P-score = 0.59). However, safety analysis demonstrated an inverse relationship between efficacy and tolerability. Placebo (P-score=0.94) and all E1224 dosages (P-scores > 0.70) had the lowest rates of adverse event-related discontinuation, whereas Benznidazole 300 mg/30 days presented the highest rate of AE-related discontinuation (P-score = 0.15). Benefit-risk trade-off analysis indicated that the short-course regimen of benznidazole 300 mg/14 days provided comparable efficacy (P-score = 0.58) and safety (P-score = 0.42) to the standard 60-day regimen (P-scores = 0.59 and 0.41, respectively). E1224 regimens demonstrated high safety profiles but lacked sustained parasitological efficacy.

ECHOCARDIOGRAPHIC SCREENING PERFORMED BY MEDICAL STUDENTS TO DETECT RHEUMATIC HEART DISEASE: A STUDY OF 257 RURAL BRAZILIAN SCHOOLCHILDREN

ALEXANDRE NEGRAO PANTALEAO1; JOÃO VÍTOR BASÍLIO BARROS1; SARA CUPERTINO1; BRUNA VIEIRA GUARÇONI1; KACIANE KRAUSS BRUNO OLIVEIRA1; ANTONIO MUTARELLI1; THIAGO DORNELAS DE OLIVEIRA1; JOSÉ DIAS DE ASSIS NETO1; BRENNO AUGUSTUS ALVES DOS SANTOS1; LUZ MARINA TACURI CHAVEZ1; BRUNO RAMOS NASCIMENTO1; MARIA DO CARMO PEREIRA NUNES1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: Rheumatic heart disease (RHD) remains a major health concern affecting over 55 million people and causing 590,000 deaths annually, primarily in developing countries. Echocardiographic screening for RHD allows early detection of subclinical cases and timely initiation of antibiotic prophylaxis. Training medical students may help scale up screening strategies of RHD in endemic regions. Objetivos: To evaluate the prevalence of subclinical RHD in rural Brazilian schoolchildren through an echocardiographic screening performed by medical students. Métodos: Four final-year medical students doing their primary care rotation in a rural Brazilian town were trained using a hybrid strategy (8-hour online course and a 3-day in-person immersion). Screening was conducted in a public school for students aged 10 to 21 years old, and parental informed consent was obtained. Two handheld Phillips Lumify® machines were used for image acquisition, including the parasternal long-axis, short-axis of the aortic valve and apical four-chamber views. All screening images were analyzed by an experienced cardiologist, and those with limited echocardiographic window or abnormal findings according to the 2023 World Heart Federation (WHF) RHD diagnostic criteria were referred for a complete echocardiogram for definitive diagnosis. Resultados e Conclusões: In total, 257 students from one public school were screened over an 8-day period. The mean age was 14.5 ± 2.2 years old, 61% were female, and mean height and weight were 1.63 ± 0.1 m and 56.9 ± 13.3 kg, respectively. Regarding housing, the mean household occupancy was 4.2 ± 1.3 residents (1.2 ± 1.0 children under 15), and 21% of patients lived in non-owned houses. Among the 257 screened students, 17 underwent a complete echocardiogram (15 due to suspected RHD and 2 due to limited echocardiographic window). Of those, after the formal echocardiogram, 9 patients had normal findings, 4 patients (1.6%) were diagnosed with other congenital abnormalities, and 4 patients (1.6%) fulfilled the 2023 WHF criteria for RHD diagnosis, all of them as stage B involving pathological mitral regurgitation. The prevalence of subclinical RHD in schoolchildren from a rural Brazilian town was 1.6% (95% CI 0.6 - 3.9%). Training medical students to acquire images for echocardiographic screening is a valuable tool to scale up RHD detection in endemic areas, enabling early diagnosis and timely secondary prophylaxis.

EFFICACY AND SAFETY OF ANGIOTENSIN RECEPTOR-NEPRILYSIN INHIBITORS IN IMPROVING CARDIAC FUNCTION IN CHAGAS CARDIOMYOPATHY: A SYSTEMATIC REVIEW

GABRIELA PIXUNA DIAS1; ALANNE RYLLARI DA SILVA DOS SANTOS1; JULIANA OLIVEIRA DE ALMEIDA1; CLÁUDIA LORENA XAVIER DA SILVA2; GLÓRIA ALBUQUERQUE FRANCO1; FERNANDA NEVES VILHENA MATOS1; MARIA GIOVANNA DA CRUZ TOCANTINS1; ANA CAROLINA RODRIGUES NASCIMENTO3; MANOELA CORRÊA DE SOUZA1; NAARA SILVEIRA ABDON MELO1; PAULA GABRIELA COSTA DA CONCEIÇÃO BARBOSA1; ANTONIO MARIA ZACARIAS ARAÚJO MONTEIRO4;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL; (3) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (4) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Chronic Chagas cardiomyopathy (CCC) is the most severe manifestation of Chagas disease, a neglected and endemic tropical zoonosis, particularly in Latin America. Characterized by fibrosis, arrhythmias, and cardiomyocyte destruction, its progression to heart failure represents the poorest prognosis of the pathology. Sacubitril/valsartan has demonstrated benefits in HFrEF of other etiologies, but little is known about its effects specifically on CCC. Objetivos: To evaluate the clinical efficacy and safety profile of angiotensin receptor-neprilysin inhibitors (ARNI) in improving cardiac function parameters in patients with chronic Chagas cardiomyopathy. Métodos: A systematic review of randomized clinical trials (RCTs) was conducted according to PRISMA 2020 guidelines and the PICO strategy. The search was performed across PubMed, Cochrane, and BVS databases between 2016 and 2026, using the descriptors “Chagas Cardiomyopathy” and “Angiotensin Receptor-Neprilysin Inhibitors,” and their synonyms, combined with Boolean operators. RCTs investigating the efficacy and safety of ARNI compared to placebo or standard of care on the cardiac function of Chagas cardiomyopathy patients were included. Research involving heterogeneous heart failure etiologies that did not present stratified analysis for Chagas was excluded. Resultados e Conclusões: Three RCTs were included (n= 1,112), with a target ARNI dose of 200 mg twice daily. Although one study did not demonstrate a significant reduction in cardiovascular deaths or heart failure (HF) hospitalizations over 25 months, the intervention outperforms standard treatment by reducing biomarkers of myocardial stress and injury. There was a robust and superior reduction in NT-proBNP levels in the ARNI group (30.6% reduction vs. 5.5% with enalapril; Win Ratio 1.52; 95% CI 1.28–1.82; p < 0.001). Other data corroborate these findings, showing no additional improvement in left ventricular ejection fraction (LVEF) at 6 months (difference of 0.9%; p = 0.36), but confirming the sharp reduction of the biomarker (ratio 0.68; 95% CI: 0.57-0.68; p < 0.001). These findings, combined with improved quality of life and a similar safety profile regarding hypotension and renal dysfunction, position ARNI as fundamental in curbing HF progression in CCC. However, further studies are required to consolidate long-term benefits across different disease phenotypes.

18597

EFFICACY OF GLP-1 RECEPTOR AGONISTS ON WEIGHT REDUCTION AND CARDIOMETABOLIC OUTCOMES IN ANTIPSYCHOTIC-TREATED PATIENTS: A SYSTEMATIC REVIEW

JOÃO PAULO CALEGARO SALVARANI1; RAFAEL CARRARO DE REZENDE1; MARSELHA MARQUES BARRAL MONTESSI1;

(1) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL;

Introdução/Fundamentos: Antipsychotics, particularly second-generation agents, are associated with weight gain and metabolic disturbances, increasing cardiovascular risk. Although strategies such as off-label metformin are used, more effective approaches are needed. GLP-1 receptor agonists (GLP-1 RAs) have emerged as a promising option due to their effects on weight and cardiometabolic parameters. Objetivos: To evaluate the effects of GLP-1 RAs on weight reduction and cardiometabolic outcomes in patients receiving antipsychotics. Métodos: A systematic review was conducted per PRISMA guidelines. MEDLINE and SciELO were searched for clinical trials published in the last 10 years using the MeSH terms: “GLP-1 receptor agonist” , “antipsychotics” and “weight gain”. Eligible studies included randomized controlled trials (RCTs) in overweight or obese patients using antipsychotics, undergoing long-acting GLP-1 RA therapy, with ≥16 weeks of follow-up. Studies without relevant cardiometabolic outcomes were excluded. Resultados e Conclusões: Three RCTs met inclusion criteria (four articles, including one long-term follow-up), comprising a total of 288 patients with schizophrenia or related disorders. Interventions involved semaglutide (N=92) and liraglutide (N=52). Semaglutide significantly reduced weight (−9.21 kg; 95% CI: −11.68 to −6.75) and increased HDL (+10.81 mg/dL; 95% CI: 2.70–18.53; p=0.007). Compared to placebo, semaglutide and liraglutide reduced body weight (respectively: −13.46 kg and −5.3 kg; p<0.01) and improved waist circumference, systolic blood pressure, and LDL (p<0.05). At one-year follow-up after liraglutide discontinuation, partial weight regain (−3.8 kg; 95% CI: −7.3 to −0.2; p=0.04) and loss of cardiometabolic benefits were observed. Regarding safety, both drugs were well-tolerated; the most frequent side effects were mild gastrointestinal symptoms (e.g., nausea and constipation), which in general did not lead to significant treatment discontinuation. GLP-1 RAs are associated with significant weight loss and cardiometabolic improvement in antipsychotic-treated patients, presenting a tolerable profile. However, evidence is limited by small samples and short follow-up, with uncertain long-term sustainability. Larger trials are needed.

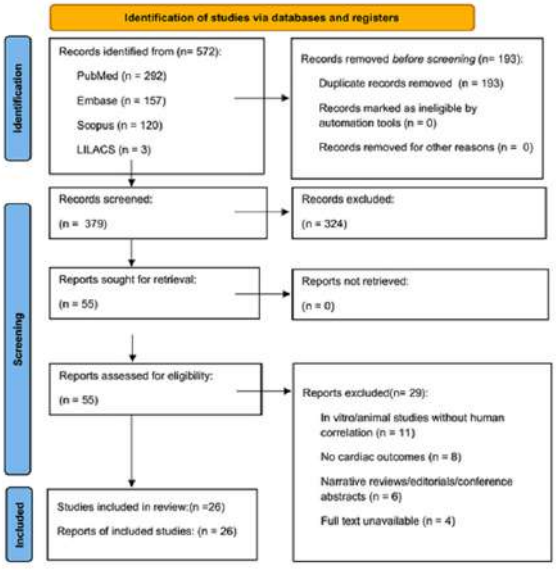
GENDER DISPARITIES IN MORTALITY FROM CHAGAS CARDIOMYOPATHY WITH HEART FAILURE AND STROKE.

NATHALIA BORGES1; ANTONIO DE PADUA MANSUR2;

(1) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases (CVD) are the leading cause of death in Brazil and worldwide. Heart failure (HF) has high mortality, reaching 39% in women and 72% in men over 15 years. The risk of stroke is slightly higher in men, while left ventricular dysfunction has a greater impact on women. In Chagas disease (CD), HF is commonly associated with systolic dysfunction and reduced ejection fraction. CD is a major cause of HF in Latin America, and understanding this relationship is essential to improve prognosis. Objetivos: To identify sex-specific risk factors for all-cause mortality and assess the impact of heart failure phenotypes and etiologies on overall and cardiovascular mortality in women and men. Métodos: This retrospective study included 634 patients with Chagas-related heart failure between 2017 and 2024, including stroke cases. Clinical characteristics, diagnostic data, and outcomes were analyzed according to HF etiologies and phenotypes defined by left ventricular ejection fraction (LVEF). The primary outcome was all-cause mortality; secondary outcomes included cardiovascular mortality, hospitalizations, and comorbidities. Statistical analysis comprised comparative tests, regression, Kaplan–Meier curves, and Cox proportional hazards models, with a 5% significance level. Resultados e Conclusões: The study included 634 patients with Chagas cardiomyopathy, with a high mortality rate (59.6%) during follow-up. Patients who died were older (65.8 vs. 61.5 years; p<0.001) and had worse ventricular function, evidenced by lower left ventricular ejection fraction both at baseline and at final evaluation (39.0% vs. 44.0% and 36.9% vs. 49.1%, respectively; p<0.001), in addition to larger cardiac dimensions and greater remodeling. Kaplan–Meier analysis showed lower survival in patients with prior stroke compared to those without. Increasing age was independently associated with higher mortality risk (HR = 1.02; 95% CI: 1.01–1.03; p < 0.001), corresponding to an approximate 2% increase per additional year of life. Clinically, there was a higher prevalence of dyspnea, atrial fibrillation, and comorbidities such as renal failure, anemia, and stroke, as well as a higher burden of risk factors and presence of intracardiac thrombus. Sex-stratified analysis showed similar findings, with anemia more strongly associated in men and diabetes in women, while renal failure predicted mortality in both groups. Therefore, Prior stroke was not an independent predictor; mortality was mainly driven by heart failure severity.



21194

IMPAIRMENT OF INNATE IMMUNITY AND EXACERBATED INFLAMMATION AS DETERMINANTS OF CARDIAC INVOLVEMENT IN CHAGAS DISEASE: A SYSTEMATIC REVIEW.

LAISA HONORATO MENESES1; LAÍS BEZERRA LIMA VERDE1; GUILHERME LUCENA DE AQUINO1; HEITOR DA JUSTA MOURÃO1; GIOVANNA TEIXEIRA GUEDES MEIRELES1; REBECA CAVALCANTE MENDES SOEIRO1; MARIA SOFIA BEZERRA FREIRE GOMES1; MARIA GIULIA MARANHÃO IBIAPINA DE PAULA1; SILVIA FERNANDES RIBEIRO DA SILVA1; SONIA LEITE DA SILVA1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Trypanosoma cruzi affects 6-8 million people across the Americas, and 30-40% develop chronic Chagas cardiomyopathy (CCC), with an annual mortality rate of 7.9%. Pathogenesis involves impaired innate immunity, sustained inflammation, and mitochondrial dysfunction, leading to myocardial damage. Objetivos: To evaluate the role of innate immunity and exacerbated inflammation in the pathophysiology of Chagas disease and their contribution to CCC development and progression. Métodos: A systematic review was conducted according to PRISMA guidelines using PubMed, EMBASE, SCOPUS, and LILACS (2021-2025). Search terms included: Trypanosoma cruzi, Chagas disease, innate immunity, immune response, cardiac involvement, cardiomyopathy, and myocarditis. Human studies with confirmed Chagas disease and cardiac outcomes were included; in vitro/animal studies, narrative reviews, and editorials were excluded. Of 572 records, 379 remained after deduplication; 55 were assessed for eligibility and 26 included. Resultados e Conclusões: Cardiac involvement results from a dysregulated immune response, insufficient to eradicate the parasite yet capable of sustaining chronic inflammation. The cardiac form was associated with activation of monocytes, cytotoxic T cells, and antigen-presenting pathways, with increased TNF-α, IFN-γ, IL-6, IL-1β, IL-17, IL-12, IL-15, and chemokines (CXCL10, CCL5, CCL2, CXCL9), alongside reduced IL-10. Lymphocyte analysis showed reduced regulatory CD4+ phenotypes and increased cytotoxic profiles expressing granzymes and perforin; CD4-CD8- and gamma delta T cells were also associated with the cardiac form. Histopathology demonstrated persistent myocarditis, CD8+ infiltrate, fibrosis, and myocardial remodeling. Preliminary genomic evidence identified the rs34238187/C18orf42 locus associated with cardiomyopathy susceptibility through immune pathways. In advanced stages, BNP and troponin T, together with reduced ejection fraction, showed greater prognostic value than inflammatory cytokines, while galectin-3, NT-proBNP, and LOXL2 emerged as progression markers. No study evaluated therapies directly targeting innate immunity. Progression to the cardiac form depends on parasite burden, genetic susceptibility, inflammation, and loss of regulatory mechanisms. Integrated biomarker panels may improve risk stratification, and immunomodulatory clinical trials are warranted.

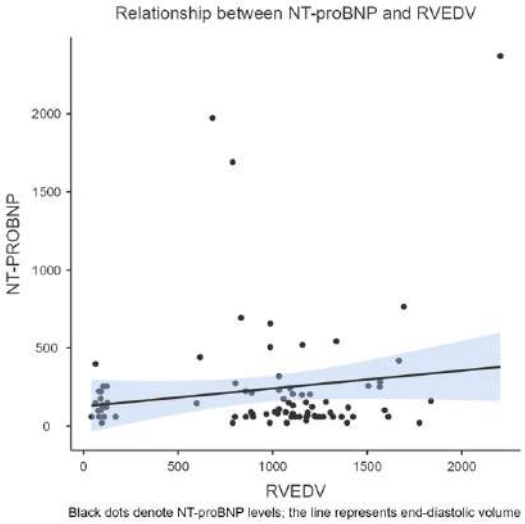
REGIONAL DISPARITIES IN RHEUMATIC HEART DISEASE MANAGEMENT: A NATIONWIDE STUDY IN BRAZIL

LUCAS BASTOS CARVALHO1; ANA LUÍSA ABREU LESSA RIBEIRO1; CATHARINA RIBEIRO LYRA1; EDUARDO FAGUNDES MURICY1; ALEXSANDRO FAGUNDES MURICY2;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL; (2) UNEB - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Clinical guidelines recommend definitive surgical or percutaneous valve interventions to prevent mortality in advanced Rheumatic Heart Disease (RHD). However, structural inequities in healthcare infrastructure may promote a reliance on palliative clinical management in vulnerable regions. This chronic allostatic burden, driven by delayed access to high-complexity cardiovascular care, potentially erodes survival outcomes among underserved populations. Objetivos: To assess regional disparities in the provision of definitive surgical treatment versus palliative clinical management for RHD in Brazil, and test whether geographic vulnerability modifies the standard of care. Métodos: We performed a population-based analytical study using individual microdata from the Brazilian Mortality Information System and Hospital Information System, extracted in R with the microdatasus package. RHD deaths (ICD-10 I05-I09) and hospital admissions for the entire population in Brazil in 2022 were analyzed. Admissions were categorized into clinical management (SIGTAP 0303060115) or definitive valve interventions (SIGTAP 0406010692, 0406010803, 0406010820, 0406030120). Differences in treatment modality across macro-regions were evaluated using Pearson's Chi-squared test. Effect modification by region was assessed using Odds Ratios (OR) and 95% confidence intervals (CI) via Fisher's Exact Test, using the South region as the reference. Resultados e Conclusões: In 2022, 2,505 deaths from rheumatic heart disease (RHD) were recorded in Brazil. Treatment patterns differed significantly across regions (p<0.001). The South showed a resolutive model, with 4.96 surgical procedures per death and low hospitalization burden. In contrast, underserved regions showed care substitution. Compared with the South, patients in the Northeast had higher odds of receiving clinical palliative care instead of surgery (OR 4.97; 95% CI 4.08–6.07; p<0.001), indicating limited surgical access. In the North, deaths occurred without corresponding surgical procedures, suggesting critical service gaps. These findings show that structural inequities modify RHD care delivery in Brazil, overriding guideline-based management. They highlight the need to decentralize high-complexity cardiovascular services and reduce reliance on clinical management when surgical treatment is indicated.



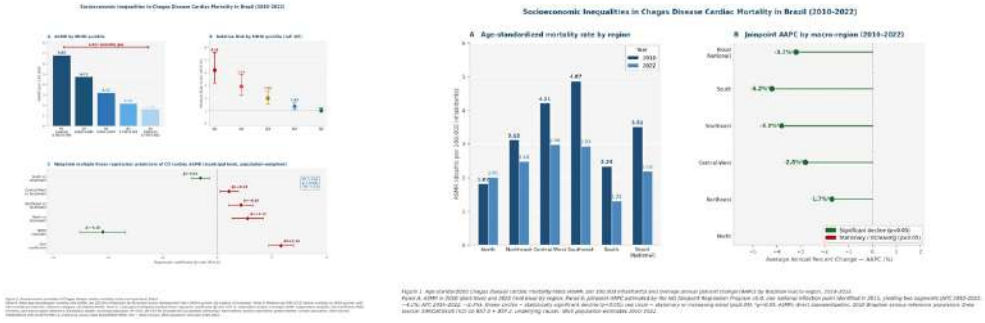
17787

RELATIONSHIP BETWEEN NT-PROBNP AND RIGHT VENTRICULAR FUNCTION: EVIDENCE OF EARLY REMODELING IN CHRONIC CHAGAS DISEASE

MARIA JULIA NASCIMENTO DE LIMA1; LUANA DO AMARAL DIAS2; ISABELLE CONCEIÇÃO ALBUQUERQUE MACHADO MOREIRA2; FLÁVIO HILTON FEIJÓ CAVALCANTI SILVA2; GABRIELLY NASCIMENTO DE LIMA3; CAMILA NOGUEIRA LEANDRO LIRA2; POLIANA MILENA DA SILVA2; SARA RODRIGUES CORDEIRO DA SILVA2; ISABELA HADASSA SILVA MENOR2; WILSON DE OLIVEIRA JÚNIOR2; LUIZ FERNANDO FERREIRA DE PINHO4; SILVIA MARINHO MARTINS ALVES2;

(1) UPE - RECIFE - PE - BRASIL; (2) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL; (3) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (4) DIAGNOSON- GRUPO FLEURY - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Chagas cardiomyopathy (CC) is characterized by intense inflammatory tropism and interstitial fibrosis, which frequently affect the right ventricle (RV) early and independently of left ventricular (LV) function. In stage B1, despite a preserved LV ejection fraction (LVEF), the loss of RV geometry and subclinical remodeling emerge as critical determinants of a worse prognosis. NT-proBNP measurement may be useful as a marker of RV wall stress in this scenario, suggesting a potential role in early risk stratification. Objetivos: To verify the association of NT-proBNP levels with the remodeling pattern and right ventricular function in chronic CC. Métodos: This is a sub-study of the PITCH trial with cardiac magnetic resonance (CMR) and laboratory (NT-proBNP) data. Clinical stratification followed the Brazilian Guideline on Chagas Heart Disease (SBC). From the initial cohort of 228 patients, those in stages B2 and C were excluded. From the initial 125 patients in stage B1, individuals with BMI≥30 kg/m² (n=40) and GFR < 60 mL/min/1.73m² (n=1), totaling 84 patients (pts). CMR was performed using late gadolinium enhancement (LGE) with normality parameters according to Kawel-Boehm et al. (JCMR 2025). Analysis was conducted via SPSS 29.0 (p<0.05). Resultados e Conclusões: The sample included 84 patients (66.7% women; 48.2 ±12.6 years), with a high prevalence of hypertension (73.80%), diabetes mellitus (20.2%), and overweight (BMI 26.4 ±4.1 kg/m²). On CMR, the mean right ventricular ejection fraction (RVEF) was 69.8% ± 7.3%. The mean right ventricular end-diastolic volume (RVEDV) was 112.5 ±18.4 mL (female) and 145.2 ± 22.6 mL (male). NT-proBNP showed a mean of 207.6 ±372.4 pg/mL (median: 105; interquartile range [IQR]: 60.0–210.0; minimum: 20; maximum: 2370). RV dysfunction was identified in 3.57% (3 pts: 2 mild, 1 moderate). There was no severe dysfunction. The groups differed significantly regarding NT-proBNP values, with a median of 2,171.5 pg/mL in the dilated RV group and 92.0 pg/mL in the group without dilation (p < 0.05). No significant correlation was found between NT-proBNP and global RVEF (r = -0.10; p = 0.34). Based on these findings, in stage B1 of CC, NT-proBNP did not correlate with RVEF, contrary to the literature, which associates a decline in systolic function with elevated levels of this biomarker. However, the peptide level increased in response to the rise in RVEDV, suggesting a potential application of NT-proBNP as a sensitive marker of volume overload and cardiac remodeling.



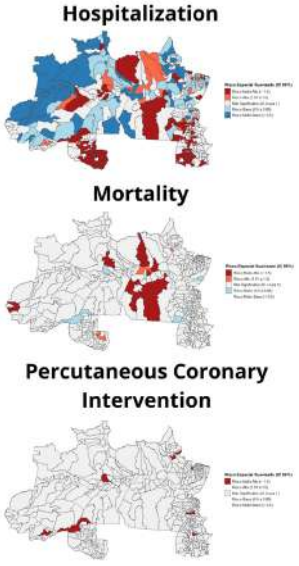
16862

SOCIOECONOMIC INEQUALITIES IN CHAGAS DISEASE CARDIAC MORTALITY IN BRAZIL: A NATIONWIDE ECOLOGICAL STUDY WITH JOINPOINT AND SPATIAL ANALYSIS (2010–2022)

DANIEL HIGOR SILVA BARROS1; JAIRO MARTINEZ ZAPATA1;

(1) UNIVERSIDADE CATOLICA DE BRASILIA - BRASÍLIA - DF - BRASIL;

Introdução/Fundamentos: Chagas disease (CD), caused by Trypanosoma cruzi, is the leading non-ischemic cardiomyopathy in Latin America. Brazil concentrates the largest chronic CD burden worldwide, yet the relationship between socioeconomic determinants and subnational cardiac mortality trends in the post-2010 period remains poorly characterized. Objetivos: To analyze temporal trends in age-adjusted CD cardiac mortality across Brazilian states (2010–2022), stratified by sex and age group; assess municipal-level socioeconomic correlates; and identify spatial clustering of high-burden territories. Métodos: Nationwide ecological study using SIM/DATASUS (ICD-10 B57.0+B57.2, underlying cause; cardiac forms only). Age-standardized mortality rates (ASMR) were computed using direct standardization (2010 census reference). Temporal trends were assessed by joinpoint regression (NCI v5.0), stratified by sex and age group. Spatial clustering was evaluated by global Moran's I and LISA maps. Socioeconomic association was examined by weighted multiple linear regression (Gini + MHDI + macro-region; VIF<3.0 for all predictors). Resultados e Conclusões: Between 2010 and 2022, 78,431 CD cardiac deaths were recorded (B57.0+B57.2, underlying cause). Men accounted for 58.1% (ASMR 1.6× higher than women); 88.6% occurred in individuals ≥50 years. Brown/Black populations represented 64.8% of deaths; 61.2% had low educational attainment. National ASMR declined significantly (AAPC: −3.2%; 95% CI: −3.9 to −2.5; p<0.001), with deceleration after 2015 (APC: −4.1% vs −2.3%), consistent with aging of the infected cohort. Men declined faster (AAPC −3.6%) than women (−2.7%). The North showed no significant decline (AAPC: +0.9%; p=0.14). Spatial clustering was confirmed (Moran's I=0.48; p<0.001), with hotspots in Minas Gerais, Bahia, and Piauí overlapping almost entirely with lowest-MHDI municipalities. The lowest MHDI quintile showed 4.21-fold higher ASMR (RR=4.21; 95% CI: 3.18–5.58). Gini remained independently associated with ASMR after multivariable adjustment (β=2.34; p<0.001; R^2=0.61). National decline masks profound structural inequalities. Failure to address them risks compromising heart failure outcomes in Brazil's most vulnerable populations. Mandatory CD screening, universal ICD/CRT access, and race-conscious primary care are urgently needed — priorities aligned with the World Heart Federation's global equity agenda.



18208

SPATIOTEMPORAL DYNAMICS OF ACUTE MYOCARDIAL INFARCTION AND PRIMARY PERCUTANEOUS CORONARY INTERVENTION IN BRAZILIAN NORTHERN REGION: A RETROSPECTIVE ECOLOGICAL ANALYSIS

FERNANDA AMBRÓSIO DE ARAÚJO1; LEONARDO REISCHOFFER DO NASCIMENTO1; VICTOR GONÇALVES SOARES2; LARA NONATO MOURA3; ERLAN GOMES DE CARVALHO FILHO4; JOÃO MARCOS BEMFICA BARBOSA FERREIRA1; KÁTIA DO NASCIMENTO COUCEIRO1;

(1) UNIVERSIDADE DO ESTADO DO AMAZONAS - MANAUS - AM - BRASIL; (2) UNIVERSIDADE FEDERAL DOS VALES DO JEQUITINHONHA E MUCURI - DIAMANTINA - MG - BRASIL; (3) UNIVERSIDADE ESTADUAL DO MARANHÃO - CAXIAS - MA - BRASIL; (4) UNIVERSIDADE FEDERAL DO AMAZONAS - MANAUS - AM - BRASIL;

Introdução/Fundamentos: Primary Percutaneous Coronary Intervention (PCI) is the gold standard for Acute Myocardial Infarction (AMI) treatment. However, in the Brazilian northern region, vast distances and logistical constraints within the Unified Health System pose significant challenges to timely reperfusion. Objetivos: This study aims to analyze the geospatial mismatch between AMI morbidity/mortality and PCI availability across northern Brazil. Métodos: A population-based, cross-sectional, ecological study was conducted to evaluate the distribution of AMI hospitalizations, mortality, and PCI procedures across Brazil's North region from 2015 to 2025. Data were obtained from the Informatics Department of the Brazilian Unified Health System and analyzed at the city level. Spatial risk clusters were identified using Integrated Nested Laplace Approximation (INLA). This Bayesian approach was applied to provide robust relative risk (RR) estimates by smoothing fluctuations in small populations and accounting for spatial dependence. Resultados e Conclusões: Hospitalizations exhibited greater spatial dispersion, with elevated risk along the Amazon River axis, particularly in the Manaus region (RR > 1.5), and secondary concentrations in the central-southern portion of Pará (RR > 1.5). Low hospitalization risk was concentrated in cities distant from state capitals (RR < 0.5). Mortality showed a more spatially constrained pattern, with statistically significant spatial clusters concentrated along a central axis, predominantly in Pará (RR > 2.0), and a marked concentration in Manaus (RR > 2.0). PCI procedures demonstrated a highly aggregated distribution, with statistically significant spatial clusters predominantly located in state capitals (RR > 2.0), including Manaus, Porto Velho, Rio Branco, Belém, Macapá, and Palmas. Territorial disparities reflect a deficient public health structure in Brazil's North Region. The concentration of AMI morbidity and mortality in specific areas, alongside the restriction of PCI services to state capitals, highlights major barriers to timely and specialized care. While spatial patterns identify priority areas, limitations regarding the ecological nature of the data and potential underreporting in remote Amazonian cities must be considered. These results underscore the need for public health policies to expand and regionalize AMI care, especially in hard-to-reach areas.

ASSOCIATION BETWEEN ANEMIA AND CARDIOVASCULAR RISK AMONG BRAZILIAN ADULTS

LUIZ FELIPE SANTIAGO LUIZ FELIPE SANTIAGO VIANA1; ELTON JUNIO SADY PRATES2; ANTÔNIO TOLENTINO NOGUEIRA DE SÁ2; GABRIEL SOARES DAMACENO,1; MARIANA PIMENTA SOUZA MELO SATIRO1; FILIPPE LIMA CAVALCANTE1; DEBORAH CARVALHO MALTA2; MARIA VITORIA LUIZ DA SILVA1; LUDMILA COSTA FARIA1; EDUARDA MOREIRA COSTA,1; JULIA FERREIRA COSTA1; ANA CAROLINA MICHELETTI GOMIDE NOGUEIRA DE SÁ1;

(1) ESCOLA DE ENFERMAGEM DA UFMG - BELO HORIZONTE - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: Anemia is a disease characterized by a decrease in hemoglobin (Hb) in red blood cells, which causes a reduction in oxygen (O2) transport to tissues. In this sense, there may be an association between individuals with anemia and increased cardiovascular risk (CVR), because inadequate oxygen transport triggers the use of compensatory mechanisms that overload the cardiovascular system. The Framingham Score is widely used to estimate CVR. In Brazil, there is a scarcity of studies that have investigated the association between anemia and CVR using this calculator. Objetivos: To analyze the association between anemia and cardiovascular risk in Brazilian adults Métodos: A cross-sectional study was conducted using data from the National Health Survey (Pesquisa Nacional de Saúde – PNS), between 2014 and 2015, with 8,952 adults. Prevalences and confidence intervals (95% CI) for anemia were estimated, stratified by sex, according to the Framingham risk score. Anemia was defined as hemoglobin levels below 13.0 g/dL in men and below 12.0 g/dL in women. CVR was classified as low, intermediate, and high. Differences were evaluated using Pearson's χ2 test (p≤0.05). To verify associations, logistic regression models were used, and Odds Ratios (OR) adjusted for race/skin color and 95% CI were estimated. Resultados e Conclusões: Among women, the prevalence of anemia was 12.0% (95% CI: 11.0–13.4), being higher in the low CVR group (7.5%; 95% CI: 6.6–8.6), followed by intermediate CVR (2.8%; 95% CI: 2.3–3.4) and high CVR (1.8%; 95% CI: 1.4–2.3) (p<0.05). Among men, the prevalence of anemia was 7.0% (95% CI: 6.0–8.1), being higher in the high CVR group (2.7%; 95% CI: 2.1–3.3), followed by intermediate CVR (2.4%; 95% CI: 1.8–3.3) and low CVR (1.9%; 95% CI: 1.3–2.6) (p<0.05). Women with high CVR (OR 1.43; 95% CI: 1.02–1.98) had a higher chance of anemia when compared to those at low risk. Men with intermediate CVR (OR 1.9; 95% CI: 1.2–3.1) and high CVR (OR 3.5; 95% CI: 2.2–5.3) had a higher chance of anemia when compared to those at low risk. Therefore, anemia was associated with CVR in Brazilian adults. Among women, high CVR was associated with a greater chance of anemia, while among men, both intermediate and high risk increased this chance. The findings highlight the relevance of fostering debates on this scenario and considering actions and policies for the prevention of cardiovascular diseases.

LATE CARDIAC REMODELING FOLLOWING HYPERTENSIVE DISORDERS OF PREGNANCY: ECHOCARDIOGRAPHIC EVIDENCE OF PERSISTENT STRUCTURAL CHANGES

BEATRIZ FERREIRA RIBEIRO DOS SANTOS1; RENATA GOMES SANCHES VERARDINO1; LUIZ APARECIDO BORTOLOTTO2; DANIEL BATISTA CONCEIÇÃO DOS SANTOS3;

(1) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (3) UNIVERSIDADE FEDERAL DE SERGIPE - ARACAJU - SE - BRASIL;

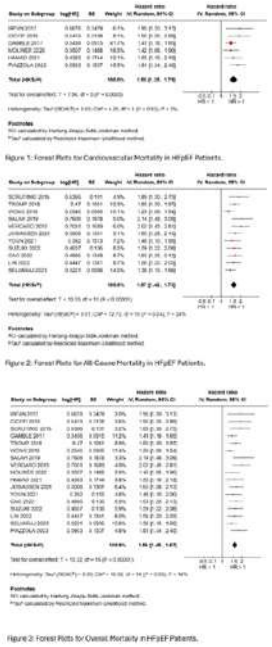
Introdução/Fundamentos: Hypertensive disorders of pregnancy, especially pre-eclampsia, are associated with higher future cardiovascular risk. However, the long-term cardiac structural effects are not yet completely clarified. Objetivos: To evaluate cardiac structural changes through echocardiography in women 2 to 5 years after a pregnancy complicated by hypertensive disease. Métodos: Cross-sectional study conducted at a tertiary hospital in São Paulo that included 120 women divided into three groups: normal pregnancy (NP=30), isolated pre-eclampsia (iPE=30), and pre-eclampsia superimposed on chronic hypertension (sPE/CH=60). Echocardiographic parameters were analyzed, in addition to clinical, anthropometric, and pressure data. Analyzes were adjusted for age. The study was approved by the institutional ethics committee. Resultados e Conclusões: Participants with sPE/CH were older (38±5 years) and presented higher BMI (32.6±6 kg/m²) compared to NP (34.6±6 years; 27.1±6 kg/m²). Higher systolic and diastolic blood pressure were observed in the groups with a history of pre-eclampsia. In the echocardiographic evaluation, the sPE/CH group presented greater septal thickness (9.7±1 vs. 8.4±1 mm) and larger left atrial diameter (38±4 vs. 34±4 mm) compared to NP. The left ventricular mass index was significantly higher in iPE (77±13 g/m²) and sPE/CH (81±17 g/m²) compared to NP (66±11 g/m²), characterizing persistent cardiac remodeling. Women with a history of pre-eclampsia present lasting cardiac structural changes, even years after pregnancy. These findings reinforce the role of pre-eclampsia as an early marker of cardiovascular risk and the need for long-term cardiological follow-up.

20441

PERSISTENT ARTERIAL STIFFNESS AND ENDOTHELIAL DYSFUNCTION AFTER HYPERTENSIVE DISORDERS OF PREGNANCY

BEATRIZ FERREIRA RIBEIRO DOS SANTOS1; RENATA GOMES SANCHES VERARDINO1; LUIZ APARECIDO BORTOLOTTO2; DANIEL BATISTA CONCEIÇÃO DOS SANTOS3;

(1) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (3) UNIVERSIDADE FEDERAL DE SERGIPE - ARACAJU - SE - BRASIL;



Introdução/Fundamentos: Pre-eclampsia is associated with higher future cardiovascular risk, possibly mediated by persistent vascular changes, such as arterial stiffness and endothelial dysfunction. Objetivos: To evaluate vascular function and structure parameters in women 2–5 years after pregnancy complicated by hypertensive disease. Métodos: Cross-sectional study conducted at a tertiary hospital in São Paulo that included 120 women divided into three groups: normal pregnancy (NP=30), isolated pre-eclampsia (iPE=30), and pre-eclampsia superimposed on chronic hypertension (sPE/CH=60). Pulse wave velocity (PWV), flow-mediated dilation (FMD), carotid intima-media thickness (cIMT), and pressure parameters were evaluated. Models adjusted for age, BMI, and blood pressure. Resultados e Conclusões: The sPE/CH group presented higher age (38±5 vs. 34.6±6 years in NP; p<0.05), BMI (32.6±6 vs. 27.1±6 kg/m²; p<0.05), and higher pressure levels. PWV was higher in sPE/CH (8.1±2 m/s) compared to NP (6.8±1 m/s) and iPE (7.0±1 m/s) (p<0.05). FMD was lower in the groups with hypertensive disease, with no significant difference after adjustment. A negative correlation was observed between PWV and FMD (p<0.05) and a positive correlation of PWV with age, BMI, and blood pressure, while FMD correlated inversely with these variables (p<0.05). In multivariate analysis, age, BMI, and blood pressure maintained an independent association with increased PWV, while FMD presented an inverse association (p<0.05). There was no difference between groups for cIMT. Women with a history of hypertensive disease of pregnancy present increased arterial stiffness and persistent endothelial dysfunction, especially in the presence of chronic hypertension. Functional changes appear to precede structural changes, contributing to greater long-term cardiovascular risk.

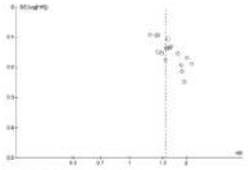
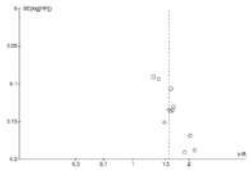
PROGNOSTIC VALUE OF NT-PROBNP IN HEART FAILURE WITH PRESERVED EJECTION FRACTION (HFPEF)



LUCAS MATEUS VERAS CARNEIRO1; ANA KELVIA OLIVEIRA RODRIGUES PONTES2;



(1) UNIVERSIDADE CHRISTUS - FORTAZLEZA - CE - BRASIL; (2) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: HFpEF is a prevalent, heterogeneous condition, complicating therapeutic identification. Although NT-proBNP marks hemodynamic stress, its prognostic specificity is limited by age, atrial fibrillation, and renal dysfunction. This leads to uncertainties in current guidelines regarding its isolated value for this population. Objetivos: To evaluate the prognostic value of NT-proBNP in HFpEF patients by analyzing its association with cardiovascular mortality, all-cause mortality, and overall mortality. Métodos: A systematic review and meta-analysis were conducted according to PRISMA guidelines and registered in PROSPERO. Seventeen studies were included (11 cohorts and 6 sub-analyses of randomized clinical trials) involving adult patients (EF ≥ 50%). Mathematical harmonization was used to standardize cutoff points, and the inverse variance method with a random-effects model was applied using RevMan software. Resultados e Conclusões: The global analysis (17 studies) revealed that elevated NT-proBNP increases the risk of overall mortality in HFpEF patients by 56% (HR 1.56; 95% CI 1.45–1.67; I²=14%). For cardiovascular mortality (n=6), the risk was 1.55 (95% CI 1.35–1.79; I²=3%), while for all-cause mortality (n=11), it was 1.57 (95% CI 1.43–1.71; I²=24%). The consistency across sub-analyses and low heterogeneity reinforce the robustness of these estimates and validate the mathematical harmonization of cutoff points. Funnel Plot analysis suggested no significant publication bias. The parity between cardiovascular and all-cause mortality risks suggests NT-proBNP acts as an integrator of systemic biological vulnerability in HFpEF. It reflects myocardial stress and the global impact of comorbidities like renal dysfunction and atrial fibrillation. However, the lack of standardized cutoffs and failure to integrate confounding variables in practice can lead to stratification errors. From a public health perspective, the underutilization of NT-proBNP hinders efficient care, resulting in inadequate resource allocation and neglect of high-risk populations. In summary, NT-proBNP is a robust, versatile predictor of death in HFpEF. Public health policies must promote its individualized and democratized interpretation. To ensure equity, NT-proBNP should be a central tool in multiparametric models, translating scientific evidence into cost-effective benefits for population health.

ACCELERATION OF OBESITY TRENDS FOLLOWING THE COVID-19 PANDEMIC IN BRAZIL: AN INTERRUPTED TIME-SERIES ANALYSIS (2006–2024)

LUCAS GABRIEL CASTRO CARVALHO1; MANOELA MASSA MOURA1; HELENA MONTE VARANDAS1; ANA CLARA MONTE VARANDAS2; LALESCA MEDEIROS1; SOFIA ARRAIS HAIDAR1; JOÃO PAULO DE SOUZA JÚNIOR1; MARIA ESTEFÂNIA BOSCO OTTO1;

(1) UNIVERSIDADE DE BRASILIA - BRASÍLIA - DF - BRASIL; (2) UNIVERSIDADE CATOLICA DE BRASILIA - BRASÍLIA - DF - BRASIL;

Introdução/Fundamentos: Obesity is a major determinant of cardiovascular risk and is associated with a higher burden of atherosclerotic disease. The COVID-19 pandemic may have exacerbated obesogenic factors, thereby altering population-level obesity trajectories. However, the pandemic's impact on these temporal trends in middle-income countries remains poorly characterized. Objetivos: To assess the COVID-19 pandemic's impact on obesity prevalence trends among Brazilian adults. Métodos: This analytical ecological interrupted time-series study used Vigitel Brazil data (2006–2024, excluding 2022 due to data unavailability). Adults (≥18 years) from Brazilian state capitals and the Federal District were included. Obesity was defined as BMI ≥30 kg/m². Using 2020 as the interruption point, the study period was divided into pre-pandemic (2006–2019) and post-pandemic (2020–2024) phases. Trends were analyzed using segmented linear regression models to evaluate baseline trends, level changes, and slope changes (Δβ). A counterfactual analysis extrapolated pre-pandemic trends to 2024. Analyses were stratified by sex and age using R version 4.3. Resultados e Conclusões: Over 700,000 adults were included in the analysis. Between 2006 and 2024, obesity prevalence increased from 11.8% to 25.7%, demonstrating sustained growth. During the pre-pandemic period (2006–2019), the annual increment was 0.71 percentage points (95% CI: 0.62–0.81). After 2020, the slope increased to 1.01 percentage points/year (95% CI: 0.78–1.24), corresponding to a Δβ of +0.30 percentage points/year, which indicates an acceleration in the trend. In the counterfactual analysis, the expected prevalence in 2024 was 23.75%, whereas the observed prevalence was 25.7%, yielding an excess of 1.95 percentage points. This acceleration was most pronounced in adults aged 25–34 years (1.31 percentage points/year) and 35–44 years (1.29 percentage points/year). In contrast, older age cohorts exhibited more modest growth. Regarding sex, a steeper increase was observed among women (1.05 percentage points/year) compared to men (0.97 percentage points/year) during the post-pandemic period. Obesity prevalence in Brazilian adults increased over the entire study period, with evidence of a steeper rise after 2020. The findings suggest a post-pandemic shift in obesity trends and highlight the importance of monitoring vulnerable subgroups.

ANALYSIS OF HOSPITALIZATIONS VERSUS DEATHS FROM ACUTE MYOCARDIAL INFARCTION IN BRAZILIAN REGIONS (2021–2025)

JOÃO RICARDO CAVLCANTI DO NASCIMENTO1; PABLO OLIVEIRA CORDEIRO1; GIOVANNA DE SOUSA OLIVEIRA1; JOÃO VICTOR DE OLIVEIRA RAMOS1; MARCELO DANTAS TAVARES DE MELO1;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL;

Introdução/Fundamentos: Acute Myocardial Infarction (AMI) leads the causes of cardiovascular death in Brazil, with heterogeneous regional patterns reflecting inequalities in access to and quality of healthcare. Evaluating hospital outcomes by region is essential to guide public policies. Objetivos: To identify Brazilian regions with better outcomes (lower in-hospital case fatality) for AMI between 2021 and 2025, to analyze temporal trends, and to compare prognosis between sexes. Métodos: Ecological study using data from the Department of Information Technology of the Unified Health System (DATASUS) (SIH/SUS), ICD-10 I21. All hospitalizations and deaths due to AMI in the five Brazilian regions from 2021 to 2025 were included. Case fatality was calculated (deaths/hospitalizations × 100), odds ratio (OR) with 95% CI, using the chi-square test and linear regression for trend (p<0.05). Resultados e Conclusões: During the period, there were 856,078 hospitalizations and 70,244 deaths (Brazil case fatality: 8.21%). The lowest cumulative case fatality was in the Central-West (6.95%), followed by South (7.65%), North (8.10%), Southeast (8.14%), and Northeast (9.44%). Significant differences were observed between regions (χ^2=1,205.7; p<0.001). Using the Northeast as reference (worst outcome), all other regions had a lower chance of death: Central-West OR=0.71 (0.69–0.74); South OR=0.79 (0.77–0.81); North OR=0.84 (0.81–0.88); Southeast OR=0.85 (0.83–0.87); all p<0.001. All regions reduced case fatality between 2021 and 2025 (p<0.001), with emphasis on the Northeast (−3.14 percentage points). Women had higher case fatality than men (9.82% vs 7.28%; OR=1.39; 95% CI: 1.36–1.42; p<0.001). The Central-West stands out as the region with the best hospital performance in AMI management, while the Northeast has the highest case fatality, although it achieved the greatest temporal reduction. The consistent improvement across the country suggests advances in the cardiovascular care pathway. Female sex constitutes an independent risk factor for worse in-hospital prognosis, requiring specific care strategies.

Tabela 1. Tendência temporal da letalidade total (2021–2025).

Região	2021 (%)	2022 (%)	2023 (%)	2024 (%)	2025 (%)	Variação (p.p.)

ASSOCIATION BETWEEN WEEKEND ADMISSION AND IN-HOSPITAL MORTALITY FOR ACUTE MYOCARDIAL INFARCTION IN MINAS GERAIS: A POPULATION-BASED ADJUSTED ANALYSIS USING SIH-SUS

MARIA LUIZA BALDIM PAIVA1; CLARA PINHO ANDRADE DE SOUZA1; MARIA EDUARDA COTTINI VILLELA1; FLÁVIO MARQUES ANDREON2; LUCAS MAGALHÃES DOS REIS1;

(1) FACULDADE DE MEDICINA DE ITAJUBÁ - ITAJUBÁ - MG - BRASIL; (2) HOSPITAL DAS CLÍNICAS DE ITAJUBÁ - ITAJUBÁ - MG - BRASIL;

Introdução/Fundamentos: Acute myocardial infarction (AMI) is one of the leading causes of morbidity and mortality worldwide. Beyond clinical factors, organizational aspects of healthcare services may influence in-hospital outcomes. The weekend effect, characterized by worse outcomes among patients admitted during weekends, has been widely reported internationally; however, it remains underexplored in analytical studies involving AMI patients in Brazil, particularly within a universal public health system. Objetivos: To evaluate the association between weekend hospital admission for acute myocardial infarction and in-hospital mortality in the state of Minas Gerais, and whether this association persists after adjustment for age and sex. Métodos: A retrospective observational study was conducted using data from the Hospital Information System of the Brazilian Unified Health System (SIH-SUS), including all hospitalizations for acute myocardial infarction in Minas Gerais between January and December 2024. This population-based analysis included all eligible hospitalizations recorded in the system during the study period. Demographic variables and in-hospital outcome (death) were analyzed. The association between weekend admission and in-hospital mortality was assessed using multivariable logistic regression adjusted for age and sex, with results expressed as odds ratios (OR) and 95% confidence intervals (CI). Resultados e Conclusões: A total of 21,371 AMI hospitalizations in Minas Gerais in 2024 were analyzed. Patients admitted on weekends showed significantly higher odds of in-hospital death compared to those admitted on weekdays (OR = 1.26; 95% CI: 1.11–1.42; p < 0.001). After adjustment for age and sex, the association remained statistically significant, indicating that the effect was not explained solely by demographic differences between groups. The findings suggest the presence of a weekend effect among AMI patients, potentially related to organizational variations in hospital care, including reduced availability of full medical teams, limited access to specialized procedures, and possible delays in the performance of interventions during weekends, particularly in time-sensitive conditions such as AMI. Despite the inherent limitations of secondary administrative data, the results underscore the need for care strategies that ensure equity in cardiovascular care regardless of the day of hospital admission within a large universal public health system.

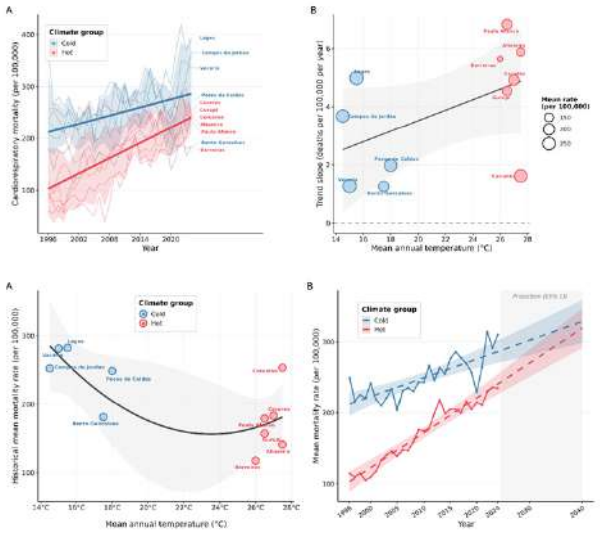
CARDIOVASCULAR MORTALITY ATTRIBUTABLE TO FINE PARTICULATE MATTER (PM 2.5) IN THE STATE OF SÃO PAULO: A POPULATION-BASED ECOLOGICAL STUDY OF HEALTH IMPACTS AND MORTALITY TRENDS ACROSS FOUR TRIENNIUMS (2013–2024)

JÚLIA LINS DANTAS1; PIETRA FIACADORI1; ITAPUAN TARGINO FILHO2;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Exposure to fine particulate matter (PM 2.5) is a critical environmental challenge for circulatory health. Due to its microscopic diameter (2.5 μ), it translocates across the alveolar-capillary barrier, triggering systemic inflammation and endothelial dysfunction. Despite clinical advances, air pollution remains a persistent contributor to cardiovascular mortality in the State of São Paulo, suggesting the need for broader discussion on environmental determinants in cardiovascular care. Objetivos: To investigate trends in cardiovascular mortality attributable to PM 2.5 across the State of São Paulo (2013–2024), assessing the impact of seasonal variations, regional exposure hotspots, and the burden of preventable deaths. Métodos: A population-based ecological study was conducted using mortality data from the DATASUS platform (SIM/SUS and SIH/SUS) for the State of São Paulo. Cardiovascular mortality in adults aged ≥ 30 years was analyzed across four trienniums (2013–2024). Health impacts were estimated using AirQ+, a software developed by the World Health Organization (WHO) to quantify air quality effects. The model applies concentration-response functions to local PM 2,5 levels to estimate the Attributable Fraction (AF), representing deaths preventable through adherence to the WHO annual safety threshold of 5 μg/m³. A temporal analysis was performed to identify months of maximum and minimum PM 2.5 concentrations, as annual averages may mask acute seasonal peaks that standard modeling might underrepresent. Resultados e Conclusões: Temporal analysis identified a marked seasonal pattern; PM 2.5 levels peaked between August and September, reaching 51.16μg/m³ in 2024. Cardiovascular mortality per 100,000 inhabitants declined from 111.50 (95%CI: 95.0–133.8) in 2013–15 to 91.50 (95%CI: 77.5–110.7) in 2022–24. However, environmental risk remains critical: the AF in the final triennium was 26.61% (95%CI: 22.54–32.18), corresponding to 19,752 deaths (95%CI: 16,735–23,894). Population exposure to concentrations >25μg/m³ expanded to 74.63% (34.8 million people). A primary limitation is the reliance on ecological data from DATASUS, subject to potential underreporting and the absence of individual clinical records. These trends support implementing environmental-specific protocols to ensure equitable cardiovascular prevention.



15701

CLIMATE ANTAGONISM AND CARDIORESPIRATORY MORTALITY: AN EXPLORATORY 29-YEAR ANALYSIS IN BRAZILIAN TROPICAL AND TEMPERATE REGIONS

LETICIA ZEN1; ARTHUR SANTANA AMORIM SILVA1; ANNA GABRIELLE CAVALINI BIZARELLO1; RENAN MORETTI COELHO1; THAYLLA ARIANY DE SOUZA OLIVEIRA1; JOÃO PEDRO COSTA ARAÚJO1; ISABELLA CAROLINA BESSA ROCHA1; BRENO AUGUSTO RAMOS DE FRANÇA1; ERNANDES SOBREIRA1;

(1) UNIVERSIDADE DO ESTADO DE MATO GROSSO - CÁCERES - MT - BRASIL;

Introdução/Fundamentos: Climate change has become increasingly evident, with pronounced effects on human populations, among which cardiorespiratory mortality represents one of the fastest-growing consequences. Objetivos: To analyze the 29-year (1996–2025) spatiotemporal trends in cardiorespiratory mortality associated with temperature gradients across 11 Brazilian municipalities. Métodos: An exploratory study was conducted using DataSUS, selecting municipalities representing a broad climatic gradient within Brazil, ranging from equatorial Amazonian climate (Altamira, AM; mean 26.5°C) to high-altitude temperate oceanic climate (Campos do Jordão, SP; mean 14.5°C), with comparable population sizes (46,000 to 168,000 inhabitants). Resultados e Conclusões: The association between temperature and mortality followed a U/J-shaped curve. Among the analyzed municipalities, colder regions exhibited higher absolute mortality rates, with a mean of 276.9 per 100,000 compared to 195.0 per 100,000 in warmer regions (42% difference). High-altitude and colder municipalities showed the highest average absolute rates, such as Vacaria, RS (307.4 per 100,000), followed by Campos do Jordão, SP (300.4 per 100,000). However, the rate of increase in mortality over time was approximately threefold higher in warmer municipalities (mean slope +4.12/year) compared to colder ones (+1.37/year), indicating a threefold greater rise in cardiorespiratory deaths per 100,000 inhabitants in warmer regions. High-temperature clusters demonstrated marked acceleration, including Paulo Afonso, BA (+6.43/year), Cáceres, MT (+5.37/year), and Barreiras, BA (+5.18/year). In contrast, colder regions showed declining trends, such as Bento Gonçalves, RS (−1.28/year), Poços de Caldas, MG (−0.71/year), and Vacaria, RS (−0.48/year). Notably, Barreiras, BA increased from a baseline rate of 79.6 to 182.6 per 100,000 (+126.5%) between the periods 1996–2000 and 2020–2024. These findings suggest that, if current trends persist, mortality rates in warmer municipalities will surpass those in colder regions within a few decades. Overall, temperature extremes amplify the risk of circulatory and respiratory diseases and mortality: while cold climates are associated with higher absolute rates, heat drives a more rapid and exponential increase in mortality in warmer regions. Therefore, climate adaptation policies are urgently needed to mitigate the burden on healthcare systems in vulnerable regions of Brazil.

17438

CROSS-CULTURAL ADAPTATION OF A PRENATAL COUNSELING QUESTIONNAIRE FOR CONGENITAL HEART DISEASE INTO BRAZILIAN PORTUGUESE

JULIA CASTRO RODRIGUES1; THAYLA LAIS LIMA ESTEVAM1; GUSTAVO YANO CALLADO2; ALEXANDER KOVACEVIC3; STEFAN BÄR4; EDWARD ARAÚJO JÚNIOR5; LUCIANE ALVES DA ROCHA AMORIM6;

(1) UNIVERSIDADE FEDERAL DO AMAZONAS - MANAUS - AM - BRASIL; (2) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL; (3) HEIDELBERG UNIVERSITY HOSPITAL, DEPARTMENT OF PEDIATRIC AND CONGENITAL CARDIOLOGY, HEIDELBERG, GERMANY - GERMANY; (4) RUPRECHT KARLS UNIVERSITY HEIDELBERG, MAX WEBER INSTITUTE OF SOCIOLOGY, HEIDELBERG, GERMANY - GERMANY; (5) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL; (6) HOSPITAL UNIVERSITÁRIO GETÚLIO VARGAS - UFAM - MANAUS - AM - BRASIL;

Introdução/Fundamentos: Congenital heart disease is the most common structural birth defect and a leading driver of neonatal morbidity and mortality globally and yet the moment of diagnosis, in many centers, remains poorly supported. Receiving a prenatal diagnosis of CHD is a profoundly distressing experience for families, and the quality of counseling provided at that moment shapes how parents cope, make decisions, and engage with care. Despite this, no validated instrument existed in Brazilian Portuguese to systematically evaluate whether that counseling is actually being done well. Objetivos: This study set out to fill that gap through the cross-cultural adaptation and content validation of the Kovacevic Questionnaire, a tool originally designed to assess parental counseling quality following prenatal CHD diagnosis. Métodos: The adaptation followed the internationally recognized framework proposed by Beaton et al., covering translation, synthesis, back-translation, expert committee review, pre-testing, and psychometric evaluation. Two independent expert committees assessed semantic, idiomatic, cultural, and conceptual equivalence across all items. Content validity was quantified using the Content Validity Index (CVI), Prevalence- and Bias-Adjusted Kappa (PABAK), and Content Validity Coefficient (CVC). The final version was pre-tested with ten pregnant women carrying fetuses diagnosed with CHD. Resultados e Conclusões: The process yielded a culturally grounded, linguistically precise Brazilian Portuguese version of the instrument. Expert agreement was consistently high — most items reached CVI and PABAK values near 1.0, and all CVC values met the ≥0.80 threshold. Minor wording adjustments were made where needed to improve clarity and cultural fit. In pre-testing, all participants rated every item as clear and relevant, with CVI and PABAK reaching 1.00. The Brazilian Portuguese Kovacevic Questionnaire showed strong validity and high acceptance, filling a critical gap in humanized prenatal care by providing a standardized way to assess support for families facing a Congenital Heart Disease (CHD) diagnosis. Given Brazil's socioeconomic disparities and expanding CHD detection, this validated tool is essential for public health, allowing for auditing, identifying institutional failures, and driving policy focused on the family experience.

20402

HEAT WAVES AND CARDIOVASCULAR MORTALITY: GLOBAL META-ANALYSIS AND THE MAGNITUDE OF THE PROBLEM IN BRAZIL

BEATRIZ DE LIMA VITORIO FERREIRA1; FLAVIA BEATRIZ DO CARMO MOREIRA2; MARCOS AURELIO FONSECA MEDEIROS2; EVELIN GABRIELLY DE VARGAS2; MARIANA VIDAL MIYAZATO2; PEDRO DE ARAUJO SANTOS1; JOSIANE DE SOUZA BEZERRA2; LUCAS MANOEL BORGES DOURADO2; ANNE KAROLLYNE ALVARES SANTOS2;

(1) UNIFACISA - CAMPINA GRANDE - PB - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Heat waves are becoming more frequent, intense, and prolonged worldwide. In Brazil, between the 1970s and 2010s, their frequency increased from 0–3 to 3–11 events per year. Although prior reviews have examined temperature and health, a quantitative synthesis integrating global evidence with Brazilian studies has not been previously performed. Objetivos: To quantify, through meta-analysis, the risk of cardiovascular (CV) mortality associated with heat waves at a global level and to systematically describe the Brazilian evidence on extreme temperature and CV outcomes. Métodos: Systematic review conducted in accordance with PRISMA guidelines. Two large global systematic reviews reporting relative risk (RR) of CV mortality during heat waves (Liu et al., 2022; Bell et al., 2024) were included. Pooled estimates were calculated using a random-effects model (inverse variance method), considering the independence of effect estimates reported in each primary study. Heterogeneity was assessed globally as described in the included reviews. Additionally, Brazilian studies evaluating the association between extreme heat/heat waves and cardiovascular outcomes (mortality and hospitalization), published between 2019 and 2026, were systematically analyzed. Resultados e Conclusões: The global quantitative synthesis demonstrated a consistent increase in CV mortality risk during heat waves, with a pooled RR of 1.118 (95% CI: 1.102–1.135), corresponding to an 11.8% increase compared to non–heat wave periods. In Brazil, studies consistently show an association between extreme heat and cardiovascular outcomes, including increased mortality and hospitalizations, particularly among vulnerable populations. Higher risks were observed among older adults, women, and socioeconomically disadvantaged groups. National estimates indicate increased mortality associated with extreme temperatures, as well as a substantial number of deaths attributable to heat waves in metropolitan areas. Additional evidence suggests a greater impact in lower-income municipalities, and projections indicate increased CV mortality under high-emission scenarios. Heat waves are associated with a significant increase in cardiovascular mortality globally. In Brazil, the impact is already substantial and disproportionately affects vulnerable populations, highlighting the urgent need for mitigation strategies, early warning systems, and climate adaptation policies.

Impact of Route of Administration on Hemodynamic Adverse Events of Nitroglycerin: A Real-World Pharmacovigilance Study.

ELIAS MENDES LEAL NETO1; RIZIA MOREIRA DE CARVALHO NEVES1; CAIO MATIAS BRITO MARQUES1; MARIANA DE AVILA FERREIRA1; ANA CECÍLIA BACCHI1; SOPHIA PEREIRA SCHOLER1; GIULIANA VIEIRA UGGERI1; HENRIQUE ANTONIOLLI SOUZA1; FELIPE MONTEIRO KIRST1; AMANDA AMORIM BRESCANCIM1; ANNA LUIZA ZUCCHETTO1; EDUARDO GARCIA ROCHA LOUREIRO1;

(1) CENTRO UNIVERSITARIO DE VARZEA GRANDE - UNIVAG - CUIABÁ - MT - Brasil;

Introdução/Fundamentos: Nitroglycerin is a cornerstone vasodilator in coronary artery disease; however, the comparative impact of the route of administration on its hemodynamic safety remains poorly characterized in real-world data. Sublingual (rapid plasma peak) and transdermal (sustained release) formulations exhibit distinct pharmacokinetic profiles and potentially divergent adverse event patterns. Objetivos: To evaluate whether the route of administration modifies the profile of reported hemodynamic adverse events in real-world settings. Métodos: Retrospective pharmacovigilance study using the FAERS database (2014–2025, 44 quarters), incorporating disproportionality analysis and causal inference. The cohort was restricted to nitroglycerin as a Primary or Secondary Suspect, identified via validated regex strategies (RxNorm/MeSH), stratified into Sublingual versus Transdermal groups, and deduplicated by case (age 18–110 years, sex M/F). Confounding was primarily addressed using entropy balancing, promoting rigorous covariate equalization and high comparability between groups. As supportive approaches, propensity score matching (PSM 1:1; caliper = 0.1) and inverse probability of treatment weighting (IPTW; ATE) were applied for triangulation. The propensity model included age, sex, PDE-5 inhibitor use, report year, polypharmacy, and severity proxy. Outcomes (syncope/presyncope, orthostatic hypotension, headache) were defined using MedDRA terms. Metrics included PRR (Haldane–Anscombe), Bayesian IC, and reporting odds ratio (ROR) estimated via Firth logistic regression and weighted models. Resultados e Conclusões: Final cohort comprised 1,480 reports, with entropy balancing achieving SMD = 0.000 across covariates. Orthostatic hypotension showed a robust and consistent signal across all models—Crude ROR = 0.020 (95% CI: 0.006–0.072); IPTW = 0.027 (0.007–0.112); Entropy = 0.013 (0.003–0.056; p < 0.001)—indicating higher disproportionality in the transdermal group. Headache showed a directional trend but lost significance after adjustment. Syncope showed no robust association, with wide confidence intervals indicating instability. Overall, the route of administration significantly modulates hemodynamic safety, with transdermal nitroglycerin associated with increased orthostatic hypotension, supporting systematic blood pressure monitoring in clinical practice.

20253

IMPACT OF THE COVID-19 PANDEMIC ON HEART FAILURE HOSPITALIZATIONS AND IN-HOSPITAL MORTALITY IN BRAZIL: A NATIONWIDE ANALYSIS OF REGIONAL DISPARITIES (2015–2023)

LUCAS MEDEIROS FRANCO1; SÉRGIO WILLIAM SILVA DE OLIVEIRA1; MARIA ISABEL SALES LIMA1; ANTONIA ELOISA DE OLIVEIRA BARROZO1; FRANCISCO SAMUEL RODRIGUES DIAS1; EDUARDA DOMINGO DA SILVA LACERDA1; JOÃO ARTHÚ ALVES DE SOUSA1; GABRIEL FERREIRA VIDAL1; LUCAS BUSTAMANTE MENEZES1; ANTÔNIO DIUARE1; KATTLEN LOPES MAIA1; SANDRA NIVEA DOS REIS SARAIVA FALCAO1;

(1) UFC - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: The COVID-19 pandemic imposed an abrupt disruption on healthcare systems, potentially compromising access to and outcomes of chronic cardiovascular care. Heart failure (HF) represents one of the leading causes of hospitalization within Brazil's public health system (SUS), making it a sensitive marker of systemic strain. Objetivos: To evaluate temporal trends in heart failure hospitalizations and in-hospital mortality in Brazil (2015–2023), quantifying regional disparities and the impact of the COVID-19 pandemic on these indicators. Métodos: Retrospective analysis of all HF hospitalizations (ICD-10: I50) recorded in Brazil's national inpatient database (SIH/SUS) from 2015 to 2023, stratified by the five Brazilian macro-regions. Temporal trends in annual hospitalization volume and in-hospital mortality rate were assessed using Prais-Winsten regression to account for first-order serial autocorrelation. Regional mortality disparities were described with exact binomial 95% confidence intervals (CI). The association between hospitalization volume and in-hospital mortality was evaluated by Pearson correlation. Resultados e Conclusões: A total of 1,784,731 hospitalizations were identified over the study period; overall in-hospital mortality was 11.54%. Hospitalization volume declined significantly during the pandemic, with the Northeast and North regions recording the steepest reductions (-23.5% and -20.6% vs. 2019). In-hospital mortality peaked at 13.54% in 2021 — the highest value in the series — compared to 11.37% in 2019, with no return to pre-pandemic levels by 2023 (11.64%). Regional disparities were substantial: the Northeast reached 12.38% (95% CI 12.04-12.73%) in 2020, compared to 9.80% (95% CI 9.51-10.09%) in the South. A strong inverse correlation was observed between annual hospitalization volume and in-hospital mortality rate ($r = -0.86$; $p = 0.003$), consistent with a severity-shift mechanism whereby restricted access selected for higher-risk admissions. In conclusion, HF hospitalizations declined sharply during the pandemic while in-hospital mortality worsened and failed to recover to pre-pandemic levels by 2023. The disproportionate impact on regions with lower healthcare infrastructure capacity highlights a critical vulnerability of the Brazilian cardiovascular care system and underscores the need for region-specific strategies to maintain continuity of care during public health emergencies.

IMPACT OF VOLCANIC ACTIVITY ON CARDIOVASCULAR HEALTH: A SYSTEMATIC REVIEW OF EVIDENCE

WAGNER RIOS-GARCIA1; CHARYS YANET TORRES VALENZUELA2; ABIGAIL D. VIA-Y-RADA-TORRES3; MARIAFE -MARTINEZ-ACUNA2; ANA LETÍCIA BUSTO MORENO4; ALONDRA A. RIOS-GARCIA5;

(1) RESEARCH NETWORK ON DIGITAL HEALTH, ARTIFICIAL INTELLIGENCE, AND EDUCATION (NET-IA WORLD), LIMA, PERU ; HOSPITAL SAN JUAN DE DIOS DE PISCO, PISCO, ICA, PERÚ - PERU; (2) SCHOOL OF MEDICINE AT UNIVERSIDAD PERUANA DE CIENCIAS APLICADAS, LIMA, PERU - PERU; (3) RESEARCH NETWORK ON DIGITAL HEALTH, ARTIFICIAL INTELLIGENCE, AND EDUCATION (NET-IA WORLD), LIMA, PERU ; SCHOOL OF MEDICINE AT UNIVERSIDAD CIENTÍFICA DEL SUR, LIMA, PERÚ - PERU; (4) FEDERAL UNIVERSITY OF PARANÁ, CURITIBA, BRAZIL - CURITIBA - PR - BRASIL; (5) RESEARCH NETWORK ON DIGITAL HEALTH, ARTIFICIAL INTELLIGENCE, AND EDUCATION (NET-IA WORLD), LIMA, PERU - PERU;

Introdução/Fundamentos: Volcanic eruptions and persistent gas emissions release ash, particulate matter, and toxic gases that may adversely affect human health. While respiratory outcomes are well documented, cardiovascular effects remain less clearly defined. Objetivos: To synthesize the scientific evidence regarding the impact between volcanic exposure and cardiovascular health outcomes. Métodos: A search was conducted on April 14, 2026, in PubMed, Embase, Scopus, and Web of Science. Gray literature, study reference lists, and the first 10 pages of Google Scholar were screened. The review followed PRISMA 2020 guidelines. Quality evaluation was assessed using the Mixed Methods Appraisal Tool (MMAT). Two reviewers independently performed study selection and data extraction after pilot training. Resultados e Conclusões: A total of 5 studies were included. The 1996 Ruapehu eruption (New Zealand) showed no consistent cardiovascular increase (IHD RR=1.44, p=0.032 for bronchitis only). Chronic SO□ exposure at Kilauea (Hawaii) was associated with hypertension (OR≈2.45) and increased systolic BP (+14.4 mmHg). During the 2002 Etna eruption (Italy), hospital admissions rose for IHD (RR=1.13), MI (RR=1.34), and cerebrovascular disease (RR=1.24). A retrospective Etna study found increased heart disease emergency visits (OR=1.36, p=0.0001). At Colli Albani (Italy), chronic gas exposure showed elevated cardiovascular mortality in high-exposure men (HR=1.6, 95%CI 0.95–2.7). Overall, 50% (3/6) of studies were rated high quality and 50% (3/6) moderate quality according to MMAT criteria. Volcanic activity can exert measurable cardiovascular impacts, particularly under sustained exposure to gases and particulates. Further longitudinal studies are needed to clarify causal pathways and vulnerable subgroups.

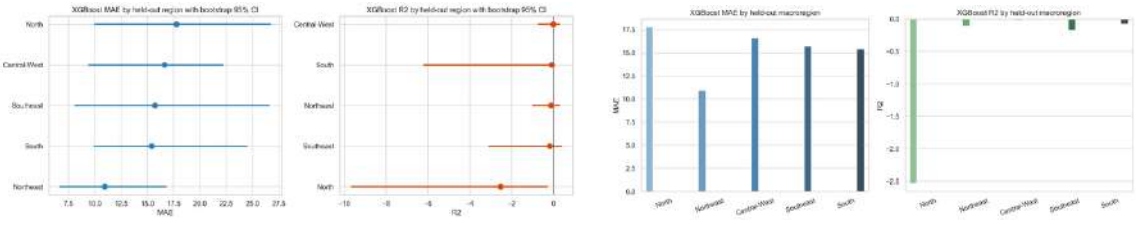
LIPID REFERENCE VALUES IN BRAZIL: LACK OF NATIONAL VALIDATION AND IMPLICATIONS FOR CARDIOVASCULAR RISK ASSESSMENT

LIVIA SOUZA TOSETTI1; DAVID GARCIA ALCARAZ CONTI1; FERNANDO LUIZ AFFONSO FONSECA1; FERNANDO LIVIA JABLONKA1;

(1) FACULDADE DE MEDICINA DO ABC - SANTO ANDRÉ - SP - BRASIL;

Introdução/Fundamentos: Lipid reference values are essential for cardiovascular risk stratification and clinical decision-making. In Brazil, these thresholds are largely derived from international guidelines, which may limit their applicability to a highly heterogeneous population. Objetivos: To assess the origin, validity, and applicability of lipid reference values currently used in the Brazilian population. Métodos: A systematic review was performed in accordance with PRISMA 2020 guidelines. Searches were conducted in PubMed, Scopus, Web of Science, SciELO, LILACS, and Embase for studies published between 2019 and 2025. Population-based studies, epidemiological analyses, systematic reviews, and clinical guidelines reporting lipid distributions or reference values relevant to Brazil were included. Study selection and data extraction were independently performed by two reviewers. Resultados e Conclusões: Among 751 identified records, 25 studies were included. Lipid reference values currently used in Brazil are predominantly adapted from international consensus documents rather than derived from nationally designed laboratory reference interval studies. National surveys describe lipid distributions but do not meet methodological criteria for establishing reference intervals. Limited stratification by sex, ethnicity, and geographic region was observed, along with interlaboratory variability in analytical methods. These limitations may affect cardiovascular risk classification. Multicenter studies using standardized laboratory criteria are needed to establish population-specific reference intervals and improve accuracy in cardiovascular risk assessment.



18024

NATIONAL POOLED PERFORMANCE MASKS HETEROGENEOUS REGIONAL TRANSPORTABILITY OF MACHINE LEARNING MODELS FOR ACUTE MYOCARDIAL INFARCTION HOSPITALIZATION ACROSS BRAZIL

ANDRÉ FELIPE CAVALCANTI FONSECA1; GABRIEL WALISSON ALEXANDRE MATIAS1; LUIZ ALBERTO REIS MATTOS JR1; GABRIEL GRANATA FIGUEIREDO1; MATHEUS CASTELO BRANCO FALCÃO ALBUQUERQUE2; JESSICA CAROLYNE ALVES SILVA3; MIRELA SILVEIRA ARENAS4; MARIA ANTONIETA ALBANEZ ALBUQUERQUE MEDEIROS LOPES5;

(1) UNIVERSIDADE FEDERAL DE PERNAMBUCO - RECIFE - PE - BRASIL; (2) UNIVERSIDADE CATOLICA DE PERNAMBUCO - RECIFE - PE - BRASIL; (3) FPS - FACULDADE PERNAMBUCANA DE SAUDE - RECIFE - PE - BRASIL; (4) UNINASSAU - RECIFE - PE - BRASIL; (5) REAL HOSPITAL PORTUGUES - RECIFE - PE - BRASIL;

Introdução/Fundamentos: Brazil has vast regional disparities in cardiovascular risk profiles and acute myocardial infarction (AMI) outcomes. Machine learning (ML) models trained on national data may appear adequate overall while masking poor accuracy in specific regions. Whether these models generalize across macroregions remains unknown. Objetivos: To evaluate the geographic transportability of ML models for AMI hospitalization rates across Brazilian macroregions. Métodos: We analyzed 27 state capitals (2013–2021; N=243 capital-year observations). A Leave-One-Region-Out (LORO) framework trained on four macroregions and tested on the fifth. We compared Linear Regression, Elastic Net, Random Forest, and XGBoost. Robustness analyses included capital-cluster bootstrap 95% CI, sensitivity excluding 2021 (COVID-19), and 1,000 random size-matched permutations. Resultados e Conclusões: Although XGBoost appeared satisfactory nationally (pooled MAE 14.75; R^2 0.105), this aggregate view was misleading. When each macroregion was held out, the model predicted AMI rates worse than simply using each region's historical mean (macro-average R^2 −0.581). No algorithm escaped this pattern: Random Forest ranked 2nd (pooled R^2 −0.032), Linear Regression 3rd (R^2 −0.259), and Elastic Net 4th (R^2 −0.402). None of the five macroregions achieved positive R^2, ranging from Northeast (−0.109) to North (−2.531; bootstrap 95% CI −9.695 to −0.276). The most striking finding was that the North, despite being statistically most similar to the rest of the country (lowest covariate shift, SMD 0.55), showed the worst failure — suggesting that its clinical-epidemiological particularities, notably distinct hypertension and diabetes prevalence, are poorly captured by models trained elsewhere. COVID-19 disruptions amplified but did not create these failures: excluding 2021 improved macro R^2 from −0.581 to −0.435 (delta +0.146), yet the North remained worst (R^2 −1.694). Permutation testing confirmed that geographic structure drives this gap (observed R^2 −0.581 vs. null mean −0.263; P=0.120). A nationally adequate ML model proved unreliable at the macroregional level, with the North showing the most robust failure. National-level validation alone is insufficient for AMI surveillance tools intended for regional use. Local recalibration or region-specific modeling should precede deployment. As an ecological study, findings do not support individual-level or causal inferences.

20923

OUT-OF-HOSPITAL CARDIAC ARREST, HEART FAILURE, AND COMPOUND HEATWAVES: A SYSTEMATIC REVIEW WITH QUANTITATIVE SYNTHESIS AND THE CRITICAL ROLE OF NIGHTTIME TEMPERATURE

BEATRIZ DE LIMA VITORIO FERREIRA1; FLAVIA BEATRIZ DO CARMO MOREIRA2; MARCOS AURELIO FONSECA MEDEIROS1; EVELIN GABRIELLY DE VARGAS2; LUCAS MANOEL BORGES DOURADO2; BIANCA RIBEIRO CORREIA LIMA3; MARIA LUIZA DUARTE ZACARIAS1; ANNE KAROLLYNE ALVARES SANTOS2;

(1) UNIFACISA - CAMPINA GRANDE - PB - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (3) CENTRO UNIVERSITARIO MAURICIO DE NASSAU - RECIFE - PE - BRASIL;

Introdução/Fundamentos: Extreme heat imposes acute cardiovascular stress capable of triggering catastrophic events. Although increased cardiovascular mortality is well established, the specific risks of out-of-hospital cardiac arrest (OHCA) and heart failure (HF)-related mortality remain incompletely integrated. Nighttime heat as an amplifier of these outcomes is also underestimated in traditional heatwave definitions. Objetivos: To estimate, through quantitative synthesis, the risk of OHCA associated with extreme heat and heatwaves; describe the impact of compound heatwaves (day+night) and hot nights on cardiac mortality; and assess temporal trends in HF mortality related to temperature. Métodos: A systematic review was conducted according to PRISMA guidelines. Meta-analyses reporting relative risk (RR) of OHCA associated with extreme heat and primary studies on sudden cardiac arrest, compound heatwaves, and HF were included. Quantitative synthesis was performed using a random-effects model. Overlap among studies from prior meta-analyses was assessed to minimize double counting. Resultados e Conclusões: The quantitative synthesis included 38 independent studies and over 1 million OHCA events. The pooled RR was 1.067 (95% CI: 1.051–1.084), representing a 6.7% increase. Heatwaves showed an RR of 1.248 (95% CI: 1.091–1.427), with elderly individuals and men as more vulnerable subgroups. Hot nights alone were associated with a 28% increase in sudden cardiac arrest risk (OR=1.28; 95% CI: 1.22–1.34), while heatwaves increased this risk by 40% (OR=1.40). Compound heatwaves showed an OR of 1.86 for cardiac mortality, exceeding daytime-only (OR 1.19) and nighttime-only (OR 1.16) definitions, with an estimated 41,869 excess deaths. Traditional metrics based only on maximum daily temperature underestimated mortality burden by 35%. The most sensitive causes were sudden cardiac arrest, myocardial infarction, and HF. Recent evidence also suggests increasing HF vulnerability to high temperatures. Extreme heat is associated with increased OHCA risk, while heatwaves exert an even greater impact. Compound heatwaves are substantially more lethal than traditional definitions, and HF-related mortality shows a rising temporal trend. Emergency services mabenefit from reinforcement during heat alerts, and nighttime temperature should be incorporated into warning systems. These findings have important implications amid climate change and the growing global burden of cardiovascular disease.

PREVALENCE OF CHAGAS DISEASE AMONG POPULATIONS AT RISK IN LATIN AMERICA: AN UPDATED SYSTEMATIC REVIEW AND META-ANALYSIS OF OBSERVATIONAL STUDIES

FRANCISCO ROGERLÂNDIO MARTINS-MELO1; LUCAS MEDNES BARBOSA2; EWERTON COUSIN3; MARIÂNGELA CARNEIRO2; STEPHANIE PRICE3; ASHLEY HARRIS3; CAROLINE DEMACQ4; MONICA QUIJANO4; PABLO PEREL5; JONATHAN MOSSER3; BRUNO RAMOS NASCIMENTO2; ANTONIO LUIZ PINHO RIBEIRO2;

(1) FEDERAL INSTITUTE OF EDUCATION, SCIENCE AND TECHNOLOGY OF CEARÁ - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) INSTITUTE FOR HEALTH METRICS AND EVALUATION - UNITED STATES; (4) NOVARTIS AG - SWITZERLAND; (5) WORLD HEART FEDERATION - SWITZERLAND;

Introdução/Fundamentos: Chagas disease (ChD) poses a significant public health challenge in Latin America (LA), with a notable scarcity of up-to-date data on its prevalence. Objetivos: This study assesses the seroprevalence of ChD in Latin American endemic countries, among populations at risk, through a systematic review and meta-analysis. Métodos: Medline, Web of Science, Science Direct, and SciELO were searched to identify population-based studies that investigated the seroprevalence of ChD among individuals at risk in endemic countries published from Jan/1980 to Dec/2021. Study quality was assessed using the Joanna Briggs Institute's tool. Pooled prevalence estimates and 95% confidence intervals (CIs) were calculated using random-effects models with a generalized linear mixed model. Heterogeneity was assessed using the I2 statistic. Subgroup, sensitivity, and publication bias analyses were performed. Endemic countries were grouped into regions based on geographic proximity and similar epidemiological patterns. A separate analysis was performed focusing exclusively on children and adolescents (≤21 years). Resultados e Conclusões: Results: A total of 141 studies were included, encompassing 615,553 participants and 44,627 ChD cases. The overall pooled prevalence of ChD among at risk population was 5.8% (95% CI: 4.4 - 7.7), varying between regions: Andean LA (7.6% [95% CI: 3.9 - 14.2]; 21 studies), Central LA (4.4% [95% CI: 2.9 - 6.7]; 52 studies), Southern LA (13.93% [95% CI: 8.31 - 22.43]; 30 studies), and Tropical LA (5.8% ([95% CI: 4.4 - 7.7;] 38 studies). In the sub-analysis of children, pooled prevalence was 2.7% (95% CI: 1.8 - 3.8; 89 studies), with region rates as follows: Andean LA (5.9% [95% CI: 2.9 - 11.7]; 15 studies), Central LA (1.6% [95% CI: 1.0 - 2.5]; 30 studies), Southern LA (7.9% [95% CI: 4.3 - 14.1]; 23 studies), and Tropical LA (0.9% [95% CI: 0.4 - 1.9]; 21 studies). The highest prevalence rates were observed in Bolivia, Paraguay, and Argentina. Conclusion: The findings indicate a higher prevalence of ChD among populations at risk in Southern and Andean LA, consistent across the general population and the subset of children. High heterogeneity was observed overall, attributed to the suboptimal quality of the included studies

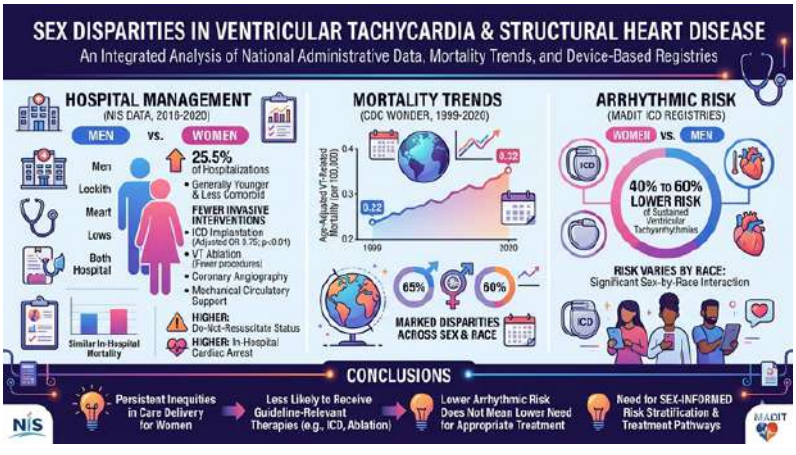
PREVALENCE OF ELEVATED BLOOD PRESSURE AND ASSOCIATED FACTORS IN MILITARY POLICE OFFICERS IN AMAZONAS: PRELIMINARY ANALYSIS OF THE HIPER-PMAM STUDY

MATHEUS DE OLIVEIRA DUTRA1; MIGUEL ARCANJO SIMAS NOVO FILHO1; HECTOR DANIEL LOBO FERREIRA1; GABRIEL SILVA SANTOS GUIMARÃES1; ESTEFANNY MARIA DE SOUZA SCHUCK2; VANUSA DO NASCIMENTO3; JOÃO MARCOS BEMFICA BARBOSA FERREIRA3; FÁBIO FERNANDES4; ARISTÓTELES COMTE DE ALENCAR NETO3;

(1) CENTRO UNIVERSITÁRIO FAMETRO - MANAUS - AM - BRASIL; (2) UNIVERSIDADE NILTON LINS - MANAUS - AM - BRASIL; (3) UEA - MANAUS - AM - BRASIL; (4) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;



Introdução/Fundamentos: Systemic arterial hypertension is a multifactorial condition and an important modifiable risk factor for cardiovascular morbidity and mortality. Among police officers, chronic occupational stress, irregular routines, sedentary behavior, and other behavioral factors may increase this risk and impair quality of life. In this context, the Hiper-PMAM project was designed to investigate this condition among military police officers in Amazonas. Objetivos: To analyze the prevalence of elevated blood pressure and associated factors among military police officers in Amazonas, and describe quality-of-life indicators related to mental health and well-being. Métodos: Cross-sectional, quantitative, descriptive-analytical study with 142 military police officers. Data were collected through a structured questionnaire, anthropometric assessment, standardized blood pressure measurement in three readings, considering the mean of the last two according to the 2025 Brazilian Guideline on Arterial Hypertension, and administration of the WHOQOL-BREF, an instrument developed by the World Health Organization (WHO) to assess quality of life. Sociodemographic, occupational, clinical, and behavioral variables, blood pressure, BMI, medication use, and quality-of-life scores were analyzed. Resultados e Conclusões: A total of 142 military police officers were analyzed, with a mean age of 37.4±6.8 years, 86.6% were male, with a predominance of privates and corporals, accounting for 68.3%, followed by sergeants with 30.3%. Elevated blood pressure was observed in 80.3%. Self-reported hypertension or antihypertensive use occurred in 5.6%. Hypertensive patients not meeting blood pressure targets accounted for 75%. Overweight or obesity was present in 86.6% of cases, with obesity observed in 31%. Police officers with elevated blood pressure had a higher mean age (38.9 years; p=0.007), longer service duration (12.4 years; p=0.014), and higher BMI (30 kg/m²; p<0.001). In the WHOQOL-BREF, the environment domain, suggesting a greater influence of external and occupational factors on perceived quality of life, showed the poorest performance (67.0±11.5), and 19.6% reported negative feelings occurring frequently to always. The findings reveal a concerning scenario for the cardiovascular health of military police officers, marked by high prevalence of abnormal blood pressure, excess weight, and poorer perceived quality of life, reinforcing the need for continuous institutional strategies focused on prevention, monitoring, and health promotion.

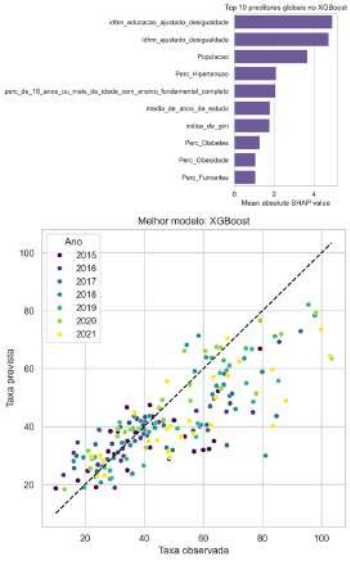
19545

SEX DISPARITIES IN VENTRICULAR TACHYCARDIA WITH STRUCTURAL HEART DISEASE: EPIDEMIOLOGY, MANAGEMENT, AND OUTCOMES FROM NATIONAL ADMINISTRATIVE AND DEVICE-BASED REGISTRIES

WAGNER ANTIDES RIBEIRO DE ALMEIDA PINA1; JADY BONARDI JOSE LIMA1; MARILIA DOS SANTOS ANDRADE1;

(1) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Sex-related differences in ventricular arrhythmias are increasingly recognized; however, comprehensive epidemiological data on disparities in presentation, management, and outcomes of ventricular tachycardia (VT) in patients with structural heart disease remain limited. Objetivos: To evaluate sex differences in the epidemiology, hospital management, and outcomes of patients admitted with VT and structural heart disease using national administrative databases and multicenter implantable cardioverter-defibrillator registries. Métodos: This retrospective study integrated data from the National Inpatient Sample (NIS), CDC WONDER mortality records, and multicenter implantable cardioverter-defibrillator cohorts from the MADIT studies. Adults aged ≥18 years hospitalized with a primary diagnosis of VT (ICD-10 code I47.2) and concomitant structural heart disease between 2016 and 2020 were identified in the NIS. Multivariable logistic regression was used to assess the association between sex and in-hospital outcomes and management patterns. Long-term arrhythmic risk was examined in device-based cohorts, and mortality trends were evaluated using age-adjusted rates from CDC WONDER. Resultados e Conclusões: Among approximately 193,600 hospitalizations for VT/ventricular fibrillation in the NIS between 2016 and 2020, women accounted for 25.5% of cases. Women were younger and had fewer comorbidities, yet underwent fewer invasive and advanced therapeutic interventions, including coronary angiography, mechanical circulatory support, implantable cardioverter-defibrillator implantation (adjusted odds ratio 0.75; p<0.01), and VT ablation. Women also had higher rates of do-not-resuscitate status and in-hospital cardiac arrest, whereas in-hospital mortality did not differ significantly by sex. Age-adjusted VT-related mortality increased from 0.22 to 0.32 per 100,000 between 1999 and 2020, with significant disparities across sex and race. In implantable cardioverter-defibrillator cohorts, women had a 40% to 60% lower risk of sustained ventricular tachyarrhythmias, although this association varied by race, with a significant interaction between sex and race. Marked sex disparities exist in the management and outcomes of VT among patients with structural heart disease. Despite lower arrhythmic risk in device-based cohorts, women were less likely to receive guideline-relevant therapeutic interventions, raising concern for persistent inequities in care delivery.



17368

SOCIAL AND EDUCATIONAL INDICATORS SURPASS TRADITIONAL CARDIOVASCULAR RISK FACTORS IN EXPLAINING DIFFERENCES IN MYOCARDIAL INFARCTION HOSPITALIZATION RATES ACROSS BRAZILIAN CAPITALS: AN ECOLOGICAL PREDICTIVE MODELING STUDY

ANDRÉ FELIPE CAVALCANTI FONSECA1; GABRIEL WALISSON ALEXANDRE MATIAS1; MARIA ANTONIETA ALBANEZ ALBUQUERQUE MEDEIROS LOPES2; MATHEUS CASTELO BRANCO FALCÃO ALBUQUERQUE3; GABRIEL GRANATA FIGUEIREDO1; JESSICA CAROLYNE ALVES SILVA4; MIRELA SILVEIRA ARENAS5; LUIZ ALBERTO REIS MATTOS JR1;

(1) UNIVERSIDADE FEDERAL DE PERNAMBUCO - RECIFE - PE - BRASIL; (2) REAL HOSPITAL PORTUGUES - RECIFE - PE - BRASIL; (3) UNIVERSIDADE CATOLICA DE PERNAMBUCO - RECIFE - PE - BRASIL; (4) FPS - FACULDADE PERNAMBUCANA DE SAUDE - RECIFE - PE - BRASIL; (5) UNINASSAU - RECIFE - PE - BRASIL;

Introdução/Fundamentos: Acute myocardial infarction (AMI) hospitalization rates vary markedly among Brazilian state capitals. While individual-level risk factors like hypertension and diabetes are well-established predictors, the role of population-level social determinants in driving these geographic disparities remains poorly characterized. Objetivos: To identify the most influential population-level predictors of AMI hospitalization rates across Brazilian capitals and to evaluate whether nonlinear predictive models outperform conventional linear approaches. Métodos: This ecological study analyzed 243 observations from all 27 Brazilian state capitals (2013–2021). The outcome was AMI hospitalizations per 100,000 inhabitants. Sixteen predictors spanning four domains — cardiovascular risk factors, demographics, education, and social development — were examined. Four models (linear regression, elastic net, random forest, XGBoost) were compared using temporal validation. Robustness was assessed by excluding 2021, using a reduced variable set, and performing permutation testing (n=200). Resultados e Conclusões: The model XGBoost achieved the best performance (MAE 10.59/100,000; R^2=0.50, 95% CI 0.36–0.64), outperforming random forest (R^2=0.39), linear regression (R^2=0.33), and elastic net (R^2=0.24). Permutation testing confirmed non-chance findings (p=0.005). The inequality-adjusted human development index, population size, educational indicators, and income inequality consistently ranked as the most influential predictors — above hypertension (5th) and diabetes (8th). A structural break in 2021 (R^2 dropping from 0.75 to 0.34) was consistent with pandemic-related disruption rather than model failure. Social determinants, particularly education and human development, were stronger ecological predictors of geographic AMI hospitalization variation than traditional cardiovascular risk factors. These findings suggest that addressing educational and socioeconomic inequalities may be as relevant to reducing AMI disparities as clinical risk factor management. These population-level associations should not be interpreted as individual-level causal effects and may partly reflect differences in healthcare access across capitals.

22063

SOCIOECONOMIC VULNERABILITY AND ACUTE MYOCARDIAL INFARCTION MORTALITY: A SPATIAL ECOLOGICAL ANALYSIS OF BRAZILIAN MUNICIPALITIES (2015–2023)

JOSÉ RICARDO ANDRADE1; RENATO MAX FARIA1; ICARO HEICKMEN TAVEIRA1; TIAGO JOSE NOGUES1; LUCAS QUEIROZ MENEZES1; ARTHUR AMORIM FELISARDO1; ANDRE JORGE NOGUES1;

(1) UFRN - NATAL - RN - BRASIL;

Introdução/Fundamentos: Socioeconomic inequities are structural determinants of cardiovascular mortality. Ischemic heart disease remains the leading cause of death in Brazil, with a heterogeneous distribution. Ecological analyses correlating social indicators with acute myocardial infarction (AMI) mortality are crucial for identifying public health priorities and mitigating notification biases. Objetivos: To investigate the association between socioeconomic vulnerability and AMI mortality in Brazilian municipalities using spatial analysis and adjusted Poisson regression (2015–2023), accounting for age-standardization and ill-defined causes. Métodos: Nationwide ecological study using AMI mortality data (ICD-10: I21) from SIM/DataSUS. Rates were adjusted for ill-defined causes (ICD-10: R00-R99) and age- standardized (Direct Method). Vulnerability was assessed via the Social Vulnerability Index (SVI) and Municipal Human Development Index (MHDI). Spatial analysis (LISA) identified mortality clusters. Poisson regression, adjusted for primary care coverage and population density, estimated Incidence Rate Ratios (IRR). Resultados e Conclusões: From 2019–2023, 473,861 AMI deaths were recorded (mean: 94,772/year), predominantly among males (59.4%) and elderly ≥60 years (76.5%). While the Southeast (46.1%) concentrated the highest absolute volume of deaths, adjusting for ill-defined causes revealed significantly higher rates of mortality in the North and Northeast compared to crude rates. Higher SVI was associated with increased AMI mortality (p<0.05), with an estimated Incidence Rate Ratio (IRR) of 1.12 (95% CI: 1.08–1.16) for each 0.1 increase in SVI, consistent with findings for broader cardiovascular diseases. LISA identified “high-high” mortality clusters in low-MHDI municipalities, particularly in North/Northeast hinterlands, confirming a strong correlation between structural poverty and cardiovascular outcomes. Socioeconomic vulnerability is a robust predictor of AMI mortality. Crude data mask the true burden in vulnerable regions due to notification biases. Policies must prioritize high-SVI areas and low primary care coverage to reduce cardiovascular inequities, addressing the distinct patterns of absolute volume versus adjusted mortality rates

TEMPORAL TRENDS AND IN-HOSPITAL OUTCOMES OF RHEUMATIC HEART DISEASE IN BRAZIL (2015–2024): A SEGMENTED REGRESSION ANALYSIS

LETICIA SANTANA POPADIUK1; ANA CLARA SCHREIBER2; EDUARDA TORMEM GIROTTO1; ISABELLA KLOSTER DE PAULA2; GABRIEL PETECK1; GLAUCO WILLIAN DE OLIVEIRA TRAMUJAS1; MARIANA GALEGO CANTERO2; GISELLE CAVALI DA COSTA RAITZ1;

(1) UNIVERSIDADE ESTADUAL DO CENTRO OESTE - GUARAPAVA - PR - BRASIL; (2) UNIVERSIDADE ESTADUAL DO OESTE DO PARANÁ - CASCAVEL - PR - BRASIL;

Introdução/Fundamentos: Rheumatic heart disease (RHD) remains a cause of preventable hospitalizations in Brazil and contributes substantially to cardiovascular mortality. Disruptions in healthcare services during the COVID-19 pandemic may have influenced the dynamics of diagnosis and management of this condition. In this context, the temporal trend and epidemiological profile of hospitalizations for RHD in Brazil were analyzed. Objetivos: To describe the epidemiological profile and temporal trend of hospitalizations and in-hospital mortality for RHD in Brazil from 2015 to 2024, comparing hospitalization and mortality trends across the pre-, intra-, and post- pandemic periods. Métodos: This ecological time-series study used data from the SUS Hospital Information System (SIH/SUS). Hospitalizations for RHD (ICD-10: I05-I09) were stratified by sex and region. Temporal trend analysis was performed using Joinpoint Analysis to identify inflection points in the slopes of the rates. Resultados e Conclusões: During the analyzed period, Brazil recorded 73,613 hospitalizations for rheumatic heart disease, with an in-hospital case fatality rate of 8.16%. The regional distribution revealed higher average annual hospitalization rates in the Central-West (4.71/100,000 inhabitants) and Northeast (4.19/100,000 inhabitants). The South region, although having a moderate hospitalization rate (3.39/100,000), presented the highest case fatality rate among the regions (10.19%). A higher proportion of deaths was observed in women (59.6%). Joinpoint analysis identified a significant inflection point in 2020 (p = 0.01), with a change in the trend pattern of hospitalizations over time. A progressive decline was observed pre-pandemic (APC=-16.8%), followed by a reversal of the pattern in 2020 and a subsequent increase in the post-pandemic period (APC=45.26%). The magnitude of the reduction in 2020 was 30.62% compared to 2019, followed by an increase of 67.22% in 2024. This pattern suggests a shift in hospitalization trends during the pandemic period, followed by partial recovery. Regional inequalities and variations in hospital mortality were also observed, indicating persistent heterogeneity in healthcare outcomes.

TEMPORAL TRENDS AND SOCIODEMOGRAPHIC INEQUALITIES IN OBESITY, DIABETES, AND HYPERTENSION IN BRAZILIAN CAPITALS, 2006–2024

LUCAS GABRIEL CASTRO CARVALHO1; MANOELA MASSA MOURA1; LALESCA MEDEIROS1; SOFIA ARRAIS HAIDAR1; HELENA MONTE VARANDAS1; ANA CLARA MONTE VARANDAS2; JOÃO PAULO DE SOUZA JÚNIOR1; MARIANA UBALDO BARBOSA PAIVA1; MARIA ESTEFÂNIA BOSCO OTTO1; ARMINDO JREIGE JÚNIOR3;

(1) UNIVERSIDADE DE BRASILIA - BRASÍLIA - DF - BRASIL; (2) UNIVERSIDADE CATOLICA DE BRASILIA - BRASÍLIA - DF - BRASIL; (3) HOSPITAL SÍRIO-LIBANÊS BRASÍLIA - BRASÍLIA - DF - BRASIL;

Introdução/Fundamentos: Cardiometabolic risk factors are major contributors to cardiovascular disease. In Brazil, long-term trends in obesity, diabetes, and hypertension, as well as their sociodemographic distribution, remain incompletely characterized. Objetivos: To assess temporal trends and sociodemographic inequalities in the prevalence of obesity, diabetes, and hypertension in Brazilian capitals from 2006 to 2024. Métodos: We conducted a population-based analytical cross-sectional study using Vigitel Brazil data from adults aged ≥18 years living in the capitals of the 26 Brazilian states and the Federal District between 2006 and 2024, excluding 2022 because data were unavailable. Obesity was defined as body mass index ≥30 kg/m², while diabetes and hypertension were based on self-reported medical diagnosis. Sex, age group, education level, and survey year were included as independent variables. Multivariable logistic regression models adjusted for these variables were used to estimate adjusted odds ratios (aORs), 95% confidence intervals (95%CIs), and p-values. Year was modelled as a continuous variable. All analyses accounted for the complex survey design. Resultados e Conclusões: A total of more than 700,000 adults were included. Between 2006 and 2024, the prevalence of obesity increased from 11.8% to 25.7%, diabetes from 5.5% to 12.9%, and hypertension from 22.0% to 27.0%. Older age was strongly associated with a higher burden of cardiometabolic risk factors, with adults aged ≥60 years showing fourfold higher odds than younger individuals (aOR 4.0, 95%CI 3.5–4.5; p<0.001). Lower educational attainment was also independently associated with these conditions (aOR 1.8, 95%CI 1.6–2.0; p<0.001). Female sex was independently associated with higher odds of obesity and hypertension (aOR 1.3, 95%CI 1.2–1.4; p<0.001). Each survey year was associated with increased odds of the analysed outcomes (aOR 1.04, 95%CI 1.03–1.05; p<0.001), indicating a persistent upward trend and marked sociodemographic inequalities. From 2006 to 2024, obesity, diabetes, and hypertension increased substantially across Brazilian capitals. Their unequal distribution by age, education, and sex highlights a persistent and unequal cardiometabolic burden, reinforcing the need for equity-oriented public health strategies in Brazil.

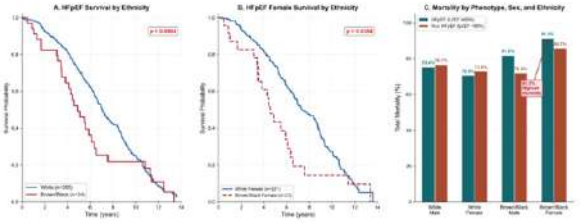
THE HIDDEN BURDEN OF HEART FAILURE WITH PRESERVED EJECTION FRACTION: ETHNICITY AS A MARKER OF EXTREME MORTALITY RISK

LUAN C VILACA LIMA1; GIOVANNI POSSAMAI DUTRA1; BRUNO FERRAZ DE OLIVEIRA GOMES1; JOÃO LUIZ FERNANDES PETRIZ1; PLINIO RESENDE DO CARMO JUNIOR2; DAVI DE VASCONCELLOS DIAS3; FABIANA CARDOSO DE OLIVEIRA3; EMILIA MATOS NASCIMENTO1; BASILIO DE BRAGANCA PEREIRA1; GLAUCIA MARIA MORAIS DE OLIVEIRA3;



(1) BARRA D`OR - RIO DE JANEIRO - RJ - BRASIL; (2) IDOR - RIO DE JANEIRO - RJ - BRASIL; (3) INSTITUTO DO CORACAO EDSON SAAD/UFRJ - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Heart failure with preserved ejection fraction (HFpEF) is the fastest-growing HF phenotype, yet its long-term prognosis and the role of social determinants of health (SDH) in this population remain poorly defined. In middle-income countries with marked racial and socioeconomic inequalities, HFpEF may carry a hidden burden of social vulnerability that conventional clinical assessment fails to capture. Objetivos: To characterize the clinical profile, SDH distribution, and long-term mortality of HFpEF patients in a dual-center decompensated heart failure (DHF) cohort, with emphasis on the intersection of ethnicity, sex, and socioeconomic context. Métodos: From 1,023 consecutive DHF patients at two tertiary centers in contrasting socioeconomic zones (West Zone HDI 0.959 vs. North Zone HDI 0.814; median follow-up 6.9 years, IQR 4.4–9.9), patients with LVEF ≥50% were classified as HFpEF. Clinical characteristics, SDH markers (hospital zone, ethnicity, sex), and outcomes were compared against non-HFpEF patients. Subgroup analyses explored SDH–phenotype interactions. Resultados e Conclusões: HFpEF comprised 389 patients (38.0%): predominantly female (244/389; 62.7%), older (median 82 years, IQR 73–88), with high prevalence of hypertension (329/389; 84.6%) and chronic AF (104/389; 26.7%). Despite preserved systolic function, long-term mortality was 287/389 (73.8%), with 34 (8.7%) in-hospital deaths. SDH markedly amplified mortality within HFpEF: Brown/Black patients had 88.2% (30/34) mortality versus 72.4% (257/355) in White patients (P=0.064). Among Brown/Black women with HFpEF, mortality reached 91.3% (21/23) — the highest rate in any phenotype–sex–ethnicity subgroup — compared with 70.6% (156/221) in White women with HFpEF. Hospital zone did not significantly differentiate HFpEF outcomes (West Zone 75.6% vs. North Zone 72.9%; P=0.80), suggesting that ethnicity-related social vulnerability operates through pathways independent of institutional context. HFpEF represents a substantial, predominantly female phenotype with high long-term mortality in which ethnicity — as a proxy for cumulative social disadvantage — identifies an extremely high-risk subgroup that clinical variables alone cannot detect.

Table. HFpEF Clinical Profile and Mortality by SDH Subgroups (n=389)

Characteristic	HFpEF Total (n=389)	White HFpEF (n=355)	Brown/Black HFpEF (n=34)	P-value
Age, median (IQR), years	82 (73–88)	82 (73–88)	82 (73–87)	NS
Female sex, n (%)	244 (62.7%)	221 (62.3%)	23 (67.6%)	NS
LVEF, median (IQR), %	62 (54–70)	62 (55–70)	59 (53–68)	NS
Hypertension, n (%)	329 (84.6%)	300 (84.5%)	29 (85.3%)	NS
Chronic AF, n (%)	104 (26.7%)	96 (27.0%)	8 (23.5%)	NS
Total mortality, n (%)	287 (73.8%)	257 (72.4%)	30 (88.2%)	0.064
In-hospital mortality, n (%)	34 (8.7%)	30 (8.5%)	4 (11.8%)	NS
Female mortality, n (%)	177/244 (72.5%)	156/221 (70.6%)	21/23 (91.3%)	0.046
West Zone mortality	99/131 (75.6%)	—	—	—
North Zone mortality	188/258 (72.9%)	—	—	0.80*

**West Zone vs. North Zone within HFpEF. LVEF=left ventricular ejection fraction; AF=atrial fibrillation; NS=not significant.*

THE HYPERTENSION PARADOX IN DIABETIC BLACK WOMEN: HIGH BASELINE RISK VS. MITIGATED PROGRESSION THROUGH INTENSIVE CLINICAL MANAGEMENT – ELSA-BRASIL STUDY.

IAN DANTAS LEITE FIGUEIREDO1; LEONARDO FONSECA MAIA2; LARISSA MENEZES PIANCÓ LEAL1; ELAINE CHAVES GADELHA3; LARISSA BARBOSA PAIVA3; ANE KAROLINE MEDINA NÉRI3; BRUNO DE MOURA FÉ RIOS1; LARA SILVEIRA BARROS LESSA1; RAFAEL SOARES MOTA E OLIVEIRA1; TIAGO JUCÁ TELES1; GERALDO BEZERRA DA SILVA JÚNIOR1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE FEDERAL DO PIAUI - PIAUÍ - PI - BRASIL; (3) HOSPITAL UNIVERSITARIO WALTER CANTIDIO - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Diabetes mellitus (DM) combined with hypertension represents a high-risk combination for renal and cardiovascular complications, with an uneven distribution across racial and gender groups. Black women constitute the group with the highest prevalence of hypertension among people with DM in the ELSA-Brasil cohort, facing significant sociodemographic disadvantages, such as lower educational attainment, lower income, and reduced access to health insurance. Paradoxically, evidence from the cohort suggests that this group makes more intensive use of antihypertensive medications and diuretics, raising the hypothesis that intensive clinical management may mitigate the progression of complications. Understanding this paradox is essential for guiding strategies for equitable care in vulnerable populations. Objetivos: To investigate whether intensive antihypertensive management mediates the reduction in renal and cardiovascular risk among black women with diabetes in the ELSA-Brasil cohort, by comparing blood pressure burden, treatment intensity, and the incidence of diabetic kidney disease (DKD) and cardiovascular disease (CVD) across intersectional sex/race subgroups, adjusting for sociodemographic and clinical determinants. Métodos: A prospective longitudinal study using data from 2008 to 2019 from the ELSA-Brasil cohort. The study included individuals with DM (self-reported, use of antidiabetic medications, or laboratory criteria) and complete data on HbA1c, renal function, and albuminuria. Exposures were race/skin color and sex, using an intersectional approach. Outcomes included DKD and major cardiovascular events, such as acute myocardial infarction, stroke, and heart failure. Survival analysis and Cox regression were used, with p<0.05. Resultados e Conclusões: At the start of the study, the group of black women had the highest prevalence of hypertension, being 68.3% among those without DKD and 82.7% among those with DKD, as well as a higher prevalence of obesity. However, after clinical adjustments, it was not possible to establish an independent association between the group and the risk of developing DKD or CVD, highlighting the group's greater access to and use of clinical treatment as protective factors not as prominently present in the other groups, thereby mitigating social inequalities and those related to pre-existing comorbidities over time. Therefore, the clinical surveillance promoted by the ELSA-Brasil study acted as an essential protective factor against DKD and CVD progression.

19342

THE INTERACTION BETWEEN SOCIAL DETERMINANTS AND CLINICAL FACTORS ON CARDIO-RENAL OUTCOMES IN INDIVIDUALS WITH DIABETES: RESULTS FROM THE ELSA-BRASIL STUDY

LARISSA MENEZES PIANCÓ LEAL1; ANE KAROLINE MEDINA NÉRI2; LEONARDO FONSECA MAIA3; BIANCA SENA MACEDO1; FILIPO TELIS MOREIRA1; JOÃO PEDRO CUNHA DE MOURA1; JULIANA ROCHA FERIANCI1; IAN DANTAS LEITE FIGUEIREDO1; ELAINE CHAVES GADELHA2; LARISSA BARBOSA PAIVA2; GERALDO BEZERRA DA SILVA JÚNIOR1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (2) HOSPITAL UNIVERSITARIO WALTER CANTIDIO - FORTALEZA - CE - BRASIL; (3) UNIVERSIDADE FEDERAL DO PIAUI - PIAUÍ - PI - BRASIL;

Introdução/Fundamentos: Type 2 diabetes mellitus (T2DM) is the primary cause of diabetic kidney disease (DKD) and increases the risk of cardiovascular events (CVD) by up to four times. The distribution of these complications aligns with structural markers of inequality such as race/ethnicity, gender, and educational attainment. An intersectional analysis allows us to examine how these markers produce distinct risks. Objetivos: To analyze, from an intersectional perspective, the combined influence of race/color, sex, and socioeconomic status on renal and cardiovascular complications in individuals with diabetes in the ELSA-Brasil cohort. Métodos: A prospective longitudinal study using data from waves 1 (2008–2010), 2 (2012–2014), and 3 (2017–2019) of the ELSA-Brasil cohort. The study included individuals with diabetes who had complete laboratory data. DKD was defined by persistent albuminuria (≥30 mg/g) and/or glomerular filtration rate <60 mL/min/1.73 m² in two consecutive waves. CVD included myocardial infarction, stroke, and heart failure. The analysis considered intersectionality between sex, race/ethnicity, and education level, using Kaplan-Meier curves, Cox regression and Hazard Ratios (HR) Resultados e Conclusões: A total of 1,138 individuals with diabetes were analyzed (51,7% men; 58.5% black/pardo and 45.4% with a university degree). Black women exhibited greater social vulnerability, with lower educational attainment (32.4% with a university degree), poorer self-perceived health (47.2% regular and 4.8% poor), and a higher prevalence of hypertension (68.3%), while white men were more likely to be in a higher socioeconomic class (52.7% in class B). The sex/race intersection was not independently associated with DKD or CVD. For DKD, the main predictor was duration of diabetes (10–19 years: HR =1.71, 95%Confidence Interval (CI): 1.28–2.28; ≥20 years: HR=1.99, 95%CI 1.37–2.63). For CVD, low educational attainment stood out as the main determinant (elementary/illiterate: HR 1.83, 95% CI 1.41–2.37; p < 0.001; high school: HR 1.57, 95% CI 1.27–2.07; p < 0.001), independent of clinical factors Despite social disparities, race/color, gender and socioeconomic status intersectionality was not an independent predictor of DKD or CVD in diabetic participants of ELSA-Brasil cohort. DKD was mainly related to prolonged metabolic exposure, while CVD more significantly reflected the influence of structural social determinants, especially educational attainment.

URBAN GREEN INFRASTRUCTURE AND CARDIOVASCULAR MORTALITY DURING HEATWAVES: A SYSTEMATIC REVIEW OF INTERVENTION AND MODELLING STUDIES

BEATRIZ DE LIMA VITORIO FERREIRA1; FLAVIA BEATRIZ DO CARMO MOREIRA2; MARCOS AURELIO FONSECA MEDEIROS1; EVELIN GABRIELLY DE VARGAS2; PEDRO DE ARAÚJO SANTOS1; LUCAS MANOEL BORGES DOURADO2; MARIANA VIDAL MIYAZATO2; ANNE KAROLLYNE ALVARES SANTOS2;

(1) UNIFACISA - CAMPINA GRANDE - PB - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Urban heat islands (UHI) may increase local temperatures by up to 4.4°C and are associated with 4.3% of summer mortality (Iungman et al., 2023). Nature-based interventions, such as urban tree planting, have emerged as promising mitigation strategies, but their quantitative impact on cardiovascular (CV) outcomes remains insufficiently consolidated. Objetivos: To systematically review studies evaluating the effects of urban green infrastructure (tree canopy expansion, cool roofs) on CV mortality, emergency department (ED) visits, and temperature during extreme heat events. Métodos: Systematic review conducted according to PRISMA guidelines. Original studies assessing the impact of increased urban green coverage or high-albedo surfaces on cardiovascular outcomes or ambient temperature during extreme heat were included. Both modelling and observational studies with quantitative data were considered. Seven studies published between 2022 and 2026 were included, covering Europe, China, the United States, and Hong Kong. Resultados e Conclusões: Studies consistently demonstrated associations between higher urban green coverage and reductions in temperature and heat-related CV outcomes. In 93 European cities, increasing tree coverage to 30% reduced mean temperature by 0.4°C and prevented 2,644 summer deaths, corresponding to 39.5% of deaths attributable to UHI. In 232 Chinese cities, an 18.3% increase in green coverage could prevent 19,764–26,360 annual CV deaths under future climate scenarios. In 10 US cities, a 10% increase in tree canopy could prevent 50–3,800 deaths, with up to 22% lower heat-related mortality in Phoenix. In Los Angeles, combining tree canopy and high-albedo surfaces reduced ED visits by 25–50% during heat events. In Hong Kong, relative risk decreased from 1.103 in low-green areas to 0.943 in high-green areas. Meta-analyses also showed reduced CV mortality associated with greater vegetation exposure. Urban green infrastructure, particularly tree canopy expansion, is consistently associated with lower temperatures and reduced cardiovascular mortality during heatwaves across different settings and methodologies, supporting its role as a relevant climate adaptation strategy, especially for vulnerable populations.

“SOCIOECONOMIC INEQUALITY AND HEART FAILURE OUTCOMES IN BRAZIL: A NATIONWIDE ECOLOGICAL ANALYSIS”

LUAN NASCIMENTO LAZARO1; RODOLFO LEITE ARANTES1; AGATHA FARIA1;

(1) UNIVERSIDADE DE RIBEIRAO PRETO - GUARUJA - SP - BRASIL;

Introdução/Fundamentos: Heart failure (HF) is a complex syndrome with high morbidity and mortality worldwide. In Brazil, HF prevalence is estimated at 1.1% among adults and 3.3% among individuals over 60 years old. Although the association between poorer socioeconomic conditions and higher HF mortality has been established, recent Brazilian studies linking cardiovascular diseases to socioeconomic conditions remain scarce. Objetivos: To analyze the association between heart failure morbidity and mortality indicators (hospitalizations, mortality rate, and deaths) and socioeconomic variables such as the Gini index, average income, and years of schooling. Métodos: This was an ecological, cross-sectional study using data obtained from public databases. Hospitalizations, mortality rates, and deaths—stratified by Brazilian states—were collected from DATASUS. Socioeconomic indicators were obtained from census data published by the Brazilian Institute of Geography and Statistics (IBGE). Initially, descriptive analyses of the studied variables were performed. Bivariate associations between socioeconomic indicators and heart failure outcomes were assessed using Pearson’s correlation coefficient, considering the continuous nature of the variables. Subsequently, a multiple linear regression model was constructed to evaluate the independent association between socioeconomic factors and heart failure mortality. Regression coefficients (β), 95% confidence intervals, and p-values were estimated, adopting a significance level of 5%. Resultados e Conclusões: In the bivariate analysis, the Gini index showed a moderate positive correlation with heart failure mortality (r = 0.42). In contrast, average income showed a weak negative correlation (r = -0.18), while years of schooling showed no relevant association with mortality (r = -0.09). Regarding HF hospitalizations, average income showed a moderate positive correlation (r = 0.35). Schooling showed a weak association (r = 0.15), while the Gini index showed a weak negative correlation with hospitalizations (r = -0.19). In the multivariate analysis using multiple linear regression, the Gini index remained significantly associated with HF mortality (β = 38.9; p = 0.045). In contrast, neither average income (p = 0.623) nor schooling (p = 0.963) showed statistically significant associations.

INTEGRATED EVALUATION OF CLINICAL PARAMETERS, PLASMA BIOCHEMICAL MARKERS, AND CARDIAC PROTEOMICS IN SPRAGUE-DAWLEY RATS SUBMITTED TO A HIGH-FAT DIET AND BETA-ALANINE SUPPLEMENTATION

ISABELA MARIA SANTOS1; KARINA OLIVEIRA SANTOS2; AMANDA ALVES RABELO1; LARISSA TERCÍLIA GRIZZO THOMASSIAN2; ANA CAROLINA MAGALHÃES2;

(1) FACULDADE DE MEDICINA UNIVERSIDADE DE SÃO PAULO - BAURU - SP - BRASIL; (2) FACULDADE DE ODONTOLOGIA DE BAURU - USP - BAURU - SP - BRASIL;

Introdução/Fundamentos: Obesity is associated with important inflammatory and metabolic alterations, including insulin resistance, dyslipidemia, and increased visceral adiposity. In this context, compounds with potential antioxidant effects, such as beta-alanine, have gained scientific interest. Objetivos: To evaluate the effects of a high-fat diet and beta-alanine supplementation on clinical parameters, plasma biochemical markers, and the proteomic profile of the left ventricle. Métodos: The study was approved by the Animal Ethics Committee (Protocol 005/2023). Forty male Sprague-Dawley rats were divided into four groups: control (CO), control supplemented with beta-alanine (COBA), high-fat diet (HI), and high-fat diet supplemented with beta-alanine (HIBA). The experimental protocol consisted of 10 weeks of diet consumption, including 4 weeks of supplementation with agar containing beta-alanine. At the end of the experimental period, the animals were euthanized, and body weight, energy efficiency, blood glucose, plasma cholesterol, triglycerides, and visceral adiposity were evaluated. In addition, proteomic analysis of the left ventricle was performed. Biochemical parameters were analyzed using two-way ANOVA ($p<0.05$), while proteomic data were analyzed using Student's t-test, considering $p<0.05$ for proteins with lower abundance and $1-p>0.95$ for proteins with higher abundance. Resultados e Conclusões: Animals submitted to the high-fat diet showed greater weight gain, with a 1.5-fold increase compared to the control group, as well as increased visceral adiposity, higher energy efficiency, and elevated blood glucose levels. These findings were associated with increased abundance of proteins such as Paternally-expressed gene 3 protein (2.46-fold) and mitochondrial long-chain specific acyl-CoA dehydrogenase (1.46-fold) compared with control groups. Beta-alanine supplementation did not significantly affect body weight, plasma triglycerides, blood glucose, or visceral adiposity. However, reduced plasma cholesterol levels were observed in obese animals supplemented with beta-alanine compared to non-supplemented obese animals, which was associated with increased abundance of proteins such as mitochondrial Carnitine O-palmitoyltransferase 2 (1.09-fold) and mitochondrial Superoxide dismutase [Mn] (1.23-fold). These findings suggest that the high-fat diet induced an obesity-related metabolic profile, whereas beta-alanine showed a potential beneficial effect by reducing plasma cholesterol and increasing antioxidant proteins.

MODULATION OF CARDIOMETABOLIC RISK BY DIFFERENT FATTY ACID COMPOSITIONS IN KETOGENIC DIETS: AN EXPERIMENTAL STUDY IN WISTAR RATS

ISABELLA DE ALMEIDA NERLICH1; GLAUCIVAN GOMES GURGEL1; CHAYANE GOMES MARQUES1; LÍVIA ALVARENGA1; NÁGILA RAQUEL TEIXEIRA DAMSCENO1;

(1) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: The ketogenic diet has gained prominence in nutrition, but its effects on cardiometabolic risk remain controversial, particularly due to the qualitative composition of fatty acids. Objetivos: Accordingly, the aim of this experimental study was to evaluate the effect of different fatty acid compositions in ketogenic diets on cardiometabolic markers. Métodos: The study involved 24 male Wistar rats, divided into 3 groups: control diet (CD), classic ketogenic diet (CKD), rich in saturated fatty acids, and modified ketogenic diet (MKD), rich in mono- and polyunsaturated fatty acids, including eicosapentaenoic acid (EPA). At the end of the intervention, body composition was analyzed by Dual-Energy X-ray Absorptiometry (DEXA), and serum samples were collected to assess antioxidant capacity via lag time, and plasma samples were collected to analyze the lipid profile (total cholesterol, HDL-c, LDL-c, triglycerides, and free fatty acids) using specific kits, except for LDL-c, which was estimated based on the Friedewald equation. Data were analyzed using ANOVA with Bonferroni post hoc tests, with a significance level of 5%. Resultados e Conclusões: Regarding changes in body composition, fat mass in the CKD group [167.78 (22.80 g)] was higher than that in the CD group [87.67 (12.55 g), $p = 0.009$]. The MKD group [142.67 (13.38 g), $p = 0.095$] did not differ from the others. For lean mass, we observed a similar yet opposite pattern, as the CKD group [273.82 (10.94 g), $p = 0.029$] had a lower value compared to the CD group [324.14 (14.10 g)]. Once again, the MKD group [280.91 (12.17 g), $p = 0.069$] did not differ from the others. Regarding triglycerides, a reduction was observed in the MKD group compared to the CD group [134.57 (4.44) mg/dL vs. 155.69 (4.64) mg/dL, $p = 0.013$], while the CKD group showed no significant difference [149.91 (4.99) mg/dL, $p > 0.05$]. Regarding total cholesterol, reductions were observed in the MKD [110.73 (2.23) mg/dL, $p < 0.01$] and CKD [116.90 (3.61) mg/dL, $p = 0.007$] groups when compared to the CD group [138.81 (6.55) mg/dL]. A reduction in HDL-c was also observed in the MKD [45.16 (2.23) mg/dL] and CKD [44.92 (2.23) mg/dL] groups compared to the CD group [65.89 (5.02) mg/dL]. There was no significant difference in LDL-c, free fatty acids, and antioxidant capacity among the groups. It is concluded that the classic ketogenic diet presented a worse body composition and triglyceride profile compared to the control diet and that both DCC and DCM decreased total cholesterol, but also HDL-c.

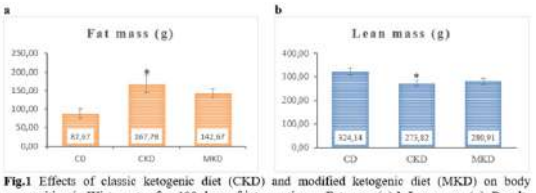

Fig.1 Effects of classic ketogenic diet (CKD) and modified ketogenic diet (MKD) on body composition in Wistar rats after 100 days of intervention. **a** Fat mass (g) **b** Lean mass (g). Results presented as mean (SEM). N = 8/group. *Difference from CD; $p<0.05$.

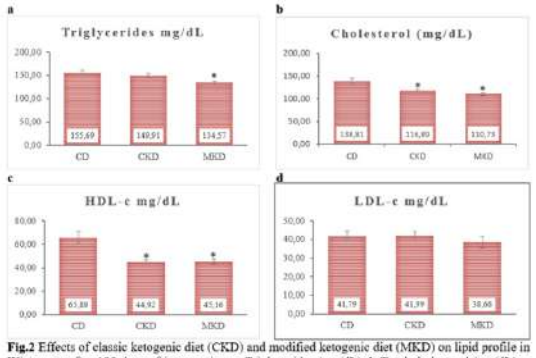

Fig.2 Effects of classic ketogenic diet (CKD) and modified ketogenic diet (MKD) on lipid profile in Wistar rats after 100 days of intervention. **a** Triglycerides (mg/dL). **b** Total cholesterol (mg/dL). **c** High density lipoprotein cholesterol (mg/dL). **d** Low density lipoprotein cholesterol (mg/dL). Results presented as mean (SEM). N = 8/group. *Difference from CD; $p<0.05$.

REMNANT CHOLESTEROL IS ASSOCIATED WITH ATHEROSCLEROTIC RISK, BUT NOT HEART FAILURE RISK, EVEN AT NORMAL TRIGLYCERIDE CONCENTRATIONS

BEATRIZ TELES LEAL1; RIBANNA APARECIDA MARQUES BRAGA2; ROSANA APARECIDA MANÓLIO SOARES FREITAS1; JÚLIA GALBIATI DE SOUZA2; LIVIA ALVARENGA3; ERNANI T. SANTA HELENA4; NÁGILA RAQUEL TEIXEIRA DAMASCENO1;

(1) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (3) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (4) UNIVERSIDADE REGIONAL DE BLUMENAU - BLUMENAU - SC - BRASIL;

Introdução/Fundamentos: Remnant cholesterol has emerged as a marker of residual cardiovascular risk. However, whether it identifies risk in individuals with normal plasma triglyceride concentrations and across different cardiovascular outcomes remains unclear. Objetivos: To evaluate the association between remnant cholesterol and predicted cardiovascular risk using PREVENT risk equations, and to investigate whether this association differs according to plasma triglyceride concentrations. Métodos: This cross-sectional study used baseline data (2014–2018) from 500 adults aged 20–79 years in the SHIP-Brazil cohort. Sociodemographic and lifestyle data were obtained through structured questionnaires, including smoking, alcohol consumption, physical activity, and dietary intake. The lipid profile included analyses of total cholesterol, LDL-C, HDL-C, and triglycerides. Remnant cholesterol was calculated as total cholesterol – LDL-C – HDL-C. Predicted 10-year risks for total cardiovascular disease, atherosclerotic cardiovascular disease (ASCVD), and heart failure were estimated using PREVENT equations. Multivariable linear regression models were adjusted for age, sex, LDL-C, smoking, alcohol consumption, and caloric intake. Collinearity diagnostics showed low variance inflation factors (VIF<1.14). Resultados e Conclusões: The sample comprised predominantly women (56.6%), with a mean age of 51 years (SD 14.5); 19.6% were former smokers and 9.6% were current smokers. Most participants reported low-risk alcohol consumption (75.4%). Mean LDL-C concentration was 118.1 mg/dL (36.3), HDL-C 42.6 mg/dL (10.8), triglycerides 124.7 mg/dL (69.6), and remnant cholesterol 27.6 mg/dL (8.6). Mean predicted risks were 7.72% (8.7) for total cardiovascular disease, 4.56% (5.1) for ASCVD, and 4.04% (5.7) for heart failure. In stratified analyses, remnant cholesterol was positively associated with predicted total cardiovascular risk among individuals with normal plasma triglyceride concentrations (β=0.146; 95%CI: 0.038–0.254; p=0.008), but not among those with elevated triglyceride concentrations (p=0.417). Similar findings were observed for ASCVD risk (β=0.092; 95%CI: 0.029–0.155; p=0.004 vs p=0.142, respectively). No significant association was observed for predicted heart failure risk. Remnant cholesterol was associated with atherosclerotic cardiovascular risk, particularly among individuals with normal triglyceride concentrations, indicating residual risk. These findings support its clinical utility for improving cardiovascular risk stratification.

THE ASSOCIATION BETWEEN DIETARY QUALITY AND ATHEROSCLEROTIC CARDIOVASCULAR DISEASE RISK IN A POPULATION-BASED COHORT

JÚLIA TIEKO YANO IORIO1; LIVIA DE ALMEIDA ALVARENGA2; RIBANNA A M BRAGA2; ERNANI T SANTA HELENA1; NÁGILA RAQUEL TEIXEIRA DAMASCENO2;

(1) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Dietary patterns are among the top modifiable risk factors driving the global burden of cardiovascular diseases (CVD), with atherosclerosis being the primary underlying cause of these conditions. Objetivos: We aimed to investigate the association between diet and atherosclerotic cardiovascular disease risk (ASCVDR) using the validated Brazilian Healthy Eating Index-Revised (BHEI-R). Métodos: This is a cross-sectional study in which sociodemographic data were collected using a structured questionnaire, and trained personnel measured weight and height to assess Body Mass Index (BMI) and waist circumference (WC). Total cholesterol, triglycerides (TG) and cholesterol in high-density lipoprotein (HDL-c) and low-density lipoprotein (LDL-c) were measured using an automatic analyzer. Overall diet quality was assessed using the Revised Brazilian Healthy Eating Index (BHEI-R), which ranges from 0 to 100, with higher scores indicating better diet. Ultrasound was used to assess the presence of atherosclerotic plaques and stenosis in the arteries. ASCVDR was assessed by the PREVENT calculator, and its association with diet quality was analyzed using logistic regression models. Resultados e Conclusões: Three hundred and eighty-five individuals, in which 55.9% were females, with a mean age of 51.2 ± 14.7 years, a mean BMI of 29.4 ± 5.5 kg/m², and a mean BHEI-R score of 66.2 ± 8.2 points. The prevalence of increased ASCVDR was 32.7%. Individuals with high ASCVDR were men (54.8% vs. 45.2%; p=0.038), older (66.7 ± 7.8 vs. 44.0 ± 10.8 years; p<0.001), presented high WC (99 ± 13 vs. 90 ± 13 cm; p<0.001), and TG (145 ± 91 vs. 115 ± 58 mg/dL; p=0.001), and low BHEI-R (65 ± 9 vs. 69 ± 6 points; p<0.001). There were no significant statistical differences for BMI, total cholesterol, LDL-c, or HDL-c (p>0.05). Additionally, high prevalence of ASCVDR was seen among individuals with arterial stenosis (80.0% vs. 31.1%; p<0.0001) and atherosclerotic plaque (82.8% vs. 28.8%; p<0.001). In logistic regression analyses, high BHEI-R points were associated with low chances of high ASCVDR (OR = 0.93; 95% CI:0.90–0.96; p<0.001). Similar profile was observed for arterial stenosis (OR=0.93; 95% CI:0.89–0.98; p=0.006), however no significant association was found between BHEI-R score and atherosclerotic plaque (OR=0.96; 95% CI:0.91–1.02; p=0.239). In conclusion, high diet quality was associated with lower chances of increased ASCVDR and arterial stenosis, reinforcing the relevance of diet in the global management of CVD risk factors.

ANTICOAGULATION CONTROL IN PATIENTS WITH MECHANICAL HEART VALVES IN THE BRAZILIAN PUBLIC HEALTH SYSTEM

THIEGO BELLO RIBEIRETE1; NICOLE CAROLINE ALCÂNTARA1; KATIUSCA ISABELLE VALDERRAMA PADILHA1; EDUARDO MARTELLI MOREIRA1; MARCIA OLANDOSKI2; PEDRO FELIPE GOMES NICZ1; TALITA BEITHUM RIBEIRO MIALSKI1; FABIO ROCHA FARIAS1; BRUNA OLANDOSKI ERBANO1;

(1) COMPLEXO HOSPITAL DE CLÍNICAS DA UNIVERSIDADE FEDERAL DO PARANÁ (CHC-UFPR) - CURITIBA - PR - BRASIL; (2) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL;

Introdução/Fundamentos: Mechanical heart valves require lifelong warfarin therapy and regular International Normalized Ratio (INR) monitoring. Maintaining anticoagulation within the therapeutic range is critical to reduce thromboembolic and bleeding complications. However, the multiple factors influencing warfarin response make anticoagulation control particularly challenging, especially in public healthcare settings. Objetivos: To assess the quality of warfarin anticoagulation control in patients with mechanical aortic and/or mitral valves treated in the Brazilian public health system, and to identify clinical and demographic factors associated with poor therapeutic control and adverse events. Métodos: This retrospective longitudinal study included patients aged 18 years or older with mechanical aortic and/or mitral valves receiving warfarin and followed at a tertiary hospital in Paraná, Brazil, between 2023 and 2025. Patients with fewer than five INR measurements were excluded. Demographic and clinical data, adverse events (thrombotic and bleeding), and INR values were collected. Time in therapeutic range (TTR) was calculated using the Rosendaal method. ROC curves were used to determine TTR and INR coefficient of variation (CV) cutoffs associated with adverse events. Logistic regression models were also performed. Resultados e Conclusões: A total of 133 patients were analyzed; 66.9% were women, mean age was 59.3 ± 10.8 years, and valve position was mitral in 45.1%, aortic in 38.8%, and mitro-aortic in 21.1%. Rheumatic heart disease was the leading etiology (54.1%), and 49.6% of patients had atrial fibrillation. Mean TTR was 53.4% ± 23.0%; 58.6% of patients had TTR <60%, and 27.8% had INR CV ≥37%. Adverse events occurred in 17.3% of patients during a median follow-up of 975 days (111-1065). TTR <44% was associated with higher odds of adverse events (OR 3.27, 95% CI 1.26-8.48; p=0.015), as was INR CV ≥37% (OR 4.13, 95% CI 1.58-10.7; p=0.004), independently of age and sex. In this cohort, adequate anticoagulation control was difficult to achieve, with a predominance of TTR <60% and marked INR variability. TTR <44% and INR CV ≥37% were independently associated with adverse events. These findings highlight the need for more effective anticoagulation monitoring strategies for patients with mechanical heart valves in the Brazilian public health system.

BEDSIDE SCREENING FOR ABDOMINAL AORTIC DILATIONS IN HEMODIALYSIS PATIENTS: A POCUS-BASED STUDY

ANA LIZ LIMA BARRETO1; HELLEN CARVALHO LIMA1; ADSON ARAGÃO ARAÚJO SANTOS1; LARA VITÓRIA SOUSA MARINHO1; MATHEUS RODRIGUES LOPES1; ADIRLENE PONTES OLIVEIRA TENÓRIO1;

(1) UNIVERSIDADE FEDERAL DO VALE DO SAO FRANCISCO - PAULO AFONSO - BA - BRASIL;

Introdução/Fundamentos: Abdominal aortic aneurysm (AAA) rupture carries high mortality. While arterial dilation frequently affects patients with chronic kidney disease (CKD) on dialysis, a cohort plagued by accelerated vascular aging, detecting these anomalies before a crisis strikes remains a clinical challenge. Point-of-care ultrasound (POCUS) offers an accessible alternative. It bypasses the need for specialized imaging technicians, allowing frontline physicians to efficiently evaluate cardiovascular structures directly at the dialysis chair. Objetivos: To assess the prevalence of abdominal arterial dilations using POCUS in hemodialysis patients. Métodos: In this cross-sectional study of 154 stage 5 CKD patients, intra-dialytic POCUS measurements of the abdominal aorta were systematically paired with clinical data gathered from semi-structured interviews and routine medical records. To preserve blinding protocols, the specific dialysis center remains undisclosed. Investigators measured the transverse diameter of the abdominal aorta (proximal, middle, and distal) using POCUS while subjects rested semi-supine during their treatment sessions. A semi-structured interview questionnaire was used to collect clinical and epidemiological data, and laboratory results, including calcium, phosphorus, and parathyroid hormone levels, were obtained from medical records. Clinical and sociodemographic variables were analyzed using the Chi-square test. Resultados e Conclusões: Investigators identified 31 cases of aortic dilation (20.1% prevalence). Ectasias accounted for this number (18.8%), whereas true AAA were present in a minority of the cohort (1.3%). Classic lifestyle and demographic risk factors proved highly predictive: male gender and black ethnicity strongly correlated with dilation (both p=0.001; Table 1), closely followed by smoking (p=0.03) and alcohol use (p=0.004; Table 2). Surprisingly, neither advancing age nor deranged bone mineral profiles showed any significant statistical link. This unexpected disconnect illustrates the multifactorial nature of vascular aging in nephrology. Ultimately, waiting for symptoms is a dangerous strategy. These findings suggest that POCUS could serve as a valuable adjunct in cardiovascular risk stratification for hemodialysis patients, potentially identifying structural decay before symptomatic progression.

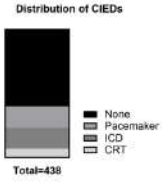
CLINICAL AND MICROBIOLOGICAL PREDICTORS OF IN-HOSPITAL MORTALITY IN INFECTIVE ENDOCARDITIS: A 25-YEAR COHORT STUDY



BEATRIZ VELOSO DE ALMEIDA VENUTO1; ANTÔNIO MARCONDES MUTARELLI1; EDUARDO ENRIQUE CARVALHO GRADE VALLEJO1; JOÃO GABRIEL FRANCISCO RODA1; LAURA DELPHINI CORRÊA PEREIRA1; SARA REGINA SILVA CUPERTINO1; WILLIAM SILVA BARBOSA1; WILLIAM ANTÔNIO DE MAGALHÃES ESTEVES1; MARILDES LUIZA DE CASTRO1; PEDRO VIANA DINIZ1; TERESA CRISTINA ABREU FERRARI1; MARIA DO CARMO PEREIRA NUNES1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: Infective endocarditis (IE) remains a major global health burden accounting for over 1.09 million cases and 66,000 deaths annually. Current literature suggests that its epidemiological profile has evolved alongside an aging population, healthcare-related factors and growing use of cardiovascular implantable eletronic devices (CIEDs). In this scenario, Staphylococcus aureus remains the most common agent, responsible for 29% of cases, alongside other pathogens. Therefore, evaluating the prognostic impact of microbiological etiology and baseline host characteristics on in-hospital mortality is crucial to refine risk stratification and improve clinical care. Objetivos: To identify independent predictors of in-hospital mortality by analyzing the clinical and microbiological characteristics of inpatients in a Brazilian quaternary care teaching hospital. Métodos: This cohort study included 450 patients with IE according to the modified Duke criteria, who were admitted to a teaching hospital in Belo Horizonte, Brazil, between 2001 and 2026. To identify independent predictors of in-hospital mortality, a multivariable logistic regression analysis was performed using a generalized linear model with a binomial distribution and logit link. Odds ratios (ORs) and 95% confidence intervals (CIs) were estimated. Statistical significance was assessed using Wald tests. Resultados e Conclusões: Among the 450 pacients, the median age was 57 years (IQR 42–66). Predisposing conditions were common, particularly prior CIEDs (n=147; 33.6%) and prosthetic valves (n=92;21.0%). Multivariable analysis identified advanced age (OR 1.02(1.00–1.04); p=0.019) and heart failure (OR 1.72(1.03–2.92);p=0.042) as the two primary independent clinical predictors of in-hospital death. Regarding microbiological etiology, Staphylococcus aureus (n =101;29%) and coagulase-negative staphylococci (n=70;20%) were the most prevalent pathogens and both were independent predictors of mortality (OR 4.62(1.69–15.02); p=0.005 and OR 4.31(1.45–14.87);p=0.012). Additionally, Gram-negative bacilli (OR 7.51(1.96–31.72);p=0.004) as well as fungi (OR 5.17(1.06–26.61);p=0.043) and unidentified pathogens (OR 4.12 (1.45–13.73); p=0.012) were also associated with increased risk of death. In summary, although Staphylococcus spp. remain the predominant etiology, atypical and unidentified pathogens are also associated with a substantially higher risk of in-hospital mortality underscoring the need for further studies to address the profile of these unidentified cases

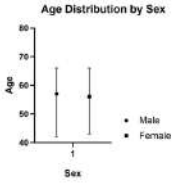


Table 2. Predictors of In-Hospital Mortality in Patients with IE.

Variable	OR (IC95%)	p-value
Age	1.02 (1.00–1.04)	0.019
Heart Failure	1.72 (1.03–2.92)	0.042
Embolic events	1.81 (0.96–3.44)	0.067
Chronic Kidney Disease	1.84 (0.97–3.52)	0.062
Previous Endocarditis	0.82 (0.34–1.90)	0.657
Previous Condition – Prosthetic valve	0.41 (0.16–1.03)	0.057
Previous Condition – Devices	0.29 (0.11–0.73)	0.008
Previous Condition – Systemic diseases	0.47 (0.17–1.29)	0.145
Previous Condition – Non-identified	0.58 (0.21–1.62)	0.300
Previous Condition – Prolapse	0.19 (0.01–1.57)	0.176
Previous Condition – Bicuspid Aortic Valve	0.91 (0.24–3.39)	0.892
Previous Condition – Degenerative	0.24 (0.03–1.47)	0.138
Staphylococcus aureus	4.62 (1.69–15.02)	0.005
Staphylococcus coagulase negativo	4.31 (1.45–14.87)	0.012
Enterococcus	3.26 (0.92–12.71)	0.074
GNB	7.51 (1.96–31.72)	0.004
Fungi	5.17 (1.06–26.61)	0.043
HACEK	2.97 (0.12–40.03)	0.421
Polymicrobial	4.45 (0.85–23.07)	0.071
Unidentified pathogens	4.12 (1.45–13.73)	0.012
Other pathogens	0.99 (0.04–8.70)	0.992

IMPACT OF PRIOR ACUTE RHEUMATIC FEVER ON OUTCOMES IN CHRONIC RHEUMATIC HEART DISEASE

MATHEUS HENRIQUE PEREIRA NUNES1; DANIELLY RAMOS PEREIRA2; KLICIA JARDIM PEREIRA2; LUIZA HAIKAL DE PAULA2; LAURA MUSTAFÁ UMBELINO VIEIRA2; VIVIAN BARROSO SANTOS2; HENRIQUE FAUSTINO VIEIRA DA SILVA2; SILVIO MENDES MAGALHÃES2; LUISA VARGAS MARINHO2; LUZ MARINA TACURI CHAVEZ2; WILLIAM ANTÔNIO DE MAGALHÃES ESTEVES2; BRUNO RAMOS NASCIMENTO2;

(1) FACULDADE DE MEDICINA DE BARBACENA - BARBACENA - MG - BRASIL; (2) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: Acute rheumatic fever (ARF) and rheumatic heart disease (RHD) are post-infectious autoimmune sequelae of group A streptococcal infection. Secondary antibiotic prophylaxis reduces disease progression. However, most patients with established RHD lack a documented history of ARF, missing a critical window for intervention. Objetivos: To assess the association between prior ARF diagnosis and disease progression in adults with RHD. Métodos: We retrospectively analysed 425 adults with echocardiographically confirmed RHD (mean age 48 ± 12 years; 83% women). Prior ARF was defined by documented Jones criteria requiring hospitalization. Patients without prior ARF were diagnosed based on established echocardiographic features of RHD (Figure 1). The primary outcome was progression to severe mitral valve disease requiring intervention (percutaneous mitral valvuloplasty or valve replacement). Resultados e Conclusões: Results: Isolated mitral valve involvement was present in 228 patients, predominantly mitral stenosis (valve area 1.27 ± 0.5 cm²), while 165 had combined mitral and aortic disease. Over a median follow-up of 6.4 years (IQR 2.1–10.7), 164 patients required intervention (105 percutaneous valvuloplasty; 59 valve replacement). In multivariable analysis adjusted for age and sex, prior ARF diagnosis was associated with a lower risk of intervention (HR: 0.32; 95% CI: 0.11–0.93; p=0.036). Longer duration of secondary prophylaxis was independently protective (HR: 0.94 per year; 95% CI: 0.91–0.98; p=0.006). Conversely, carditis at ARF presentation predicted adverse outcomes (HR: 2.75; 95% CI: 1.14–6.62; p=0.024). Conclusions: Prior diagnosis of ARF and implementation of secondary prophylaxis are associated with reduced progression to severe valvular disease requiring intervention. These findings highlight the critical importance of early detection of ARF to prevent long-term RHD complications.

INCIDENCE AND THERAPEUTIC MANAGEMENT OF BIOPROSTHETIC VALVE THROMBOSIS AFTER MITRAL VALVE-IN-VALVE PROCEDURES: A SINGLE-CENTER REGISTRY

MARCOS RENATO COUTINHO FALEIRO1; NOEMI ROCÍO ANDRADE ALBAN2; CARLOS DANIEL LUCIO LÓPEZ2; ANTHONY JOSUÉ LUCIO LÓPEZ2; LEONARDO ANDRADE CACERES2; FRANKLIN IVÁN ALARCÓN VELA2; ARIEL IVAN MENA AMALUIZA2; WOLNEY DE ANDRADE MARTINS1; MARCOS MERULA DE ALMEIDA1;

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (2) UNIVERSIDAD TECNICA DE AMBATO (UTA) - ECUADOR;

Introdução/Fundamentos: Mitral Valve-in-Valve (MViV) is an established therapeutic option for bioprosthetic dysfunction in high-risk patients. However, bioprosthetic valve thrombosis (BVT) remains a challenging complication with uncertain incidence and management. Objetivos: To evaluate the incidence, clinical profile, and response to intensified anticoagulation in patients with BVT following MViV. Métodos: A prospective registry included 102 patients (mean age 61.8 years; 68.6% female) who underwent MViV between 2023 and 2025. High surgical risk was confirmed by mean EuroSCORE II (7.95) and STS Score (8.09). Clinical and echocardiographic follow-up was performed at baseline, 30 days, and 1 year. BVT was diagnosed based on clinical worsening and echocardiographic criteria. Resultados e Conclusões: BVT occurred in 3 patients (2.9%), all female, at a mean of 40 days post-procedure. The BVT subgroup showed a high prevalence of atrial fibrillation (66.6%) and renal dysfunction (66.6%). At diagnosis, mean transmitral diastolic gradients (MG) were significantly elevated (14 to 22 mmHg). All three patients were treated with intensified vitamin K antagonist therapy (target INR 2.5–3.5). After approximately 30 days, all cases showed clinical improvement to NYHA class II and a significant reduction in MG (to 6–9 mmHg), confirming thrombus resolution. The mechanism of BVT appears multifactorial, involving patient-related factors (e.g., chronic AF, low flow states) and prosthesis-related factors (e.g., incomplete endothelialization, local flow disturbances). Despite the high prevalence of AF and baseline anticoagulation in this cohort (83.3%), BVT still occurred early, highlighting the pro-thrombotic environment of the mitral position. This study suggests that BVT should be strongly suspected in patients with clinical deterioration and a >50% increase in echocardiographic gradients. While surgery or thrombolysis are options, intensified anticoagulation proved to be a safe and effective first-line therapy in this frail population. Bioprosthetic valve thrombosis after MViV is uncommon but impactful. Early detection through serial imaging and an intensified anticoagulation strategy (INR 2.5–3.5) are effective and safe, leading to complete clinical and hemodynamic resolution.

LONGITUDINAL VARIATION IN END-SYSTOLIC VOLUME AS AN INFLECTION POINT FOR EARLY LEFT VENTRICULAR MALADAPTATION IN PRIMARY MITRAL REGURGITATION

ANA LUIZA BARBOSA1; JOÃO PAULO ARAÚJO SILVA1; MARCELO DANTAS CAMPOS1; FRANCIS RIBEIRO DE SOUZA2; RON11EY ORISMAR SAMPAIO2; FLÁVIO TARASOUTCHI2; ROBERTO KALIL FILHO2; MARIA JANIEIRE DE NAZARÉ NUNES ALVES2;

(1) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Primary mitral regurgitation (PMR) increases volumetric overload, promoting adaptive changes of the left ventricle (LV) in response to the ejection load. Two-dimensional echocardiography (2D echocardiography) is the principal clinical tool for assessing ventricular remodelling, with left ventricular dimensions (LVD), left ventricular ejection fraction (LVEF), global longitudinal strain (GLS), and left atrial (LA) volume being the variables most commonly monitored. However, these parameters reflect later stages in the natural history of the disease and lack clearly defined prognostic predictors to better anticipate the transition to maladaptation. Objetivos: To evaluate structural and functional parameters in order to identify early diagnosis of the LV maladaptive phase in patients with PMR and to better determine optimal surgical timing. Métodos: This was a retrospective, observational, longitudinal cohort study including patients with primary PMR (n = 224), in New York Heart Association (NYHA) functional class I and II, with a mean follow-up of 21.07 ± 10.92 months and uncertain surgical indication. Serial 2D echocardiographic assessments were performed, and the following parameters were analysed: left ventricular end-diastolic diameter (LVEDD), left atrial volume (LA), LVEF, fractional shortening (Δ%), and end-systolic volume (ESV). Appropriate statistical analyses were applied, adopting $p < 0.05$ as statistically significant. Resultados e Conclusões: Results: A total of 64,000 medical records of mitral regurgitation were screened, and 224 patients with primary PMR were included. The mean age was 63.2 ± 16 years, and 109 were male. Absolute ESV (cut-off 51 mL) showed moderate discrimination for predicting reductions in LVEF and Δ% (AUC ≈ 0.77 and 0.60, respectively). Longitudinal variation in ESV proved to be a superior predictor, with improved discriminatory performance (AUC = 0.73 and 0.75). For every 2 mL increase in ESV over time, a corresponding 1% reduction in LVEF and Δ% was observed. Pearson's correlation showed strong negative associations between ΔLVEF and ΔESV ($r = -0.636$; $p = 1.92e{-}27$) and between Δ% and ΔESV ($r = -0.634$; $p = 3.14e{-}27$). The remaining parameters showed no significant correlation. C: Longitudinal anatomo-functional changes in ESV, LVEF, and Δ% more sensitively detected early left ventricular maladaptation in primary PMR (NYHA I–II). These 2D echocardiographic markers may help identify the inflection point of reverse remodeling exhaustion and guide surgical decision-making.

20261

PERIVALVULAR ABSCESS: A DEADLY THREAT IN INFECTIVE ENDOCARDITIS

CRISTIANE LAMAS1; NICOLAS FEIJOÓ1; VANESSA VON DOELLINGER1; KAROLINE GARRETT1; CAROLINA BARRETTO CASTRO1; MANOELA LEITE SALES1; GUILHERME POMPEO1; RAFAEL GARRIDO1; GIOVANNA BARBOSA1; BRUNO ZAPPA1; GUILHERME AMORIM1; WILMA GOLEBIOVSKI1;

(1) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Perivalvular abscess (PA) is a feared complication of endocarditis and is a class IB indication for valve replacement surgery. Most studies report it involves left side prosthetic valves more often and is associated with S. aureus etiology. Objetivos: We aimed to describe features of PA and assess risk factors associated with in- hospital mortality. Métodos: The study is a post hoc analysis of PA episodes in a prospective cohort of adult patients with definite IE, according to the modified Duke criteria, in the years 2010 to 2025. PA was identified echocardiographically. Patients with PA were compared to those without (group 1, G1, and Group 2, G2). Statistical analyses were performed using JAMOVI software. Factors associated with in-hospital death were assessed using stepwise multivariable logistic regression. The significance level was set at 5%. Resultados e Conclusões: There were 110 PA in 517(21.3%) episodes of IE in the study period. Median age was 50 years in G1, and 52 in G2. PA was not associated with any comorbidities. Males predominated in G1 (75.5% vs 62.9%, p=0.014), and in patients with late PVE (30.9% vs 19.7%; p=0.012). There was no difference in the frequency of community or healthcare associated IE. The aortic valve (AV) was more often affected in G1 (68.2% vs 33.6%, p<0.001). Valve leaflet perforation was seen in 25.5% vs 11.4% (p<0.001), paravalvular leak in 27.5% vs 15.3% (p=0.003) and new severe regurgitation in 59.6% vs 43.7%(p=0.003). High degree atrioventricular (AV) block was seen in 24.5% vs 7.6% of G2(p<0.0001). Splenic emboli (44% vs 29.4%, p=0004), acute kidney injury (42.7% vs 31%, p=0.020) and the need for inotropes (38.2% vs 23.8%, p=0.003) were more frequent in G1. In G1, coagulase-negative staphylococci (CNS) were more frequent (21.5% vs 8.6%, p<0.0001). Surgery was indicated for 97.3% of patients in G1 and 78.4% of G2 (p<0.0001). In- hospital surgical mortality was 31.6% in G1 vs 19.9% of G2(p=0.013). In-hospital mortality associated risk factors on multivariable analysis were age, the presence of pacemakers, CNS and fungal etiology, previous IE, need for inotropes, having surgical indication and not being operated. PA more often affected AV, patients with late PVE, and males. CNS were the main pathogens and were related to death. PA resulted in higher frequency of local destructive and systemic complications. Mortality was higher, even in those who were operated on. PA needs to be diagnosed early and acted upon swiftly.

PREDICTORS OF EARLY POSTOPERATIVE ATRIAL FIBRILLATION AFTER MITRAL VALVE SURGERY

JULIA MOREIRA CERQUEIRA DOS SANTOS1; VITOR EMER EGYPTO ROSA1; HELEUTÉRIO MADOGOLELE1; MARCELLA MARIA SILVA ALVES PEREIRA1; FERNANDA C. TESSARI1; DANIELLA C. NAZZETTA1; ALBERTO R. HUNING1; TALITA R. MASCARENHAS1; MARIANA P. LOPES1; JOÃO RICARDO C. FERNANDES1; RONEY O. SAMPAIO1; FLÁVIO TARASOUTCHI1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

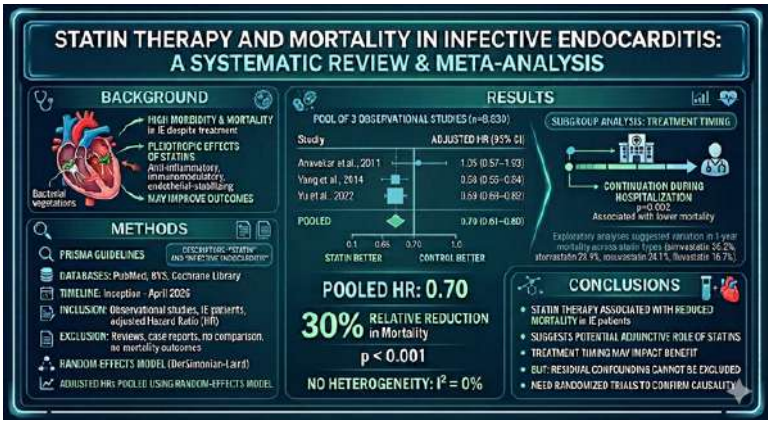
Introdução/Fundamentos: Background: Postoperative atrial fibrillation (POAF) following mitral valve surgery is common and associated with increased mortality and stroke. Although previous studies have identified electrocardiographic and echocardiographic predictors of POAF, findings remain heterogeneous. Objetivos: Purpose: To identify clinical and echocardiographic predictors of POAF in patients undergoing native mitral valve surgery. Métodos: Methods: This was a single-centre retrospective registry including patients undergoing native mitral valve surgery. Postoperative events were assessed up to 30 days after the procedure. Resultados e Conclusões: Results: A total of 205 patients were included, with a median age of 54 (44–63) years, and 67% were female. Diabetes mellitus and coronary artery disease were present in 18% and 11%, respectively. Median left atrial volume was 78 (55–103) mL/m², left ventricular ejection fraction was 61 (55–66) %, and left ventricular mass index (LVMI) was 100 (81–126) g/m². Median creatinine clearance was 67 (51–88) mL/min. Median cardiopulmonary bypass time was 93 (72–115) minutes, and aortic cross-clamp time was 74 (54–93) minutes. Regarding mitral valve disease, 27% had stenosis, 36% regurgitation, and the remainder had mixed lesions. POAF occurred in 25% of patients, with 71% of cases observed in those undergoing mitral valve replacement (p=0.006). These patients had higher LVMI and a higher prevalence of diabetes mellitus. Coronary artery disease was less frequent among patients who developed POAF. In multivariable analysis adjusted for cardiopulmonary bypass time, cross-clamp time, diabetes mellitus, and left atrial volume, LVMI emerged as an independent predictor of POAF (OR 1.019; 95% CI 1.002–1.036; p=0.028). An LVMI threshold >84.4 g/m² yielded 83% sensitivity and 39% specificity for POAF prediction, with an area under the ROC curve of 0.63 (95% CI 0.54–0.72; p=0.004). Conclusions: LVMI was independently associated with the occurrence of POAF after mitral valve surgery. However, its moderate discriminatory performance suggests that LVMI may reflect underlying ventricular remodeling related to structural comorbidities rather than serving as a strong stand alone predictor.

15989

PROGNOSTIC VALUE OF BNP FOR POSTOPERATIVE MORTALITY IN PATIENTS WITH VALVULAR HEART DISEASE

JULIA MOREIRA CERQUEIRA DOS SANTOS1; VITOR EMER EGYPTO ROSA1; HELEUTÉRIO MADOGOLELE1; MARCELLA MARIA SILVA ALVES PEREIRA1; FERNANDA C. TESSARI1; DANIELLA C. NAZZETTA1; ALBERTO R. HUNING1; TALITA R. MASCARENHAS1; MARIANA P. LOPES1; JOÃO RICARDO C. FERNANDES1; RONEY O. SAMPAIO1; FLÁVIO TARASOUTCHI1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;



Introdução/Fundamentos: Background: B-type natriuretic peptide (BNP) is a widely used biomarker for the assessment of hemodynamic overload and cardiac dysfunction and may provide relevant prognostic information in patients with valvular heart disease undergoing cardiac surgery. Objetivos: Purpose: To evaluate the prognostic accuracy of BNP for predicting postoperative mortality in patients with valvular heart disease. Métodos: Methods: This was a single-centre, retrospective registry of patients undergoing valve surgery. BNP values collected up to 12 months before surgery were included. The primary endpoint was 30-day all-cause mortality. Resultados e Conclusões: Results: A total of 437 patients were included, with a median age of 57 (46–68) years, and 52% were female. A history of atrial fibrillation was present in 43%, and previous valve surgery in 32%. Dyspnea was reported in 96% of patients, predominantly NYHA functional class II–III (82%). The most frequent valvular lesions were severe mitral regurgitation (35%), severe mitral stenosis (29%), severe tricuspid regurgitation (18%), and severe aortic stenosis (15%). Median BNP was 245 (124–698) pg/mL, corresponding to a BNP ratio of 2.45 (1.24–6.98). Median EuroSCORE II was 2.80 (1.31–6.20)%, and median STS score was 2.07 (1.12–3.80)%. Overall, 30-day mortality was 10%, and postoperative stroke occurred in 2.3%. The BNP ratio was an independent predictor of 30-day mortality (OR 1.04; 95% CI 1.01–1.06; p<0.01), demonstrating incremental risk increase with rising values. A cut-off >2.9 yielded 74% sensitivity and 58% specificity, with an area under the ROC curve of 0.70 (95% CI 0.63–0.76; p<0.01). The inclusion of absolute BNP levels in the model containing BNP ratio did not provide incremental prognostic value, suggesting superior predictive performance of BNP ratio compared with absolute BNP alone. Conclusions: BNP ratio demonstrated superior prognostic performance compared with absolute BNP in predicting postoperative mortality in patients with valvular heart disease. It remained independently associated with adverse outcomes and showed moderate discriminatory ability. These findings suggest that BNP ratio may enhance perioperative risk stratification and support more accurate clinical decision-making.

Introdução/Fundamentos: Infective endocarditis (IE) remains associated with high morbidity and mortality despite advances in antimicrobial and surgical treatment. Statins exert pleiotropic anti-inflammatory, immunomodulatory, and endothelial-stabilizing effects that may improve clinical outcomes in this population, particularly in the context of systemic inflammation and endothelial dysfunction. Objetivos: To evaluate the association between statin therapy and all-cause mortality in patients with infective endocarditis and to explore the potential impact of treatment timing. Métodos: This systematic review and meta-analysis was conducted in accordance with PRISMA guidelines. A comprehensive search was performed in PubMed, WOS, Google Scholar, Embase and Cochrane Library databases from inception through April 2026. The following descriptors were used: “Statin” AND “Infective Endocarditis”. Observational studies evaluating statin therapy and all-cause mortality in adult patients with IE were included. Only studies reporting adjusted hazard ratios (HR) with 95% confidence intervals were considered. Reviews, meta-analyses, case reports, studies without a comparison group, and those not reporting mortality outcomes were excluded. Heterogeneity was assessed using the I² statistic. Resultados e Conclusões: Three observational studies (n = 8,830) were included. Statin therapy was associated with reduced mortality (pooled HR 0.70; 95% CI 0.61–0.80; p < 0.001), corresponding to a 30% relative reduction, with no heterogeneity (I² = 0%) and consistent direction of effect across studies. In a subgroup analysis from one of the included cohorts, continuation of statins during hospitalization was associated with a greater reduction in mortality (HR 0.52; 95% CI 0.34–0.78; p = 0.002), suggesting a potential effect of treatment timing, with exploratory differences in mortality across statin types. The inclusion of a smaller cohort with neutral findings did not materially change the overall estimate, supporting the robustness of the observed association. These findings suggest a potential adjunctive role of statins in IE; however, residual confounding cannot be excluded, and randomized trials are needed to confirm causality and define optimal therapeutic strategies.

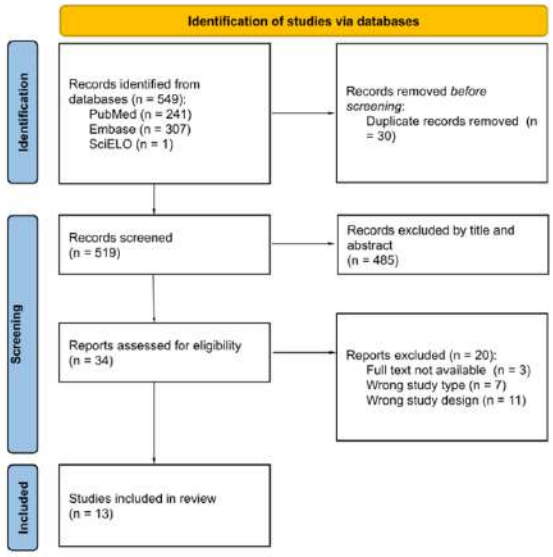
TRANSCATHETER TRICUSPID VALVE INTERVENTION VERSUS MEDICAL THERAPY IN SEVERE TRICUSPID REGURGITATION: A SYSTEMATIC REVIEW AND BAYESIAN META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

CAMILLA ROCHA COSTA LIMA1; LEONARDO DEXHEIMER SILVA2; BIANCA SILVA COSTA3; LUIS GUSTAVO RIZZOLLI4; GIULIA CALDEIRA GAELZER5; RICARDO FONSECA OLIVERIRA SURUAGGY-MOTTA6; ALEXANDRE MANTOVANI BEZERRA7; SAMUEL ROXSANDER1; VITOR EMER EGYPTO ROSA8; RONEY ORISMAR SAMPAIO8; FLAVIO TARASOUTCHI8; LAYARA FERNANDA VICENTE PEREIRA LIPARI8;

(1) UNIVERSIDADE FEDERAL DE CAMPINA GRANDE - UFCG - CAMPINA GRANDE - PB - BRASIL; (2) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (3) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (4) UNIVERSIDADE DE CAXIAS DO SUL - CAXIAS DO SUL - RS - BRASIL; (5) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (6) CENTRO UNIVERSITARIO CESMAC - MACEIO - AL - BRASIL; (7) FACULDADE DE CIENCIAS MEDICAS DA SANTA CASA DE SAO PAULO - SÃO PAULO - SP - BRASIL; (8) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Severe tricuspid regurgitation causes disabling symptoms and predicts adverse outcomes independently of left-sided disease. Transcatheter tricuspid interventions have emerged as minimally invasive therapeutic options; however, their benefit compared with optimized medical therapy remains uncertain. Conventional meta-analyses provide dichotomous statistical conclusions, which may limit clinical interpretability. Objetivos: To perform a Bayesian meta-analysis of randomized trials comparing transcatheter tricuspid interventions versus optimized medical therapy to quantify the probability of benefit and harm and better inform clinical decision-making. Métodos: A systematic search of MEDLINE, Embase, and Cochrane databases was performed to identify studies comparing transcatheter tricuspid valve intervention (TTVI) with optimized medical therapy (OMT). Primary outcomes were improvement in NYHA functional class and Kansas City Cardiomyopathy Questionnaire (KCCQ) score. Bayesian random-effects meta-analyses were conducted in R (version 4.5.1) using the bayesmeta package. Posterior probabilities of benefit were estimated as P(RR > 1) for binary outcomes and P(MD > 0) for continuous outcomes. Resultados e Conclusões: Four randomized controlled trials including 1,292 patients (710 TTVI, 582 OMT) were analyzed, with a mean age of 78.6 years (78.6 TTVI vs 78.5 OMT). At one year, TTVI significantly improved health-related quality of life (KCCQ) compared with OMT (MD 13.28 points; 95% CrI 9.89–16.62; P(MD > 0) 100%; I²=69.4%) and increased the likelihood of NYHA functional class improvement (RR 2.07; 95% CrI 1.09–3.89; P(RR > 1): 98.9%; I²=76.6%). Although heterogeneity was high for both outcomes, prior sensitivity analyses did not demonstrate any meaningful impact on the results. TTVI also reduced tricuspid regurgitation severity (RR 7.71; 95% CrI 4.76–12.42; P(RR > 1): 100%; I²=11%). No evident differences were observed in heart failure hospitalization (RR 0.89; 95% CrI 0.53–1.47; P(RR < 1): 68.1%; I²=0%), all-cause mortality (RR 1.21; 95% CrI 0.78–1.87; P(RR < 1): 19.5%; I²=0%), or cardiovascular mortality (RR 1.07; 95% CrI 0.62–1.83; P(RR < 1): 40.1%; I²=0%). These findings demonstrate transcatheter tricuspid intervention provides clear symptomatic benefit, while survival benefit may require longer follow-up to emerge.



15937

TRANSCATHETER VERSUS SURGICAL AORTIC VALVE REPLACEMENT IN LOW-INTERMEDIATE AND HIGH-RISK PATIENTS: A SYSTEMATIC REVIEW OF LONG-TERM OUTCOMES IN AORTIC STENOSIS

JULIANA LUIZA PAULA DE ARAÚJO1; BRUNA FELISBERTO DOS SANTOS1; EMANUELLE APARECIDA DE AGUIAR FAUSTO1; LAURA SETRAGNI FREITAS1; VITÓRIA DA CUNHA MOREIRA1; LUANA LINS SILVA TÉRCIO1; RENÊH DANTAS DE SÁ1; EDUARDA DE SOUZA MARINHO1; VANDERLEIA MATOS DA SILVA1; SANNY CRISTINA DE CASTRO FARIA1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: Aortic stenosis (AS) is the most common non-rheumatic valvular disease, and its treatment continues to evolve. While TAVI was initially reserved for high-risk patients, its indication expanded to lower-risk populations, but comparative data on long-term valve durability, mortality, and reintervention rates across different surgical risk strata remain limited. This systematic review aims to compare TAVI and SAVR outcomes stratified by surgical risk (low-intermediate versus high-risk) to better inform valve selection. Objetivos: Synthesize comparative durability of TAVI versus SAVR, analyzing structural valve deterioration (SVD), reintervention, and mortality in ≥5 years. Métodos: A systematic review was conducted following PRISMA 2020 guidelines, using databases PubMed, Embase, and SciELO through March 2026. Descriptors "TAVI", "SAVR", and "long-term outcomes" were combined using Boolean AND, and alternative MeSH descriptors with Boolean OR. Randomized clinical trials and observational studies comparing TAVI versus SAVR in AS patients, with follow-up ≥5 years, published in the last 10 years, were selected. Two independent researchers selected the articles, with conflicts resolved by a third researcher. A narrative synthesis was made of the findings. Resultados e Conclusões: 13 studies (9 RCTs, 4 cohorts), totalling 31,770 patients (13,953 TAVI; 17,817 SAVR) were included. Among low-intermediate-risk patients <75 years (4 studies), 3 showed comparable mortality, reintervention, or SVD; 1 with younger cohort (mean age 60) showed higher TAVI mortality. In patients ≥75 years (5 studies), mortality was similar in 3 and favored SAVR in 2 (one study showed higher frailty in TAVI); SVD favored TAVI in 2 studies, with no difference in 1; reintervention was similar in 4 studies comparing it. Among high-risk patients (3 studies), all were ≥80 years; 2 showed comparable mortality and SVD but higher TAVI reintervention; 1 favored TAVI in both outcomes. One unstratified study using propensity score weighting found higher 5-year TAVI mortality, though patient frailty, surgical risks, and other factors might have contributed. TAVI shows comparable durability to SAVR in patients ≥75 years across risk profiles, though younger, lower-risk patients may benefit from SAVR. In high-risk elderly patients, outcomes are similar despite higher TAVI reintervention rates. These findings support risk and age-stratified valve selection, though more studies are needed to guide definitive recommendations.

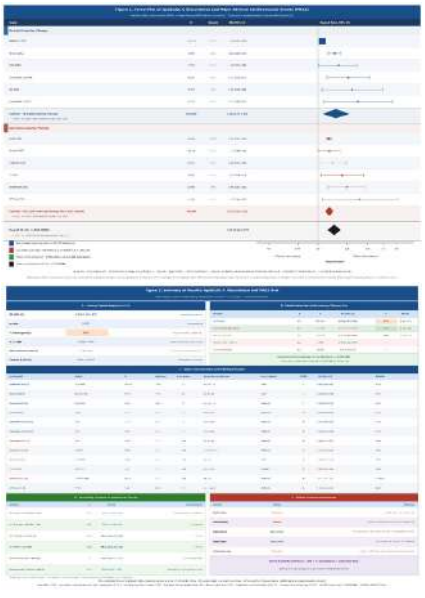
A SYSTEMATIC REVIEW ON MYOCARDITIS AND CARDIAC DYSFUNCTION IN LONG COVID: CLINICAL AND IMMUNOLOGICAL EVIDENCE ASSOCIATED WITH THE PRESENCE OF AUTOANTIBODIES

LUANA PAULA CARDOSO GUIMARAES1; FABIANA DOS SANTOS SOUSA1; SOFIA SILVA PASSOS1; RAFFAELA ADRIANA DOS SANTOS ARAÚJO1; JAMYLLY SOEIRO CARVALHO1; LUIZE PAULA RAMOS BALTAZAR1; LUIZ ANTÔNIO FERREIRA FARIAS2; FABIANA COSTA CARDOSO1; THAÍS PINHEIRO ALMEIDA DOS SANTOS1; TONIÉLITON MATHEUS GOMES RIBEIRO1; LÍDIA DIAS GONÇALVES1;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Post-acute SARS-CoV-2 syndrome (Long COVID) frequently presents with persistent multisystemic complications, such as myocarditis and chest pain. Unlike the acute phase, chronic cardiac dysfunction suggests an immune-mediated pathogenesis involving the breakdown of self-tolerance and sustained inflammation, mechanisms that remain underutilized in clinical practice. Objetivos: To analyze the clinical and immunological evidence of myocarditis in Long COVID, focusing on the identification of specific autoantibodies in persistent myocardial injury. Métodos: A systematic review conducted in accordance with the PRISMA guidelines. Searches were performed in the PubMed, Embase, and Elsevier databases between 2020 and 2026, using the search terms “Long COVID,” “Myocarditis,” and “Autoantibodies,” combined using the Boolean operator AND. A total of 12 studies were included, consisting of observational studies, prospective cohorts, and immunological analyses in humans that investigated the persistence of cardiac symptoms 12 weeks after acute infection. Studies involving only animals, isolated case reports, and narrative reviews were excluded. Resultados e Conclusões: The selected articles demonstrated that myocarditis in Long COVID is immune-mediated by a dysregulated adaptive immune response. Radiological evidence from cardiac magnetic resonance imaging (CMRI) revealed the presence of myocardial edema, hyperemia, and delayed gadolinium enhancement in symptomatic patients. Immunologically, the role of autoantibodies (AABs) against G protein-coupled receptors, specifically β1, β2 adrenergic, and angiotensin II receptors, is noteworthy. The detection of these markers correlates directly with cases of dysautonomia, tachycardia, and exercise intolerance. Furthermore, the persistence of viral reservoirs and spike protein fragments may act as a continuous antigenic stimulus, maintaining T-cell activation and the chronic secretion of pro-inflammatory cytokines. Thus, the evidence supports the notion that myocarditis in Long COVID has a strong immune-mediated component, in which reactivity against cardiac receptors plays a central role in dysfunction. The convergence of imaging findings CMR and the identification of autoantibodies reinforces the need for diagnostic protocols that include screening for autoimmunity, and this understanding is crucial for the development of immunomodulatory strategies aimed at mitigating persistent myocardial damage.



20771

APOLIPOPROTEIN B AND LOW-DENSITY LIPOPROTEIN CHOLESTEROL DISCORDANCE AND MAJOR ADVERSE CARDIOVASCULAR EVENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS STRATIFIED BY LIPID-LOWERING THERAPY USE

AKIRA LEAL MORITA1; FILIPE JOSÉ TORRES DA SILVA2; VICTOR CARLOS LUZ DE OLIVEIRA3; LAÍS CAMILLY SANTOS3; LARISSA TALIANI COELHO SAMPAIO3; LUCIANA COELHO MARQUES3; GABRIELA PERAZZOLO MENATO3; RAUL DIAS DOS SANTOS FILHO1; MARCIO HIROSHI MINAME1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) CENTRO UNIVERSITÁRIO FAM - ARGENTINA; (3) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Apolipoprotein B (ApoB) quantifies total circulating atherogenic particles and may reveal residual cardiovascular risk when LDL-cholesterol (LDL-C) appears controlled. Discordance between elevated ApoB and on-target LDL-C is frequent in metabolic syndrome, hypertriglyceridemia, and under lipid-lowering therapy. Despite its clinical relevance, quantitative synthesis of this association stratified by treatment status is lacking. Objetivos: To quantitatively synthesize the association between ApoB/LDL-C discordance and incident major adverse cardiovascular events (MACE) in prospective cohorts, stratified by lipid-lowering therapy use, per a pre-specified PROSPERO protocol. Métodos: Systematic review and meta-analysis (PRISMA 2020; PROSPERO registered). Databases: PubMed, Embase, Cochrane, Web of Science. Eligibility (PICOT): prospective cohorts, ApoB measured, incident MACE, adjusted HR with 95% CI. After deduplication, 915 records screened and 34 full-texts assessed; 12 studies (n≈534,000, adjusted for cohort overlap) included. Risk of bias: QUIPS (3 low, 9 moderate). Analysis: random-effects model (REML, HKSJ); I^2, τ^2, 95% prediction interval (PI). Pre-specified stratification: no lipid-lowering therapy (k=6) vs. any therapy (k=5). Meta-regression: statin proportion (k=11). Leave-one-out sensitivity. Publication bias: Egger test. Software: R (metafor, meta). Resultados e Conclusões: Pooled (k=12; n≈534,000): HR=1.25 [95% CI 1.14–1.37], p=0.0002; I^2=83%; PI [1.00–1.57]. No lipid-lowering therapy (k=6; n=425,355): HR=1.28 [1.07–1.54], I^2=83%. Any therapy (k=5; n=150,209): HR=1.17 [1.11–1.23], I^2=25%, PI [1.10–1.24]. Interaction: p=0.948 (NS); meta-regression (statin %): p=0.96. Sensitivity — prospective only (k=10): HR=1.25 [1.12–1.40]; ≥5-year follow-up (k=10): HR=1.29 [1.15–1.45]. Leave-one-out: Δmax=2.6%. Egger p=0.0005. ApoB/LDL-C discordance predicts 25% excess MACE risk independently of lipid-lowering therapy (interaction p=0.948) — the study’s central finding. In treated patients, heterogeneity fell markedly (I^2=25% vs. 83%) and the prediction interval excluded the null [1.10–1.24], indicating a more consistent and actionable association. Despite LOW evidence certainty (methodological heterogeneity across 6 discordance definitions; potential publication bias), these data demonstrate that LDL-C alone is insufficient to capture residual atherogenic risk. Therefore, our findings support routine ApoB measurement in high-risk patients with apparently controlled LDL-C, regardless of treatment status.

ARE POLYGENIC RISK SCORES SUPERIOR TO TRADITIONAL RISK SCORES AND CORONARY ARTERY CALCIUM SCORE FOR EARLY DETECTION OF SUBCLINICAL ATHEROSCLEROSIS? A SYSTEMATIC REVIEW

HANIEL FELIPE DE OLIVEIRA SAMPAIO1; ANA BEATRIZ BRAGA DIAS1; CAMILA SOUSA MATOS1; FELIPE CELESTINO MARTINS LOPES1; LÍVIA FERREIRA DE CARVALHO1; ANTÔNIA RAFAELA LIMA DE SOUZA1; SARAH BRAGA DE CASTRO1; MARIA FERNANDA FREITAS NUNES1; PEDRO GONÇASLVES NOGUEIRA NETO1; EDUARDO HENRIQUE FREITAS BARREIRA LIMA1; MATHEUS DUARTE PIMENTEL1; HERALDO GUEDIS LOBO FILHO1;

(1) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Polygenic Risk Scores (PRS) have emerged as a promising tool for cardiovascular risk stratification, while coronary artery calcium score (CACS) is an important imaging marker of subclinical atherosclerosis. However, the predictive value of PRS compared with traditional cardiovascular risk scores (TCRS) and CACS remains uncertain. Objetivos: To compare PRS with TCRS and CACS in the early detection of subclinical atherosclerosis. Métodos: A systematic review was performed in accordance with PRISMA guidelines across PubMed, Embase, and Cochrane databases, including studies published between 2010 and 2026. Following the PICO framework, we included adults without established cardiovascular disease. The intervention consisted of PRS compared with TCRS and CACS. Screening was conducted by two reviewers with data extraction focusing on discrimination capacity (area under the curve [AUC]) and risk reclassification (net reclassification improvement [NRI]), followed by qualitative synthesis. Resultados e Conclusões: Four studies encompassing 16,610 patients, including 1 randomized trial and 3 observational studies, were included. In the early detection of subclinical atherosclerosis, TCRS showed moderate discrimination (AUC: 0.60–0.67), while PRSs demonstrated slightly higher performance (AUC: 0.63–0.69). Adding PRS to clinical models resulted in limited discrimination gain (ΔAUC up to 0.12) and modest risk reclassification improvement (NRI up to 0.47; IDI up to 0.008). In a cross-sectional study (50–60 years), PRS alone showed better discrimination than clinical factors in women (AUC: 0.711 vs 0.662). Combining PRS with clinical factors improved discrimination in both sexes (ΔAUC: 0.055 in men; 0.076 in women), with greater improvement in low- to moderate-risk women compared to men (NRI = 0.649 vs 0.450) Coronary artery calcium score (CACS) consistently demonstrated superior predictive (ΔAUC up to 0.09; NRI up to 0.79) value compared with PRS alone. Combined models (TRCS + CACS + PRS) achieved the best predictive performance (AUC up to 0.80). PRS remained independently associated with cardiovascular events (HR up to 3.2), although less strongly than CACS (HR up to 5.0). PRSs have moderate utility in the early detection of atherosclerosis and in predicting cardiovascular events, performing slightly better than TCRS. However, their isolated incremental gain is still limited. The CACS demonstrated greater predictive capacity, while the combination of PRS, clinical factors, and CACS showed the best overall performance.

ASSOCIATION BETWEEN APOLIPOPROTEINS A AND B AND THE TRADITIONAL LIPID PROFILE IN AN OUTPATIENT POPULATION: IMPLICATIONS FOR CARDIOVASCULAR RISK STRATIFICATION

LARA PONTES COELHO1; JOÃO PEDRO FEITOSA CAJUAZ CASTRO1; ALICE PETROLA BEZERRA SAYÃO1; LAIS FARIAS MASULLO2; JOÃO ÍTALO PEREIRA CAVALCANTE3; RACHEL PETROLA2;

(1) INTERNSHIP PROGRAM AT EMED – EMÍLIO RIBAS MEDICINA DIAGNÓSTICA - FORTALEZA - CE - BRASIL; (2) EMÍLIO RIBAS MEDICINA DIAGNÓSTICA - FORTALEZA - CE - BRASIL; (3) INTERNSHIP PROGRAM AT EMED – EMÍLIO RIBAS MEDICINA DIAGNÓSTICA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases are the leading cause of death and dyslipidemias are among the main modifiable risk factors. Although widely used, the conventional lipid profile has limitations, as LDL-C estimates cholesterol mass without fully reflecting the atherogenic profile. In this context, apolipoproteins have emerged as a more precise approach for cardiovascular assessment. Objetivos: To evaluate the association of apoA-I, apoB, and the apoB/apoA-I ratio with the traditional lipid profile in a Brazilian outpatient population. Métodos: We conducted a retrospective cross-sectional study of 18,082 outpatients who underwent laboratory evaluation between January 2021 and December 2025 at a clinical laboratory in northeastern Brazil. The variables analyzed included apoA-I, apoB, apoB/apoA-I ratio, total cholesterol, HDL-C, LDL-C, triglycerides, HbA1c, fasting glucose, urea, creatinine, uric acid, hs-CRP, and insulin. For qualitative data, analysis was conducted using absolute and relative values (%). For quantitative data, descriptive statistical analysis was performed (mean, median, standard deviation), between-sex comparisons using Student's t-test, Pearson's correlation matrix, and two multiple linear regression models. Statistical significance was set at $p<0.05$. Resultados e Conclusões: A total of 18.082 individuals were analyzed (66.8% women). Mean apoA-I and apoB levels were 132 ± 24.3 and 87.1 ± 23.2 mg/dL, respectively, with a mean apoB/apoA-I ratio of 0.68. Women had higher apoA-I (137.5 vs 122.5; $p<0.001$) and HDL-C (58.0 vs 46.5; $p<0.001$), while men had higher apoB (89.0 vs 86.1; $p<0.001$), triglycerides ($p<0.001$), and metabolic markers. ApoB was strongly correlated with LDL-C ($r = 0.938$; $p<0.001$) and total cholesterol ($r = 0.872$; $p<0.001$), and apoA-I with HDL-C ($r = 0.872$; $p<0.001$). The apoB/apoA-I ratio was associated with LDL-C ($r = 0.670$; $p<0.001$), total cholesterol ($r = 0.478$; $p<0.001$), triglycerides ($r = 0.203$; $p<0.001$), and negatively with HDL-C ($r = -0.480$; $p<0.001$). Regression models for apoB ($R^2 = 0.907$) and apoA-I ($R^2 = 0.807$) demonstrated high explanatory power. The apoB/apoA-I ratio was higher in individuals with total cholesterol >190 mg/dL (0.789 vs 0.587; $p<0.001$) and triglycerides ≥150 mg/dL (0.821 vs 0.662; $p<0.001$). The findings confirm a strong association between apolipoproteins and the traditional lipid profile, and that the apoB/apoA-I ratio identifies atherogenic dyslipidemia with good accuracy, reinforcing its utility in outpatient cardiovascular risk stratification.

ASSOCIATION BETWEEN CARDIOVASCULAR HEALTH AND EDUCATION LEVEL AMONG INDUSTRIAL SECTOR WORKERS

ISABELLA BEATRIZ DE PAIVA MENDES1; PEDRO HENRIQUE DE ALMEIDA SILVA1; SARA FERNANDES CORREIA BESSA1; KRYSTEN PADILHA DE MOURA LANDE1; GIOVANA FERREIRA VAZ1; AMANDA FREITAS MENDONÇA FIRMINO1; VIVIANE SOARES1;

(1) UNIVERSIDADE EVANGELICA DE GOIAS - UNIEVANGELICA - ANÁPOLIS - GO - BRASIL;

Introdução/Fundamentos: Social determinants of health (SDH) include socioeconomic, environmental, cultural, and behavioral factors that influence the development of cardiovascular diseases. Education level stands out as an important SDH and impacts cardiovascular outcomes, meaning that lower educational levels are associated with poorer cardiovascular health (CVH). Objetivos: To investigate the association between CVH and education level among industrial sector workers. Métodos: This was a cross-sectional study conducted with 293 workers, with a mean age of 35.5 (±11.7) years; 64.6% were male and 35.4% female. Sociodemographic data (marital status), clinical data (continuous-use medications – CUM and presence of comorbidities), and anthropometric data for body mass index (BMI) calculation were collected. CVH was assessed using the 8 metrics established in the Life's Essential 8 study by the American Heart Association (AHA), categorized into health behaviors (physical activity level, diet, nicotine exposure, and sleep health) and health factors (BMI, non-HDL cholesterol levels, blood pressure, and fasting glucose or glycated hemoglobin). CVH classification was defined as low (0–49 points), moderate (50–79 points), and high (80–100 points). The average of the metrics established the total score. Education level, considered the SDH outcome variable, was classified as completed elementary school, completed/incomplete high school, completed/incomplete higher education, and postgraduate education. Student's t-test was used for group comparisons, and the chi-square test was applied to assess associations between categorical variables. Resultados e Conclusões: Among workers, 68% presented moderate CVH and 32% low CVH. Most participants were married (46.3%) or single (43.2%); 22.1% used continuous-use medications and 15.6% had comorbidities. Workers with elementary school education had lower mean CVH scores (46.8, ±12.4, n=41) than those with high school (53.2, ±10.2, p=0.002, n=137), higher education (53.2, ±10.2, p<0.001, n=97), and postgraduate education (58.0, ±8.3, p<0.001, n=19). Education level was associated with CVH classification (x^2=22.58, p<0.001), and most workers with high school education presented low (53.2%) or moderate (43.5%) CVH. Education level may be considered a marker of cardiovascular vulnerability. In this sense, educational inequalities should be regarded as a strategic factor in cardiovascular health promotion and prevention actions.

ASSOCIATION BETWEEN ELEVATED LIPOPROTEIN(A) LEVELS AND EARLY ATHEROSCLEROTIC DISEASE IN YOUNG ADULTS

GABRIEL BUONORA REIS1; ANTONIO FRANCISCO NETO1; DAVID BARROSO AMAR1; RAFAEL DE OLIVEIRA CECILIANO1; MARIA ELIZABETH FERREIRA1;

(1) INSTITUTO DE EDUCACAO MEDICA (IDOMED) - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Premature coronary artery disease in young adults, in the absence of LDL-c dyslipidemia or diabetes, poses a clinical challenge. Thus, Lipoprotein(a) [Lp(a)] emerges as an independent and genetically determined risk predictor. This study is justified by the need to improve risk stratification in asymptomatic young adults, mitigating early ischemic events and providing evidence for the update of cardiology guidelines. Objetivos: To analyze the association between elevated Lipoprotein(a) levels and the early development of atherosclerosis and atherosclerotic cardiovascular disease in young adults. Métodos: This is a review, adopting the PRISMA guideline for systematizing the search and selection, 95 records were screened and 5 articles were included. MeSH/DeCS descriptors were used in the following databases: PubMed, Scopus, Web of Science, SciELO, Embase, LILACS. Original studies published between 2020-2025, focusing on individuals (18-40 years old) without previous cardiovascular disease, were included. Studies that did not correlate Lp(a) levels with cardiovascular outcomes were excluded. Resultados e Conclusões: Physiopathologically, Raitakari et al. confirmed that chronic exposure to high levels of Lp(a) (≥30 mg/dL) from youth doubles the risk of cardiovascular events in adulthood. This is due to the dual mechanism of Lp(a): the transport of oxidized phospholipids that promote endothelial dysfunction (pro-atherogenic) and the inhibition of fibrinolysis by apolipoprotein(a) (pro-thrombotic). Clinically, Namitokov et al. associated Lp(a) ≥50 mg/dL with early myocardial infarctions (MI) and a higher multi-vessel disease burden. However, the YOUNG-MI registry revealed that 71% of post-MI young adults with elevated Lp(a) had low traditional risk scores (<7.5%), evidencing severe clinical underestimation. The analysis shows a strong correlation between elevated Lipoprotein(a) [Lp(a)] levels and premature atherosclerotic cardiovascular disease (ASCVD). Tian et al. demonstrated that Lp(a) doubles the risk of ASCVD in young adults (OR 2.15), particularly for coronary artery disease, and Koh et al. found a higher risk of ischemic stroke (OR 1.61). Lp(a) shows a strong correlation with cardiovascular outcomes, independent of early atherosclerosis and cardiovascular events secondary to atherosclerotic processes, justifying its routine incorporation into cardiovascular risk stratification in young adults, aiming at accurate stratification and early prevention.

ASSOCIATION BETWEEN SARCOPENIA AND ARTERIAL STIFFNESS IN OLDER ADULTS: AN UPDATED SYSTEMATIC REVIEW AND META-ANALYSIS

GUILHERME AUGUSTO GUIMARÃES RESENDE1; MARIA CLARA DE MATTOS MIRA1; PEDRO HENRIQUE GORRI CUSTÓDIO DE MELO BRITES1; MATHEUS HENRIQUE SANTOS ANANIAS1; LAURA DONATTI ETO1; STÉPHANIE SAMPAIO DALLAGNOL1; CAIO AUGUSTO FREITAS BIZERRA1; PEDRO HENRIQUE LABEGALINI SANCHES1; YURI FERREIRA DE OLIVEIRA1; ANA CAROLINA AMARAL CARNEIRO1; STEPHANIE VITORIA RODRIGUES MENDES RHEIO1; ROGÉRIO TOSHIRO PASSOS OKAWA1;

(1) UNIVERSIDADE ESTADUAL DE MARINGA - MARINGÁ - PR - BRASIL;

Introdução/Fundamentos: Sarcopenia and arterial stiffness are both hallmarks of aging and significant predictors of cardiovascular risk and physical disability. Although a bidirectional relationship has been hypothesized, the strength of the association between muscle depletion and vascular aging remains to be fully synthesized. This meta-analysis investigated the relationship between sarcopenia and arterial stiffness, specifically focusing on Pulse Wave Velocity (PWV) and the Cardio-Ankle Vascular Index (CAVI) in individuals over 50 years of age. Objetivos: To evaluate the association between sarcopenia and arterial stiffness (PWV/CAVI) in individuals over 50 years old through a systematic review and meta-analysis, investigating if muscle loss correlates with increased vascular aging and worse cardiovascular prognostic risk factors. Métodos: A systematic search was conducted on October 10, 2025, across PUBMED, EMBASE, COCHRANE, and ELSEVIER databases. We included observational studies and randomized controlled trials evaluating the association between sarcopenia and markers of arterial stiffness. The meta-analysis was performed using a random-effects model with the Restricted Maximum-Likelihood (REML) estimator and the Hartung-Knapp adjustment. Effect sizes were expressed as Hedges' g standardized mean difference (SMD) to account for potential bias in smaller samples. Resultados e Conclusões: From an initial pool of 1,484 articles, 12 studies met the final inclusion criteria after rigorous screening and deduplication. The quantitative synthesis for Brachial-Ankle Pulse Wave Velocity (baPWV) included 10 studies with a total of 18,505 participants, revealing that sarcopenic individuals had significantly higher baPWV compared to non-sarcopenic peers with a moderate effect size (SMD 0.58; 95% CI: 0.33 to 0.84; p = 0.0006), despite high heterogeneity (I2 = 94.1%). Regarding the Cardio-Ankle Vascular Index (CAVI), the analysis of 3 studies involving 2,768 participants also showed a significant association (SMD 0.39; 95% CI: 0.00 to 0.77; p = 0.0499) with notably lower heterogeneity (I2 = 18.9%). In conclusion, sarcopenia is significantly associated with increased arterial stiffness in the aging population. The stronger association observed with baPWV suggests that muscle loss is closely linked to increased vascular stiffness. These findings highlight the clinical importance of integrated screening for both muscle health and vascular aging to better identify older adults at high risk for cardiovascular events and physical frailty.

ASSOCIATION OF PULSE WAVE VELOCITY WITH SOCIODEMOGRAPHIC AND LIFESTYLE FACTORS IN A COMMUNITY-BASED COHORT

LUIZ FELIPE NAPOLI FERRARI1; MHUNIR ZOGBI FERRASSO1; ERNANI TIAJURU SANTA HELENA2; SIEGMAR LUIZ STARKE2; SERGIO LUIZ ZIMMERMANN2;

(1) UNIVERSIDADE REGIONAL DE BLUMENAU - BLUMENAU - SC - BRASIL; (2) UNIVERSIDADE REGIONAL DE BLUMENAU (FURB) - BLUMENAU - SC - BRASIL;

Introdução/Fundamentos: Pulse wave velocity (PWV) is a marker of arterial stiffness and a predictor of cardiovascular risk. In community settings, PWV may also capture how social position, cultural background and daily behaviours cluster with vascular ageing, which can inform targeted prevention in populations underrepresented in arterial stiffness research. Objetivos: To examine associations between PWV quartiles and sociodemographic and lifestyle factors in adults from a community based cohort Métodos: Cross sectional analysis of 1,848 adults. PWV was measured using a validated brachial cuff based oscillometric method and categorised into quartiles: Q1 <5.4 m/s; Q2 5.4 to 6.3 m/s; Q3 6.3 to 7.7 m/s; Q4 7.7 m/s or higher. Exposures included age, sex, self reported skin colour, educational attainment, German ancestry (highly prevalent in the population), smoking status, alcohol use, physical activity level, sleep quality, and occupational stress domains (demand, control and social support). Associations across quartiles were tested with appropriate methods for categorical and continuous variables (two sided p values). Resultados e Conclusões: PWV increased markedly with age (mean age: 28.3 in Q1, 35.0 in Q2, 46.8 in Q3, 63.1 in Q4; p<0.001). Age distribution shifted sharply across quartiles, with younger participants concentrated in Q1 and 99.4% of those aged 60 to 79 years in Q4 (p<0.001). PWV was also associated with sex (p<0.001), lower educational attainment (64.1% in Q4 among those with 0 to 4 years vs 6.8% among those with ≥12 years; p<0.001), self reported skin colour (p=0.0001), and German ancestry (32.0% in Q4 vs 13.5% without; p<0.001). Adverse lifestyle factors clustered in higher PWV quartiles, including former smoking (39.7% in Q4; p<0.001), physical inactivity (36.7% vs 18.6% in active participants; p=0.002), and poor sleep quality (30.7% vs 22.0%; p=0.0001). Alcohol use and occupational stress domains also differed across quartiles (all p<0.05). These findings show that higher PWV clusters with sociodemographic disadvantage, adverse behaviours, and sociocultural context, supporting its use in community risk profiling and in identifying modifiable targets to slow vascular ageing.

ASSOCIATION OF REMNANT CHOLESTEROL WITH CARDIOVASCULAR RISK MARKERS ASSESSED BY CENTRAL ADIPOSITY AND C-REACTIVE PROTEIN IN ADOLESCENTS

PEDRO VINICIUS POMPEU DE OLIVEIRA1; NÁGILA RAQUEL TEIXEIRA DAMASCENO2; MARIA DINARA DE ARAÚJO NOGUEIRA3; LIDIELE CORRREIA PONTE3; ANA CAMILY BIZZARIA DUARTE3; RIBANNA APARECIDA MARQUES BRAGA4; LARA PEREIRA SARAIVA LEAO BORGES3; RAYSHA MARQUES BRAGA5; RODRIGO COSTA MAIA6; MARIA CLARA COSTA MAIA7; MANUELA SOUZA DE ASSIS3; LUIS FELIPE NUNES DE OLIVEIRA3;

(1) UNIVERSIDADE ESTADUAL DO CEARA - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (3) UNIVERSIDADE ESTADUAL DO CEARÁ - FORTALEZA - CE - BRASIL; (4) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (5) UNIVERSIDADE ESTADUAL DO CEARÁ - CRATEÚS - CE - BRASIL; (6) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (7) UNIVERSIDADE FEDERAL RURAL DO SEMI-ARIDO - MOSSORÓ - RN - BRASIL;

Introdução/Fundamentos: Introduction: Remnant cholesterol (RC), which represents the cholesterol content of triglyceride-rich lipoproteins, has emerged as a marker of cardiovascular risk (CVR) and may be more sensitive than LDL-c in adolescents. In this context, inflammatory markers such as C-reactive protein (CRP) and anthropometric indicators, including waist-to-height ratio (WHtR), have been widely used to predict CVR. Objetivos: Objective:This study aimed to assess the association of RC and LDL-c levels with CVR, evaluated by central adiposity and CRP, in adolescents Métodos: Methods: This cross-sectional study was conducted with adolescents from public schools in Fortaleza, Brazil. Blood samples were collected to measure total cholesterol, HDL-c, LDL-c, and CRP. RC was calculated by subtracting HDL-c and LDL-c from total cholesterol. CVR classification based on CRP was defined as low risk (<1 mg/L), intermediate risk (1–3 mg/L), and high risk (>3 mg/L). Central adiposity was assessed using WHtR, calculated as waist circumference divided by height, with CVR defined as values ≥0.5. Statistical analysis: Associations between lipoprotein markers and CVR were evaluated using binary and multinomial logistic regression models. Analyses were adjusted for sex, age, and HDL-c levels. Results were expressed as odds ratios (OR) with 95% confidence intervals (95% CI). Resultados e Conclusões: Results: A total of 251 adolescents were evaluated, with a mean age of 12.53 (1.15) years, and a predominance of females (52.2%). Most participants presented CVR based on WHtR (54.6%), while 84 (33.5%) were classified with some degree of risk according to CRP. RC was associated with CVR assessed by central adiposity in both crude [OR = 1.16; 95% CI (1.10–1.24)] and adjusted models [OR = 1.17; 95% CI (1.09–1.25)], whereas LDL-c showed a weaker association in the adjusted model [OR = 1.03; 95% CI (1.01–1.04)]. Regarding CRP-based CVR, RC remained associated in adjusted models for both intermediate [OR = 1.09; 95% CI (1.02–1.19)] and high risk [OR = 1.11; 95% CI (1.04–1.18)]. Conclusion: Remnant cholesterol was associated with cardiovascular risk assessed by central adiposity and C-reactive protein, demonstrating better performance than LDL-c in identifying this risk in the studied population.

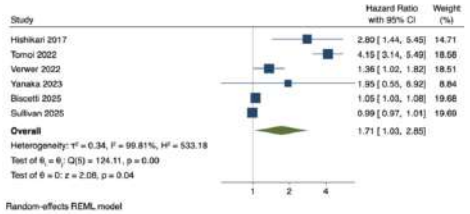
BASELINE LIPOPROTEIN(A) AND MAJOR ADVERSE LIMB EVENTS AFTER PERIPHERAL REVASCULARIZATION: A SYSTEMATIC REVIEW AND META-ANALYSIS.

VITOR P. DE ALMEIDA1; CHRISTIAN K. FUKUNAGA2; ANA BEATRIZ VALVERDE RAMOS3; VICTOR XAVIER DE PAULA1; YOHANA HELOISE MIRALLIA1; NOÊMIA AZEVEDO NASCIMENTO1; NATHALIA FERREIRA JUSTINO1; CRISTAL VICTORIA PAIVA1; GEOVANNA SAMILLY1; CARLOS A. V. SANCHEZ4; THIAGO AQUINO DE AMORIM1;

(1) UNIVERSIDADE FEDERAL DE CATALÃO - CATALÃO - GO - BRASIL; (2) CENTRO UNIVERSITÁRIO FACULDADE DE MEDICINA DO ABC - SANTO ANDRE - SP - BRASIL; (3) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (4) MAYO CLINIC FLORIDA - UNITED STATES;

Introdução/Fundamentos: Lipoprotein(a) [Lp(a)] is an established genetic risk factor for atherosclerotic cardiovascular disease (ASCVD). While its association with coronary artery disease (CAD) is known, its prognosis on peripheral artery disease (PAD) undergoing revascularization remains unclear. Objetivos: To evaluate the association between baseline lipoprotein(a) levels and clinical outcomes in patients with peripheral artery disease undergoing revascularization through a systematic review and meta-analysis of observational studies. Métodos: We performed a systematic search of MEDLINE, Embase, and Cochrane databases from inception through July 2025, without language restrictions to identify studies that assessed the association between baseline Lp(a) levels and clinical outcomes in patients with PAD undergoing revascularization. Study selection and data extraction were performed independently by two reviewers, following PRISMA guidelines. Risk of bias was assessed using Cochrane standardized tools. Primary endpoints were Major Adverse Cardiovascular Events (MACE), Major Adverse Limb Events (MALE), myocardial infarction (MI), stroke, and cardiovascular death. Effect sizes were pooled using a random-effects model and reported as Odds Ratios (OR) or Hazard Ratios (HR) with 95% confidence intervals (CI); HRs were used when time-to-event data were available, while ORs were applied otherwise. Resultados e Conclusões: 15 studies were included, with a total of 3,097 patients. The mean age was 71.5 years, and 70.2% were males. Hypertension was present in 85.3% of patients, and 73.9% had dyslipidemia. Patients with higher Lp(a) levels presented a higher incidence of MALE (HR 1.71; 95% CI 1.03-2.85). Pooled effect sizes showed no statistically significant differences of MACE (HR 1.31; 95% CI 0.9-1.91), and cardiovascular death (HR 2.44; 95% CI 0.9-6.59). Similarly, MI (OR 1.08; 95% CI 0.68-1.72) and stroke (OR 1.73; 95% CI 0.55-5.40) did not differ statistically between groups. High Lp(a) may increase MALE in PAD patients, while effects on thromboembolic outcomes and cardiovascular mortality remain uncertain.

Figure 1a) Random-effects meta-analysis of HR for MALE after PAD revascularization, comparing higher versus lower baseline Lp(a) levels. Diamonds indicate pooled HR with 95% confidence intervals (CI); horizontal lines show 95% CI. Heterogeneity: I^2 = 99%, P = 0.04 .



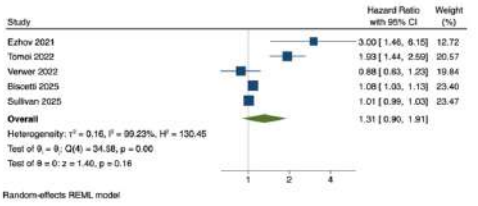


Figure 1b) Random-effects meta-analysis of HR for MACE after PAD revascularization by baseline Lp(a) level. Diamonds show pooled HR with 95% CI; horizontal lines represent 95% CI. Heterogeneity: I^2 = 99%, P = 0.16.

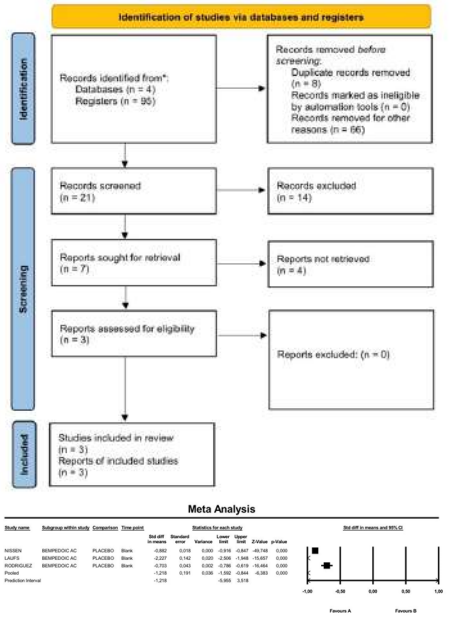


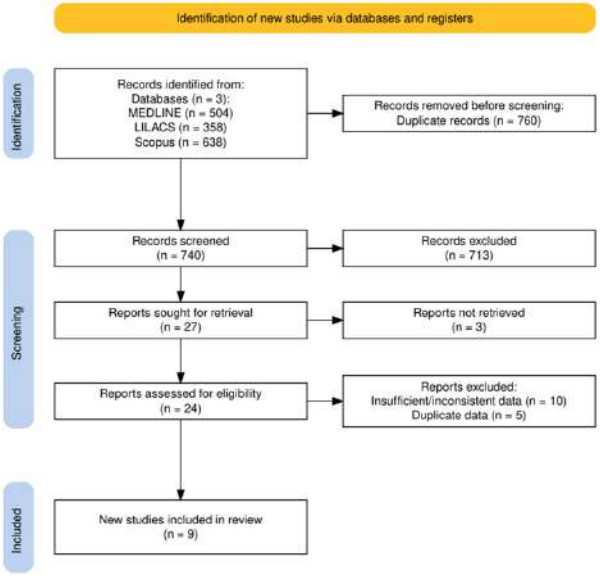
16524

BEMPEDOIC ACID EFFECT ON LDL-COLESTEROL LEVELS IN STATIN-RESISTANT PATIENTS: A SYSTEMATIC REVIEW WITH META-ANALYSIS.

DHIEGO ALVES DE LACERDA1; MARIA NANÍZIA DE ANDRADE FERREIRA1; LETÍCIA KAREN PIRES DE MENDONÇA1; RENATA BRAGA VALE1; PEDRO FECHINE HONORATO1; ELLEN DA COSTA BARRETO1; CAROLINA JERONIMO MAGALHÃES2; RODRIGO RUFINO PEREIRA SILVA2;

(1) CENTRO UNIVERSITÁRIO SANTA MARIA - CAJAZEIRAS - PB - BRASIL; (2) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL;

Introdução/Fundamentos: Statins are the first line treatment for dyslipidemia, but alternative therapies are necessary for approximately 10-15% of patients who do not tolerate them. Bempedoic acid lowers low-density lipoprotein cholesterol (LDL-C) by 21% to 24% as monotherapy in patients with statin-attributed side effects, and by an additional 17% to 18% in combination with the maximally tolerated statin. These benefits raise the question of whether this medication could be an ideal adjunct in statin-resistant patients' therapy who can not achieve their LDL-C targets with traditional treatment. Objetivos: Observe the extent to which bempedoic acid reduces LDL-C levels as add-on therapy for patients who do not tolerate statins. Métodos: Systematic review combined with meta-analysis, which searched for randomized studies in the Scielo, PubMed and Cochrane databases using the keywords "bempedoic acid", "statin-resistant" and "LDL-C", resulting in 95 articles. Articles published in the last 15 years, in Portuguese and English were included. Using the PRISMA system, three articles were ultimately selected. Resultados e Conclusões: The use of bempedoic acid in the studies was an add-on therapy to standard treatment, which included other non-statin drugs or minimum tolerated doses of statins. The total sample analyzed consisted of 7,222 individuals with documented intolerance to at least two statins. The risk of bias assessed by RoB 2 for the included clinical trials is classified as low in all domains, due to the rigorous randomization process, double blinding, and intention-to-treat analysis. Overall, there was a reduction in LDL-C levels with the use of bempedoic acid with a decrease from 26 to 34 mg/dL in these levels (SMD -1.21), while in the control group it was only -1.0 to 0.1 mg/dL (95% CI: -1.59 to -0.84; $p < 0.001$), with a confidence interval of -1.59 to -0.84. However, high statistical heterogeneity can be observed among the studies ($I2=98.1\%$; $Q=106.7$; $p<0.001$). This may have occurred because Laufs et al. presented a more significant reduction in their experience (SMD: -2.22) compared to Nissen et al. (SMD: -0.88) and Rodriguez et al. (SMD: -0.70), and the latter only included the Latin American population. Despite these more subtle effects, likely due to differences in populations or study designs, it is still possible to state that even across diverse population contexts, bempedoic acid had a significant impact on reducing LDL-C levels in statin-resistant patients.



15905

BEMPEDOIC ACID FOR CARDIOVASCULAR PREVENTION IN STATIN-INTOLERANT PATIENTS: A SYSTEMATIC REVIEW

YURI CANATO MIESSA CHAGAS1; CARLOS EDUARDO MACHADO GONTIJO1; JULIA YURI VERGINASSI KOGA1; LUARA CANATO MIESSA BARRETO1; RAFAEL BORELLI PEREIRA DOS SANTOS1; HUGO RAFAEL DA COSTA BENALIA1; NANCY CHRISTIANE FERREIRA SILVA1;

(1) CENTRO UNIVERSITARIO UNICESUMAR - MARINGA - PR - BRASIL;

Introdução/Fundamentos: Bempedoic acid (BA) has emerged as an alternative for the statin-intolerant population regarding cardiovascular risk reduction, due to fewer muscle-related side effects. This medication has enabled the treatment of a subset of patients with uncontrolled dyslipidemia and high cardiovascular risk. Objetivos: To analyze the effects of BA on cardiovascular prevention through markers such as low-density lipoprotein (LDL) levels, major adverse cardiovascular events (MACE), C-reactive protein (CRP), and side effects. Métodos: This systematic review followed the PRISMA guidelines. The search was conducted in the MEDLINE, LILACS, and Scopus databases, using the keywords: Bempedoic acid, Statin intolerant, Statin, and Cardiovascular prevention. Using a time restriction from 2018 to January 2026, a total of 27 articles were identified, of which 9 English-language studies were included. Duplicate works, systematic reviews, meta-analyses, narrative review, pediatric population studies, animal studies, and those without full-text access were excluded. Resultados e Conclusões: Of the total, 9 studies demonstrated a reduction in LDL levels by at least 23%, with similar values in primary and secondary prevention, highlighting the fundamental role of BA for cardiovascular protection in populations with higher baseline LDL levels. Furthermore, 3 studies revealed data on the incidence of MACE, including coronary revascularization, cardiovascular death, nonfatal myocardial infarction, and nonfatal stroke. The use of BA demonstrated a reduction in MACE incidence in 2 studies, mainly in primary prevention, with a relative risk reduction of at least 13%; 1 study showed inconclusive results on the topic. Similarly, 6 studies reported a decrease in inflammation, assessed through an estimated reduction of 24% in CRP levels, suggesting a potential pleiotropic effect of BA, as observed with statins. Additionally, 7 studies reported adverse effects during BA use, consisting mainly of hyperuricemia, increased liver enzymes, and kidney impairment, with low rates of discontinuation due to side effects. Therefore, the relevance of BA in cardiovascular prevention is evident, as it demonstrates positive results in reducing LDL, MACE, and systemic inflammation parameters in statin-intolerant patients and presents minimal side effects, contributing to treatment adherence in these patients.

19283

BETWEEN PREVENTION AND TREATMENT: WHERE ARE WE FAILING IN LDL CONTROL BEFORE ACUTE MYOCARDIAL INFARCTION?

PEDRO HENRIQUE BRAMBILA RODRIGEUS BINOTTO1; GIOVANNA VOIGT PISCONTI MACHADO1; ANA CLARA SANTOS DE OLIVEIRA1; ISADORA DELLA GIUSTINA SOMBRIO1; CAROLINA STOLL1; SARAH FAGUNDES GROBE1;

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL;

Introdução/Fundamentos: Low-density lipoprotein (LDL) is a key determinant of atherosclerosis and a central target in cardiovascular prevention strategies. Despite well-established guidelines and the availability of effective lipid-lowering therapies, acute myocardial infarction (AMI) still occurs in patients who are potentially eligible for treatment. This raises an important clinical question: are these failures related to gaps in primary prevention, inadequate risk stratification, or insufficient therapeutic intensification? Objetivos: To evaluate lipid profiles and lipid-lowering therapy at the time of acute myocardial infarction, investigating potential failures in LDL control prior to the event. Métodos: This cross-sectional observational study included patients admitted for AMI at a university hospital between February 2022 and December 2024. Clinical variables, lipid profiles, and ongoing lipid-lowering treatments were analyzed. Patients were categorized according to statin use (none, moderate-intensity, or high-intensity), as well as the use of ezetimibe. Statistical analyses included Kolmogorov-Smirnov tests, Student's t-test or Kruskal-Wallis for continuous variables, and chi-square tests for categorical variables, with post hoc analyses when appropriate. A significance level of 5% was adopted. Resultados e Conclusões: A total of 380 patients were included, with a mean age of 62.2 ± 11.9 years, and 69.2% were male. A high prevalence of cardiovascular risk factors was observed, including hypertension (73.2%), diabetes (36.8%), and prior smoking (47.9%). At the time of the event, most patients were not receiving statins (73.2%), while 20.8% were on moderate-intensity and 6.1% on high-intensity statins. LDL levels progressively decreased according to treatment intensity (122 mg/dL without statins, 113 mg/dL with moderate-intensity, and 102 mg/dL with high-intensity; p 0.003). However, lipid control remained suboptimal: only 35.8% had LDL <100 mg/dL, 12.4% <70 mg/dL, and 2.6% <50 mg/dL. Conclusion: The occurrence of AMI in a population largely untreated with statins and with inadequate LDL control highlights a significant gap between prevention and treatment. These findings reinforce the need for earlier identification of high-risk individuals and more aggressive lipid-lowering strategies to achieve LDL targets and prevent future cardiovascular events.

BRAIN ALARMINS HMGB1 AND S100B AND BLOOD–BRAIN BARRIER DYSFUNCTION AS DRIVERS OF ATHEROSCLEROSIS: A SYSTEMATIC REVIEW OF TRANSLATIONAL AND CLINICAL STUDIES

BEATRIZ DE LIMA VITORIO FERREIRA1; FLAVIA BEATRIZ DO CARMO MOREIRA2; MARCOS AURELIO FONSECA MEDEIROS1; EVELIN GABRIELLY DE VARGAS2; MARIANA VIDAL MIYAZATO2; MARIA LUIZA DUARTE ZACARIAS1; ANNE KAROLLYNE ALVARES SANTOS2;

(1) UNIFACISA - CAMPINA GRANDE - PB - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Acute brain injury induces release of alarmins (HMGB1, S100B), triggering systemic inflammation and potentially accelerating atherosclerosis. Blood–brain barrier (BBB) dysfunction enables leakage of neurogenic mediators into circulation, linking cerebral injury to cardiovascular outcomes. However, the magnitude and mechanisms of these associations remain incompletely integrated. This review summarizes translational and clinical evidence on these pathways. Objetivos: To evaluate associations between brain alarmins (HMGB1, S100B), BBB markers (CDH5, CD93, ICAM2, GP1BB, PlGF), and cardiovascular outcomes, and to explore mechanisms in the brain–atherosclerosis axis. Métodos: Systematic review following PRISMA. Clinical and translational studies were retrieved from PubMed (2011–2026). Inclusion: human studies assessing HMGB1, S100B, brain endothelial cell (BEC) proteins or PlGF; cardiovascular outcomes (functional myocardial ischemia by QFR, acute coronary syndrome [ACS], heart failure, dementia); and effect measures (OR, HR, adjusted correlations). Disease severity and mortality were extracted when available. Due to heterogeneity, qualitative synthesis was performed without meta-analysis. Resultados e Conclusões: S100B – In unstable angina (n=233), levels >33.28 pg/mL predicted ischemia (QFR ≤0.8) (OR=5.058; 95%CI 2.912–8.793; p<0.001) and correlated with Gensini score (Liu 2024). In ACS (n=420), levels were higher vs. stable angina/controls (p<0.01) (Cai 2011). In chronic HF (n=242), independently associated with major events (Li 2011). HMGB1 – Elevated in ACS/stroke vs. controls, associated with severity and mortality (de Souza 2012). Experimental stroke showed HMGB1 activates monocytes via RAGE, increasing plaque burden/vulnerability; inhibition attenuated progression (Roth 2018). BEC proteins – Composite score (CDH5, CD93, ICAM2, GP1BB) explained 11% of white matter lesion variability and predicted dementia risk over 25 years (Cordon 2023). PlGF – In 488 participants, correlated with white matter hyperintensity volume (r=0.20), GFAP (r=0.11), and NfL (r=0.19) (Edwards 2025). Results should be interpreted considering heterogeneity. HMGB1 and S100B associate with myocardial ischemia, ACS, and HF, while BBB markers and PlGF reflect neurovascular dysfunction and cognitive risk. Translational data support a RAGE-mediated monocyte activation mechanism linking brain injury to atherosclerosis. These biomarkers may aid risk stratification and future therapies.

BRAIN INFLAMMATORY MARKERS PREDICT CARDIOVASCULAR EVENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF MOLECULAR IMAGING, SERUM BIOMARKERS, AND MRI STUDIES

BEATRIZ DE LIMA VITORIO FERREIRA1; FLAVIA BEATRIZ DO CARMO MOREIRA2; MARCOS AURELIO FONSECA MEDEIROS1; EVELIN GABRIELLY DE VARGAS2; JOSE HENRIQUE LISBOA DA SILVA NETO2; PEDRO DE ARAUJO SANTOS1; ANNE KAROLLYNE ALVARES SANTOS2;

(1) UNIFACISA - CAMPINA GRANDE - PB - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Brain inflammation—triggered by stress-related neural activity, neuronal injury, or small vessel disease—has been linked to atherosclerosis and cardiovascular (CV) events, but its magnitude across different biomarkers remains incompletely integrated. Objetivos: To quantify, via systematic review and meta-analysis, the association between brain inflammatory markers (amygdalar activity, NfL, GFAP, sTREM2, IL-6, hsCRP, white matter hyperintensities, microbleeds) and major adverse cardiovascular events (MACE), stroke, and CV mortality. Métodos: Systematic review following PRISMA guidelines using PubMed (studies up to 2026). Included prospective cohorts or meta-analyses (≥100 participants) assessing brain inflammatory markers (FDG-PET amygdalar activity; serum biomarkers NfL, GFAP, sTREM2, IL-6, hsCRP; MRI markers) and reporting CV outcomes (MACE, stroke, CV death) with adjusted HR or RR. Random-effects models were applied; heterogeneity was assessed with I^2. Resultados e Conclusões: Seventy-one studies (>120,000 participants) were included. Amygdalar activity was associated with MACE (HR 1.61, 95% CI 1.12–2.32) and all-cause mortality (HR 2.49, 1.96–3.17). NfL was associated with stroke (HR 1.31, 1.09–1.57), CV death (HR 1.36, 1.20–1.54), all-cause mortality (HR 1.41, 1.27–1.56) in atrial fibrillation, mortality in HFrEF (HR 4.44, 3.02–6.53), and CV death in REGARDS (HR 2.16, 1.66–2.81). GFAP was linked to CV mortality (REGARDS HR 2.06; CHAP HR 1.87). sTREM2 post-stroke predicted death/CV events (HR 1.57, 1.11–2.21). IL-6 was associated with CV events (RR 1.12 per log-unit; RR 1.35 Q4 vs Q1), and hsCRP modestly (RR 1.09). Galectin-3 predicted incident CVD (HR 1.74). MRI markers were also predictive: white matter hyperintensities (HR 1.72), microbleeds (HR 1.88), silent infarcts (HR 2.9). Mechanistically, brain alarmins (HMGB1) may activate monocytes via RAGE. BDNF showed protective association (HR 0.88). Brain inflammatory markers across imaging and circulating biomarkers are consistently associated with higher risk of MACE, stroke, and CV mortality. Their integration into risk stratification may improve identification of high risk individuals and support anti-inflammatory strategies.

BURDEN AND REGIONAL DISTRIBUTION OF HOSPITALIZATIONS FOR AMI, HF AND DM IN THE BRAZILIAN UNIFIED HEALTH SYSTEM (SUS) AND THEIR TEMPORAL CO-VARIATION.

ANITA NUNES DE OLIVEIRA1; LÍVIA MARIA GALLI2; THÉO DUARTE EBOLI1; GABRIELA WANDER FOSSATI2; MARIA EDUARDA ISALINO E SILVA2; BERNARDO DELLA LATTA DA ROSA1; YAN DE SOUZA CARVALHO1; JEAN PIERRE WASSAF YOUSSEF3;

(1) UFCSPA - PORTO ALEGRE - RS - BRASIL; (2) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL; (3) HOSPITAL MOINHOS DE VENTO - PORTO ALEGRE - RS - BRASIL;

Introdução/Fundamentos: Diabetes Mellitus (DM) is a major risk factor for cardiovascular diseases, especially Acute Myocardial Infarction (AMI) and Heart Failure (HF), contributing to high morbidity, mortality and healthcare burden. The temporal and regional analysis of these conditions allows for an understanding of the impact of cardiometabolic diseases on the Brazilian Unified Health System (SUS). Objetivos: To analyse the burden and regional distribution of hospitalizations for DM, AMI, and HF in SUS between 2014-2024, evaluating temporal trends, population rates and co-variation among these conditions. Métodos: Descriptive ecological study using SIH/SUS. Hospitalizations with primary diagnoses corresponding to ICD-10 codes E10-14 (DM), I21 (AMI), and I50 (HF) between 2014 and 2024 were included. DM hospitalization rates per 100,000 inhabitants were calculated using IBGE population estimates. The co-variation between DM and cardiovascular conditions was assessed by simple linear regression, considering each year-region combination as the unit of analysis. Resultados e Conclusões: AMI hospitalizations increased from 94399 in 2014 to 180876 in 2024. In contrast, HF hospitalizations decreased from 224377 to 205373, with a sharper decline between 2020 and 2021 and subsequent partial recovery. DM hospitalizations remained stable, varying from 139819 to 139598; when adjusted for population, the rates decreased from 68,9 to 65,7 hospitalizations per 100.000 inhabitants. Regional heterogeneity was observed, with the highest absolute concentration in the Southeast and Northeast, while the North showed the most marked proportional growth. Positive correlation was found between hospitalizations for DM and AMI (r=0,80; β=1,108) and between DM and HF (r=0,87; β=1,484). Linear regression demonstrated a stronger association between DM and HF (R^2=0,757; p<0,05). AMI, HF, and DM represent a high hospital burden in SUS, with significant regional inequalities. The stability of DM hospitalizations and a slight reduction in population rates suggests the persistence of the cardiometabolic burden in Brazil. Although the data does not allow for casual inference, the observed temporal co-variation reinforces the relevance of the cardiometabolic axis. In this context, the STEP-HFpEF randomized clinical trial demonstrated the benefits of semaglutide in patients with obesity, type 2 diabetes, and heart failure with preserved ejection fraction, highlighting the potential of cardiometabolic therapies in reducing the future burden of these conditions.

CAR T-CELL THERAPY FOR THE REDUCTION OF MYOCARDIAL FIBROSIS: A SYSTEMATIC REVIEW OF PRECLINICAL STUDIES

RAFAELA MARIA DOS SANTOS NASCIMENTO1; CARLOS VITOR MIRANDA VIEIRA1; EWERTHON KEYICHI SHIBATA1; VERÔNICA OLIVEIRA RODRIGUES1; SOPHYA DOS SANTOS TITO1; ISABELA MACIEL TEIXEIRA1; EMILI DA CONCEIÇÃO RISUENHO DOS SANTOS1; ALICE LIANDRA UCHOA VENANCIO1; CRISTIANE AKINA MONMA TSUTSUMI2;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (2) FUNDACAO HOSPITAL DE CLINICAS GASPAR VIANNA PA - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Heart failure (HF) triggers pathological ventricular remodeling, where fibrotic tissue replaces functional myocardium, severely impairing cardiac compliance and contractility. While current pharmacological therapies delay disease progression, reversing established fibrosis remains a significant clinical challenge. Recently, Chimeric Antigen Receptor (CAR) T-cell therapy targeting Fibroblast Activation Protein (FAP) has emerged as a transformative cardioregenerative strategy to eliminate activated fibroblasts. This systematic review synthesizes preclinical evidence regarding FAP-targeted CAR-T cells as an antifibrotic intervention, evaluating their impact on cardiac structural and functional parameters in in vivo experimental models. Objetivos: To synthesize preclinical findings regarding CAR-T cell therapy as an antifibrotic strategy, evaluating its impact on cardiac structural and functional parameters in in vivo experimental models. Métodos: Following PRISMA 2020 guidelines, a comprehensive search was conducted across PubMed, SciELO, LILACS, and Embase without language or date restrictions. The search strategy utilized DeCS/MeSH terms and Boolean operators: (“CAR-T Cells” OR “Chimeric Antigen Receptor T-Cell”) AND (“Cardiac Fibrosis” OR “Heart Failure”) AND (“FAP” OR “Fibroblast Activation Protein”). Inclusion criteria targeted in vivo preclinical experimental studies involving the induction of fibrosis and heart failure in murine models. Study selection and data extraction were performed by two independent, double-blind reviewers using Rayyan software. Methodological quality was rigorously assessed using the SYRCLE’s Risk of Bias tool. Resultados e Conclusões: A total of 144 studies were identified; four high-impact preclinical trials were selected. Results demonstrate that CAR-T immunotherapy promotes significant regression of adverse ventricular remodeling. Myocardial injury was established through distinct protocols, such as pathway reprogramming via mRNA-encoded lipid nanoparticles or alpha-MHC immunization. Analysis reveals robust efficacy, with fibrotic load reductions ranging from 60% to undetectable levels. Furthermore, data indicating the restoration of cardiac function suggest that this therapy not only halts lesion progression but also promotes effective tissue-level regeneration. Despite being a disruptive approach, CAR-T therapy provides a solid translational basis for restoring myocardial architecture.

CARDIOAI: AN ARTIFICIAL INTELLIGENCE-BASED PROTOTYPE FOR THE IDENTIFICATION OF HIDDEN CARDIOVASCULAR RISK BEYOND TRADITIONAL RISK SCORES

THIAGO SALES DE OLIVEIRA1; MILENA BRÁS DA SILVA MARTINS1; JULIANA MARILIA PEREIRA DE OLIVEIRA1; MAURÍCIO MEGDA DE ANDRADE JÚNIOR1;

(1) FACULDADE DE MEDICINA UNIVERSIDADE PROFESSOR EDSON ANTONIO VELANO - UNIFENAS - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases remain the leading cause of mortality worldwide. Although risk scores such as Framingham, SCORE2, and the Pooled Cohort Equations are widely used, a proportion of individuals classified as low risk still experience major cardiovascular events, highlighting the existence of residual cardiovascular risk. In addition, these models have limited capacity to incorporate behavioral and psychosocial determinants, as well as emerging biomarkers such as lipoprotein(a). In this context, artificial intelligence may facilitate the integration of multidimensional data and the identification of non-linear patterns, with potential applications in precision medicine. Objetivos: To develop a digital platform based on explainable artificial intelligence to support the identification of residual cardiovascular risk in individuals classified as low risk by conventional models. Métodos: This was a descriptive technological development study. The platform was designed to integrate two groups of variables: traditional variables (age, sex, blood pressure, lipid profile, body mass index, smoking status, and family history of premature cardiovascular disease) and expanded variables (psychosocial stress, sleep quality, sedentary behavior, and subclinical biomarkers such as high-sensitivity C-reactive protein, fibrinogen, and lipoprotein(a)). The prototype includes the application of supervised machine learning models, including Random Forest, Gradient Boosting, and neural networks, with explainability features based on variable importance and interpretable outputs. Resultados e Conclusões: The developed prototype features a structured interface for sequential data collection and integrated cardiovascular risk stratification, with transparent visualization of the relative contribution of the analyzed variables. The platform was designed to support the identification of profiles potentially underestimated by traditional risk scores and to provide guidance for individualized complementary investigation, while also anticipating scalability, interoperability, and integration into digital health ecosystems. CardioAI represents a promising proposal for expanding residual cardiovascular risk stratification through a multidimensional and explainable approach. The incorporation of emerging biomarkers, such as lipoprotein(a), reinforces its potential alignment with precision medicine. Future studies should assess external validity, discrimination, calibration, algorithmic bias, equity, and clinical utility.

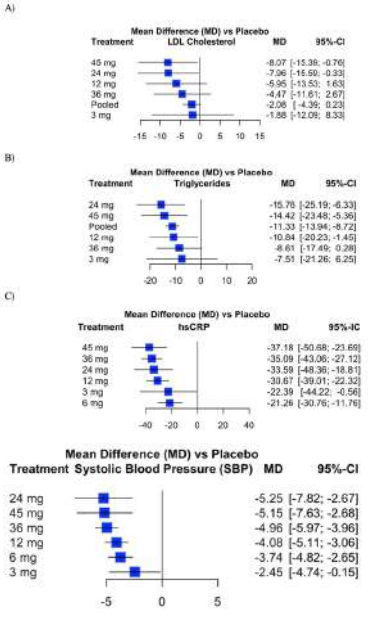
CARDIOMETABOLIC AND HEMATOLOGICAL ALTERATIONS ASSOCIATED WITH SUPRAPHYSIOLOGICAL TESTOSTERONE EXPOSURE

JOÃO PEDRO FEITOSA CAJUAZ CASTRO1; MARIANA FAÇANHA PESSOA1; RACHEL PETROLA2; MILENA TELES2; DELANIE BULCÃO MACEDO2;

(1) INTERNSHIP PROGRAM AT EMED – EMÍLIO RIBAS MEDICINA DIAGNÓSTICA - FORTALEZA - CE - BRASIL; (2) EMÍLIO RIBAS MEDICINA DIAGNÓSTICA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: The increasing use of supraphysiological doses of testosterone, both for medical and non-medical purposes, has raised concerns regarding cardiovascular safety. However, real-world data evaluating the cardiometabolic effects of extreme testosterone exposure, particularly including women, remain limited. Objetivos: To evaluate the association between supraphysiological testosterone levels and metabolic, inflammatory, and hematological parameters in adults using exogenous testosterone. Métodos: This retrospective cross-sectional study evaluated laboratory tests collected between 2022 and 2024 from a clinical laboratory in northeastern Brazil. Individuals aged ≥18 years with elevated testosterone levels and reported testosterone use were included. Testosterone test results were stratified according to sex-specific testosterone ranges. Fasting glucose, HbA1c, hematocrit, lipid profile, hs-CRP, and insulin were analyzed using Pearson correlation and one-way ANOVA, with significance defined as $p < 0.05$. Resultados e Conclusões: A total of 1,890 testosterone test results were analysed, of which 82.4% were male. Among men, 35.0% showed testosterone levels >2500 ng/dL and 12.7% exceeded 3400 ng/dL, while among women, 29.2% showed testosterone levels >250 ng/dL and 12.0% exceeded 500 ng/dL. Testosterone levels positively correlated with hematocrit ($r = 0.511$, $p < 0.001$) and inversely correlated with HbA1c ($r = -0.106$, $p < 0.001$), total cholesterol ($r = -0.092$, $p < 0.001$), and HDL cholesterol ($r = -0.370$, $p < 0.001$). In men, higher testosterone levels were associated with increased hematocrit ($F = 6.29$, $p = 0.002$; 50.7 ± 3.5 in >3400 ng/dL vs 49.8 ± 3.6 in 1440–2500 ng/dL and 49.9 ± 3.3 in 2500–3400 ng/dL) and lower HDL cholesterol levels ($F = 3.94$, $p = 0.020$; 38.5 ± 11.3 in >3400 ng/dL vs 41.0 ± 10.7 in 1440–2500 ng/dL and 40.8 ± 11.0 in 2500–3400 ng/dL). In women, testosterone levels were associated with hematocrit ($F = 7.29$, $p < 0.001$; 44.4 ± 3.0 in >500 ng/dL vs 43.1 ± 2.8 in 100–250 ng/dL and 42.0 ± 2.7 in 72–100 ng/dL) and hs-CRP levels ($F = 4.79$, $p = 0.005$). No significant differences were observed for glucose, insulin, LDL cholesterol, or triglycerides. Overall, supraphysiological testosterone exposure was strongly associated with increased hematocrit levels in both sexes and reduced HDL cholesterol levels in men, reinforcing potential cardiovascular risks associated with extreme androgen exposure.



19291

CARDIOMETABOLIC EFFICACY AND SAFETY OF VARYING DOSAGES OF ORAL ORFORGLIPRON IN ADULTS WITH OVERWEIGHT, OBESITY, OR TYPE 2 DIABETES: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

ANA LUÍSA ABREU LESSA RIBEIRO1; LUCAS BASTOS CARVALHO1; CATHARINA RIBEIRO LYRA1; EDUARDO FAGUNDES MURICY1; ALEXSANDRO ALVES FAGUNDES2;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL; (2) UNEB - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Orforglipron is an oral, non-peptide glucagon-like peptide-1 receptor agonist with promising metabolic effects in adults with overweight, obesity, or type 2 diabetes. However, the dose that best balances cardiometabolic efficacy and safety remains uncertain. Evidence to date has focused mainly on weight loss and glycaemic control, while dose-specific effects on cardiometabolic risk markers and tolerability have not been comprehensively synthesised. Objetivos: To compare the cardiometabolic efficacy and safety of different doses of oral orforglipron versus placebo and to identify the most favourable dose range. Métodos: We performed a systematic review and network meta-analysis of randomised controlled trials comparing different doses of oral orforglipron with placebo in adults with overweight, obesity, or type 2 diabetes. MEDLINE, Embase, and the Cochrane Central Register of Controlled Trials were searched from inception to April 6, 2026. Eligible studies reported at least one prespecified cardiometabolic or safety outcome. Continuous outcomes were analysed as mean differences and dichotomous outcomes as relative risks with 95% confidence intervals in a frequentist random-effects model. Treatments were ranked using the surface under the cumulative ranking curve (SUCRA). The protocol was prospectively registered in PROSPERO (CRD420261363012). Resultados e Conclusões: A total of 381 records were identified, 124 duplicates removed, and 8 full-text reports assessed; 5 studies (6 publications) including 5982 participants were included. All evaluated doses reduced systolic blood pressure versus placebo, with the greatest reduction observed at 24 mg. Improvements in lipid markers and high-sensitivity C-reactive protein showed a plateau at approximately 24–36 mg, while heart rate increased in a dose-dependent manner. Gastrointestinal tolerability worsened above 12 mg, and treatment discontinuation due to adverse events was higher with orforglipron than placebo (RR 2.53, 95% CI 1.84–3.48; p<0.001). Serious adverse events were not increased overall (RR 0.97, 95% CI 0.73–1.29; p=0.84). Overall, orforglipron improved cardiometabolic risk markers without increasing serious adverse events. Among evaluated doses, 24 mg showed the most favourable balance between efficacy and tolerability, although gastrointestinal side effects remain a limitation. Long-term outcome trials are needed to confirm whether surrogate improvements translate into reduced cardiovascular events and mortality.

20326

CARDIOVASCULAR BENEFITS OF FINERENONE IN PATIENTS WITH CHRONIC KIDNEY DISEASE AND TYPE 2 DIABETES MELLITUS: A SYSTEMATIC REVIEW.

ISABELLA DE CARVALHO SALU DOS SANTOS1; MARIANA MARTINS DE OLIVEIRA1; MARIO PIETRO SCUPINO ROCCO1; CATARINA MELLO DA MATA1; GABRIELA TAIRA MORENO1; LARISSA HIROMI YAMAMOTO1; PEDRO HENRIQUE NOVOA FERREIRA1; VICTORIA LUQUE DE BARROS COBRA1; IRVING GABRIEL ARAUJO BISPO1;

(1) UNIVERSIDADE MUNICIPAL DE SAO CAETANO DO SUL - SÃO PAULO - SP - BRASIL;11

Introdução/Fundamentos: Patients with type 2 diabetes mellitus (DM2) associated with chronic kidney disease (CKD) have a substantially elevated cardiovascular risk, contributing to increased morbidity and mortality in this population. In this context, finerenone, a non-steroidal antagonist of the mineralocorticoid receptor, has emerged as a promising therapeutic option in reducing cardiovascular outcomes. Objetivos: The objective is to evaluate, through a systematic review, the available evidence on the cardiovascular benefits of finerenone in patients with chronic kidney disease (CKD) associated with type 2 diabetes mellitus (DM2). Métodos: A systematic review was conducted in the PubMed, SciELO, and LILACS databases, including randomized clinical trials, combined analyses, and meta-analyses that investigated cardiovascular outcomes in patients with type 2 diabetes mellitus (DM2) and chronic kidney disease (CKD) treated with finerenone. The main outcomes evaluated were major cardiovascular events (MACE), hospitalization for heart failure, and cardiovascular mortality. The descriptors used were: "finerenone," "diabetes mellitus," "chronic kidney disease," and "cardiovascular mortality." The search period was from September 2025 to January 2026. The PRISMA 2020 workflow was used to select articles, along with the Rayyan QCRI platform. Three independent researchers evaluated the articles in a blinded manner. Resultados e Conclusões: After analysis according to inclusion and exclusion criteria, reading of abstracts or full text, and exclusion of duplicate articles, 11 studies were selected according to the PRISMA 2020 flowchart. Phase III studies, such as FIDELIO-DKD and FIGARO-DKD, were included, in addition to the combined FIDELITY analysis, totaling more than 13,000 patients. The use of finerenone was associated with a significant reduction in the risk of composite cardiovascular outcomes, notably a decrease in hospitalizations for heart failure. Regarding safety, a higher incidence of hyperkalemia was observed, generally manageable through adequate laboratory monitoring.Available evidence indicates that finerenone provides consistent cardiovascular benefit in patients with CKD and type 2 diabetes, establishing itself as an effective additional therapeutic strategy in reducing cardiorenal risk in a high-risk population.

18068

CARDIOVASCULAR EVENTS AND MORTALITY IN OBESE PATIENTS RECEIVING BARIATRIC SURGERY: A MULTI-CENTER RETROSPECTIVE COHORT

GIOVANNA DE SOUSA OLIVEIRA1; JOÃO VICTOR DE OLIVEIRA RAMOS1; PABLO DE OLIVEIRA CORDEIRO1; JOÃO RICARDO CAVALCANTI DO NASCIMENTO1; DAVI ALBUQUERQUE MADRUGA1; LUCAS GRANGEIRO PEQUENO1; ÉRIKA ALVES DA SILVA1; MARCO ANTÔNIO PANET DE VIVO BARROS1; EMMILY NEVES DE ARAÚJO PEREIRA1; ANTÔNIO LACERDA CAVALCANTI NETO1; FABYAN ESBERARD DE LIMA BELTRÃO1; MARCELO DANTAS TAVARES DE MELO1;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL;

Introdução/Fundamentos: Obesity is a major driver of cardiovascular morbidity and mortality worldwide. Although bariatric surgery (BS) produces sustained weight loss and metabolic improvement, its real-world impact on major cardiovascular events and survival at scale remains incompletely defined. Objetivos: To evaluate the association between BS and cardiovascular events and mortality in obese patients. Métodos: This retrospective, propensity-score-matched (PSM) cohort study was completed using the TriNetX database, which includes data from 93 different large healthcare organizations with over 132 million patient records. Primary outcomes included all-cause mortality (ACM) and major adverse cardiac events (MACEs). Secondary outcomes included the assessment of acute myocardial infarction (MI), arrhythmias, heart failure (HF), ischemic cardiomyopathy (ICM), ischemic stroke (IS), and thromboembolic events. Risk ratios (RRs) and (HRs) with 95% confidence intervals (CI) were calculated using TriNetX analytical tools. Resultados e Conclusões: The TriNetX database yielded a total of 244,070 patients (122,035 underwent BS; 122,035 for control group) after PSM. BS was associated with a consistent reduction in MACEs (RR 0.92, 95% CI 0.88–0.96; HR 0.84, 95% CI 0.81–0.88) and ACM (RR 0.83, 95% CI 0.79–0.86; HR 0.75, 95% CI 0.71–0.78) when compared with non-surgical controls. The incidence of acute MI was significantly lower in the surgical group (RR 0.71, 95% CI 0.66–0.76; HR 0.66, 95% CI 0.62–0.70), as were HF (RR 0.86, 95% CI 0.83–0.90; HR 0.81, 95% CI 0.77–0.84), atrial fibrillation/flutter (RR 0.90, 95% CI 0.85–0.94; HR 0.83, 95% CI 0.79–0.88), ventricular arrhythmias (RR 0.78, 95% CI 0.72–0.85; HR 0.72, 95% CI 0.67–0.79), and ICM (RR 0.76, 95% CI 0.67–0.85; HR 0.70, 95% CI 0.62–0.79). BS was also associated with a modest reduction in ischemic stroke (RR 0.95, 95% CI 0.89–1.02; HR 0.89, 95% CI 0.83–0.95). In contrast, no significant differences were observed for venous thromboembolic outcomes, including pulmonary embolism (RR 0.99, 95% CI 0.92–1.08; HR 0.93, 95% CI 0.86–1.01) and deep vein thrombosis (RR 1.08, 95% CI 1.01–1.17; HR 1.02, 95% CI 0.94–1.09). BS was associated with substantial reductions in MACEs, ACM, and other cardiovascular events among patients with obesity. These findings support the role of BS as a powerful intervention not only for its metabolic benefit but also for long-term cardiovascular risk reduction and survival benefit.

Cardiovascular and Mortality Outcomes in Bariatric Surgery vs. Non-Surgical Controls

Outcome	Incidence (n/N, %)		Risk Ratio (RR)	Hazard Ratio
	Bariatric Surgery	Controls	(95% CI)	(HR)(95% CI)
Acute Myocardial Infarction	1,498/119,677 (1.3%)	2,075/117,398	0.71 (0.66–0.76)	0.66 (0.62–0.70)
Heart Failure	3,725/113,915 (3.3%)	4,159/109,674	0.86 (0.83–0.90)	0.81 (0.77–0.84)
Atrial Fibrillation / Flutter	2,898/114,014 (2.5%)	3,190/112,726	0.90 (0.85–0.94)	0.83 (0.79–0.88)
Ventricular Arrhythmias	1,024/120,649 (0.8%)	1,298/119,630	0.78 (0.72–0.85)	0.72 (0.67–0.79)
Ischemic Cardiomyopathy	470/121,280 (0.4%)	619/120,574	0.76 (0.67–0.85)	0.70 (0.62–0.79)
Ischemic Stroke	1,631/119,363 (1.4%)	1,684/117,708	0.95 (0.89–1.02)	0.89 (0.83–0.95)
3P-MACE	4,050/115,524 (3.5%)	4,233/111,196	0.92 (0.88–0.96)	0.84 (0.81–0.88)
Pulmonary Embolism	1,177/119,311 (1.0%)	1,174/118,327	1.00 (0.92–1.08)	0.93 (0.86–1.01)
Deep Vein Thrombosis	1,525/118,625 (1.3%)	1,393/117,457	1.08 (0.92–1.08)	1.02 (0.94–1.09)
All-Cause Mortality	3,711/119,970 (3.1%)	4,478/119,722	0.83 (0.79–0.86)	0.75 (0.71–0.78)

CARDIOVASCULAR EVENTS AND MORTALITY IN OBESE PATIENTS RECEIVING GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONISTS: A MULTI-CENTER RETROSPECTIVE COHORT

GIOVANNA DE SOUSA OLIVEIRA1; JOÃO VICTOR DE OLIVEIRA RAMOS1; JOÃO RICARDO CAVALCANTI DO NASCIMENTO1; PABLO OLIVEIRA CORDEIRO1; FABYAN ESBERARD DE LIMA BELTRÃO1; MARCELO DANTAS TAVARES DE MELO1;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL;

Introdução/Fundamentos: Glucagon-like peptide-1 receptor agonists (GLP-1As) have demonstrated cardiometabolic benefits in patients with obesity; however, their real-world impact on cardiovascular outcomes and mortality in large, diverse populations remains incompletely characterized. Objetivos: To evaluate the association between GLP-1A therapy and cardiovascular events and mortality in obese patients. Métodos: This retrospective, propensity-score-matched (PSM) cohort study was completed using the TriNetX database, which includes data from 93 different large healthcare organizations with over 132 million patient records. Primary outcomes included all-cause mortality (ACM) and major adverse cardiac events (MACEs). Secondary outcomes included the assessment of acute myocardial infarction (MI), atrial arrhythmias, heart failure (HF), ischemic stroke (IS), and thromboembolic events. Risk ratios (RRs) and (HRs) with 95% confidence intervals (CI) were calculated using TriNetX analytical tools. Resultados e Conclusões: The TriNetX database yielded a total of 327,351 GLP-1As users before PSM, with 226,054 patients being matched for each arm (users and non-users). GLP-1A utilization was associated with a reduced risk of: MACE (RR 0.45, 95% CI 0.44–0.47; HR 0.95, 95% CI 0.92–0.98); ACM (RR 0.32, 95% CI 0.31–0.33; HR 0.69, 95% CI 0.66–0.71); acute MI (RR 0.44, 95% CI 0.42–0.46; HR 0.90, 95% CI 0.86–0.94); IS (RR 0.48, 95% CI 0.45–0.50; HR 0.95, 95% CI 0.91–1.00); HF (RR 0.48, 95% CI 0.46–0.49; HR 0.97, 95% CI 0.94–1.00); atrial fibrillation/flutter (RR 0.44, 95% CI 0.42–0.46; HR 0.88, 95% CI 0.84–0.91); pulmonary embolism (RR 0.45, 95% CI 0.41–0.48; HR 0.88, 95% CI 0.82–0.95); and deep vein thrombosis (RR 0.45, 95% CI 0.42–0.47; HR 0.86, 95% CI 0.81–0.92). In this large, multicenter retrospective cohort, GLP-1A therapy in obese patients was associated with substantial reductions in MACEs, ACM, thromboembolic complications and many cardiovascular events. Consistent findings across RR and HR analyses reinforce the cardioprotective benefits of GLP-1As in real-world clinical practice and reinforce their use as a cornerstone therapy in high-risk obese populations.

Cardiovascular and Mortality Outcomes (PSM Cohort)

Outcome	GLP-1 RA (n/N, %)	Control (n/N, %)	Risk Ratio (95% CI)	Hazard Ratio (95% CI)
3P-MACE	5,416/208,858 (2.6%)	11,515/201,537 (5.7%)	**0.45** (0.44–0.47)	**0.95** (0.92–0.98)
Acute Myocardial Infarction	2,694/218,233 (1.2%)	5,993/214,974 (2.8%)	**0.44** (0.42–0.46)	**0.90** (0.86–0.94)
Ischemic Stroke	2,312/218,992 (1.1%)	4,785/215,748 (2.2%)	**0.48** (0.45–0.50)	**0.95** (0.91–1.00)
Heart Failure	5,905/205,924 (2.9%)	12,076/201,096 (6.0%)	**0.48** (0.46–0.49)	**0.97** (0.94–1.00)
Atrial Fibrillation / Flutter	3,981/210,184 (1.9%)	8,965/207,811 (4.3%)	**0.44** (0.42–0.46)	**0.88** (0.84–0.91)
Pulmonary Embolism	1,104/221,844 (0.5%)	2,470/220,866 (1.1%)	**0.45** (0.41–0.48)	**0.88** (0.82–0.95)
Deep Vein Thrombosis	1,420/221,056 (0.6%)	3,151/219,093 (1.4%)	**0.45** (0.42–0.47)	**0.86** (0.81–0.92)
All-Cause Mortality	4,056/224,188 (1.8%)	12,570/222,602 (5.6%)	**0.32** (0.31–0.33)	**0.69** (0.66–0.71)

CARDIOVASCULAR IMPACT OF ELECTRONIC CIGARETTES: A SYSTEMATIC REVIEW OF VASCULAR AND HEMODYNAMIC EFFECTS

JOSÉ GUSTTAVO COSTA CORDEIRO1; TÂMARA KARINE SALES GALLINDO1; ANA CAROLINA SHUAN LACO1; MARIA LINA BRITTO DE SOUZA1; SUELLEN LIMA DA COSTA1; FLAVIA FERREIRA DA SILVA CRUZ1;

(1) AFYA MANACAPURU - MANACAPURU - AM - BRASIL;

Introdução/Fundamentos: Electronic Nicotine Delivery Systems (ENDS) have been promoted as safer alternatives to conventional cigarettes. However, growing evidence indicates that their aerosols contain nicotine, heavy metals, and oxidative compounds capable of inducing significant cardiovascular changes. With the increasing popularity of e-cigarettes, especially among young individuals, understanding their cardiovascular effects is essential to support preventive strategies and public health policies. Objetivos: To systematically review the scientific evidence on the cardiovascular impacts of e-cigarette use, focusing on hemodynamic changes, endothelial dysfunction, and vascular stiffness. Métodos: A systematic review was conducted following PRISMA guidelines. Searches were performed in PubMed, Virtual Health Library (VHL), and SciELO using the descriptors “Electronic Cigarettes,” “Cardiovascular System,” and “Vascular Stiffness,” combined with Boolean operators. A total of 230 studies were identified. Notably, no studies meeting the inclusion criteria were found in SciELO. After removing duplicates and applying eligibility criteria, clinical trials, observational studies, and meta-analyses published within the last five years were considered. Narrative reviews, duplicate studies, those with insufficient data, and studies lacking specific cardiovascular outcomes were excluded. Study selection was independently conducted by two blinded reviewers, with disagreements resolved by a third evaluator. Ultimately, 21 studies were included in the qualitative analysis. Resultados e Conclusões: Among the 21 included studies, 16 reported significant increases in heart rate and blood pressure following e-cigarette exposure. Fourteen studies identified endothelial dysfunction and increased arterial stiffness, suggesting early vascular impairment. Additionally, 12 studies associated ENDS use with increased oxidative stress, vascular inflammation, and platelet activation—mechanisms directly linked to atherosclerosis and thrombotic events. The consistency of findings across different populations and study designs strengthens the association between e-cigarette use and relevant cardiovascular risk. These results challenge the “harm reduction” narrative and indicate that ENDS may contribute to early vascular injury and progression of cardiovascular disease, highlighting the need for stricter regulation and clinical monitoring of users.

CARDIOVASCULAR IMPACT OF NEXT-GENERATION INCRETIN THERAPIES (SEMAGLUTIDE, TIRZEPATIDE, AND RETATRUTIDE) IN PATIENTS WITH TYPE 2 DIABETES AND/OR OBESITY: A SYSTEMATIC REVIEW

GIOVANA AIMMÊ CALDAS RODRIGUES1; GLEYDSON AZEVEDO ALMEIDA2; CLÍVIA MARIA PINHEIRO SANTOS1; AYLA ESTEFÂNIA GAIA VIEIRA1; AMANDA QUARESMA SILVA1; JOAQUIM PEDRO JUNIOR2; JOSIÉLLY SOUZA FREITAS2; PEDRO LIMA MAUÉS1; CLEYSON PANTOJA SERRÃO3;

(1) ESCOLA SUPERIOR DA AMAZÔNIA - ABAETETUBA - PA - BRASIL; (2) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL; (3) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

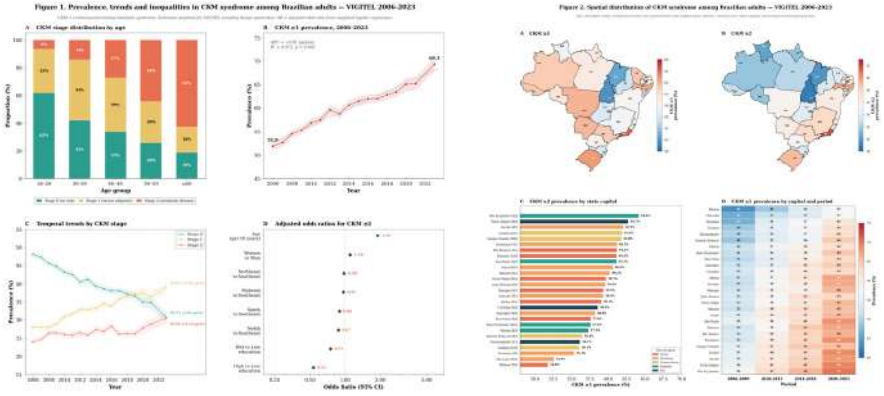
Introdução/Fundamentos: Obesity and type 2 diabetes (T2D) are associated with an increased risk of major adverse cardiovascular events (MACE), mediated by chronic inflammation, insulin resistance, and endothelial dysfunction. In this context, next-generation incretin agonists have emerged as therapies capable of reducing cardiometabolic risk beyond glycemic and weight control. Objetivos: To evaluate the cardiovascular impact of semaglutide, tirzepatide, and retatrutide in patients with T2D and/or obesity, focusing on MACE and heart failure (HF). Métodos: A systematic review was conducted according to PRISMA guidelines. PubMed, BVS, and Cochrane databases were searched for randomized clinical trials evaluating cardiovascular outcomes between 2021 and April 2026. Study selection was performed using Rayyan by two independent reviewers, and data were qualitatively synthesized. Resultados e Conclusões: A total of 277 records were identified, of which 15 studies were included in the qualitative analysis, comprising 39,459 patients. Semaglutide demonstrated a consistent reduction in MACE, notably in the SOUL trial (12.0% vs. 13.8%; HR 0.86; 95% CI 0.77–0.96; p=0.006), as well as reduction in nonfatal myocardial infarction (HR 0.74) and peripheral ischemic events (HR 0.71). In the SELECT study, a 20% reduction in MACE (HR 0.80) was observed, independent of glycemic control. In patients with HFpEF, semaglutide (STEP-HFpEF) improved quality of life (+7.8 points in KCCQ; p<0.001) and functional capacity (+20.3 m), with reduced heart failure events (HR 0.08, exploratory analysis). In the SUMMIT trial, tirzepatide demonstrated a reduction in the composite outcome of cardiovascular death or worsening HF (9.9% vs. 15.3%; HR 0.62; p=0.026), as well as in HF hospitalizations (HR 0.44), and was associated with significant functional improvement. In obesity studies (SURMOUNT-1 and SURMOUNT-5), it promoted weight reduction of up to 20.9%, with improvement in cardiovascular risk factors, without MACE during follow-up. Retatrutide demonstrated weight reduction of up to 24.2% and improved cardiometabolic parameters, without increased adverse cardiovascular events (4% in both groups), although major outcomes have not yet been evaluated. These findings consolidate incretin-based therapies as a transformative strategy for reducing cardiovascular risk.

18136

CARDIOVASCULAR RISK UNDERESTIMATION BY THE 2019 WHO CHARTS: THE IMPACT OF LOW HDL AND METABOLIC SYNDROME IN A BRAZILIAN HIGH-RISK POPULATION

GABRIELA MENDONÇA DE OLIVEIRA1; ADALBERTO TEIXEIRA DA MATTA FLORA NETO1; LEONARDO RODRIGUES FERNANDES1; LUCAS PETRAGLIA BARROSO1; YASMIN SANTOS TAVARES1; JOÃO LUCAS O'CONNELL1;

(1) UNIVERSIDADE FEDERAL DE UBERLÂNDIA - UBERLÂNDIA - MG - BRASIL;



Introdução/Fundamentos: The 2019 WHO cardiovascular risk charts remain the default stratification tool in resource-limited settings and are still widely used in Brazil's public health system, even following the 2025 SBC Guideline's shift from the Framingham Global Risk Score (FGRS) to the PREVENT score. A notable limitation is the omission of HDL-cholesterol, particularly consequential where low HDL, a hallmark of metabolic syndrome (MetS), is highly prevalent. Whether this structural gap causes clinically meaningful misclassification, and whether it disproportionately affects patients with MetS, has not been systematically evaluated in Brazil. Objetivos: To evaluate the independent association of low HDL-cholesterol and MetS with cardiovascular risk underestimation by the 2019 WHO charts, and to examine whether a reduced threshold (≥10%) preferentially recovers misclassified patients with this metabolic phenotype. Métodos: Cross-sectional study of 140 adults (aged 40–74 years) at a tertiary care center. Underestimation was defined as FGRS ≥20% combined with WHO standard risk <20%. MetS was defined by IDF 2006 criteria. HDL was compared by Mann-Whitney U test; sex-specific low HDL (men <40 mg/dL; women <50 mg/dL) by Fisher's exact test; MetS-underestimation association by chi-square. Multivariate logistic regression identified independent predictors. Reclassification rates using WHO ≥10% were stratified by MetS status. Resultados e Conclusões: MetS was present in 75.7% of patients (n=106) and 35.7% were underestimated (n=50). Mean HDL was lower in the underestimated group (35.7±10.3 vs. 46.6±19.5 mg/dL; p<0.001). Multivariate analysis identified four independent predictors. Male sex carried the strongest association (OR=8.30; 95%CI 2.97–23.21; p<0.001), followed by MetS (OR=4.71; 95%CI 1.39–15.97; p=0.013) and low HDL (OR=3.68; 95%CI 1.45–9.36; p=0.006). Older age was independently associated (OR=1.14/year; 95%CI 1.08–1.21; p<0.001), with underestimated patients averaging 8 years older (64.3±7.4 vs. 56.2±9.2 years). With the adjusted threshold, 36 of 50 were reclassified as high risk, 91.7% of whom had MetS (n=33). These findings suggest the 2019 WHO charts carry a systematic blind spot for patients with MetS and low HDL, a phenotype that accounts for the majority of Brazil's cardiovascular burden. A simple threshold adjustment to ≥10% recovered more than two-thirds of misclassified patients, nearly all with MetS, offering a pragmatic, no-cost adaptation where more sophisticated tools are unavailable.

15311

CARDIOVASCULAR-KIDNEY-METABOLIC SYNDROME AFFECTS 60% OF BRAZILIAN ADULTS AND ROSE 17 PERCENTAGE POINTS OVER 17 YEARS: A POPULATION-BASED ANALYSIS OF 735,130 PARTICIPANTS (VIGITEL, 2006–2023)

GUSTAVO SKONETZKY1; AMANDA TEIXEIRA WATERMANN1; LUIZA TREVISAN1; MILENA CHRISTINE POLLI1; SIMONE TUCHTENHAGEN1; ISADORA BIGOLIN1; TIAGO VENDRUSCOLO1;

(1) UNIVERSIDADE REGIONAL INTEGRADA DO ALTO URUGUAI E DAS MISSÕES (URI) - ERECHIM - RS - BRASIL;

Introdução/Fundamentos: Cardiovascular-kidney-metabolic (CKM) health has emerged as a key driver of cardiovascular disease burden since American Heart Association (AHA) formalized its staging framework in 2023, yet no population-level study has applied it in Latin America, reflecting a critical epidemiological gap. Objetivos: To estimate the prevalence, temporal trends, and spatial distribution of CKM syndrome across 27 Brazilian capitals, and identify factors associated with metabolic-stage CKM syndrome. Métodos: Cross-sectional study using 2006-2023 VIGITEL data. We analyzed 735,130 adults (≥18 years) from 17 waves (2006–2023) with valid BMI data. CKM staging was adapted from AHA 2023 framework: Stage 0 (no risk), Stage 1 (BMI ≥25 kg/m² without metabolic disease), and Stage 2 (self-reported hypertension and/or diabetes). Weighted prevalences with 95% CI were calculated using post-stratification raking weights. Temporal trends were assessed via survey-weighted logistic regression. Spatial autocorrelation was tested using Moran's I and LISA. Multivariable logistic regression identified factors associated with CKM ≥2. Ethics approval was waived per Resolution CNS 510/2016. Resultados e Conclusões: Overall, 60.2% (95% CI: 59.9–60.5) of adults met criteria for CKM ≥1: 33.4% at Stage 1 (excess adiposity) and 26.8% at Stage 2 (metabolic disease). Prevalence increased from 51.9% in 2006 to 69.3% in 2023 (+0.91 pp/year; R^2=0.973; p< 0.001), with a steeper rise among women (+1.06 vs +0.75 pp/year) and young adults aged 18–29 (+0.97 pp/year). A marked age gradient was observed: 38.2% at 18–29 years rising to 81.1% at ≥60 years. Educational disparities were pronounced, with a prevalence of 71.0% among those with ≤8 years of schooling versus 53.3% with higher education (p< 0.001). Spatial analysis demonstrated significant clustering (Moran's I=0.238; p= 0.024), ranging from 51.8% in Palmas to 64.2% in Rio de Janeiro across 27 capitals. Stage 0 prevalence declined from 48,1% to 30.7% (- 0.91 pp/year), while Stage 1 rose from 28.0% to 38.9% (+ 0.68 pp/year), indicating an ongoing epidemiological transition. In multivariable regression, age (aOR=1.99 per 10 years), female sex (aOR=1.07), and lower education were independently associated with CKM ≥2. CKM syndrome has become a majority-level condition among Brazilian adults, with a sustained generational shift that demands integrated cardiometabolic prevention strategies to mitigate the future burden of end-stage cardiovascular and renal diseases in middle-income countries.

CLINICAL IMPACT OF OMEGA-3 FORMULATIONS AND DOSAGE ON CARDIOVASCULAR OUTCOMES: A SYSTEMATIC REVIEW AND RISK OF BIAS ASSESSMENT (2018–2026).

HANNAH UNGER1; ESTHER ELGRABLY DE MELO E SILVA ZATZ1; MARCOS VINICIUS LOPES DE OLIVEIRA1; GABRIEL HOACY VIANA LARRAT MIRANDA1; SOFIA BARCESSAT FREIRE1; FABIANA MACHADO ALVES1; GABRIELA CARVALHO DE ASSUNÇÃO1; MARIA FERNANDA CAMPOS NEVES DOS SANTOS1; PALOMA PANZUTI RODRIGUES1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: The cardiovascular (CV) efficacy of Omega-3 supplementation is a subject of intense debate. This study synthesizes evidence from landmark trials to clarify how formulation (purified EPA vs. mixtures) and dosage influence Major Adverse Cardiovascular Events (MACE) and safety profiles. Objetivos: To compare the efficacy and safety of purified EPA versus EPA+DHA mixtures on major cardiovascular events (MACE) and atrial fibrillation (AF) risk. Métodos: A systematic review was conducted following PRISMA guidelines using clinical datasets (up to 2026) from PubMed and Cochrane. The descriptors (Decs/MeSH) used were "Fatty Acids, Omega-3", "Eicosapentaenoic Acid", "Cardiovascular Diseases" and "Atrial Fibrillation". RCTs reporting MACE and incident atrial fibrillation (AF) were included. Selection was performed through peer review. Due to clinical and methodological heterogeneity, a narrative review was conducted. Quality assessment was performed using the Cochrane Risk of Bias (RoB 2) tool. Resultados e Conclusões: Were found 9,588 records and used 4 landmark trials that met all inclusion criteria. High-dose purified EPA (REDUCE-IT, 4g/day) significantly reduced MACE by 25% (p < 0.001), although it presented "some concerns" in RoB assessment due to the mineral oil comparator. Conversely, high-dose EPA+DHA mixtures (STRENGTH, 4g/day) were clinically neutral (p=0.84) and categorized as low risk of bias. Standard-dose supplementation (VITAL, 1g/day) demonstrated absolute neutrality, with no significant reduction in MACE (p=0.24) and no increased risk of incident AF (p=0.19), maintaining a low risk of bias across all domains. Safety data indicates that arrhythmic signals (AF) are dose-dependent (observed at 4g/day but not at 1g/day). In conclusion, cardiovascular benefits are exclusively associated with high-dose purified EPA. While high doses of any formulation may carry an arrhythmic risk, standard doses (1g/day) as seen in VITAL are safe but ineffective for MACE reduction. These findings support a precision-medicine approach to Omega-3 prescription based on specific clinical goals.

16360

COMPARATIVE ANALYSIS OF FINERENONE VERSUS SGLT2 INHIBITORS IN CARDIOVASCULAR PROTECTION IN PATIENTS WITH CHRONIC KIDNEY DISEASE: A SYSTEMATIC REVIEW

VITOR MORAIS BRAMBILA1; IRVING GABRIEL ARAÚJO BISPO1;

(1) UNIVERSIDADE MUNICIPAL DE SAO CAETANO DO SUL - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Chronic kidney disease (CKD) is closely linked to an elevated cardiovascular risk, requiring therapeutic strategies that go beyond glycemic and blood pressure control. Farinone, a selective non-steroidal mineralocorticoid receptor (MR) antagonist, and sodium-glucose cotransporter 2 (SGLT2) inhibitors have emerged as cornerstones of cardiorenal protection, acting through distinct yet complementary pathophysiological mechanisms. While finerenone focuses on reducing MR-mediated inflammation and fibrosis, SGLT2Is primarily act to restore tubuloglomerular feedback and provide hemodynamic and metabolic benefits. Objetivos: A comparison of the cardiovascular efficacy, mechanisms of action, and safety of finerenone versus SGLT2 inhibitors in patients with CKD, while also evaluating the potential of combination therapy. Métodos: An systematic review was conducted following the PRISMA flowchart recommendations, encompassing the stages of identification, screening, eligibility, and inclusion of studies. The search was performed in the PubMed, Cochrane, and LILACS databases. Resultados e Conclusões: Results: Fineronone demonstrated a 14% reduction in the composite cardiovascular outcome, driven primarily by a 22% decrease in hospitalizations for heart failure (HF). Its benefit is particularly robust in patients with elevated albuminuria, preventing adverse cardiac remodeling and diastolic dysfunction. On the other hand, iSGLT2 inhibitors show a 17% reduction in cardiovascular death and a 30% reduction in hospitalization for HF (p<0.05; RR 0.70). Although there are no direct head-to-head trials, network meta-analyses suggest comparable efficacy for major adverse cardiovascular events (MACE). In terms of safety, finerenone is associated with an increased risk of hyperkalemia (10.8% vs. 5.3% with placebo), while iSGLT2 inhibitors show a reduced risk of acute kidney injury and hypoglycemic events (p<0.05; RR 0.93). Recent data indicate that adding finerenone to iSGLT2s may reduce all-cause mortality by 63% (HR 0.37), suggesting a significant additive cardioprotective effect. Conclusions: Both finerenone and iSGLT2s are effective in reducing cardiovascular events in patients with CKD. iSGLT2s show superiority in preventing hospitalization for HF, while finerenone offers an essential pathway for blocking fibrosis and inflammation, especially in patients with persistent albuminuria. Combination therapy is a rational and promising strategy for the comprehensive management of patients with chronic kidney diseas

COMPARISON OF ANKLE-BRACHIAL INDEX VALUES OBTAINED BY POINT-OF-CARE ULTRASOUND AND THE OSCILLOMETRIC METHOD IN HEMODIALYSIS PATIENTS

ANA LIZ LIMA BARRETO1; ADSON ARAGÃO ARAÚJO SANTOS1; HELLEN CARVALHO LIMA1; MATHEUS RODRIGUES LOPES1; ADIRLENE PONTES OLIVEIRA TENÓRIO1;

(1) UNIVERSIDADE FEDERAL DO VALE DO SAO FRANCISCO - PAULO AFONSO - BA - BRASIL;

Introdução/Fundamentos: Peripheral arterial disease (PAD) increases mortality risk in the dialysis unit. While the ankle-brachial index (ABI) serves as a classic, non-invasive screening standard, its traditional oscillometric application has a blind spot: it relies purely on pressure readings. Point-of-care ultrasound (POCUS), however, addresses this issue. It allows clinicians to visually assess vascular damage, providing an immediate morphological assessment of stiffened arteries at the bedside. Objetivos: To determine whether ABI values derived from modern POCUS align with the traditional oscillometric method in an end-stage renal disease cohort. Métodos: In this cross-sectional study of 85 hemodialysis patients, bilateral systolic blood pressures (brachial, posterior tibial, and dorsalis pedis) were measured after a five-minute rest. To determine the ABI, investigators applied two concurrent techniques: a portable POCUS device (pulsed Doppler mode with a linear transducer) and the traditional oscillometric approach (stethoscope and sphygmomanometer). Concordance between the methods was subsequently evaluated using Spearman's rank correlation. Resultados e Conclusões: The cohort exhibited a high prevalence of vascular disease, nearly a quarter of the cohort (24.7%) presenting an ABI indicative of PAD (≤ 0.9), and 22.4% showing severe arterial calcification (≥ 1.3). Despite this high degree of arterial calcification, results demonstrated a strong correlation between ABI values obtained through the oscillometric method and POCUS (p<0.0001, r>0.98; Figure 1). This high correlation suggests that the low-cost, accessible oscillometric technique remains reliable for routine ABI assessment in hemodialysis patients. However, POCUS offers the clinical benefit of directly visualizing arterial calcifications, which are very common in this group. It provides a detailed morphological assessment along with physiological information screening.

19352

COMPARISON OF THE EFFICACY AND SAFETY OF EZETIMIBE, INCLISIRAN, AND BEMPEDOIC ACID AS ADJUNCTIVE THERAPY TO STATINS FOR REDUCING LDL CHOLESTEROL IN PATIENTS WITH HYPERCHOLESTEROLEMIA: A SYSTEMATIC REVIEW.

ISA MENDES MOREIRA1; AMANDA COELHO CALANDRINI DE AZEVEDO1; GLEYDSON DE AZEVEDO ALMEIDA2; JOSE CARLOS FAVACHO FURLAN2; MARIA EDUARDA ZAMBRUNA SANTANA LIMA1; ANTONIO MARIA ZACARIAS ARAUJO MONTEIRO1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Hypercholesterolemia, characterized by elevated LDL levels, is a significant risk factor for cardiovascular disease. Although statins are the first-line treatment, adjuvant therapies such as ezetimibe, inclisiran, and bempedoic acid are recommended when statins fail to achieve therapeutic goals or are poorly tolerated. The aim of this study was to compare the efficacy and safety of these adjuvant therapies, when combined with statins, in reducing LDL cholesterol in patients with hypercholesterolemia. Objetivos: Evaluate the efficacy and safety of the adjuvants ezetimibe, inclisiran, and bempedoic acid, when associated with statins, for the reduction of LDL cholesterol in patients with hypercholesterolemia. In addition, it seeks to guide clinical practice regarding the most appropriate therapeutic choice, contributing to better management of hypercholesterolemia and to the reduction of associated cardiovascular events. Métodos: A systematic review was conducted using PubMed, BVS, and Cochrane Library, following the PRISMA 2020 guidelines and using the RoB 2.0 tool to assess the risk of bias. Randomized clinical trials were selected that compared ezetimibe, inclisiran, and bempedoic acid in combination with statins. The primary outcome was the reduction of LDL-c levels, with additional analysis of adverse events. Resultados e Conclusões: 255 studies were identified, with inclusion of 10 randomized clinical trials. Combination therapies showed consistent superiority over statin monotherapy. Studies with ezetimibe demonstrated significant additional LDL-c reductions, including >50% when combined with pitavastatin, while combinations with rosuvastatin had comparable efficacy to higher doses alone, with less drug exposure. The triple combination (atorvastatin + ezetimibe + bempedoic acid) had the greatest impact, with >90% of patients achieving reductions >50% and LDL-c <70 mg/dL. Inclisiran showed sustained LDL-c reductions of approximately 47–50% with semi-annual administration. Bempedoic acid reduced LDL-c by 21–28%, especially in statin-intolerant patients. Regarding safety, all studies reported low rates of serious adverse events, with no significant increase versus monotherapy. Tolerability was particularly favorable for inclisiran and bempedoic acid. Combination therapies are effective and safe alternatives, especially for patients who struggle to achieve targets with statins. However, further long-term studies are needed to consolidate their role in hypercholesterolemia treatment.

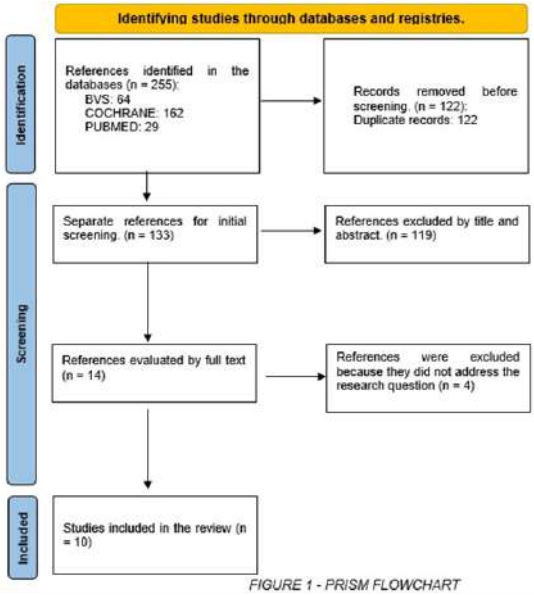

FIGURE 1 - PRISM FLOWCHART

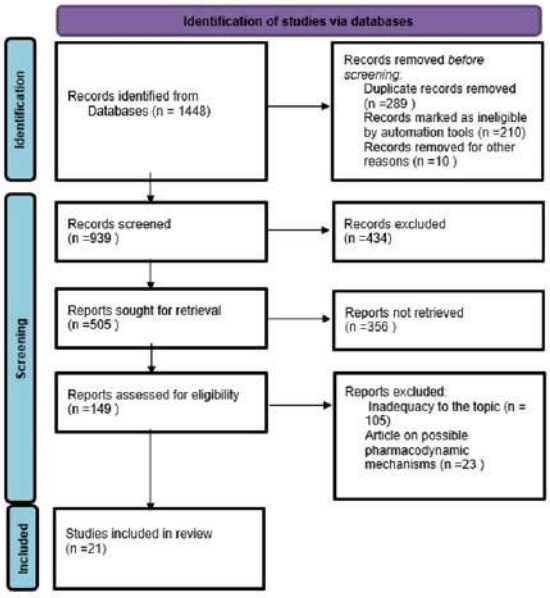
CORRELATION BETWEEN DIASTOLIC DYSFUNCTION AND DIFFERENT DEGREES OF HEPATIC STEATOSIS: A CROSS-SECTIONAL ANALYSIS OF PATIENTS FOLLOWED AT A TERTIARY CARE HOSPITAL

GABRIEL MOHR HENN1; ROBERTO DONIZETE NOBRE JUNIOR1; THIEGO BELLO RIBEIRETE1; NICOLE CAROLINE DE ALCANTARA1; ANA CRISTINA CAMAROZANO WERMELINGER1;

(1) UNIVERSIDADE FEDERAL DO PARANÁ - CURITIBA - PR - BRASIL;

Introdução/Fundamentos: Metabolic Dysfunction–Associated Steatotic Liver Disease (MASLD) is currently one of the leading causes of chronic liver disease worldwide and is characterized by the presence of hepatic steatosis associated with criteria for metabolic syndrome.Recent evidence has suggested that MASLD may also be associated with subclinical cardiovascular abnormalities detectable on echocardiography. Objetivos: This study aimed to evaluate alterations in diastolic function parameters among patients with hepatic steatosis who underwent transthoracic echocardiography. Métodos: A cross-sectional analytical study was conducted including 72 patients diagnosed with MASLD and followed at the Metabolic Syndrome outpatient clinic of a tertiary care hospital. Hepatic elastography and abdominal ultrasound were used to stratify steatosis severity into two distinct groups according to controlled attenuation parameter (CAP) values, using a cutoff of 268 dB/m: Group 1 (mild steatosis, n = 23) and Group 2 (moderate/severe steatosis, n = 49). Echocardiographic variables related to the diastolic phase of the cardiac cycle were assessed, including degree of diastolic dysfunction (DD), E/e' ratio, E/A ratio, left atrial volume (LAV), and left ventricular ejection fraction (LVEF). Inclusion criteria comprised age ≥18 years and a previous diagnosis of MASLD. Exclusion criteria included inability to undergo hepatic elastography, abdominal ultrasound, or echocardiography, as well as isolated liver cirrhosis. Resultados e Conclusões: Categorical variables were analyzed using the Chi-square test, whereas numerical variables were assessed using the Mann–Whitney U test. Comparison of numerical variables (LVEF, LAV, E/e' ratio, and DD) between groups did not demonstrate statistically significant differences in any parameter (p > 0.05). However, analysis of the E/A ratio revealed a statistically significant difference between groups (p = 0.0321), with Group 2 presenting slightly higher values. These findings are summarized in Table 1. Overall, most of the echocardiographic parameters previously associated with MASLD in the literature were not significantly correlated with steatosis severity in the present sample, except for the E/A ratio. This finding may be partly explained by the relatively limited sample size. Nevertheless, the results suggest that the E/A ratio may represent one of the earliest markers of cardiac involvement in patients with advanced hepatic steatosis.



15841

DIFFERENCE IN OUTCOME REDUCTION BETWEEN GLP-1 ANALOGS IN PATIENTS WITH PREVIOUS CARDIOVASCULAR EVENT: A SYSTEMATIC REVIEW

ISABELLA DE CARVALHO SALU DOS SANTOS1; MARIANA MARTINS DE OLIVEIRA1; MARIO PIETRO SCUPINO ROCCO1; CATARINA MELLO DA MATA1; IRVING GABRIEL ARAUJO BISPO1; GABRIELA TAIRA MORENO1; LARISSA HIROMI YAMAMOTO1; PEDRO HENRIQUE NOVOA FERREIRA1; VICTORIA LUQUE DE BARROS COBRA1;

(1) UNIVERSIDADE MUNICIPAL DE SAO CAETANO DO SUL - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Glucagon-like peptide-1 (GLP-1) analogs have emerged in the last two decades as an important therapeutic strategy in the treatment of type 2 diabetes mellitus (T2DM), especially after the demonstration of additional cardiovascular benefits beyond glycemic control. These drugs have come to occupy a central role in cardiometabolism with growing evidence demonstrating a favorable impact on cardiovascular parameters, including anti-inflammatory and anti-atherogenic effects. Objetivos: To conduct a systematic review addressing the different types of GLP-1 analogs according to their cardiovascular benefits. Métodos: This systematic review was developed according to the PRISMA flowchart. The review protocol was registered in the Open Science Framework. The search for articles was conducted in the electronic databases PubMed (MEDLINE), LILACS, and Cochrane Central Register of Controlled Trials (Cochrane Library), using the MeSH descriptors: “GLP-1 Analogs”, “Cardiovascular Disease”, and “Cardiovascular Mortality”.1448 articles were found published in the PubMed, SciELO, Cochrane Library, and LILACS platforms. After evaluating the articles, we selected 21 studies for our systematic review. The quality of the Randomized Controlled Trials was assessed using the revised Cochrane tool for risk of bias in randomized trials (RoB2). Resultados e Conclusões: In the recent STEP HFpEF DM study, which evaluated the efficacy of semaglutide in patients with heart failure with preserved ejection fraction (HFpEF) related to obesity and type 2 diabetes, a reduction in time to the first heart failure event was observed in the intervention group, but as a secondary outcome. In a large clinical study, liraglutide reduced cardiovascular events (non-fatal myocardial infarction or non-fatal stroke) and cardiovascular mortality compared to placebo in patients with at least one cardiovascular disease or cardiovascular risk factor.The results of the Select study demonstrated a 19% reduction in all-cause mortality (95% CI 0.71–0.93), a 28% reduction in non-fatal myocardial infarction (95% CI 0.61–0.75), a 23% reduction in coronary artery bypass graft procedures (95% CI 0.68–0.87), and a 22% reduction in nephropathy progression.Randomized clinical trials and prospective studies have indicated improved clinical, metabolic, and quality of life outcomes in this patient profile, suggesting a potential therapeutic role for GLP-1 agonists in this context.

EFFECT OF ANTI-TNF AND ANTI-IL-6 THERAPY ON THE CARDIOVASCULAR RISK OF PATIENTS WITH RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW

EDER OLIVEIRA COSTA1; GIULIA OLIVEIRA RAMALHO1; DAVI DANTAS FREIRE1; RODRIGO GOUVEIA AZEVEDO BORGES1; RAFAEL LIMA ARAUJO CECCHINI SOUZA1; RODRIGO ALVES DE SOUZA GALVÃO2;

(1) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL; (2) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Rheumatoid arthritis (RA) confers a high cardiovascular (CV) risk. Biologic therapies like Tumor Necrosis Factor (TNF) and Interleukin-6 (IL-6) inhibitors are essential for clinical control. However, their impact on atherothrombotic risk remains debated, mainly due to the known effect of IL-6 inhibitors in elevating LDL levels. Objetivos: To compare the incidence of MACE and atherogenic biomarker profiles between RA patients treated with Anti-IL-6 versus Anti-TNF therapies. Métodos: Following PRISMA guidelines, a systematic review of PubMed and EMBASE was conducted, restricted to articles from the last 10 years. Using PICOT criteria, clinical trials and observational studies comparing cardiovascular risk between Anti-TNF and Anti-IL-6 therapies in adult RA patients were included. Two independent reviewers screened 274 initial records; conflicts were resolved by a third author. After duplicate removal and title/abstract screening, 30 full-text articles were reviewed. Ultimately, 7 studies met the eligibility criteria and were selected. Methodological quality was evaluated using a standardized risk of bias tool. Resultados e Conclusões: An analysis of the evidence demonstrated no increased risk of major adverse cardiovascular events (MACE) associated with anti-IL-6 therapy compared to anti-TNF therapy (Hazard Ratios: 0.84 to 1.05). In cohort studies, tocilizumab exhibited a vascular safety profile superior to that of specific biologics, yielding a relative risk reduction when compared with etanercept (HR 1.10) and adalimumab (HR 1.33). Despite the isolated increase in low-density lipoprotein (LDL) induced by IL-6 inhibitors, this effect was counterbalanced by substantial reductions in proatherogenic biomarkers, including lipoprotein(a) (-41%) and C-reactive protein (-94%; p < 0.0001). Furthermore, evidence indicated that the presence of baseline cardiovascular comorbidities did not compromise the clinical efficacy of anti-IL-6 treatment, in contrast to anti-TNF therapy, which demonstrated a loss of efficacy. In conclusion, Anti-IL-6 therapies exhibit a cardiovascular safety profile equivalent or superior to that of anti-TNF agents, demonstrating that the isolated elevation in LDL does not translate into an increased incidence of MACE. Therefore, anti-IL-6 therapy is consolidated as a safe and effective strategy for mitigating cardiovascular risk in patients with rheumatoid arthritis (RA).

EFFECTIVE ARTERIAL ELASTANCE REVEALS ALTERED VENTRICULAR–ARTERIAL COUPLING IN CYSTIC FIBROSIS: POSITIVE ASSOCIATION WITH AUGMENTATION INDEX

ISABELLA VASCONCELOS FERNANDES1; IGOR ANTÔNIO CARVALHO-RIBEIRO1; ANNA CLARA GUEDES-SARAIVA1; REBECA HELLEM DA SILVA BORGES1; MARCELO BICALHO DE FUCCIO2; BRUNO PORTO PESSOA1; MARIA DA GLÓRIA RODRIGUES-MACHADO1;

(1) FACULDADE DE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) FACULDADE DE MEDICINA UNIVERSIDADE PROFESSOR EDSON ANTONIO VELANO - UNIFENAS - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: Cystic Fibrosis (CF) is recognized as a disease with significant cardiovascular involvement. While the Augmentation Index (AIx@75) reflects arterial stiffness and ventricular afterload, the Effective arterial elastance (Ea) provides a more integrated assessment of arterial load and ventricular–arterial coupling. However, the role of Ea in CF remains poorly characterized, particularly in relation to established indices of arterial stiffness. Objetivos: To compare and verify the association between the AIx@75 and Ea in CF patients. Métodos: This cross-sectional observational analytical study included 164 patients allocated into CF group (n=82, 31.21±11.59 years) and CTRL (n=82, 31.09±11.74 years), matched by age and sex. The oscillometric Mobil-O-Graph device (IEM, Solberg, Germany) was used to noninvasively estimate cardiovascular parameters based on brachial blood pressure. Ea was estimated by ratio of peripheral mean arterial pressure (MAP) to stroke volume (SV). The variables were compared using the unpaired test or the Mann-Whitney test when appropriate. Pearson or Spearman correlation coefficients were used, as appropriate, to assess the association between the AIx@75 and Ea and p<0.05 was considered statistically significant. Resultados e Conclusões: Ea and AIx@75 were significantly higher in the CF group (1.80±0.34mmHg/mL and 29.11±10.22%) compared to the CTRL (1.53±0.3mmHg/mL and 18.48±7.93%). There was a strong positive correlation between Ea and AIx@75 (r 0.84 | CI95%0.7652–0.8957;p<0.001). Reflection coefficient and augmentation pressure were also significantly higher in the CF group (62.44±6.54% and 6.52±2.89mmHg) compared to the CTRL (57.71±7.34% and 5.30±2.39mmHg). Peripheral systolic blood pressure (pSBP) was significantly smaller in the CF group (113.9±11.84mmHg) compared to the CTRL (117.3±10.76mmHg). Heart rate was significantly higher in the CF group (87.26±14.65bpm) compared to the CTRL (76.93±9.46bpm), while stroke volume and cardiac output were significantly lower in the CF group (52.53±13.44ml and 4.55±0.56 L/min) compared to the CTRL (63.95±12.97ml and 4.83±0.61L/min). These findings reveal a previously underrecognized cardiovascular phenotype in CF, characterized by increased afterload despite lower peripheral blood pressure and reduced SV. Noninvasive assessment of Ea may provide incremental value for early cardiovascular risk stratification and pathophysiological understanding in this population.

EFFECTS OF SGLT2 INHIBITORS ON BLOOD PRESSURE IN INDIVIDUALS WITHOUT THE CLASSIC INDICATIONS FOR THESE DRUGS: A SYSTEMATIC REVIEW

ERIK WILLIAM FARIAS COELHO1; ZILDIVAN ROCHA DO NASCIMENTO ARAUJO1; LEANDRO RAFAEL OLIVEIRA E SILVA1; VICTOR LENO SILVA PAES1; ALEF HENRIQUE DO ESPÍRITO SANTO LIMA1; KHAELSON ANDREY BARROSO MOURA1; KAMILA LUANA SANTOSS SILVA2; VIVIANE PATRICIA LOPES CARDOSO1; RITA DE CASSIA SILVA DE OLIVEIRA1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Systemic arterial hypertension remains a leading modifiable cardiovascular risk factor worldwide. Sodium-glucose cotransporter 2 inhibitors (SGLT2i), initially developed for type 2 diabetes mellitus, have demonstrated pleiotropic effects, including blood pressure reduction, through natriuresis, osmotic diuresis, and attenuation of sympathetic activity, mechanisms potentially independent of glycemic status. Objetivos: To evaluate the effects of SGLT2 inhibitors on blood pressure in adults without classic indications for their use, specifically without diabetes mellitus, heart failure, or chronic kidney disease. Métodos: Systematic review conducted according to PRISMA 2020 guidelines. Searches were performed in PubMed/MEDLINE, Cochrane, Embase, LILACS, and Web of Science, covering publications up to March 2026 with no language restrictions. Randomized clinical trials (RCTs) in non-diabetic adults without heart failure or chronic kidney disease, receiving SGLT2i as monotherapy or add-on therapy versus placebo or comparable standard treatment, reporting blood pressure as an outcome, were included. Risk of bias was assessed using the Cochrane RoB 2.0 tool and evidence quality by the GRADE approach. The protocol for this review was registered on the PROSPERO platform (CRD420261362873). Resultados e Conclusões: Of 195 records identified, 4 RCTs were included (canagliflozin, dapagliflozin, empagliflozin vs. placebo; follow-up: 4–52 weeks). Two trials showed statistically significant reductions in systolic blood pressure (−5.1 mmHg and −12.0 mmHg). Significant diastolic reduction was observed in one study (−2.0 mmHg via 24-hour ABPM). Weight loss was consistent (−2.7 to −3.0 kg) in three trials; no hypoglycemia episodes were reported. GRADE assessment indicated low evidence quality for blood pressure outcomes and moderate quality for weight and glycemic safety. SGLT2 inhibitors may offer modest antihypertensive benefits in non-diabetic individuals, but confirmation by larger, well-designed trials is needed before incorporation into routine antihypertensive management.

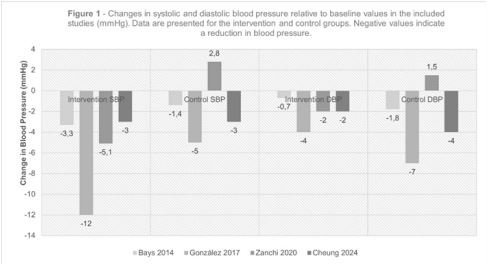

Figure 1 - Changes in systolic and diastolic blood pressure relative to baseline values in the included studies (mmHg). Data are presented for the intervention and control groups. Negative values indicate a reduction in blood pressure.

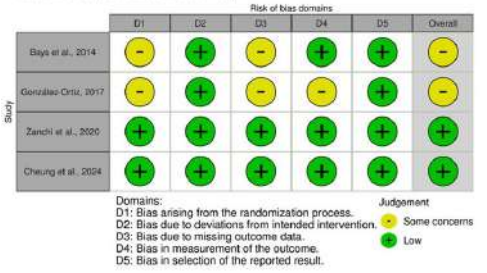

Figure 2 - Assessment of the risk of bias in the included randomized clinical trials, according to the RoB 2 tool (Cochrane Risk of Bias Tool)

EFFICACY AND SAFETY OF BEMPEDOIC ACID IN PATIENTS WITH ESTABLISHED ATHEROSCLEROTIC CARDIOVASCULAR DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSES OF RANDOMIZED CLINICAL TRIALS

HENRIQUE GABRIEL SANTOS1; JAMES NOBRE DE SENA2; MARIA CLARA AGUIAR TOMAZ3; DOUGLAS MENDES SOARES4; CLEYTON CAUÃ SANTOS BRITO1; ROBERTO VICTOR PAIVA CAMURÇA1; EMILLY BITTENCOURT DE SOUZA MARTINS1; NEWTON DIÓGENES PINHEIRO NETO2; THAÍS PEREIRA BELO5; ANTONIO JHONATA ALVES LIMA1; AILTON CESAR DE ARAÚJO FILHO1; LUIZ GUSTAVO DA SILVA CASTELO BRANCO1;

(1) UNIVERSIDADE ESTADUAL DO CEARÁ - UECE - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (3) UNIVERSIDADE CHRISTUS - UNICHRISTUS - FORTALEZA - CE - BRASIL; (4) UNIVERSIDADE ESTADUAL DO CEARÁ - FORTALEZA - CE - BRASIL; (5) UNIVERSIDADE ESTADUAL DO CEARÁ - UECE - QUIXERAMOBIM - CE - BRASIL;

Introdução/Fundamentos: Atherosclerotic Disease Cardiovascular (ASCVD) is the leading cause of morbidity and mortality worldwide. Although statin therapy is the mainstay of treatment, many patients do not achieve therapeutic goals or experience intolerance. The Bempedoic Acid (BA) emerges as a promising alternative, with a distinct mechanism of action and a favorable safety profile. This systematic review with meta-analysis evaluated the efficacy and safety of BA in patients with established ASCVD. Objetivos: To evaluate the efficacy and safety of BA 180 mg/day in combination with a statin, compared to placebo, in patients with ASCVD. Métodos: This study is a systematic review with meta-analysis of randomized, double-blind, placebo-controlled clinical trials, following the PRISMA guidelines. The PUBMED, Cochrane Central, Scopus and Web of Science databases were consulted. Inclusion criteria were patients older than 18 years with ASCVD who received BA 180mg/day in combination with a statin. The primary efficacy outcomes were MACE - 4 (Cardiovascular death, non-fatal acute myocardial infarction, non-fatal stroke and coronary revascularization), reduction in LDL-c levels, and high-sensitivity C-reactive protein (hs-CRP). Safety outcomes included hyperuricemia, gout, worsening renal function, cholelithiasis and muscle events. Statistical analysis was performed using a random-effect model, and the risk of bias was assessed using the Cochrane RoB 2 tool. Resultados e Conclusões: Four studies were included (CLEAR Outcomes, 2023; Serour M H, 2024; Colivicchi, Furio., 2025; Sayed, Ahmed., 2024) totaling 18.496 patients (BA: 9.959: Control: 8.537), with a median follow-up of 3,4 years (40,6 months). The mean age was 65,3 years, 45,6% were female and 42,5% had diabetes mellitus. Treatment with bempedoic acid resulted in a lower incidence of primary MACE - 4 events per 100 patient-years (5.0 vs 6.2; HR, 0.80; 95% CI, 0.72 - 0.82; P < 0.001), but increased the risk of gout, renal failure and cholelithiasis. Interestingly, it also reduced the risk of myalgia after starting statin therapy. Bempedoic acid represents an effective and safe therapeutic option for patients with established ASCVD, especially those with statin intolerance or who do not achieve therapeutic goals with standard treatment.

EFFICACY AND SAFETY OF FXIA PLUS STANDARD OF CARE VERSUS STANDARD OF CARE IN SECONDARY STROKE PREVENTION: A BAYESIAN META-ANALYSIS

DEBORA DE QUEIROZ MENEZES1; ANISIO UCHOA LEITE SANTANA2; LUCAS DE QUEIROZ MENEZES3; CLARA UCHOA LEITE SANTANA3; TIAGO JOSÉ NOGUES DE ALMEIDA3; ANDRÉ JORGE NOGUES DE ALMEIDA3; ICARO HEICKMEN TAVEIRA EGÍDIO DE MELO3; RAFAEL NUNES DAHER2; AMANDA LIRA GONÇALVES DE MEDEIROS3; MARINA UCHÔA DE ARAÚJO3; ISABELLY LOUISE DE SOUZA PORANGABA1; HENRIQUE TROMBINI PINESI4;

(1) FACULDADE DE MEDICINA DE OLINDA - OLINDA - PE - BRASIL; (2) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (3) UFRN - NATAL - RN - BRASIL; (4) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Secondary prevention of ischemic stroke remains a clinical challenge, requiring a balance between antithrombotic efficacy and bleeding risk. While Factor XI (FXI) inhibitors like asundexian and milvexian are theorized to decouple hemostasis from thrombosis, their clinical utility as an add-on therapy to standard of care (SoC) requires rigorous quantification. Objetivos: To evaluate the efficacy and safety of FXIa 50mg plus SoC compared with SoC alone in patients undergoing secondary stroke prevention. Métodos: We systematically searched Pubmed, Embase, Cochrane, and ClinicalTrials.gov through March 2026 for Randomized Controlled Trials (RCTs). A Bayesian hierarchical model was fitted in Stan using Hamiltonian Monte Carlo with the No-U-Turn Sampler. Treatment effects were expressed as hazard ratios (HR) with 95% credible intervals (CrI). We calculated the posterior probability of any benefit [Pr(HR<1)] and of a clinically relevant effect [Pr(HR<0.85)]. For safety, a non-inferiority tolerance threshold was set at Pr(HR<1.25). Statistical analysis was performed using the brms package in R. Resultados e Conclusões: We included 14,239 patients across 3 RCTs with FXIa as an add-on therapy. For stroke recurrence, asundexian demonstrated a clear protective signal (HR 0.74; 95% CrI 0.58–0.97), driven by a 98.2% posterior probability of superiority [Pr(HR<1)], an 89.8% probability of delivering a clinically relevant risk reduction of at least 15% [Pr(HR<0.85)], and a 93.4% predictive probability that a future study will demonstrate benefit. Regarding safety, the risk of major bleeding was higher in the FXIa group (HR 1.14; 95% CrI 0.65–2.15), characterized by substantial uncertainty. Posterior estimates revealed an almost 73% probability of increased bleeding risk, and the probability that the therapy meets the clinical tolerance threshold for safety (HR < 1.25) was 64.8%. Consequently, the probability of a future study finding a safety benefit for the intervention was 27.2%. In conclusion, while FXIa provides a highly probable signal for stroke reduction, its safety profile remains a concern due to the high posterior probability of increased major bleeding pending confirmation in future studies.

EFFICACY OF RESPIRATORY VACCINATION IN CORONARY ARTERY DISEASE

ISABELL LUCENA MENDES1; RODRIGO RUFINO PEREIRA SILVA2;

(1) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PB - BRASIL; (2) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases, especially coronary artery disease, are the leading global cause of death. Despite modern therapies, patients face residual risks of major adverse cardiovascular events. Acute respiratory infections like influenza and pneumonia act as potent systemic triggers, heavily exacerbating this risk. Influenza elevates the likelihood of myocardial infarction by up to ten times rapidly after infection. These infections provoke an inflammatory cytokine storm that leads to atherosclerotic plaque rupture and thrombosis. Objetivos: Although guidelines strongly advocate for influenza and pneumococcal immunizations, actual vaccination rates remain inadequately low in clinical practice. Métodos: Researchers systematically reviewed databases including MEDLINE and Embase for literature published between 2021 and 2026. The focus was on adult patients with stable coronary artery disease receiving influenza or pneumococcal vaccines versus placebo or no vaccine. The selection included randomized controlled trials and observational studies, explicitly excluding pediatric or uncontrolled reports. Independent reviewers evaluated bias using standard tools and performed quantitative meta-analysis utilizing a random-effects model. Resultados e Conclusões: The analysis of 45 studies revealed distinct efficacy profiles for both interventions. Influenza clinical trials demonstrated a significant 30% to 34% relative risk reduction for major cardiovascular events, mortality, and myocardial infarction. This protective benefit is most pronounced in patients with recent acute coronary syndromes and rivals the efficacy of interventions like statins and smoking cessation. Furthermore, evidence indicates that standard vaccine doses are completely sufficient to achieve this cardiovascular protection. In contrast, pneumococcal vaccination outcomes remain actively debated. While large observational studies indicated reduced mortality and infarction, the primary clinical trial failed to show significant decreases in ischemic events. This discrepancy may stem from healthy user bias in observational data or a lack of statistical power in the clinical trial. Despite limitations regarding seasonal variables, the low number needed to treat confirms the high cost-effectiveness of implementing these immunizations in cardiology. Influenza immunization is an indispensable, cost-effective measure that reduces cardiovascular events in coronary disease. Pneumococcal vaccine efficacy still requires further randomized trials.

Table 1 Main studies on vaccination efficacy in MACE reduction in cardiovascular disease patients

Author(s)	Study Design	Studied Population	Intervention	Main Results	Limitations
Vardeny et al., 2021 (INVESTED)	Multicenter RCT, double-blind, active comparator; 157 centers, USA/Canada; 3 influenza seasons	5,260 patients with recent AMI or HF hospitalization + ≥1 additional risk factor; mean age 65 years; 75% men	High-dose trivalent vs. standard-dose quadrivalent influenza vaccine	Primary: all-cause death or cardiopulmonary hospitalization. Co-primary: HR 1.06; 95% CI 0.91-1.24; P=0.21. No difference between high dose and standard dose. More adverse reactions in the high-dose group	Absence of placebo arm; comparison between formulations, not against non-vaccination; possible attenuation of the effect due to high seroprotection rate in both groups
Loeb et al., 2022 (IVVE)	Multicenter RCT, double-blind, placebo-controlled; 30 centers in 10 countries (Asia, Africa, Middle East)	5,129 patients with HF (NYHA II-IV); age ≥≥18 years; 52.1% women; annual vaccination for up to 3 years	Standard-dose inactivated influenza vaccine vs. placebo (saline)	Co-primaries: (1) CV death, non-fatal AMI, non-fatal stroke; (2) recurrent composite including HF hospitalization. 1: HR 0.93; 95% CI 0.81-1.07; P=0.30. 2: HR 0.92; 95% CI 0.84-1.02; P=0.12. Significant reduction in all-cause	Recruitment impacted by the COVID-19 pandemic; variable seasonality among regions; predominantly NYHA II population (70%); low influenza circulation in some periods
Ware et al., 2026 (AUSPICE)	Multicenter RCT, double-blind, placebo-controlled; 6 centers in Australia; mean follow-up of 7 years	4,725 community-dwelling adults, 55-80 years old, with ≥2 CV risk factors (obesity, HTN, hypercholesterolemia), no previous CV event; 52% men	23-valent pneumococcal polysaccharide vaccine (PPSV23) vs. placebo (saline)	Primary: composite of fatal/non-fatal AMI or ischemic stroke. HR 0.80, 95% CI 0.63-1.28; P=0.57. No significant difference in the primary endpoint nor in the exploratory endpoints (all-cause mortality, hospitalizations)	Study significantly underpowered (event rate lower than expected); primary prevention population; single dose without booster; endpoints obtained by registry linkage
Anderson et al., 2025 (PANDA II)	Cluster-randomized RCT, open-label, multicenter; 12 hospitals in China; 3 influenza seasons (2021-2024)	Hospitalized patients with acute HF (NYHA II-IV), age ≥18 years; pre-hospital discharge vs. outpatient vaccination	Free influenza vaccine pre-hospital discharge vs. usual care (vaccination counseling)	Primary: all-cause death or hospital readmission in 12 months (specific data in the original article). Significant reduction in the primary endpoint	Open-label design (cluster-randomized); exclusively Chinese population; vaccination rate in the control group 1%; potential performance

21913

EFFICACY OF THE POLYPILL IN THE PREVENTION OF MAJOR CARDIOVASCULAR EVENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

THIAGO VITTOR SILVA FREITAS1; LUCAS MARINHO REIS DA CUNHA SILVA1; BRUNO DE FREITAS SILVA1; RAFAEL ALVES DE OLIVEIRA1; POLIANA MARCELINO JOIA1; GIOVANA CASAGRANDE DE ALENCAR1; TAYNARA TAVARES DOS SANTOS1; ISAC DIAS DE OLIVEIRA1; ANA CAROLINA CAVALCANTE GALVÃO1; EDUARDO BERTI ALVIZI1; DANIELLY MARQUES ALVES2; AMANDA OLIVA SPAZIANI1;

(1) UNIVERSIDADE BRASIL - UB - FERNANDÓPOLIS - SP - BRASIL; (2) FACERES - SÃO JOSÉ DO RIO PRETO - SP - BRASIL;

Introdução/Fundamentos: Low adherence to pharmacological treatment is one of the main challenges in the prevention of cardiovascular diseases. The polypill strategy, which combines multiple drugs into a single tablet, has been proposed as an alternative to improve adherence and reduce cardiovascular events. However, the magnitude of its clinical benefit still requires consolidation through quantitative analysis. Objetivos: To evaluate the efficacy of the polypill in reducing major cardiovascular events compared to conventional treatment. Métodos: A systematic review conducted according to PRISMA guidelines, with searches in PubMed, Embase, and Cochrane Library databases up to January 2026. Randomized controlled trials comparing the use of a polypill versus standard treatment in patients with high cardiovascular risk or established disease were included. The primary outcome was a composite of major cardiovascular events (MACE). The meta-analysis was performed using a random-effects model, with calculation of relative risk (RR) and 95% confidence intervals (95% CI). Heterogeneity was assessed using the I^2 index. Resultados e Conclusões: Seven studies were included, totaling 15,238 patients. The use of the polypill was associated with a significant reduction in major cardiovascular events (RR=0.73; 95% CI: 0.65–0.82; p<0.001), with low heterogeneity (I^2=26%). A significant improvement in treatment adherence was observed, without a relevant increase in serious adverse events. The polypill strategy was shown to reduce major cardiovascular events and improve therapeutic adherence in high-risk patients. These findings reinforce its potential as an effective large-scale intervention, especially in public health settings and resource-limited systems.

FUNCTIONAL CAPACITY AND CLINICAL PROFILE OF SMOKERS WITH COPD UNDERGOING SMOKING CESSATION: INSIGHTS FROM THE 6-MINUTE WALK TEST

VITOR HUGO EUZEBIO DE MELLO1; LUISA PALMA SCHIAVON1; LUIS FELIPE PARREIRA PELUSO1; MAX GRAVINA RODRIGUES1; LUCAS CASTRO DE MENDONÇA1; GUILHERME SOUZA NASCIMENTO1; CAROLINA SOARES DE SÁ MENDONÇA PINTO1; SOFIA SILVA OLSTHOORN1; LAYSE GONÇALVES KISTENMCKER1; THIAGO = SILVA1; ARISE GARCIA DE SIQUEIRA GALIL1; DIANE MICHELA NERY HENRIQUE1;

(1) UFJF - JUIZ DE FORA - MG - BRASIL;

Introdução/Fundamentos: The 6-Minute Walk Test (6MWT) assesses functional capacity through cardiovascular, respiratory, and musculoskeletal responses during submaximal exercise. In Chronic Obstructive Pulmonary Disease (COPD), chronic inflammation, structural lung changes, and progressive exercise intolerance can be measured by the 6MWT. Objetivos: To evaluate smokers with multimorbidities, including COPD, undergoing smoking cessation treatment and its association with clinical characteristics, smoking history, and functional capacity. Métodos: Cross-sectional study conducted in a multidisciplinary smoking cessation outpatient clinic from October 2023 to April 2026. Cognitive-behavioral therapy and pharmacological treatment were provided, along with clinical and smoking history assessment. Positive COPD screening was defined as post-bronchodilator FEV1/FVC <0.70; high nicotine dependence as Fagerström Test ≥5; and heavy smokers as ≥20 cigarettes/day. Functional capacity was assessed by the 6MWT, with blood pressure (BP), heart rate (HR), peripheral oxygen saturation (SpO□), and modified Borg scale recorded before, during, and after the test. Descriptive analyses used mean±SD or percentages. Associations were tested using Student's t-test and Chi-square test (p<0.05). Resultados e Conclusões: : Fifty smokers were evaluated: 80% women, mean age 58.10±10.53 years; 50% sedentary; 57.1% hypertensive; 50% diabetic; and 42% with COPD. Mean smoking duration was 40.20±12.79 years, cigarette consumption 23.68±12.75/day, and 75.5% had high nicotine dependence. All participants performed the 6MWT, with mean distance of 422.83±66.25 m. Compared with smokers without COPD, those with COPD had longer smoking duration (p<0.051) and higher prevalence of heavy smoking (p<0.047). In the 6MWT, smokers with COPD showed lower baseline systolic and diastolic BP (p<0.022; p<0.047), a trend toward higher HR at baseline and peak (p<0.063; p<0.065), higher respiratory Borg scores at baseline and peak (p<0.009; p<0.014), and higher peak lower-limb Borg score (p=0.051).

GLP-1 AGONIST RECEPTORS AND CARDIOPROTECTION: NEW PERSPECTIVES ON THE TREATMENT OF TIPE 2 DIABETES

GABRIELA RUBIA RAMOS MARCUSSI1; DÉBORA CORDEIRO NOLASCO1; GABRIELLE BROCENSCHI GALASTRI1; JOÃO PEDRO SOUSA RIOLA1; NATHALIA MASUNO MACIAS1; LUIZA LIMA LOPES PONTES1; LIVIA TEOTÔNIO TRUFELI1; WILLIAM ALEXANDRE SOARES OLIVEIRA1; LIVIA MARIA DELLA PORTA COSAC1;

(1) UNIVERSIDADE DE RIBEIRÃO PRETO - RIBEIRÃO PRETO - SP - BRASIL;

Introdução/Fundamentos: The glucagon-like peptide-1 receptor agonist (GLP1RA) has shown an important role in the treatment of type 2 Diabetes (T2DM) and obesity, once it stimulates the biosynthesis and release of insulin, suppresses glucagon release, delays gastric emptying and improves glucose metabolism, in addition to increasing satiety. It can be activated in pancreatic cells, digestive tract, myocardium, skeletal muscle, hepatocytes, central nervous system and immune system. Cardiovascular diseases (CVD) are the main complications of T2DM and studies have shown that GLP1RA can improve outcomes in these patients Objetivos: This literature review seeks to elucidate the role of GLP1R in reducing cardiovascular events. Métodos: This is a narrative literature review conducted in the PubMed and LILACS databases using the descriptors 'GLP-1', 'cardiovascular', 'Semaglutide', and 'Diabetes', combined by the Boolean operators AND and NOT. Articles from the last 5 years in English that addressed cardiovascular outcomes related to the use of GLP-1 receptor agonists were included Resultados e Conclusões: Studies such as SUSTAIN-6, which evaluated the use of weekly subcutaneous Semaglutide, and PIONEER 6, which evaluated the use of daily oral Semaglutide, observed that in diabetic patients with high cardiovascular risk there was a reduction in major CV events and that the use of the oral medication achieved a significant reduction in cardiovascular and all-cause mortality, without evidence of superiority among the different types of GLP1RA. In addition, in the phase 3 SELECT study it showed that Semaglutide mitigated major cardiovascular events, especially in patients with heart failure with preserved and reduced ejection fraction, despite this result GLP1RA do not treat this comorbidity. The SOUL CVOT study also shows a reduction of major events in patients with T2DM, atherosclerotic cardiovascular disease and chronic kidney disease. Due to these results these medications are recommended in guidelines. GLP-1 receptor agonists demonstrate relevant cardiovascular benefits in patients with type 2 diabetes mellitus and obesity, especially in reducing major cardiovascular events. Recent studies highlight the cardioprotective potential of this drug class, however, despite the promising results, additional studies are still needed for a better understanding of the mechanisms involved on the benefits in different patient profiles.

HIGH-SENSITIVITY TROPONIN IN RISK STRATIFICATION OF CHEST PAIN: A SYSTEMATIC REVIEW AND META-ANALYSIS

THIAGO VITTOR SILVA FREITAS1; POLIANA MARCELINO JOIA1; GIOVANA CASAGRANDE DE ALENCAR2; TAYNARA TAVARES DOS SANTOS1; LUCAS MARINHO REIS DA CUNHA SILVA1; BRUNO DE FREITAS SILVA1; RAFAEL ALVES DE OLIVEIRA1; RAFAEL ALVES PINA1; EDUARDO BERTI ALVIZI1; DANIELLY MARQUES ALVES1; LAÍS DURAN GOMES1; AMANDA OLIVA SPAZIANI1;

(1) UNIVERSIDADE BRASIL - UB - FERNANDÓPOLIS - SP - BRASIL; (2) UNIVERSIDADE BRASIL - FERNANDÓPOLIS - SP - BRASIL;

Introdução/Fundamentos: Chest pain is one of the leading causes of emergency department visits. The use of high-sensitivity troponin (hs-cTn) has revolutionized the early diagnosis of acute myocardial infarction, enabling faster detection of myocardial injury. However, its role in risk stratification for major cardiovascular events still requires further clarification. Objetivos: To evaluate the accuracy of high-sensitivity troponin in risk stratification for major cardiovascular events in patients presenting with chest pain. Métodos: A systematic review conducted according to PRISMA guidelines, with searches in PubMed, Embase, and Cochrane Library databases up to January 2026. Prospective studies evaluating high-sensitivity troponin in patients presenting with chest pain in emergency departments were included. The primary outcome was a composite of major cardiovascular events within 30 days. The meta-analysis was performed using a random-effects model, with calculation of sensitivity, specificity, and area under the ROC curve (AUC). Heterogeneity was assessed using the I^2 index. Resultados e Conclusões: Thirteen studies were included, totaling 67,845 patients. High-sensitivity troponin demonstrated high sensitivity for predicting cardiovascular events (sensitivity=0.94; 95% CI: 0.91–0.96), with moderate specificity (0.78; 95% CI: 0.72–0.83). The overall AUC was 0.91 (95% CI: 0.88–0.93), indicating excellent diagnostic accuracy. Heterogeneity was moderate (I^2=44%). High-sensitivity troponin shows high accuracy in risk stratification of patients with chest pain, being an essential tool for decision-making in emergency departments. Its use may optimize care pathways and reduce adverse outcomes.

HIV-1 SUBTYPE, ANTIRETROVIRAL RESISTANCE, AND SEX DISPARITIES IN CARDIOVASCULAR RISK: A NATIONWIDE STUDY IN BRAZIL

LARA GOMES TEIXEIRA1; FLÁVIA FIGUEIRA2; ANA SANTOS PEREIRA2; MATHEUS DE SÁ FREITAS TAVARES2; NUNO MIGUEL S. OSÓRIO2; BERNARDINO GERALDO ALVES SOUTO1;

(1) UNIVERSIDADE FEDERAL DE SAO CARLOS - SÃO CARLOS - SP - BRASIL; (2) UNIVERSIDADE DO MINHO - PORTUGAL;

Introdução/Fundamentos: Cardiovascular disease (CVD) is one of the leading causes of non-AIDS-related morbidity and mortality in people living with HIV (PLWH). However, current cardiovascular risk stratification models neglect virological determinants, such as HIV-1 genetic diversity and antiretroviral resistance profiles, limiting diagnostic accuracy in diverse populations. Objetivos: To investigate the association between HIV-1 subtypes, resistance mutations (DRMs) and the risk of major cardiovascular events (MACE), analyzing the mediating role of biological sex. Métodos: A retrospective nationwide cohort study was conducted using database linkage of genotyping, hospital admission, and mortality records in Brazil (2008-2017), including 20,692 individuals on antiretroviral therapy (ART). Subtypes and DRMs were identified via pol gene sequencing. MACE were defined based on ICD-10 codes. Sex-stratified multivariable logistic regression models were used to estimate adjusted Odds Ratios (OR) and 95% CI, controlling for age and traditional non-HIV-related cardiovascular risk factors. Resultados e Conclusões: HIV-1 subtype C was associated with a lower risk of MACE compared with subtype B in both men (OR 0.65; p=0.001) and women (OR 0.61; p<0.001). In contrast, a distinct sex-specific pattern emerged for antiretroviral resistance, with multiple DRMs associated with increased cardiovascular risk exclusively in women. Notably, the M41L (OR 1.72; 95% CI 1.33-2.23) and M46I (OR 1.51) mutations were strong independent predictors of MACE in females. Additional signals were observed for T215F and L33F, while no consistent associations were identified in males. HIV-1 genetic architecture and resistance profile exert a differential influence on cardiovascular risk, with a disproportionate impact on women. These findings suggest that the incorporation of viral biomarkers and consideration of sex disparities can refine risk prediction and personalize cardiovascular prevention strategies in the overall management of HIV.

HYPERTENSIVE RETINOPATHY AS A PREDICTOR OF CARDIOVASCULAR EVENTS: A SYSTEMATIC REVIEW

MARCOS PAULO JORGE DE SALES1; LOUISE ARAÚJO JASSÉ SANTOS1; ANTONIO MARIA ZACARIAS ARAÚJO MONTEIRO1; RENATA GOMES DE ARAÚJO TEIXEIRA CYPRIANO2; RAFAEL ARAÚJO DE BRITO NOBRE3; GABRIEL SANTARÉM JORGE PINTO DOS REIS1; LETICIA SANFORD CARNEIRO COELHO1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DA AMAZONIA - BELÉM - PA - BRASIL; (3) CENTRO UNIVERSITÁRIO FIBRA (FACULDADE INTEGRADA BRASIL AMAZÔNIA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Hypertension stands as a leading global risk factor for cardiovascular disease (CVD), necessitating precise risk stratification to reduce major adverse outcomes. Blood pressure measurements may not fully capture the microvascular damage caused by chronic hypertension. The retina offers a non-invasive window into systemic microcirculation, where hypertensive retinopathy reflects target-organ damage. Given this pathophysiological link, hypertensive retinopathy may serve as a valuable marker for cardiovascular risk prediction. Objetivos: To systematically evaluate the current evidence examining the prognostic utility of hypertensive retinopathy as an independent predictor of incident cardiovascular events. Métodos: A systematic review was conducted in accordance with the PRISMA 2020 guidelines. PubMed and EBSCO were searched from inception to March 2026 using MeSH terms and keywords related to hypertensive retinopathy, cardiovascular events, and longitudinal study designs; the full search strategy is available upon request. Additional screening was performed in Google Scholar. Study selection was conducted independently by two reviewers. Eligible studies included longitudinal designs, primarily prospective population-based cohorts, while case reports, pediatric populations, and reviews or meta-analyses were excluded. Risk of bias was assessed using standardized tools. Primary outcomes were stroke, myocardial infarction, and cardiovascular mortality. Resultados e Conclusões: Ten studies were included, predominantly prospective cohorts. Findings consistently showed that hypertensive retinopathy was associated with increased risk of major adverse cardiovascular events (MACE), independent of traditional risk factors such as blood pressure, glycemic status, and lipid levels. Mild retinopathy was associated with incident stroke (hazard ratio [HR] 1.26, 95% confidence interval [CI] 1.01–1.58), while severe retinopathy showed a stronger association (HR 2.40, 95% CI 1.49–3.84). Retinopathy grade ≥2 was associated with more than a twofold increase in mortality risk (HR 2.08, 95% CI 1.04–4.15), and in high-risk hypertensive patients with a twofold higher risk of coronary heart disease (risk ratio [RR] 2.1, 95% CI 1.0–4.2). Hypertensive retinopathy appears to be a consistent and independent predictor of incident MACE. These findings suggest that retinal microvascular assessment may improve cardiovascular risk stratification and clinical decision-making in practice.

19427

IMPACT OF DUAL AND TRIPLE AGONISTS (GIP/GLP-1/GLUCAGON) ON ATRIAL FIBRILLATION BURDEN AND STRUCTURAL REMODELING IN PATIENTS WITH OBESITY: A SYSTEMATIC REVIEW.

LAURA FREITAS ROCHA1; MELISSA MOURA DO VALLE1; NICOLE PEREIRA MONTEIRO DA CRUZ1; ANTONIO MARIA ZACARIAS ARAÚJO MONTEIRO1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Obesity is a major driver of atrial structural remodeling and increased epicardial adipose tissue, perpetuating atrial fibrillation (AF). Although weight loss reduces arrhythmic burden, the clinical impact of emerging incretin-based therapies remains insufficiently synthesized. Objetivos: To evaluate whether dual and triple incretin agonists (GIP/GLP-1/Glucagon) reduce AF burden and promote reverse atrial remodeling compared with standard treatment in patients with obesity. Métodos: This systematic review was conducted according to PRISMA guidelines. A literature search was performed in PubMed, EMBASE, and SciELO (2020–2026) using MeSH/DeCS terms and free-text keywords related to atrial fibrillation, obesity, and dual/triple incretin agonists. Randomized clinical trials and observational studies including adults (≥18 years) with obesity and reporting AF and/or cardiovascular remodeling outcomes were included. Animal studies, reviews, and studies without relevant cardiovascular endpoints were excluded. Study selection was performed by two independent reviewers. Risk of bias was assessed using RoB 2.0 for randomized trials and ROBINS-I for observational studies. Resultados e Conclusões: From 1,240 records, 5 propensity score–matched observational studies and 2 randomized controlled trials were included (N=18,450; mean BMI 34.2 kg/m²). The use of dual/triple agonists (e.g., tirzepatide) reduced AF recurrence and burden by 38% compared with standard treatment (HR 0.62; 95% CI 0.54–0.71; p<0.001). In the structural remodeling analysis (mean follow-up of 14 months), combined incretin therapy promoted a greater reduction in left atrial volume index (-4.8 mL/m²; 95% CI -6.2 to -3.4) and significant regression of epicardial adipose tissue thickness (-2.3 mm; p<0.01). The incidence of major adverse cardiovascular events (MACE) was also lower in the intervention group. Dual and triple agonist therapy acts as a disease-modifying strategy in obesity-related atrial fibrillation. By promoting regression of epicardial adipose tissue and reverse atrial remodeling, these agents reduce arrhythmic burden. These findings suggest a paradigm shift, positioning combined incretin therapies not only as anti-obesity agents but also as key components in the management of the arrhythmogenic substrate, with potential implications for future rhythm control guidelines.

Study	Design and Population	Exposure	Outcomes	Key Findings	Conclusion
E1	Propensity-matched obese AF patients post-ablation	GLP-1 RA	AF recurrence, mortality, CV hospitalizations	Lower AF recurrence and improved clinical outcomes	GLP-1 receptor agonists are associated with improved post-ablation rhythm and clinical outcomes
E2	Evidence synthesis in obesity	Anti-obesity drugs	CV events, arrhythmias	Heterogeneous effects; GLP-1 RA most favorable	GLP-1 receptor agonists demonstrate the most robust cardiovascular safety among weight loss therapies
E3	Longitudinal obese AF cohort	GLP-1 RA	Long-term AF recurrence	Sustained reduction in recurrence	GLP-1 receptor agonists may provide durable rhythm control benefits
E4	Narrative review	GLP-1 RA and emerging agents	Cardiometabolic outcomes	Significant metabolic benefit with potential indirect antiarrhythmic effects	Incretin-based therapies may play an increasing role in cardiovascular and arrhythmia management

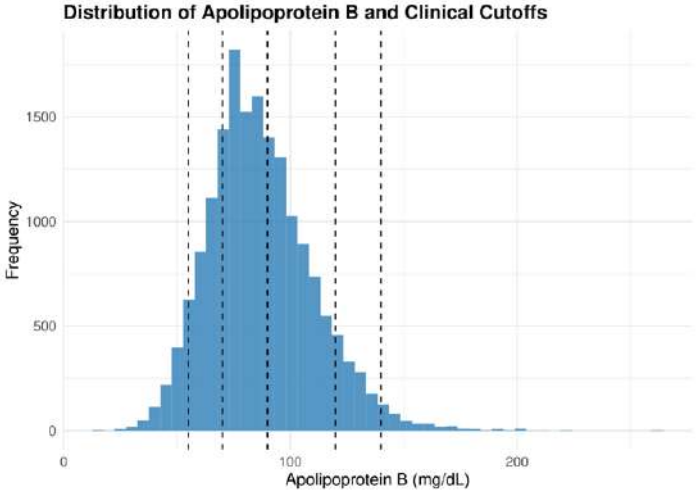
IMPACT OF GLP-1 RECEPTOR AGONISTS ON CARDIOVASCULAR OUTCOMES IN PATIENTS WITH HEART FAILURE AND OBESITY: A SYSTEMATIC REVIEW

BRUNA DE ANDRADE LIMA BARRETTO1; INÁCIO KRAUSS FARO BARRETTO DE MENEZES1; ARTUR FERRER GRIBEL1; ARTHUR MAGALHÃES RODRIGUES1; JOÃO PEDRO MESQUITA GUMES VIEIRA2; MARIA GUILHERMINA COLARES LEITE PRADO2; ANA MARIA BARRETTO LIMA2;

(1) UNIVERSIDADE TIRADENTES (UNIT) - ARACAJU - SE - BRASIL; (2) UNIVERSIDADE FEDERAL DE SERGIPE - ARACAJU - SE - BRASIL;



Introdução/Fundamentos: Obesity is a major global public health problem and is strongly associated with cardiovascular diseases, including heart failure (HF). Excess body weight contributes to metabolic and inflammatory alterations, cardiac remodeling, hypertension, and type 2 diabetes mellitus, factors linked to HF progression. In this context, glucagon-like peptide-1 (GLP-1) receptor agonists have emerged as promising therapies, initially developed for glycemic control but currently recognized for cardiovascular and metabolic benefits. Recent studies have shown significant weight loss, improved functional capacity, and reduced cardiovascular hospitalizations, especially in patients with heart failure with preserved ejection fraction (HFpEF). Objetivos: To evaluate the effects of GLP-1 receptor agonists on clinical and cardiovascular outcomes in patients with heart failure associated with obesity. Métodos: A systematic literature review was conducted using PubMed, Scopus, and the Virtual Health Library (VHL). The descriptors "GLP-1 receptor agonists," "heart failure," "obesity," and "cardiovascular outcomes" were combined using the Boolean operators AND and OR. Studies published between 2020 and 2026 in English, Portuguese, and Spanish were included. Eligible studies involved adults with HF and obesity treated with GLP-1 receptor agonists. Duplicate studies, narrative reviews, case reports, and articles without cardiovascular outcome analysis were excluded. Resultados e Conclusões: A total of 428 studies were identified, and 17 met the inclusion criteria. The findings demonstrated significant reductions in body weight, improved functional capacity, and decreased inflammatory markers among patients receiving GLP-1 receptor agonists. Several studies also reported lower hospitalization rates for HF and improved quality of life, particularly in individuals with obesity-related HFpEF. Additionally, better glycemic and blood pressure control were observed, factors associated with slower cardiovascular disease progression. However, evidence regarding cardiovascular mortality reduction remained inconsistent. Overall, GLP-1 receptor agonists appear to provide important clinical, metabolic, and functional benefits in patients with HF and obesity, although long-term randomized studies are still needed to clarify their impact on cardiovascular mortality and HF progression.

IMPACT OF GUIDELINE-BASED APOLIPOPROTEIN B THRESHOLDS IN A REAL-WORLD BRAZILIAN LABORATORY POPULATION

JOÃO ÍTALO PEREIRA CAVALCANTE1; MARINA DE ANDRADE NORÕES BEZERRA1; LAÍS FARIAS MASULLO2; RACHEL PETROLA JORGE BEZERRA3;

(1) INTERNSHIP PROGRAM AT EMED - EMÍLIO RIBAS MEDICINA DIAGNÓSTICA - FORTALEZA - CE - BRASIL; (2) EMILIO RIBAS MEDICINA DIAGNÓSTICA - FORTALEZA - CE - BRASIL; (3) EMÍLIO RIBAS MEDICINA DIAGNÓSTICA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Apolipoprotein B (Apo B) reflects the number of circulating atherogenic lipoprotein particles and has gained prominence in cardiovascular risk assessment. However, the impact of applying fixed guideline-based thresholds to real-world populations remains insufficiently characterized. Objetivos: To evaluate how different guideline-based Apo B thresholds modify atherogenic lipoprotein burden classification in a large Brazilian laboratory population, and to assess the position of these thresholds within the local Apo B distribution. Métodos: A cross-sectional study was conducted using 17,338 Apo B measurements obtained from routine laboratory data of outpatient individuals between 2021 and 2025 at a laboratory in northeastern Brazil. Sex-specific reference intervals were estimated using percentile methods (2.5th–97.5th). The proportion of individuals exceeding clinically relevant Apo B thresholds (≥55, ≥70, ≥90, ≥120, and ≥140 mg/dL) was determined, and their position within the population distribution was assessed. Group comparisons were performed using the Wilcoxon rank-sum and chi-square tests. Secondary analyses included LDL-C/Apo B discordance (LDL-C <130 mg/dL with Apo B ≥90 mg/dL), correlation between Apo A-I and Apo B (Spearman), and logistic regression. Resultados e Conclusões: Apo B values showed a right-skewed distribution (median 85 mg/dL; 97.5th percentile 137 mg/dL). Guideline-based thresholds ranged from the 6.7th percentile (55 mg/dL) to the 98.0th percentile (140 mg/dL). The proportion of individuals classified above target varied: 41.9% (≥90 mg/dL), 77.4% (≥70 mg/dL), and 93.9% (≥55 mg/dL), demonstrating threshold dependence. Elevated Apo B was observed in 8.93% (≥120 mg/dL) and 2.13% (≥140 mg/dL). Discordance was present in 9.64% and differed by sex (p<0.001). In secondary analyses, 9.64% of individuals with normal LDL-C had elevated Apo B, indicating residual risk not captured by traditional lipid parameters, and this discordance differed by sex (p<0.001). No significant correlation was observed between Apo A-I and Apo B (rho=-0.008, p=0.320), while 14.9% had an elevated Apo B/Apo A-I ratio. Male sex was independently associated with elevated Apo B (OR≈1.37, p<0.001). These findings demonstrate that guideline-based Apo B thresholds map to different points of the distribution and alter Apo B classification, highlighting the importance of distinguishing population-based reference distributions from clinical decision thresholds when interpreting Apo B in cardiovascular risk assessment.

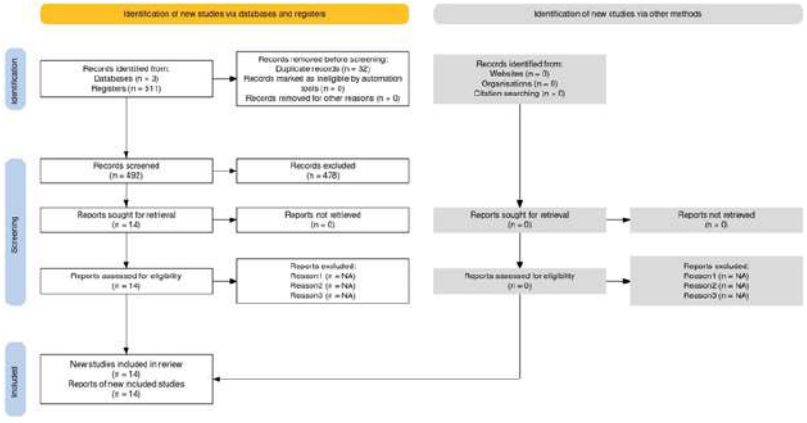
Impact of Lipoprotein(a) on Clinical Outcomes in Patients with Aortic Stenosis: A Systematic Review

ARTHUR CARNEIRO CARVALHO1; MARIA EDUARDA CAVALCANTE MARTINS1; GUSTAVO SILVA FIGUEREDO1; GUILHERME HENRIQUE MOURA LOPES1; FILLIPE SILVA CARNEIRO1; IAGO SANTOS DA SILVA1; MARLI SOUZA NASCIMENTO1; GABRIEL GUEDES BARRETO NASCIMENTO1; CLEIDIANNE SOUSA PEREIRA RODRIGUES1; ILDEBRANDO IEDO ARAÚJO CIRINO SOBRINHO2; JULIANE DI PAULA CRUZ CHAVES3; WILLY HIAMICANY ULISSES DE ANDRADE1;

(1) FARESI - CONCEIÇÃO DO COITÉ - BA - BRASIL; (2) UNIRG - PARAISO DO TOCANTINS - TO - BRASIL; (3) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Aortic stenosis (AS), the most prevalent valvular disease in older adults, is characterized by progressive calcification and fibrosis of the valve leaflets, leading to left ventricular outflow obstruction. The disease is associated with heart failure, syncope, and sudden cardiac death due to arrhythmias, while still lacking effective pharmacological therapies. In this context, lipoprotein(a) [Lp(a)] has emerged as a factor associated with accelerated disease progression and poorer clinical outcomes due to its pro-inflammatory and pro-calcific properties. Despite these associations, important gaps remain regarding the impact of Lp(a) on broader clinical outcomes and the potential benefits of targeted therapies. Therefore, this systematic review aims to synthesize the current evidence on this topic. Objetivos: The objective of this study is to synthesize the evidence regarding the contribution of Lp(a) to the progression of aortic stenosis, aiming to evaluate the still untapped potential of therapies targeting Lp(a) reduction as a novel strategy to modify the clinical course of the disease. Métodos: This systematic review, conducted according to PRISMA guidelines, searched PubMed, Web of Science, CINAHL, and Google Scholar for studies published up to April 2026 regarding the role of Lp(a) in aortic stenosis. Search terms included: “aortic stenosis”, “aortic valve stenosis”, “calcific aortic valve stenosis”, “lipoprotein(a)”, “Lp(a)”, and “aortic valve calcification”. After screening, 10 studies were included: 8 cohort studies, 1 randomized controlled trial (RCT), and 1 cross-sectional study. Methodological quality was assessed using the Newcastle-Ottawa Scale and the Cochrane Risk of Bias tool. Resultados e Conclusões: Lp(a) was shown to be a causal and independent risk factor for calcific aortic valve stenosis (CAVS). Elevated levels were associated with initial valvular calcification (OR=1.43 baseline; OR=1.30 incident) and hemodynamic progression, evidenced by increased peak aortic jet velocity (+0.26 m/s/year; p=0.005), although no consistent association was observed with calcification progression. Furthermore, elevated Lp(a) was associated with higher risks of valvular reintervention (HR=1.58), cardiovascular events/death (HR=1.43), and reduced post-TAVI survival. Thus, Lp(a) appears to be a relevant prognostic marker in CAVS, although further clinical trials are still needed.



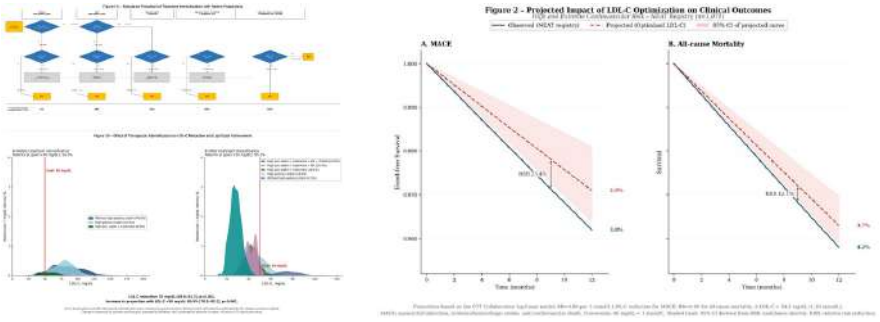
17199

IMPACT OF SUBCLINICAL HYPOTHYROIDISM ON CARDIOVASCULAR RISK: A SYSTEMATIC REVIEW

FERNANDA XAVIER TEIXEIRA FRANCI1; LARA MAGALHÃES CARNEIRO1; ARANI LUIZA ROCHA PICANÇO1; ANA LUIZA BRANDÃO DE OLIVEIRA1; MARINA ALMEIDA SIMÕES1; CLARA FLORENTINO DE QUEIROZ MAIA1; MARIA EDUARDA VIANA DA SILVA1; TALES SANTIAGO BENUCE1; ANA FLÁVIA DE ARAÚJO BARROS1; GUILHERME ROQUE MAURÍCIO1; LARA DE MORAIS CAVALCANTE1; GRAYCE ELLEN DA CRUZ PAIVA LIMA1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Subclinical hypothyroidism, characterized by elevated thyroid-stimulating hormone (TSH) levels with normal circulating thyroid hormones, is a common condition in clinical practice. Its clinical relevance has been widely debated, particularly due to its potential association with adverse cardiovascular outcomes, including increased cardiovascular mortality. However, the available evidence remains inconsistent, leading to uncertainty regarding the true impact of this condition. Therefore, it is essential to synthesize current evidence on the association between subclinical hypothyroidism and cardiovascular risk compared with euthyroid individuals. Objetivos: To evaluate the association between subclinical hypothyroidism and cardiovascular risk, including metabolic, inflammatory, and subclinical alterations, as well as major outcomes such as coronary artery disease, myocardial infarction, stroke, heart failure, and cardiovascular mortality. Métodos: A systematic review was conducted in accordance with PRISMA recommendations using PubMed, Embase, and ScienceDirect (2021–2025), based on the PICO strategy. Inclusion criteria comprised observational studies and clinical trials evaluating adults (≥18 years) with subclinical hypothyroidism compared to euthyroid individuals, considering outcomes such as acute myocardial infarction, stroke, and mortality. Resultados e Conclusões: Of 492 records identified, 478 were excluded after screening, and 14 studies were included. Subclinical hypothyroidism was consistently associated with an adverse cardiometabolic profile, including increased LDL, triglycerides, and total cholesterol, reduced HDL, and elevated atherogenic indices. A higher prevalence of insulin resistance, metabolic syndrome, and elevated high-sensitivity C-reactive protein was observed. Subclinical cardiovascular changes were also frequent, including diastolic dysfunction, reduced myocardial strain, increased epicardial fat, and greater carotid intima–media thickness. An increased risk of heart failure was reported. Overall, subclinical hypothyroidism is associated with cardiometabolic and early cardiovascular alterations, suggesting a role in atherogenesis. Although associations with myocardial infarction, stroke, and mortality is not uniform, likely due to methodological limitations, this condition should not be considered benign and may represent an early marker of cardiovascular risk, warranting careful clinical evaluation.



17267

IMPLEMENTATION OF THE 2025 BRAZILIAN DYSLIPIDEMIA GUIDELINES IN ATHEROTHROMBOTIC DISEASE: A NATIONWIDE SIMULATION BASED ON THE NEAT REGISTRY

NATÁLIA COGO GONÇALES1; MARIA LUISA PEDROZA GUIMARÃES1; RENATO LOPES2; LUCAS TRAMUJAS2; FABIANA RACHED2; ANDRÉ ZIMMERMAN2; MARCELO ARRUDA NAKAZONE3; CHARLENE TROIANI2; PEDRO GABRIEL MELO DE BARROS E SILVA2;

(1) CENTRO UNIVERSITARIO SAO CAMILO - GUARULHOS - SP - BRASIL; (2) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL; (3) BENEFICENCIA PORTUGUESA DE SAO JOSE DO RIO PRETO - SAO JOSE DO RIO PRETO - SP - BRASIL;

Introdução/Fundamentos: Suboptimal control of low-density lipoprotein cholesterol (LDL-C) remains the main unmet need in secondary prevention of atherothrombotic disease in Brazil. The 2025 Brazilian dyslipidemia guidelines introduced novel lipid-lowering strategies that may improve LDL-C goal attainment and reduce residual cardiovascular risk. Objetivos: To simulate the impact of guideline-directed lipid-lowering intensification on LDL-C control and to estimate the expected reduction in major adverse cardiovascular events (MACE) and all-cause mortality in a nationwide cohort. Métodos: The NEAT registry is a prospective, multicenter observational study including 2,005 patients with atherothrombotic disease across 25 centers in Brazil. Among individuals with available LDL-C, a deterministic stepwise simulation was performed according to the 2025 guidelines, including intensification to high-intensity statins followed by addition of ezetimibe, bempedoic acid, and PCSK9 inhibitors. Expected LDL-C reductions were applied at each step. A counterfactual model based on the log-linear relationship estimated relative reductions in MACE and all-cause mortality per 1 mmol/L LDL-C reduction. Resultados e Conclusões: After one year, 14.3% achieved LDL-C <50 mg/dL. Goal attainment varied by treatment intensity: 9.2% (95% CI 6.9–12.2) without high-intensity statins, 17.0% (95% CI 13.8–20.7) with high-intensity statins, and 27.4% (95% CI 19.0–37.6) with statin plus ezetimibe. In the simulation, 55.1% would reach target with bempedoic acid and 95.1% (95% CI 93.6–96.3) with PCSK9 inhibitors, totaling 1019/1071 patients at goal. A mean LDL-C reduction of 50.5 mg/dL (~1.26 mmol/L) across the full cohort would be associated with an estimated 23.4% (95% CI 5.1–49.9%) relative reduction in MACE and 12.1% (95% CI 2.4–27.8%) in all-cause mortality, corresponding to absolute reductions from 3.8% to 2.9% (95% CI 1.9–3.6%) and from 4.2% to 3.7% (95% CI 3.0–4.1%), respectively, over one year. Guideline-based intensification could markedly increase LDL-C control and is projected to reduce cardiovascular events and mortality, directly addressing the study objective and supporting more intensive lipid-lowering strategies in secondary prevention.

INCREMENTAL PROGNOSTIC VALUE OF ECHOCARDIOGRAPHY AND SPECT BEYOND CLINICAL ASSESSMENT IN CHRONIC CORONARY SYNDROME

ALFREDO ROGERIO DIAS DALCOMUNI1; ANISIO UCHOA LEITE SANTANA1; VITOR BATALHA DE CAMARGO1; JOÃO VITOR BIANCALANA FERREIRA PERES CALIL1; EDUARDO MARTELLI MOREIRA2; FABIO GRUNSPUN PITTA2; EDUARDO GOMES LIMA2; FABIANA HANNA RACHED2; HENRIQUE TROMBINI PINESI2; CARLOS VICENTE SERRANO JR.2;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) INSTITUTO DO CORACAO (INCOR) - HOSPITAL DAS CLINICAS DA FACULDADE DE MEDICINA DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Contemporary guidelines recommend multimodality imaging for risk stratification in chronic coronary syndrome (CCS), yet the comparative prognostic contribution of resting echocardiography and stress myocardial perfusion scintigraphy (SPECT) beyond clinical assessment remains incompletely characterized in outpatient practice. Objetivos: To evaluate whether addition of echocardiographic parameters to a baseline clinical model improves risk discrimination and reclassification for the composite primary endpoint (all-cause death, myocardial infarction, or stroke) in CCS, and whether further addition of SPECT-derived indices provides incremental information. Métodos: This single-center prospective cohort included 1,129 patients with angiographically confirmed CCS (mean age 64.4±9.2 years; 31.2% female). Three nested models were constructed: M1 (clinical variables); M2 (M1 plus echocardiography: left ventricular ejection fraction, regional wall motion abnormalities, diastolic dysfunction, left ventricular mass index); M3 (M2 plus SPECT: stress-induced perfusion defects, fixed defects, ischemia burden). Due to clinician-directed testing, echocardiography was available in 604 patients (53.5%) and SPECT in 285 (25.2%). Model comparisons used complete-case subsets (M1 vs M2: n=604; M2 vs M3: n=285). Multiple imputation (MICE; m=20) was performed as sensitivity analysis. Discrimination was assessed via C-statistic and Harrell's C-index; reclassification via continuous NRI and IDI. Resultados e Conclusões: The primary endpoint occurred in 273 patients (24.2%); all-cause death in 240 (21.3%). Addition of echocardiography improved discrimination (AUC 0.712→0.765; p=0.002; Figure 2), reclassification (NRI 0.513, p<0.001; IDI 0.067, p<0.001), and calibration (Brier 0.163→0.151). Addition of SPECT improved reclassification (NRI 0.314, p=0.019; IDI 0.022, p=0.010) but not discrimination (AUC 0.759→0.774; p=0.191), with graded ischemia-event relationship (Figure 1). In multivariable Cox analysis (C-index 0.769), independent mortality predictors were age (HR 1.063, p<0.001), NYHA class (HR 1.176, p=0.029), diabetes (HR 1.595, p=0.002), and left ventricular mass index (HR 1.013, p<0.001); no SPECT variable retained significance. Echocardiography provided incremental prognostic information beyond clinical assessment. SPECT's reclassification benefit without discrimination improvement may reflect multicollinearity or selection bias.

C-statistics (AUC, 95% CI; DeLong method) for M1 (clinical), M2 (clinical + echocardiography; n=604), and M3 (clinical + echocardiography + SPECT; n=285).

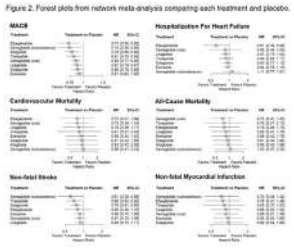
INCRETIN-BASED THERAPIES AND CARDIOVASCULAR OUTCOMES IN TYPE 2 DIABETES: A NETWORK META-ANALYSIS OF RANDOMIZED CARDIOVASCULAR OUTCOME TRIALS



VINICIUS SILVA LARA1; CARLOS EDUARDO SILVA CRUZ2; RENATO GARCIA LISBOA BORGES1; LEONARDO GOUVÊA DE OLIVEIRA1; LUANA KAORI SAKAGUCHI SAKAMOTO1; VITÓRIA CAMPOS CORDEIRO1; EDSON LUIS DE BARROS SIQUEIRA1; MARIA EDUARDA GRASSI3; JONATHAS ADRIEL TAVARES AMARAL1; LUCAS ALENCAR QUEIROZ1; MILTON CESAR VASCONCELOS MACHADO JUNIOR1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) UFMA - CAMPUS PINHEIRO - PINHEIRO - PA - BRASIL; (3) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Incretin-based therapies have demonstrated cardiovascular benefits in large cardiovascular outcome trials (CVOTs). More recently, dual GIP/GLP-1 receptor agonists have expanded this therapeutic group, raising questions about potential differences in cardiovascular effects across agents. However, a comprehensive comparative evaluation of these therapies remains uncertain. Objetivos: To compare the effects of incretin-based therapies on cardiovascular outcomes in adults with type 2 diabetes. Métodos: A systematic review and network meta-analysis of randomized CVOTs was conducted in accordance with PRISMA guidelines. Literature searches were performed in PubMed, Embase, and Cochrane databases according to predefined eligibility criteria. Studies evaluating GLP1 receptor agonists and dual GIP/GLP1 receptor agonists were eligible. The primary outcome was major adverse cardiovascular events (MACE-3). Secondary outcomes included all-cause mortality, cardiovascular mortality, nonfatal myocardial infarction, nonfatal stroke, and hospitalization for heart failure. Hazard ratios and 95% confidence intervals were extracted and pooled using a random-effects model. Sensitivity analyses were performed. Resultados e Conclusões: A total of 771 records were screened, of which 9 CVOTs including 76,827 participants were eligible for analysis. All incretin-based therapies significantly reduced the risk of MACE compared with placebo, with no heterogeneity observed ($I^2 = 0\%$). A consistent reduction in nonfatal stroke was observed for dulaglutide (HR 0.76, 95%CI 0.61–0.95), subcutaneous semaglutide (HR 0.61, 95%CI 0.38–0.98), and tirzepatide (HR 0.69, 95%CI 0.52–0.92), with significant effects and no heterogeneity. Effects on hospitalization for heart failure were largely neutral across treatments, with the exception of efpeglenatide, which demonstrated a significant reduction (HR 0.61, 95% CI 0.38–0.98). No consistent benefit was observed for nonfatal myocardial infarction, all-cause mortality, and cardiovascular mortality, which showed substantial heterogeneity across analyses. Sensitivity analyses confirmed the robustness of MACE and stroke findings, while results for myocardial infarction and mortality outcomes were sensitive to study inclusion. In conclusion, incretin-based therapies are associated with a reduction in MACE, mainly driven by decreased nonfatal stroke. No consistent benefits were observed for myocardial infarction, mortality, or heart failure outcomes, with these findings showing variability across analyses.

Figure 1. Network structure comparing each treatment and placebo.

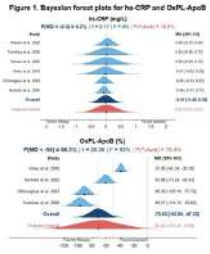
INFLAMMATORY AND OXIDATIVE LIPID BIOMARKER EFFECTS OF LP(A)-TARGETED THERAPIES: A BAYESIAN CLASS-STRATIFIED META-ANALYSIS

ANISIO UCHOA LEITE SANTANA1; MIGUEL CHAVES LENZI2; ARTHUR DE SOUSA SANTOS3; FELIPE MATOSO DE MEIROZ GRILO3; FABIO KRAMER MARQUES3; ALISON LUIZ MACEDO DE PONTES COSTA3; CLARA UCHOA LEITE SATANA3; LUCAS DE QUEIROZ MENEZES3; DEBORA DE QUEIROZ MENEZES4; ALFREDO ROGERIO DIAS DALCOMUNI1; HENRIQUE TROMBINI PINESI5; CARLOS VICENTE SERRANO JR.5;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE ESTADUAL DO RIO GRANDE DO NORTE - MOSSORÓ - RN - BRASIL; (3) UFRN - NATAL - RN - BRASIL; (4) FACULDADE DE MEDICINA DE OLINDA - OLINDA - PE - BRASIL; (5) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Lp(a)-targeted therapies reduce cardiovascular risk through mechanisms beyond Lp(a) lowering, including modulation of oxidized phospholipids (OxPL) and inflammatory pathways. While OxPL-ApoB and OxPL-ApoA are emerging as mechanistic mediators of Lp(a)-driven atherosclerosis, their class-level quantification across siRNA, ASO, and oral inhibitors, alongside hs-CRP, remains uncharacterized with formal probabilistic inference. Objetivos: To evaluate the effects of Lp(a)-targeted drug classes on hs-CRP, OxPL-ApoB, OxPL-ApoA, HDL-C, and triglycerides through class-stratified Bayesian meta-analysis with threshold-exceedance probability estimation. Métodos: We systematically searched PubMed, Embase, Cochrane, and ClinicalTrials.gov through March 2026 for RCTs evaluating Lp(a)-targeted therapies. Class-stratified Bayesian hierarchical models were fitted in Stan using Hamiltonian Monte Carlo with the No-U-Turn Sampler. Treatment effects were expressed as MD with 95% CrI. Statistical analysis was performed using the bayesmeta package in R. Resultados e Conclusões: We included 6 RCTs across three drug classes. For hs-CRP, the pooled estimate was null (MD −0.01 mg/L; 95% CrI −0.40 to 0.38; I^2=4%), with only a 4.2% posterior probability of exceeding a 0.3 mg/L reduction [Pr(<−0.3)] and a 16.8% predictive probability of future benefit, providing no evidence of an anti-inflammatory class effect. For OxPL-ApoB, the pooled estimate demonstrated a robust reductive signal (MD −70.6%; 95% CrI −93.5 to −47.2; I^2=93%), with a 96.3% posterior probability of exceeding 50% reduction and a 75.4% predictive probability of future benefit. Class-stratified analysis revealed siRNA as the strongest reducer [Pr(>70%) = 94.5%], followed by ASO [Pr(>70%) = 46.1%] and oral inhibitors [Pr(>70%) = 18.4%]. For OxPL-ApoA, the pooled estimate showed meaningful lowering (MD −51.0%; 95% CrI −72.6 to −29.7; I^2=93%), with an 86.7% probability of exceeding 40% reduction; oral inhibitors demonstrated markedly higher efficacy [Pr(>50%) = 98.6%] versus ASO [Pr(>50%) = 7.7%]. HDL-C and triglycerides showed negligible pooled effects (MD −0.21% and −0.86%, respectively), with posterior probabilities of clinically relevant changes below 5%. In conclusion, Lp(a)-targeted therapies exert a potent and highly probable effect on OxPL reduction, particularly OxPL-ApoB, with siRNA demonstrating the deepest reductive profile, while hs-CRP, HDL-C, and triglycerides remain largely unaffected, reinforcing the mechanistic specificity of this drug class.



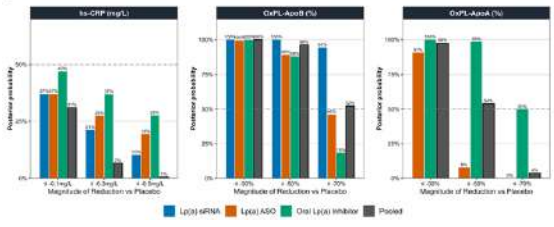


Figure 2: Posterior probabilities of clinically meaningful reductions by therapeutic class

INTESTINAL DYSBIOSIS IN THE PATHOGENESIS AND PROGRESSION OF ATHEROSCLEROTIC DISEASE: A SYSTEMATIC REVIEW

ISABELLA PEREIRA RODRIGUES VIEIRA1; LIVIA MARIA DELLA PORTA COSAC1;

(1) UNIVERSIDADE DE RIBEIRÃO PRETO, CAMPUS RIBEIRÃO PRETO - RIBEIRÃO PRETO - SP - BRASIL;

Introdução/Fundamentos: Atherosclerotic cardiovascular disease (ASCVD), including Coronary Artery Disease (CAD) and Acute Coronary Syndrome (ACS), remains the main cause of death worldwide. Despite well-established risk factors, a residual cardiovascular risk unexplained by traditional determinants persists. In this context, the intestinal microbiota emerges as an endocrine modulator of cardiometabolic homeostasis and its dysbiosis, a qualitative and quantitative imbalance of this microbial community, has been linked to the genesis and progression of atherosclerosis through bacterial product translocation and activation of systemic inflammatory pathways. Objetivos: This study aims to assess the connection between intestinal dysbiosis, elevated circulating TMAO and LPS levels, and the pathophysiology of atherosclerosis in patients with ASCVD, CAD or previous ACS. Métodos: Systematic review conducted in accordance with PRISMA guidelines, integrating studies published in PubMed and PubMed Central (PMC) over the past five years, in English. Using PICO framework: (P) patients with atherosclerosis; (I/E) exposure to gut dysbiosis and elevated LPS and TMAO levels; (C) baseline levels and absence of gut dysbiosis; (O) ASCVD and cardiovascular events. Keywords: “gut microbiota,” “dysbiosis,” “TMAO,” “LPS,” “atherosclerosis,” “endothelial dysfunction,” and “CAD.” Inclusion criteria: studies regarding patients with ASCVD, CAD, or ACS and levels of circulating TMAO or LPS. The articles were selected in two stages: title/abstract screening followed by full-text assessment. Resultados e Conclusões: The analyzed studies demonstrate that dysbiosis is associated with elevated plasmatic levels of trimethylamine N-oxide (TMAO), a bacterial metabolite that favors atherogenesis by reducing bile acid synthesis and subsequent fecal cholesterol excretion, increasing foam cell formation, and inducing endothelial dysfunction via IL-6, CRP, TNF-α, and reactive oxygen species. Furthermore, dysbiosis induces the translocation of lipopolysaccharides (LPS) from gram-negative bacteria into systemic circulation due to increased intestinal permeability, creating a chronic low-grade endotoxemia mediated by IL-1-, IL-6-, and TNF-α-. Therefore, intestinal dysbiosis represents a relevant pathophysiological link in atherosclerosis, operating through measurable bacterial metabolites. TMAO and LPS emerge as promising biomarkers and therapeutic targets in ASCVD, CAD, and ACS.

21159

IS P2Y12 INHIBITOR MONOTHERAPY SUPERIOR TO ASPIRIN FOR LONG-TERM SECONDARY PREVENTION IN ATHEROSCLEROTIC CARDIOVASCULAR DISEASE? A SYSTEMATIC REVIEW

HANIEL FELIPE DE OLIVEIRA SAMPAIO1; AUGUSTO CÉSAR DE SOUZA BELARMINO1; CAMILA VIVIANE RIBEIRA CHAGAS1; CAUAN MIRANDA MATEUS1; LÍVIA FERREIRA DE CARVALHO1; LIVIAN QUIRINO BAIA1; PEDRO GONÇALVES NOGUEIRA NETO1; ANTÔNIA RAFAELA LIMA DE SOUZA1; SARAH BRAGA DE CASTRO1; CAMILA SOUSA MATOS1; MATHEUS DUARTE PIMENTEL1; HERALDO GUEDIS LOBO FILHO1;

(1) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Antiplatelet therapy is well established in the secondary prevention of atherosclerotic cardiovascular disease (ASCVD). Aspirin (ASA) has long been the standard for long-term monotherapy; however, the role of P2Y12 inhibitor (iP2Y12) monotherapy remains uncertain. Thus, evaluating the comparative efficacy, safety, and net clinical benefit (NCB) of these strategies remains essential. Objetivos: To evaluate the net clinical benefit of iP2Y12 monotherapy versus ASA in long-term secondary prevention. Métodos: A systematic review was conducted according to PRISMA. Searches were performed in PubMed, Embase, and Cochrane using predefined terms “Coronary artery disease”, “P2Y12 inhibitors”, “Aspirin”, and “Monotherapy”. Eligibility followed the PICO framework. Studies including adult patients with coronary artery disease in long-term secondary prevention, comparing iP2Y12 monotherapy versus ASA, were included. Screening was performed by two reviewers, with disagreements resolved by consensus. Data extraction focused on major adverse cardiovascular events (MACE) and major bleeding (MB), followed by qualitative synthesis. Resultados e Conclusões: Four studies involving 25.162 patients with established ASCVD were included, comprising three randomized trials and one post-hoc analysis. Across the included studies, reported outcomes demonstrated that iP2Y12 monotherapy (mainly Clopidogrel and Ticagrelor) demonstrated superior or non-inferior efficacy compared with ASA monotherapy. Additionally, clopidogrel consistently reduced MACE (HR 0.71–0.86; 95% CI 0.54–0.96) and was associated with lower MB rates during long-term follow-up (HR 0.71; 95% CI 0.57–0.88). Conversely, ticagrelor reduced MACE versus ASA (HR 0.74; 95% CI 0.58–0.96) but increased BARC 3 to 5 bleeding (HR 1.89; 95% CI 1.03–3.45). Moreover, NCB generally favored iP2Y12 monotherapy (HR 0.78–0.85; 95% CI 0.61–1.01), primarily driven by reductions in ischemic events without significant differences in all-cause mortality. Findings were consistent across high-ischemic-risk and complex percutaneous coronary intervention (PCI) subgroups. In long-term secondary prevention, clopidogrel monotherapy provided a NCB over ASA, reducing both ischemic events and MB with no difference in all-cause mortality. Ticagrelor reduced ischemic events but increased severe bleeding. These findings were consistent even in high-ischemic-risk and complex PCI subgroups. Thus, clopidogrel represents an advantageous alternative to ASA, with the choice guided by individual bleeding risk.

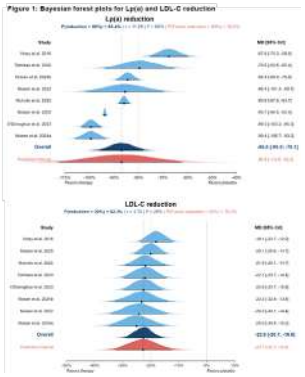
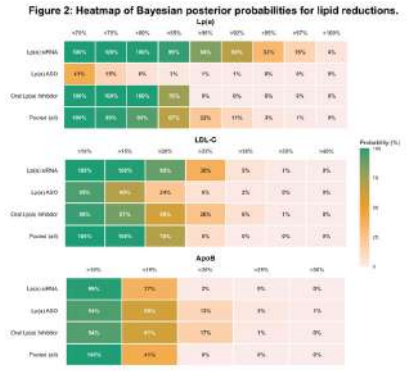
LIPID DISCORDANCE IN YOUNG ADULTS (25–35 YEARS) AND CARDIOVASCULAR RISK: A SYSTEMATIC REVIEW

INGRID THAIS FERREIRA MAGALHÃES GUIMARÃES1; EVELYN MOURA RODRIGUES DE OLIVEIRA1; LUCIANA CRISTINA MARTINS RAMOS2; MÁRCIO GENEROSO FREIRES1;

(1) UNIVERSIDADE SALGADO DE OLIVEIRA - SÃO GONÇALO - RJ - BRASIL; (2) UNIVERSIDADE SALGADO DE OLIVEIR - SÃO GONÇALO - RJ - BRASIL;



Introdução/Fundamentos: Introduction Traditional cardiovascular risk assessment is primarily based on serum LDL-cholesterol (LDL-C) levels. However, growing evidence suggests that LDL-C may underestimate true atherogenic risk in a significant portion of the population, especially in young adults and individuals with atherogenic dyslipidemia. Lipid discordance occurs when highly correlated markers such as LDL-C, non-HDL cholesterol, and apolipoprotein B (ApoB) provide conflicting information about cardiovascular risk. Each atherogenic particle contains exactly one ApoB molecule; therefore, ApoB concentration directly reflects the number of circulating particles, regardless of cholesterol content. In young adults aged 25–35 years, the window for primary prevention is particularly critical. Lipid abnormalities at this stage promote cumulative exposure to atherogenic particles and accelerate the silent progression of atherosclerosis. Identifying individuals with normal LDL-C but elevated ApoB represents a key opportunity for early intervention. This systematic review aims to synthesize current evidence on the association between lipid discordance especially ApoB/LDL-C and cardiovascular risk in young adults. Objetivos: To evaluate lipid discordance (ApoB vs. LDL-C) and cardiovascular risk in young adults aged 25–35. Métodos: Systematic review conducted according to PRISMA 2020 guidelines. Searches were performed in PubMed, Scopus, and Web of Science. Resultados e Conclusões: Twelve studies (n = 42,847). High ApoB/normal LDL-C discordance associated with subclinical atherosclerosis (OR 1.55; 95% CI: 1.38–1.74). LDL-C alone underestimates cardiovascular risk. ApoB should be incorporated into risk stratification.



21719

LIPID-LOWERING EFFICACY OF LP(A)-TARGETED THERAPIES ACROSS DRUG CLASSES: A BAYESIAN CLASS-STRATIFIED META-ANALYSIS

DEBORA DE QUEIROZ MENEZES1; LUCAS DE QUEIROZ MENEZES2; MARINA UCHOA DE ARAUJO2; CLARA UCHOA LEITE SANTANA2; ARELY VITORIA FERNANDES DA SILVA1; ANA SOFIA DONATA GERMANO2; MARIA BEATRIZ RICARDO BARBOSA1; CHRISTYELLEN JESUS SOARES ADELINO MARTINS1; LISSIA CAROLINNE TAVARES DUTRA1; MIGUEL CHAVES LENZI3; ALFREDO ROGÉRIO DIAS DALCOMUNI4; ANISIO UCHOA LEITE SANTANA5;

(1) FACULDADE DE MEDICINA DE OLINDA - OLINDA - PE - BRASIL; (2) UFRN - NATAL - RN - BRASIL; (3) UNIVERSIDADE ESTADUAL DO RIO GRANDE DO NORTE - MOSSORÓ - RN - BRASIL; (4) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (5) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Lipoprotein(a) [Lp(a)] is an independent cardiovascular risk factor inadequately addressed by conventional lipid-lowering therapies. Three mechanistically distinct drug classes, siRNA agents, antisense oligonucleotides (ASO), and oral Lp(a) inhibitors, have emerged as targeted therapies, each exerting variable effects on Lp(a), LDL-C, and ApoB. A rigorous class-level quantification with formal probabilistic inference remains lacking. Objetivos: To evaluate and compare the lipid-lowering efficacy of Lp(a)-targeted therapy classes, Lp(a) siRNA, Lp(a) ASO, and oral Lp(a) inhibitors, on Lp(a), LDL-C, and ApoB, through class-stratified Bayesian meta-analysis with threshold-exceedance probability estimation. Métodos: We systematically searched PubMed, Embase, Cochrane, and ClinicalTrials.gov through March 2026 for Randomized Controlled Trials (RCTs) evaluating Lp(a)-targeted therapies. Class-stratified Bayesian hierarchical models were fitted in Stan using Hamiltonian Monte Carlo with the No-U-Turn Sampler. Treatment effects were expressed as mean differences (MD) in percent reduction with 95% credible intervals (CrI). Statistical analysis was performed using the brms package in R. Resultados e Conclusões: We included 8 RCTs across three drug classes. For Lp(a) reduction, siRNA demonstrated the largest effect (MD −93.3%; 95% CrI −101.2 to −85.2; I²=61%), with an 83% posterior probability of exceeding a 90% reduction [Pr(>90%)], versus ASO (MD −69.6%; 95% CrI −83.9 to −57.4; Pr(>90%)=1%) and oral inhibitors (MD −85.8%; 95% CrI −88.0 to −83.6; Pr(>90%)=0%). For LDL-C, siRNA showed the strongest probabilistic signal (MD −27.0%; 95% CrI −36.8 to −18.6; I²=26%; Pr(>20%)=97%), followed by ASO (MD −39.9%; 95% CrI −90.1 to −10.3; I²=87%; Pr(>20%)=75%) and oral inhibitors (MD −21.3%; 95% CrI −32.5 to −10.1; Pr(>20%)=59%). For ApoB, all classes demonstrated near-certain efficacy exceeding a 10% reduction: siRNA (MD −15.4%; 95% CrI −20.3 to −11.1; Pr(>10%)=100%), ASO (MD −36.8%; 95% CrI −89.3 to −9.5; Pr(>10%)=99%), and oral inhibitors (MD −16.1%; 95% CrI −24.1 to −8.1; Pr(>10%)=93%). In conclusion, Lp(a) siRNA demonstrates the highest posterior probability of clinically meaningful lipid reductions across all three parameters. ASO exhibited substantial heterogeneity in LDL-C and ApoB estimates, warranting caution in pooled inference, while oral inhibitors showed robust Lp(a) lowering that nonetheless fell short of the 90% threshold, highlighting important class-level distinctions for therapeutic decision-making.

19199

LIPOPROTEIN(A) AS AN EMERGING THERAPEUTIC TARGET IN CARDIOVASCULAR PREVENTION: CURRENT EVIDENCE AND FUTURE PERSPECTIVES

ISABELA CRISTINA PEREIRA1; JONATHAN VINICIUS DA SILVA CASARIM2; MARIANA SANTOS SPINELLI2;

(1) FAMINAS - MURIAÉ - MG - BRASIL; (2) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL;

Introdução/Fundamentos: Lipoprotein(a) [Lp(a)] is recognized as an independent, genetically determined cardiovascular risk factor associated with the development of atherosclerosis and thrombotic events. Despite its clinical relevance, effective therapeutic strategies for reducing Lp(a) levels remain limited, driving the development of novel targeted approaches. Objetivos: To evaluate the role of lipoprotein(a) in cardiovascular risk stratification and to critically discuss the impact of emerging therapies on the modification of residual cardiovascular risk. Métodos: A literature review was conducted using the PubMed database, including studies published between 2020 and 2026. Clinical trials, observational studies, systematic reviews, and international guidelines addressing Lp(a) as a cardiovascular risk factor and emerging therapeutic approaches were selected. Studies were screened through title and abstract analysis, followed by full-text review according to predefined eligibility criteria. Resultados e Conclusões: Consistent evidence demonstrates that elevated Lp(a) levels are associated with an increased risk of coronary artery disease, stroke, and major adverse cardiovascular events. Mechanistically, Lp(a) contributes to the progression of atherosclerosis and promotes prothrombotic activity. Conventional therapies have shown limited efficacy in reducing its circulating levels. However, novel RNA-based approaches, including antisense oligonucleotides and small interfering RNA (siRNA) therapies, have demonstrated substantial reductions in Lp(a) levels in recent clinical trials, representing a paradigm shift in the management of residual cardiovascular risk. Therefore, Lp(a) has emerged as an important therapeutic target in cardiovascular prevention.

16931

MICROPLASTIC EXPOSURE AND RISK OF CARDIOVASCULAR DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

VITÓRIA KIMURA1; MURILO YAGUIU PACHECO2; RAFAEL SÁ CARVALHO3; LARISSA ALMEIDA ARAÚJO DE PAULA3; LÍVIA TRAVESSA CHAMBÓ3; HIGOR HENRIQUE FONSECA GUILHERMINO3; MARIA EDUARDA GERARDINI3; RICARDO JOSÉ TOFANO3;

(1) UNIVERSIDADE DE MARÍLIA - UNIMAR - MARILÍA - SP - BRASIL; (2) UNIVERSIDADE DE MARÍLIA - UNIMAR - MARÍLIA - SP - BRASIL; (3) UNIVERSIDADE DE MARÍLIA - UNIMAR - MARÍLIA - SP - BRASIL;

Introdução/Fundamentos: Plastic pollution contributes to the formation of microplastics (particles < 5 mm) and nanoplastics (particles < 1,000 nm) (MNPs), associated with toxic effects. These particles enter the body via ingestion, inhalation, and skin contact. Evidence suggests MNPs are risk factors for cardiovascular disease through oxidative stress, inflammation, and apoptosis, and have been detected in atherosclerotic plaques. Objetivos: To assess the association between microplastics exposure and cardiovascular outcomes. Métodos: This systematic review followed PRISMA guidelines. A literature search was performed in the PubMed database. MeSH terms and free-text keywords included “microplastics”, “nanoplastics”, AND “atherosclerosis”, “atheroma”, “plaque”, “cardiovascular”, “carotid”, “coronary”. Boolean operators (AND, OR) were applied. Resultados e Conclusões: A total of eight studies have demonstrated that microplastics and nanoplastics are widely present in human vascular tissues, associated with vascular inflammation and atherosclerotic plaque instability. Approximately 58% of patients have MNPs in plaques, reaching >90% in carotid arteries, suggesting bioaccumulation. Mechanistically, these particles induce M1 macrophage activation, increasing phagocytosis, altering lipid metabolism, and promoting the accumulation of foam cells, contributing to vascular toxicity and arterial thickening. Clinical data demonstrate an increased risk of major cardiovascular events in individuals with MNPs (HR 4.53; 95% CI: 2.00–10.27; $p < 0.001$; Δ absolute risk: 15–18%), maintaining an association with nonfatal myocardial infarction. Experimental studies confirm increased total cholesterol, LDL, lipid uptake by macrophages, and increased plaque area ($p < 0.005$). Taken together, the findings indicate a strong, plausible, and potentially causal association, highlighting MNPs as an emerging environmental risk factor for atherosclerotic cardiovascular disease. Finally, it is concluded that microplastics are widely present in human vascular tissues, associated with atherosclerotic plaque instability. These findings demonstrate a significant increase in cardiovascular risk due to their potential role in atherogenesis. Therefore, they emerge as a possible environmental risk factor for cardiovascular disease, requiring further studies.

MYOCARDITIS AFTER COVID-19 AND VACCINATION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF INCIDENCE AND MORTALITY

MANOELA LENZI PINTO1; MILENA DIAS DA SILVA1; RAFAELA SUMIENSKI GIRARDI1; ALICE POLENZ WIELEWICKI1; FERNANDA DEI RICARDI1; FABIO ALBAN2; MARA RÚBIA ANDRÉ ALVES DE LIMA1;

(1) UFCSPA - PORTO ALEGRE - RS - BRASIL; (2) POMPÉIA ECOSSISTEMA DE SAÚDE - CAXIAS DO SUL - RS - BRASIL;

Introdução/Fundamentos: Myocarditis is an inflammatory condition of the myocardium commonly associated with viral infections and may lead to arrhythmias, cardiac dysfunction and death. During the COVID-19 pandemic, its incidence increased, occurring both as a complication of SARS-CoV-2 infection and, less-frequently, as a post-vaccination event. Although vaccine-related myocarditis has been identified as a potential adverse event, a comparative evaluation of its relative risk to infection is essential. Despite its low frequency following vaccination, widespread media coverage contributed to vaccine hesitancy. Therefore, quantifying and comparing incidence and mortality is essential to better inform clinical practice and public health policies. Objetivos: To quantitatively assess and compare the incidence and mortality of myocarditis associated with SARS-CoV-2 infection and COVID-19 vaccination through meta-analysis. Métodos: This systematic review and meta-analysis was conducted according to PRISMA guidelines. Studies were screened by two independent reviewers based on predefined eligibility criteria. Observational studies reporting myocarditis incidence and/or mortality associated with COVID-19 infection or vaccination were included. Random-effects meta-analyses of proportions with logit transformation were performed, with subgroup analyses by exposure type (COVID-19 vs vaccination). Results were reported as pooled estimates with 95% Confidence Intervals (CI). Statistical analyses were conducted in R using the meta package. Resultados e Conclusões: Twelve studies were included, comprising over 95 million individuals for incidence analysis and 10,140 myocarditis cases for mortality assessment. The incidence of myocarditis was higher in patients with COVID-19 compared to vaccination, with a pooled estimate of 135.29 cases per 100,000 individuals (95% CI: 36.32–502.60) versus 1.68 per 100,000 (95% CI: 0.83–3.42), respectively ($p < 0.0001$). Mortality among myocarditis cases was higher in COVID-19–associated cases, with a rate of 12.11% (95% CI: 3.44–34.77) compared to 2.65% (95% CI: 1.48–4.71) in vaccination-related cases ($p = 0.0316$). Substantial heterogeneity was observed ($I^2 > 90\%$), likely reflecting differences in study populations, diagnostic criteria, and clinical settings; however, the direction of effect remained consistent. In conclusion, both the incidence and mortality of myocarditis are higher in patients with COVID-19 compared to vaccination, supporting the relative safety of vaccines regarding this outcome.

16902

NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD)/METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) AND RISK OF MAJOR ADVERSE CARDIOVASCULAR EVENTS (MACE): A SYSTEMATIC REVIEW AND META-ANALYSIS

LOUISE ARAUJO JASSE SANTOS1; MARCOS PAULO JORGE DE SALES1; ANTONIO MARIA ZACARIAS ARAUJO MONTEIRO1; RENATA GOMES DE ARAUJO TEIXEIRA CYPRIANO2; RAFAEL ARAUJO DE BRITO NOBRE3; LETÍCIA SANFORD CARNEIRO COELHO1; GABRIEL SANTARÉM JORGE PINTO DOS REIS1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DA AMAZONIA - BELÉM - PA - BRASIL; (3) CENTRO UNIVERSITÁRIO FIBRA (FACULDADE INTEGRADA BRASIL AMAZÔNIA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases remain the leading cause of morbidity and mortality worldwide. Non-alcoholic fatty liver disease (NAFLD), recently redefined as metabolic dysfunction-associated steatotic liver disease (MASLD), is the most common chronic liver disease and is strongly linked to metabolic risk factors. Given its association with metabolic dysfunction, systemic inflammation, and endothelial impairment, NAFLD/MASLD may contribute to increased cardiovascular risk; however, this relationship has not been fully characterized across different cardiovascular outcomes. Objetivos: To evaluate the association between NAFLD/MASLD and major adverse cardiovascular events (MACE). Métodos: This systematic review and meta-analysis followed PRISMA guidelines. PubMed and EBSCO were searched (January 2005–March 2026) using predefined terms for NAFLD/MASLD and MACE. Google Scholar was used for supplementary search. Observational cohort studies reporting cardiovascular outcomes were included; reviews, case reports, and editorials were excluded. Two reviewers screened studies and extracted data by consensus. Study quality was assessed using the Newcastle–Ottawa Scale. Studies reporting adjusted hazard ratios (HR) or subdistribution hazard ratios (sHR) were pooled in the meta-analysis, while studies reporting other measures (e.g., odds ratios or risk ratios) were included qualitatively but not pooled due to limited numbers. Pooled estimates were calculated using a random-effects model with inverse variance in RevMan 5.4 (Cochrane), with predefined subgroup analyses. Resultados e Conclusões: Fifty-four studies were included in the qualitative synthesis, of which 32 were included in the meta-analysis (33 entries, as one study contributed to two outcomes), totaling over 86 million participants. Overall, NAFLD/MASLD was associated with increased risk of MACE (HR 1.60, 95% CI 1.43–1.79). In outcome-specific analyses, significant associations were observed for myocardial infarction (HR 1.31, 95% CI 1.20–1.43) and stroke (HR 1.29, 95% CI 1.07–1.56). No significant association was found for cardiovascular mortality (HR 1.68, 95% CI 0.85–3.33) or heart failure (HR 1.75, 95% CI 0.84–3.63), likely due to the small number of studies (n=2 each). Despite high heterogeneity (I^2 = 99%), effect direction was consistent, likely reflecting differences in MACE definitions, populations, and diagnostic methods. Findings support NAFLD/MASLD as a marker of increased cardiovascular risk, but highlight the need for standardization across studies.

PARTICULARITIES OF SMOKERS WITH DEPRESSIVE SYMPTOMS UNDERGOING SMOKING CESSATION

LUIS FELIPE PARREIRA PELUSO1; VITOR HUGO EUZEBIO DE MELLO1; LUISA PALMA SCHIAVON1; MAX GRAVINA RODRIGUES1; LUCAS CASTRO DE MENDONÇA1; CLARA AZARA SENNA1; SAMUEL TOLEDO FILHO1; ANA CLARA KOZLOWSKI CARAVIERI1; DIANE MICHELA NERY HENRIQUE1; ELIANE FERREIRA CARVALHO BANHATO1; ARISE GARCIA DE SIQUEIRA GALIL1;

(1) UFJF - JUIZ DE FORA - MG - BRASIL;

Introdução/Fundamentos: Depression is a mood disorder associated with clinical and behavioral comorbidities, including smoking. The Patient Health Questionnaire-9 (PHQ-9) identifies probable depression and symptom severity. Smoking may contribute to the development of depression, while depression may hinder smoking cessation. Investigating its association with clinical profile, including smoking history, comorbidities, and functional parameters, may improve understanding the interaction between these factors and their impact on overall health. Objetivos: To evaluate depressive symptom screening and its clinical and smoking-history associations among smokers with multimorbidities. Métodos: Observational cross-sectional study of smokers attending a university hospital smoking cessation clinic, coordinated by a multidisciplinary team, from August 2021 to April 2026. Cognitive-behavioral and pharmacological therapies were offered, with follow-up for up to 12 months. Depressive symptoms were defined as PHQ-9 >9. High nicotine dependence was defined as Fagerström Test ≥5; heavy smoking as ≥20 cigarettes/day; and cognitive decline as MoCA <26. Data were expressed as mean±SD or percentages. Associations were tested using Student's t-test and Chi-square test (p<0.05). Resultados e Conclusões: A total of 294 smokers (40 consecutive treatment groups) were evaluated. Depressive symptoms were present in 59.2%. Overall, 76.9% were women; mean age was 58.03±10.24 years; smoking duration 40.5±12.17 years; cigarette consumption 22.65±12.92/day; 67.8% were heavy smokers; and 75.3% had high nicotine dependence. Compared with smokers without depressive symptoms, those with depressive symptoms had lower prevalence of older adults (p<0.038), higher prevalence of COPD (p<0.001) and anxiety (p<0.002), higher cholesterol (p<0.026) and triglycerides (p<0.009), a trend toward sedentary lifestyle (p<0.087), and lower MoCA scores (p<0.086). Regarding smoking history, they had higher Fagerström scores (p<0.021), more dependence triggers related to phone use (p<0.018) and stress (p<0.017), more previous withdrawal symptoms (p<0.008), and more lapses (p<0.011). Conclusions: Depressive symptoms were highly prevalent and associated with younger smokers, worse metabolic and respiratory markers, and greater nicotine and behavioral dependence. Early screening for depressive symptoms may support timely pharmacological and behavioral interventions and improve smoking cessation outcomes.

VARIABLE	MEAN±SD or PERCENTAGES
Depressive symptoms	59.2%
Women	76.9%

PERFORMANCE OF THE SAMPSON EQUATION FOR LDL-C ESTIMATION IN PRIMARY CARE: AN OBSERVATIONAL STUDY IN A BRAZILIAN POPULATION

DAVID GARCIA DE ALCARAZ CONTI1; FERNANDO LUIZ AFFONSO FONSECA1;

(1) FACULDADE DE MEDICINA DO ABC (FMABC) - SANTO ANDRÉ - SP - BRASIL;

Introdução/Fundamentos: Accurate estimation of low-density lipoprotein cholesterol (LDL-C) is essential for cardiovascular risk stratification in primary care. The Friedewald equation remains widely used but shows reduced accuracy in hypertriglyceridemia and low LDL-C levels. The Sampson equation was developed to improve LDL-C estimation across a broader triglyceride spectrum without increasing operational complexity. Objetivos: To evaluate the analytical performance and clinical impact of the Sampson equation compared with the Friedewald formula in a primary care population. Métodos: An observational analytical study was conducted using lipid profiles from adult patients followed in primary care units in São Bernardo do Campo, Brazil. The study was approved by the local Research Ethics Committee (CEP nº 7.714.125; CAAE 89741425.9.0000.0082). LDL-C was estimated using Friedewald and Sampson equations and compared with directly measured LDL-C in a representative subset. Subgroup analyses were performed according to triglyceride levels (<150, 150–399, and ≥400 mg/dL). Agreement with direct LDL-C was assessed using correlation coefficients, mean absolute error, and Bland–Altman analysis. Reclassification across clinically relevant LDL-C thresholds (70 and 100 mg/dL) was evaluated. Resultados e Conclusões: A total of 1,372 patients were included (mean age 59.2 years; 58.6% female; 36.9% diabetes). Median triglycerides were 192 mg/dL. In the validation subset (n=348), the Sampson equation demonstrated lower mean absolute error compared with Friedewald (9.1 vs 14.7 mg/dL; p<0.001) and stronger correlation with direct LDL-C (r=0.93 vs 0.87). Differences were modest at triglycerides <150 mg/dL but became clinically significant above 150 mg/dL. In patients with triglycerides ≥400 mg/dL, Sampson maintained better agreement (mean absolute error 15.6 vs 33.4 mg/dL; p<0.001), whereas Friedewald showed marked underestimation. Reclassification occurred in 21.4% of patients, predominantly shifting individuals to higher-risk LDL-C categories. The Sampson equation did not increase operational cost, as it is based on a fixed formula without variable adjustments. These findings support the Sampson equation as a more accurate and cost-neutral alternative for LDL-C estimation in primary care, particularly in populations with high metabolic burden.

PREVALENCE AND CHARACTERISTICS OF CORONARY ARTERY LESIONS IN PATIENTS UNDER 40 YEARS: A CORONARY COMPUTED TOMOGRAPHY ANGIOGRAPHY STUDY

ISABELA MALMACEDA DE MORAES1; LISIANE CERVIERI MEZZOMO2; MARIA ANTÔNIA PERES SALDANHA3; ALEFF KURY BERTHIER2; AMANDA NICHELE1; GABRIELA CARMINATI LINO1; GUILHERME KRIPKA3; LAURA CRISTINA PUDELL4; CECYRA BAUERMANN COLLARES MACHADO4; PAULO ROBERTO SCHVARTZMAN4; EDUARDO DYTZ DE ALMEIDA4; MATHEUS WERLANG DONADEL4;

(1) UNISINOS - SÃO LEOPOLDO - RS - BRASIL; (2) UNIVERSIDADE LUTERANA DO BRASIL- ULBRA - CANOAS - RS - BRASIL; (3) PUCRS - PORTO ALEGRE - RS - BRASIL; (4) HOSPITAL MOINHOS DE VENTO - PORTO ALEGRE - RS - BRASIL;

Introdução/Fundamentos: Coronary artery disease (CAD) is uncommon in individuals under 40 years of age; however, when present, it may have significant clinical implications. Data regarding this population remain limited, and strategies for early diagnosis and identification of high-risk individuals continue to be challenging in modern cardiology. Objetivos: To evaluate the prevalence of coronary artery lesions and anatomical characteristics in patients aged ≤40 years undergoing coronary computed tomography angiography (CCTA). Métodos: This retrospective cross-sectional study included all CCTA examinations performed between January 2023 and January 2025. Patients were stratified by age, focusing on those ≤40 years. The analyzed variables included the presence of coronary artery lesions, coronary artery calcium (CAC) score, and anatomical characteristics of lesions, when present. Resultados e Conclusões: A total of 2083 CCTA examinations were performed, of which 94 were in patients aged ≤40 years. Age ranged from 8 to 40 years (median 36 years). Elevated CAC score was observed in 11% of patients (mean 4.4 AU), with only one patient presenting CAC >100 AU. Coronary artery lesions were identified in 14% of patients, most commonly involving the left anterior descending artery. Only two patients (2.1%) had moderate or severe lesions. Most patients with coronary lesions had detectable CAC, with only one patient (1.06%) presenting a lesion despite a CAC score of 0. In this population, the prevalence of coronary artery lesions was low and predominantly mild, and most frequently involved the left anterior descending artery. The presence of CAC was associated with coronary calcification and atherosclerosis, even in younger individuals. These findings support the selective use of CCTA in this age group and highlight the importance of individualized clinical assessment.

CORONARY ARTERY	NUMBER OF LESIONS
LEFT MAIN CORONARY ARTERY	0
LEFT ANTERIOR DESCENDING ARTERY	11
RIGHT CORONARY ARTERY	2
LEFT CIRCUMFLEX ARTERY	1

PREVENT VS. FRAMINGHAM RISK SCORE IN A HIGH-RISK POPULATION: CARDIOVASCULAR RISK RECLASSIFICATION AND THE ROLE OF METABOLIC SYNDROME

GABRIELA MENDONÇA DE OLIVEIRA1; ADALBERTO TEIXEIRA DA MATTA FLORA NETO1; LEONARDO RODRIGUES FERNANDES1; LUCAS PETRAGLIA BARROSO1; ELOARA GOMES DE PAULA1; MATHEUS PAGNANO DE SOUZA1; JOÃO LUCAS O'CONNELL1;

(1) UNIVERSIDADE FEDERAL DE UBERLÂNDIA - UBERLÂNDIA - MG - BRASIL;

Introdução/Fundamentos: The 2025 Brazilian Guideline on Dyslipidemia and Atherosclerosis Prevention adopts the PREVENT score for cardiovascular risk stratification, replacing the Framingham Global Risk Score (FGRS). By incorporating heart failure outcomes and lowering the high-risk threshold from ≥20% to ≥10%, PREVENT substantially modifies risk classification, however, its clinical impact remains uncertain. Objetivos: To compare cardiovascular risk reclassification by PREVENT versus FGRS and to characterize the clinical and metabolic profile of reclassified patients, emphasizing metabolic syndrome (MetS). Métodos: Cross-sectional study including 140 patients (40–74 years) followed at a tertiary care center. The base PREVENT model was calculated according to Khan SS et al., incorporating age, sex, systolic blood pressure, total cholesterol, HDL-cholesterol, diabetes, smoking, antihypertensive use, and statin therapy. Agreement between scores was assessed using Cohen's kappa coefficient, with net reclassification analysis. Between-group differences were analyzed using Fisher's exact test and Mann-Whitney U test. Resultados e Conclusões: PREVENT category distribution was: low risk 48 (34.3%), borderline 40 (28.6%), intermediate 31 (22.1%), and high (≥20%) 21 (15.0%). Applying the ≥10% high-risk threshold recommended by the 2025 Brazilian guideline, 52 patients (37.1%) were classified as high risk (intermediate + high), compared with 66 (47.1%) by FGRS. Overall agreement was moderate (κ=0.652). Downward reclassification by PREVENT occurred in 13.6% of patients, who were significantly younger (median 55 vs. 67 years, p=0.0002) and had lower systolic blood pressure (p=0.040) compared with the concordant high-risk individuals. Among these reclassified patients, 84% were male and 79% had MetS. Agreement was substantial in patients with MetS (κ=0.645; n=106) but significantly lower in those without MetS (κ=0.370; n=34). Pearson correlation between continuous scores was r=0.608. PREVENT adoption shifts in cardiovascular risk stratification compared with FGRS, with notable proportion of downward reclassification, that largely affects younger male patients with high prevalence of metabolic syndrome, raising concerns about potential underestimation of risk. Lower agreement observed in individuals without MetS further highlights heterogeneity in risk assessment. These findings support the need for complementary risk refinement strategies, such as coronary artery calcium scoring, during the transition to PREVENT-based risk assessment.

PROGNOSTIC VALUE OF CORONARY ARTERY CALCIUM SCORE IN PREDICTING MAJOR CARDIOVASCULAR EVENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

THIAGO VITTOR SILVA FREITAS1; RAFAEL ALVES PINA1; LUCAS MARINHO REIS DA CUNHA SILVA1; BRUNO DE FREITAS SILVA1; RAFAEL ALVES DE OLIVEIRA1; POLIANA MARCELINO JOIA1; GIOVANA CASAGRANDE DE ALENCAR1; TAYNARA TAVARES DOS SANTOS1; ISAC DIAS DE OLIVEIRA1; ANA CAROLINA CAVALCANTE GALVÃO1; LAÍS DURAN GOMES1; AMANDA OLIVA SPAZIANI1;

(1) UNIVERSIDADE BRASIL - UB - FERNANDÓPOLIS - SP - BRASIL;

Introdução/Fundamentos: Cardiovascular risk stratification is essential to guide preventive interventions. The coronary artery calcium (CAC) score, obtained by computed tomography, has emerged as a noninvasive tool for detecting subclinical atherosclerosis. However, the magnitude of its association with major cardiovascular events still requires quantitative consolidation. Objetivos: To evaluate the prognostic value of the coronary artery calcium score in predicting major cardiovascular events in asymptomatic adults. Métodos: A systematic review conducted according to PRISMA guidelines, with searches in PubMed, Embase, and Cochrane Library databases up to January 2026. Prospective studies evaluating the association between CAC and cardiovascular events were included. Participants were stratified according to CAC levels (0, 1–100, >100). The primary outcome was a composite of major cardiovascular events (MACE). The meta-analysis was performed using a random-effects model, with calculation of relative risk (RR) and 95% confidence intervals (95% CI). Heterogeneity was assessed using the I² index. Resultados e Conclusões: Eleven studies were included, totaling 102,457 participants. Individuals with CAC >100 had a significantly higher risk of cardiovascular events compared to those with CAC=0 (RR=3.12; 95% CI: 2.65–3.67; p<0.001). Even intermediate levels (CAC 1–100) showed increased risk (RR=1.78; 95% CI: 1.45–2.18; p<0.001). Heterogeneity was low (I²=23%). The coronary artery calcium score demonstrated strong prognostic value in predicting major cardiovascular events, allowing more precise risk stratification. Its use may assist in clinical decision-making, especially in guiding preventive therapies such as statins.

QUALITATIVE VS. QUANTITATIVE CHANGES IN EPICARDIAL FAT UNDER GLP-1 RECEPTOR AGONIST THERAPY: A SYSTEMATIC REVIEW OF TISSUE COMPOSITION AND VOLUMETRIC IMAGING

LAURA BEATRIZ SOUZA COLPO1; EDUARDO FREITAS SANTOS1; JOÃO NUNO BARATA DA COSTA BISPO1; JOSÉ MANUEL COMPRIDO1; KAUÃ FIGUEIREDO MACHADO1; SELMA GUIMARÃES FERREIRA MEDEIROS1;

(1) UNIVERSIDADE FEDERAL DE MATO GROSSO DO SUL - CAMPO GRANDE - MS - BRASIL;

Introdução/Fundamentos: Epicardial adipose tissue (EAT) acts as an inflammatory reservoir contributing to cardiometabolic diseases. Although glucagon-like peptide-1 receptor agonists (GLP-1 RAs) have established cardiovascular benefits, their direct effect on EAT remains debated, prompting a shift from volumetric to qualitative microstructural analysis. Objetivos: To evaluate the impact of GLP-1 RAs and co-agonists on the qualitative and quantitative modulation of EAT in adults with overweight, obesity, or Type 2 Diabetes Mellitus, and its correlation with weight loss. Métodos: A systematic review conducted in strict accordance with the PRISMA 2020 guidelines, standardized searches (PubMed, Embase, Cochrane, LILACS) selected clinical trials and cohorts assessing EAT via Computed Tomography (CT) or Magnetic Resonance (MRI). Due to high heterogeneity, summary measures were inapplicable; data extraction followed the SWiM (Synthesis Without Meta-analysis) narrative synthesis model. Resultados e Conclusões: Six studies (383 patients) were included. EAT volumetric reduction proved inconsistent and, in most cases, passive and mathematically dependent on global weight loss. Liraglutide and tirzepatide induced significant systemic weight loss without achieving superior EAT volume reduction compared to placebo. With exenatide, EAT reduction occurred but was strongly linked to weight loss (r = 0.50). Semaglutide was the anatomical exception, reducing EAT independently of BMI (Body mass index). Regarding qualitative assessment (primary outcome), intracardiac lipotoxicity (triglyceride fraction via MRI) did not change significantly. In sharp contrast, CT revealed early inflammatory modifications: semaglutide significantly increased EAT radiodensity (+4.9 Hounsfield Units; p = 0.010). This increase acts as a radiological marker of tissue “de-inflammation” and beneficial microenvironment remodeling, occurring entirely independently of systemic weight loss. EAT structural reduction is, in most cases, a passive anatomical reflection of global weight loss rather than an intrinsic drug effect. However, the cardioprotection conferred by these therapies appears linked to a direct pleiotropic effect that promotes de-inflammation (increased radiodensity) and beneficial remodeling of the perivascular microenvironment. This phenotypic transition of EAT from a pro-inflammatory organ to a metabolically healthy state occurs regardless of variations in its size or physical shrinkage.

Lead Author (Year)	Main Findings
Dutour et al. (2016)	Exenatide promoted a significant reduction in epicardial adipose tissue (EAT) volume by 8.8% and in hepatic fat (HTGC) by 23.8% when compared to the reference treatment. The decrease in EAT was mathematically dependent on the systemic weight loss of the patients (r = 0.50; p = 0.018). There was no significant change in intracardiac/myocardial lipotoxicity (MTGC).
Manubolu et al. (2024)	The use of semaglutide resulted in a 9% reduction in EAT volume and, innovatively, promoted a 5% (or +4.9 HU) increase in epicardial fat radiodensity. This density increase on computed tomography acts as a marker of tissue "de-inflammation", occurring independently of BMI and body weight reduction (proven in multivariable models)
van Eyk et al. (2019)	Liraglutide induced significant weight loss in South Asian patients, but the intention-to-treat analysis did not reveal significant macrostructural reductions in EAT volume, paracardial fat, or myocardial triglyceride content, The reduction was limited to visceral adipose tissue in the per-protocol analysis, which was associated with improved HbA1c
Kramer et al. (2025)	Tirzepatide was effective in reducing left ventricular mass and global paracardial fat in patients with heart failure and obesity. However, the isolated modulation of EAT showed no significant statistical difference when compared to placebo (adjusted difference of -2 mL, p = 0.57), indicating that overall weight loss did not directly translate into an epicardial fat decrease.
Zhao et al. (2021)	In a single-arm clinical trial, liraglutide therapy significantly reduced EAT thickness by an average of 1.62 mm after 3 months. This effect was accompanied by a marked decrease in body weight (-4.38 kg), waist circumference, and BMI. The study, however, did not perform tests to verify whether this reduction was independent of weight loss
Bizino et al. (2020)	Despite promoting greater weight loss than placebo (-4.5 kg), liraglutide predominantly reduced subcutaneous adipose tissue. No statistically significant reductions in EAT, visceral adipose tissue (VAT), or hepatic and myocardial steatosis were observed compared to the control group

RISK OF MAJOR ADVERSE CARDIOVASCULAR EVENTS IN PATIENTS WITH SEVERE PSORIASIS TREATED WITH BIOLOGICS VERSUS CONVENTIONAL THERAPY: A SYSTEMATIC REVIEW AND META-ANALYSIS

BEATRIZ DE LIMA VITORIO FERREIRA1; FLAVIA BEATRIZ DO CARMO MOREIRA2; MARCOS AURELIO FONSECA MEDEIROS1; EVELIN GABRIELLY DE VARGAS2; ANNA JULIA RUY BOBBIO2; BIANCA RIBEIRO CORREIA LIMA3; JOSIANE DE SOUZA BEZERRA2; VALESKA TAVARES DA SILVA RORIS RODRIGUEZ SCAVARDA DO CARMO2;

(1) UNIFACISA - CAMPINA GRANDE - PB - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (3) CENTRO UNIVERSITARIO MAURICIO DE NASSAU - RECIFE - PE - BRASIL;

Introdução/Fundamentos: Psoriasis is a chronic systemic inflammatory disease associated with an increased cardiovascular risk. While biologic therapies may mitigate inflammation-driven atherosclerotic burden, their precise effect on major adverse cardiovascular events (MACE) remains uncertain. Objetivos: To compare the risk of MACE in patients with severe psoriasis treated with biologic agents versus conventional therapies. Métodos: This systematic review and meta-analysis followed PRISMA guidelines and included trials and observational cohorts. Data were obtained from registries and databases, TriNetX, Korean National Health Insurance, BIOBADADERM, BADBIR, MarketScan, and European cohorts. Twenty-five studies involving 300,000 patients were analyzed. Biologic therapies included anti-TNF, anti-IL-17, anti-IL-12/23, and anti-IL-23 agents. Conventional therapies comprised methotrexate, cyclosporine, phototherapy, and topicals. HR, adjusted HR, OR, and IRR were pooled using random-effects models. The primary outcome was MACE, myocardial infarction, stroke, or cardiovascular death. Resultados e Conclusões: Large real-world cohorts consistently demonstrated a lower cardiovascular risk with biologics compared to conventional therapy. Specifically, in TriNetX (n=25,464), biologics reduced MACE (HR 0.697; 95%CI 0.614–0.792). In the Korean nationwide cohort (n=183,212), biologics were associated with a lower incidence of MACE (aHR 0.454; 95%CI 0.359–0.574) and recurrent MACE (aHR 0.343; 95%CI 0.245–0.479) versus phototherapy. Anti-TNF agents showed significant benefit, including lower myocardial infarction risk versus topical therapy (aHR 0.50; 95%CI 0.32–0.79) and lower MACE risk versus methotrexate (HR 0.55; p<0.01). In contrast, randomized trial meta-analyses showed no significant differences, likely attributable to short follow-up periods and low event rates. Ustekinumab demonstrated an overall neutral profile, although one cohort suggested an early excess risk in patients with high baseline cardiovascular risk. Cyclosporine was associated with an increased MACE risk (IRR 3.59; 95%CI 1.17–10.99). In patients with severe psoriasis, biologic therapy—particularly anti-TNF and anti-IL-17 agents—is associated with a lower risk of MACE compared with conventional treatment in large observational studies. Randomized trials remain underpowered for cardiovascular outcomes. These findings support systemic inflammation control as a relevant strategy for cardiovascular risk reduction in psoriasis.

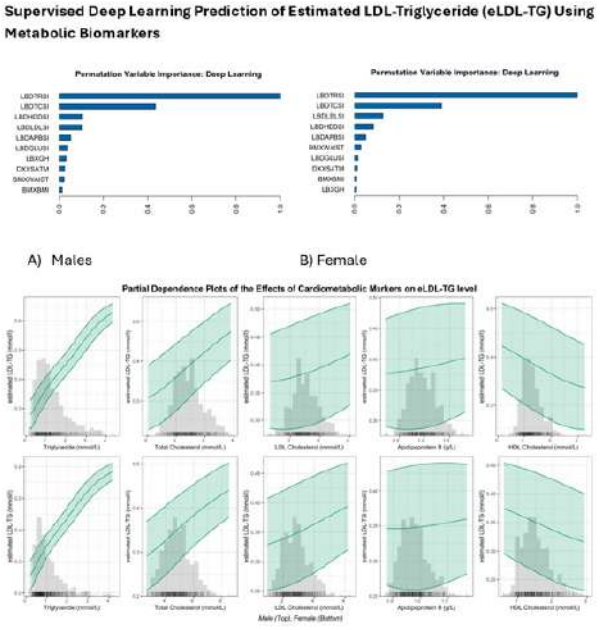
SEX DISPARITIES AND TEMPORAL TRENDS IN CARDIOVASCULAR MORTALITY IN BRAZIL (2015–2024)

GUSTAVO CAMPOS SABINO1; RAQUEL FAKHOURI CARDOSO2; MARIA MARINA VIZIOLI PEDROSO DA CRUZ3; ÂNDREA GABRIELLE BATISTELA DA SILVA4; THEODORA CRISTINA CRUZ DE ASSIS5; JOÃO CARLOS ANTUNES DE FIGUEIREDO6; YASMIN NICOLETTI THULLER7; BEATRIZ DA SILVA DE OLIVEIRA8; BRUNO CARNEVALE SINI9; LARISSA DE ALMEIDA DOURADO10; CARLA JANICE BAISTER LANTIERE10; ANTÔNIO CARLOS PALANDRI CHAGAS10;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (2) UNIVERSIDADE ANHEMBI MORUMBI - SÃO PAULO - SP - BRASIL; (3) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (4) FACULDADE DE MEDICINA DE SÃO JOSÉ DO RIO PRETO (FAMERP) - SÃO JOSÉ DO RIO PRETO - SP - BRASIL; (5) UNICAMP - CAMPINAS - MT - BRASIL; (6) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL; (7) CENTRO UNIVERSITÁRIO DE BRUSQUE (UNIFEBE) - BRUSQUE - SC - BRASIL; (8) UNIVERSIDADE DE MOGI DAS CRUZES - MOGI DAS CRUZES - SP - BRASIL; (9) CLINICA PRO CORACAO - SÃO PAULO - SP - BRASIL; (10) CENTRO UNIVERSITÁRIO FACULDADE DE MEDICINA DO ABC - SANTO ANDRÉ - SP - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases (CVD) remain the leading public health challenge in Brazil, with fatal outcomes distributed unequally between sexes. While male mortality is linked to earlier onset, female mortality is often masked by atypical symptoms, diagnostic neglect, and a distorted perception of risk. Objetivos: This study analyzes sex disparities in atherosclerotic cardiovascular mortality in Brazil, comparing ischemic profiles from 2015 to 2024. Métodos: This cross-sectional, descriptive epidemiological study utilized data from the Mortality Information System (SIM/DATASUS). Deaths were analyzed using ICD-10 codes: I21 (Acute Myocardial Infarction), I63 (Cerebral Infarction), I70 (Atherosclerosis), and I25 (Chronic Ischemic Heart Disease). Variables included sex, age, race, education level, and geographic region. Resultados e Conclusões: Out of 2,721,498 recorded deaths, males accounted for 53.3% (n=1,450,418). The age-related contrast highlights significant inequality: men show peak lethality between 60–69 years, whereas 35.5% of female deaths occur after age 80 (n=452,261). Female longevity does not imply protection; the survival benefit provided by estrogen during fertile years shifts fatal events to senescence, often exacerbated by decades of underdiagnosis. Furthermore, regarding the identified ICD codes, there was a higher number of male deaths related to AMI (59.3%) and Ischemia (15.1%). Concerning Stroke, both groups showed similar figures (51.1% vs. 48.9%). However, deaths from atherosclerosis suggest that women may be more affected (52.4%), although the lack of age stratification hinders analytical precision. Socioeconomically, low education (1–3 years of schooling) concentrated the highest death toll (n=558,917), proving social vulnerability is as critical as biological factors. Regionally, the Southeast led in volume (São Paulo: 624,582 cases), reflecting population density and the urgency for targeted strategies. Brazil faces dual challenges: the necessity for early lifestyle intervention in men and the recognition of female ischemic risk, which shifts over time and requires continuous cardiovascular surveillance throughout a woman's life.



19952

SUPERVISED DEEP LEARNING PREDICTION OF ESTIMATED LDL-TRIGLYCERIDE (ELDL-TG) USING METABOLIC BIOMARKERS

SAHEED OLADELE AMUSAT1;

(1) NOTTINGHAM TRENT UNIVERSITY - UNITED KINGDOM;

Introdução/Fundamentos: Recent studies have shown that estimated LDL triglycerides (eLDL-TG) are more strongly associated with atherosclerotic cardiovascular disease (ASCVD) risk than both estimated LDL-C and directly measured LDL-C. Using a novel equation proposed by Wolska et al. (2024), eLDL-TG was matched to LDL-TG levels measured using the BQ reference method (BQLDL-TG). Despite its clinical significance, there is a paucity of findings exploring the relationships between eLDL-TG and metabolic risk predictors. Objetivos: This study aims to investigate the effects of metabolic risk predictors on eLDL-TG in adult males and females. Métodos: This study was conducted using a subsample of the NHANES 2015–2016 dataset, which included 1,308 participants (660 females and 648 males) aged 18 years or older. A neural network regression model was built using the H2O deep learning framework to predict eLDL-TG levels based on 14 metabolic predictors. The model employed a Gaussian distribution, adaptive learning rate, dropout regularization, and cross-validation to optimize performance. Key hyperparameters such as hidden layers, L1 and L2 regularization, and learning rate were carefully tuned to enhance model performance. Resultados e Conclusões: The models demonstrated strong predictive accuracy for both men and women, with training RMSEs of 0.0148 (men) and 0.0106 (women), and validation RMSEs of 0.0177 (men) and 0.0164 (women), indicating robust performance. While both models showed minimal overfitting, the slightly higher RMSE on validation datasets suggests moderate variability in predictions, particularly in women. Permutation variable importance plots of the top 5 predictors identified triglycerides as the most significant predictor in both sexes, while apo B the least. Partial dependence plots revealed nonlinear positive associations between eLDL-TG and triglycerides, total cholesterol, apo B and LDL-C, while negative correlation with HDL-C respectively in both genders. This study demonstrates that eLDL-TG is significantly associated with routine lipid profile parameters in both genders. This highlights its potential as an adjunct biomarker in hypertriglyceridaemia where calculated LDL-C becomes unreliable. Further studies are warranted to evaluate, and validate its performance relative to LDL-C, non-HDL-C, Lp(a), and Apo B in routine lipid profile measurement, and cardiovascular risk assessment.

SYSTEMIC ATHEROSCLEROSIS AND MULTIORGAN DYSFUNCTION IN CARDIOGENIC SHOCK: A SYSTEMATIC REVIEW.

GÉSSYCA DI MILO LOPES FERNANDES1; LETICIA DE AVILA CARVALHO1; NATHALIA RIBEIRO COELHO1; SUED HENRIQUE DE CARVALHO VASQUES MACHADO1; AUGUSTO MORENO VILARINS CARDOSO1; GEORGIA CABRERA FARHATE DA CAMARA2; EDIR JUNIO FERNANDES DE OLIVEIRA3; LISANDRA CRISTINA CALVO NECCHI2; BRUNA GUIMARÃES MARQUES1; ANA BEATRIZ FERNANDES2; AURELIO MORENO VILARINS CARDOSO DA SILVA4;

(1) UNIVERSIDADE DE RIO VERDE CAMPUS FORMOSA - FORMOSA - GO - BRASIL; (2) FACERES - SÃO JOSE DO RIO PRETO - SP - BRASIL; (3) UNICEUB - BRASÍLIA - DF - BRASIL; (4) UNIVERSIDADE DE BRASILIA - BRASÍLIA - DF - BRASIL;

Introdução/Fundamentos: Atherosclerosis is a systemic inflammatory disease that compromises multiple vascular beds. In cardiogenic shock, a life-threatening syndrome characterized by severe hypoperfusion, multiorgan dysfunction, and high mortality, this condition makes the outcomes worse by reducing perfusion reserves and fueling a cycle of inflammation and organ failure. Effective treatment must look beyond the patient through a multisystemic strategy that considers the total impact of vascular disfunction. Objetivos: To assess the association between systemic atherosclerosis and multiorgan dysfunction in cardiogenic shock. Métodos: This systematic review followed PRISMA guidelines. Pubmed, Scopus, and Embase were watched from 2019 to 2025 for studies evaluating cardiogenic shock and atherosclerosis-related outcomes. Eligible studies reported least one and-organ outcome, including renal, neurologic, hepatic, or overall mortality endpoints. Resultados e Conclusões: A total of 284 studies were identified, and fourteen were included. Atherosclerosis was associated with worse outcomes, including acute kidney injury, neurological and hepatic dysfunction. Mortality ranged from thirty to fifty percent. The interaction between hypoperfusion, congestion and inflammation drives multiorgan failure. These findings support cardiogenic shock as a systemic condition requiring integrated management beyond hemodynamic support.Thus outcomes depend not only on the heart failure, but on the integrated vulnerability of the renal, cerebral and peripheral systems. Therefore, the majority of the outcomes in cardiogenic shock depends not only on advances in circulatory support, but also in a physiopathological vision capable of recognizing the atherosclerosis as a multiorganic affection and central determining of the vulnerability of the patient's clinic.

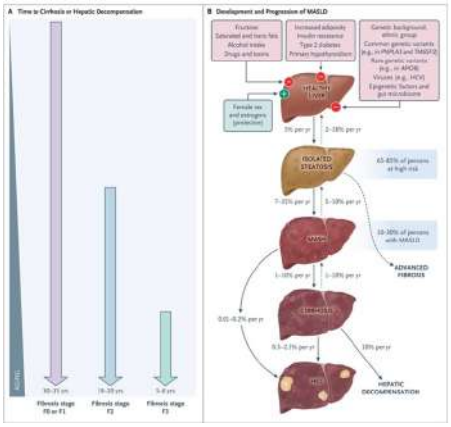
TARGETED THERAPIES FOR ELEVATED LIPOPROTEIN(A): A SYSTEMATIC REVIEW AND META-ANALYSIS OF PLACEBO-CONTROLLED RANDOMIZED TRIALS

DAVID GARCIA DE ALCARAZ CONTI1; FERNANDO LUIZ AFFONSO FONSECA1;

(1) FACULDADE DE MEDICINA DO ABC (FMABC) - SANTO ANDRÉ - SP - BRASIL;



Introdução/Fundamentos: Elevated lipoprotein(a) [Lp(a)] is an independent and causal risk factor for atherosclerotic cardiovascular disease. Conventional lipid-lowering therapies have minimal impact on Lp(a), whereas novel targeted agents, including antisense oligonucleotides and small interfering RNA therapies, have shown promising results in randomized trials. Objetivos: To evaluate the efficacy of targeted Lp(a)-lowering therapies compared with placebo in randomized controlled trials. Métodos: A systematic review was conducted according to PRISMA 2020 and Cochrane recommendations. PubMed/MEDLINE, Embase, and Web of Science were searched from inception to 2025 for placebo-controlled randomized trials evaluating Lp(a)-targeted therapies. The strategy combined controlled vocabulary and free-text terms. Eligible studies included adults with elevated Lp(a) reporting percentage change from baseline. Two reviewers independently performed selection and data extraction. Risk of bias was assessed using RoB 2. A random-effects meta-analysis (DerSimonian–Laird) was performed using mean difference (MD). Heterogeneity was assessed using I^2 and τ^2. Prespecified subgroup and sensitivity analyses were conducted. Certainty of evidence was evaluated using GRADE. Resultados e Conclusões: Six randomized trials (n≈1,950 participants), including pelacarsen phase 2 (2019), OCEAN(a)-DOSE with olpasiran (2022), SLN360 phase 1 (2022), and LY3819469 studies (2023), were included. Targeted therapies significantly reduced Lp(a) compared with placebo (pooled MD: −78.4%; 95% CI: −85.2 to −71.6; p<0.001), with moderate heterogeneity (I^2=52%; τ^2=48.1). Subgroup analyses suggested greater reductions with siRNA-based therapies (MD: −85.1%) compared with antisense approaches (MD: −70.3%). Results were robust across sensitivity analyses, with no single study significantly influencing pooled estimates. Publication bias was not detected on qualitative assessment. The effect was consistent across baseline Lp(a) levels and dosing regimens. Risk of bias was low across trials. According to GRADE, certainty of evidence was high for Lp(a) reduction but moderate for clinical outcomes, as cardiovascular endpoint trials remain ongoing. These findings demonstrate that targeted therapies achieve profound and consistent Lp(a) lowering, representing a major advance in lipid management. Ongoing phase 3 trials will determine whether these reductions translate into cardiovascular risk reduction.

THE CARDIOVASCULAR IMPACT OF GLP-1 RECEPTOR AGONISTS IN STEATOTIC LIVER DISEASE ASSOCIATED WITH METABOLIC DYSFUNCTION: A SYSTEMATIC REVIEW.

LUCAS ARAUJO ROMAO1; PEDRO HENRIQUE BARBOSA RODRIGUES1; KAUE CONTRO COSTA1; IRVING GABRIEL ARAUJO BISPO1; THAIS DE LIMA BROSCO1;

(1) UNIVERSIDADE MUNICIPAL DE SAO CAETANO DO SUL - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Metabolic liver disease associated with metabolic dysfunction (MASLD), formerly known as non-alcoholic fatty liver disease, is currently the most prevalent form of chronic liver disease globally. MASLD has a complex and multifactorial pathophysiology, whose natural history, as summarized, involves insulin resistance, lipid metabolism dysfunction, and alterations in hepatic metabolic signaling. The recent incorporation of drugs targeting metabolic liver disease, such as semaglutide, has broadened interest in pharmacological approaches with systemic metabolic and cardiovascular impact. Objetivos: The objective is to evaluate the impact of glp1 analogs on MALSD and their correlation with a reduction in cardiovascular outcomes in these patients. Métodos: A systematic search was conducted in the PubMed/MEDLINE and Elsevier databases, encompassing studies published in the last 10 years. Search strategies were developed using descriptors, combined with Boolean operators AND and OR. The descriptors were “Non-alcoholic Fatty Liver Disease”, “Glucagon-Like Peptide-1 Receptor Agonists”, and “Incretin mimetic”. All identified records were exported to a reference manager – the Rayyan platform. 492 articles were identified. After analysis, 35 studies were included in the systematic review. Resultados e Conclusões: Randomized clinical trials demonstrate that semaglutide promotes significantly higher rates of histological resolution of Metabolic Steatohepatitis-Associated Dysfunction (MASH) without worsening fibrosis when compared to placebo. The LEAN study with 52 patients established that liraglutide is capable of inducing histological resolution of MASLD and reducing fibrosis progression. Nine (39%) of 23 patients who received liraglutide and underwent end-of-treatment liver biopsy had resolution of definite non-alcoholic steatohepatitis compared with two (9%) of 22 such patients in the placebo group (relative risk 4·3 [95% CI 1·0-17·7]; p=0·019). Large-scale studies demonstrate an association between the use of GLP-1 analogs and a reduction in cardiovascular events, clinically significant portal hypertension, and all-cause mortality, with semaglutide showing superiority in some outcomes.The decrease in visceral adiposity—a metabolically active compartment strongly associated with systemic inflammation—provides a plausible pathophysiological mechanism for the improvement in steatosis, hepatic necroinflammatory activity, and associated cardiometabolic impact.

THE MIR-34A/SIRT1 AXIS IS ASSOCIATED WITH MOLECULAR DYSREGULATION AND REFINEMENT OF CARDIOVASCULAR RISK STRATIFICATION IN TYPE 2 DIABETES MELLITUS

SOFIA MORAIS TORNIS1; EDUARDO VIGNOTO FERNANDES1; MAYARA BOCCHI FERNANDES1; DAVID MICHEL DE OLIVEIRA1; GABRIELA MARQUES MACEDO1; FÁBIO MORATO DE OLIVEIRA1;

(1) UNIVERSIDADE FEDERAL DE JATAI - JATAÍ - GO - BRASIL;

Introdução/Fundamentos: Type 2 diabetes mellitus (T2DM) is associated with increased cardiovascular risk, even under clinical control, suggesting the involvement of molecular mechanisms not captured by traditional risk scores. MicroRNAs, particularly miR-34a, have been implicated in the integration of inflammatory, oxidative stress, and endothelial dysfunction pathways, which are central processes in the cardiovascular pathophysiology of T2DM. Objetivos: To characterize the miR-34a/SIRT1 axis as an integrator of inflammatory, redox, and endothelial pathways and to investigate its potential role in cardiovascular risk stratification in individuals with T2DM. Métodos: An observational study was conducted including 128 participants (96 with T2DM and 32 controls). miR-34a expression was quantified by RT-qPCR, while circulating SIRT1, IL-6, TNF-α, hs-CRP, VCAM-1, and ICAM-1 levels were measured by ELISA. Oxidative stress was assessed through malondialdehyde (MDA) and total antioxidant capacity. Cardiovascular risk was estimated using the Framingham risk score. Correlation analyses, multivariate regression models, and ROC curve analyses were performed. Resultados e Conclusões: Individuals with T2DM exhibited significantly increased miR-34a expression, particularly in the high cardiovascular risk group ($p<0.001$), accompanied by reduced SIRT1 levels and intensification of inflammatory, oxidative, and endothelial pathways. In multivariate analysis, miR-34a, SIRT1, IL-6, and MDA were independent predictors of high cardiovascular risk. A multimarker model based on these components demonstrated high discriminative accuracy (AUC=0.92), outperforming isolated biomarkers and conventional clinical assessment. Collectively, these findings characterize an integrated molecular signature associated with metabolic, inflammatory, and vascular dysregulation in T2DM. The superior performance of the multimarker model highlights its ability to identify subclinical alterations not detected by traditional risk scores, supporting its use as a complementary strategy for refining cardiovascular risk stratification in the context of precision medicine. Thus, these findings reinforce the role of immunometabolic pathways in determining cardiovascular risk in T2DM and underscore the potential of integrating molecular biomarkers for the early identification of high-risk cardiometabolic profiles.

THERAPEUTIC EFFECTS OF PCSK9-TARGETING THERAPIES IN HETEROZYGOUS FAMILIAL HYPERCHOLESTEROLEMIA: A SYSTEMATIC REVIEW OF RANDOMIZED CLINICAL TRIALS

ISABELA CRISTINA SILVA DA SILVA1; LUÍDI LOBATO GONÇALVES1; JULIANE DA SILVA AZEVEDO1; JENIFER DE MOURA PEIXOTO1; DEBORAH VICTÓRIA DOS SANTOS GANZER1; CLÁUDIA LORENA XAVIER DA SILVA2; STER MARQUES DE LIMA SILVA1; FELIPE FERREIRA PINHEIRO3; NELSON VEIGA GONÇALVES1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITÁRIO METROPOLITANO DA AMAZÔNIA (UNIFAMAZ) - BELÉM - PA - BRASIL; (3) UNIVERSIDADE FEDERAL DO AMAPÁ (UNIFAP) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Individuals with heterozygous familial hypercholesterolemia (HeFH) are at increased risk of atherosclerotic cardiovascular disease due to lifelong exposure to elevated low-density lipoprotein cholesterol (LDL-C) levels. Despite the use of currently available lipid-lowering therapies, many patients with HeFH fail to achieve guideline-recommended LDL-C targets. Objetivos: In this context, the aim of this study was to evaluate the efficacy of PCSK9 (protease convertase subtilisin/kexin type 9)-targeted therapies in reducing lipid levels in adults with HeFH. Métodos: A systematic search was conducted in PubMed, Embase, and The Cochrane Library. Randomized clinical trials were included if they enrolled adults with HeFH, compared PCSK9-targeting therapies with placebo, and reported outcomes in LDL-C, non-HDL cholesterol, lipoprotein(a), and apolipoprotein B. Resultados e Conclusões: Five randomized clinical trials were included, evaluating evolocumab, alirocumab, tafolecimab, recaticimab, and enlicitide. Statistically significant reductions ($p<0.001$) in LDL-C levels were observed in all studies, reported as differences between treatment groups compared with placebo. Reductions exceeding 59% were identified with evolocumab and enlicitide, as well as comparable results with tafolecimab at different dosing regimens (57.4% and 61.4%, respectively); alirocumab and recatitimab also showed significant reductions, albeit of lesser magnitude (39.1% and 49.8%, respectively). Substantial decreases were observed in non-HDL cholesterol, including a 41.9% reduction with alirocumab and a −53.0% difference with enlicitida. Tafolecimab and recaticimab also demonstrated superiority over placebo, with robust statistical significance. Similar results were observed for apolipoprotein B, with significant reductions for enlicitida and alirocumab, as well as significant decreases with tafolecimab and recaticimab. Regarding lipoprotein(a), all agents analyzed produced reductions, notably tafolecimab, which showed the greatest effect magnitudes, followed by consistent reductions with recaticimab and alirocumab, demonstrating an additional benefit in the overall lipid profile. It is concluded that PCSK9-targeted therapies provide substantial and consistent lipid-lowering effects in patients with HeFH, demonstrating efficacy across different pharmacological classes and dosing regimens.

Study	Location	Total (N)	Population	Intervention (N)	Control (N)	Duration
Raal F et al. (2014)	Australia, Asia, Europe, New Zealand, North America, South Africa	331	Adults (18–80 years) with HeFH, on stable lipid-lowering therapy (including statins), fasting LDL-C ≥100 mg/dL (2.6 mmol/L), triglycerides ≤400 mg/dL (4.5 mmol/L)	Evolocumab 140 mg SC every 2 weeks (n=111); Evolocumab 420 mg monthly (n=110)	Placebo every 2 weeks (n=55) or monthly (n=55)	12 weeks
Ginsberg HN et al. (2016)	Canada, United States, Netherlands, Russia, South Africa	107	Patients with HeFH, LDL-C ≥160 mg/dL on maximally tolerated statin therapy ± other lipid-lowering therapy	Alirocumab 150 mg SC (n=72)	Placebo (n=35)	78 weeks
Chai M et al. (2023)	China	149	Adults (18–80 years) with definite or probable HeFH (Simon Broome criteria), LDL-C ≥1.8 mmol/L (ASCVD) or ≥2.6 mmol/L (no ASCVD), on stable lipid-lowering therapy ≥4 weeks	Tafolecimab 150 mg SC every 2 weeks (n=52); Tafolecimab 450 mg SC every 4 weeks (n=49)	Placebo every 2 weeks (n=23) or placebo (n=25)	12 weeks
Li L et al. (2025)	China	143	HeFH patients on stable lipid-lowering therapy ≥28 days, LDL-C ≥2.6 mmol/L (or ≥1.8 mmol/L with ASCVD), triglycerides ≤5.6 mmol/L	Recaticimab 150 mg SC (n=95)	Placebo every 4 weeks (n=48)	12 weeks
Ballantyne CM et al. (2026)	United States, Australia, Brazil, Canada, Chile, Colombia, Czech Republic, Finland, Hong Kong, Hungary, Israel, Netherlands, New Zealand, Norway, Singapore, Spain, Taiwan	303	HeFH patients on lipid-lowering therapy (at least moderate/high-intensity statin), LDL-C ≥55 mg/dL with ASCVD or ≥70 mg/dL without ASCVD	Enlicitide 20 mg orally daily (n=202)	Placebo daily (n=101)	52 weeks

Notes: HeFH: heterozygous familial hypercholesterolemia; ASCVD: atherosclerotic cardiovascular disease; LDL-C: low-density lipoprotein cholesterol; SC: subcutaneous; LLT: lipid-lowering therapy.

TITLE: CORRELATION BETWEEN AIR POLLUTION AND ACUTE MYOCARDIAL INFARCTION (AMI): A SYSTEMATIC REVIEW.

HEITOR COELHO KREMER1; ALEXANDRE FONTOURA CHIESORIN1; MOHAMED GAZE HAJAR1; GUSTAVO RISKALLA MENDONÇA1; LARA MARIA BROLINI DELLÊ URBAN1; AFONSO LUÍS ETGES1; RAFAELA GONZALES COSTA1; FELIPE GONÇALVES PELEGRINO1; MARIA CLARA REZENDE BORTOLUZZI1; CAIO TEIXEIRA DE SOUZA1; MARIA EDUARDA RIBEIRO DE PAULA1; JOÃO VITOR ASSMANN FONTANA1;

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL;

Introdução/Fundamentos: Introduction: The association between air pollution and cardiovascular outcomes has been widely investigated in different contexts. Studies indicate that exposure is linked to a higher risk of acute coronary events and poorer prognosis in individuals previously affected. Short-term exposure acts as a trigger, whereas long-term exposure represents a risk factor for cardiovascular alterations. Objetivos: Objectives: To evaluate the role of air pollution as both a trigger and a risk factor for AMI, emphasizing short- and long-term effects. Métodos: Methods: This systematic review followed PRISMA guidelines. Searches in PubMed, SciELO, and Web of Science (2015-2025) retrieved 1,248 studies; 10 were included for directly assessing the relation between air pollution and AMI. Resultados e Conclusões: Results: For acute exposure, elevated PM2.5, PM10, CO, and SO2 were associated with increased AMI admissions from the exposure day up to 5 days post-exposure. A 10 μg/m³ increase in PM2.5 was associated with higher hospitalization risk (RR=1.02; 95% CI: 1.01-1.03). For chronic exposure, a 10 μg/m³ rise in PM2.5 was related to greater AMI risk (RR=1.18; 95% CI: 1.11-1.26) and worse prognosis. Conclusion: This systematic review indicates that the air pollution exposure is associated with increased AMI morbidity and mortality. Both short- and long-term exposure contribute to coronary events. Despite limitations due to heterogeneity and observational designs, evidence supports air pollution as a modifiable AMI risk factor.

21528

USE OF PRAVASTATIN IN THE PREVENTION OF PRE-ECLAMPSIA IN HIGH-RISK PREGNANT WOMEN AND MATERNAL-FETAL SAFETY PROFILE: A SYSTEMATIC REVIEW

ISABELA MACIEL TEIXEIRA1; VERÔNICA OLIVEIRA RODRIGUES1; ALICE LIANDRA UCHOA VENANCIO1; EMILI DA CONCEIÇÃO RISUENHO DOS SANTOS1; RAFAELA MARIA DOS SANTOS NASCIMENTO1; RAYAN MOURA PATRIK NAIM2; LÍVIA DA SILVA FERREIRA3; ELANNA BATISTA BARBOSA2;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (3) UNIRG - PARAISO DO TOCANTINS - TO - BRASIL;

Introdução/Fundamentos: Preeclampsia is a hypertensive disorder of pregnancy and an important cause of maternal and neonatal morbidity and mortality, with limited pharmacological options for prevention. Pravastatin, a statin widely used in cardiovascular prevention, presents low transplacental transfer due to its hydrophilic profile and has demonstrated potential effects in reducing preeclampsia in preclinical studies. Therefore, it has emerged as a possible preventive strategy for the disease. Objetivos: To evaluate the efficacy of pravastatin in the prevention of preeclampsia and its maternal-fetal safety profile. Métodos: This is a systematic review conducted according to the PRISMA protocol. Searches were performed in the PubMed, Cochrane, and Embase databases using the descriptors “Pravastatin,” “Preeclampsia,” and “Gestational Hypertension,” combined with the Boolean operators AND and OR, within the last 10 years. Randomized clinical trials evaluating the prophylactic use of pravastatin in high-risk pregnant women were included. Other study designs, protocols, and studies evaluating pravastatin as treatment were excluded. Outcomes included preeclampsia, preterm birth, and maternal-fetal safety. Resultados e Conclusões: A total of 392 articles were identified, of which 4 were included. Pilot studies observed no relevant maternal-fetal risks with pravastatin (10mg and 20mg) initiated during the second trimester, with anomaly rates similar to the control group and no reduction in fetal cholesterol levels. Regarding prevention, a large multicenter double-blind clinical trial (n=1120) did not demonstrate a preventive effect with a 20 mg/day dose initiated late in pregnancy (35–37 weeks) (P=0.65). In contrast, a smaller open-label study (n=173) showed that a 20 mg twice-daily regimen initiated earlier (10–20 weeks) and combined with aspirin and calcium significantly reduced the occurrence of preterm preeclampsia (13.8% vs 26.7%; p=0.03) and preterm birth (16.1% vs 36%; p=0.003) compared to standard treatment alone. No significant increase in severe adverse events was reported. Therefore, the findings highlight heterogeneity among studies and suggest that therapeutic window, dosage, and drug association may influence outcomes. However, evidence remains limited, and larger randomized clinical trials are necessary to confirm the efficacy of pravastatin in the prevention of preeclampsia.

EFFICACY AND SAFETY OF DEXMEDETOMIDINE IN PATIENTS UNDERGOING TRANSCATHETER AORTIC VALVE REPLACEMENT: A SYSTEMATIC REVIEW AND META-ANALYSIS

EMILY MARTINS ARRUDA1; BRUNO NAPOLEÃO GAMA SALLES1; MARIA LUÍSA CEOLIN XAVIER SILVEIRA1; PEDRO GOMES BARISTA2; CAROLINE OLIVEIRA FISCHER-BACCA1;

(1) UNIDAVI - CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL; (2) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL;

Introdução/Fundamentos: Transcatheter aortic valve replacement (TAVR) has become the standard treatment for patients with severe symptomatic aortic stenosis (AS). Although initially performed under general anesthesia (GA), monitored anesthesia care with procedural sedation has emerged as a feasible alternative. Dexmedetomidine provides sedation, analgesia, and sympatholysis with minimal respiratory depression, making it particularly attractive for high-risk TAVR patients. However, evidence regarding its efficacy and safety compared with other sedative strategies remains limited. Objetivos: To evaluate the efficacy and safety of dexmedetomidine in patients undergoing TAVR. Métodos: A systematic search of PubMed, Embase, and Cochrane databases was performed to identify studies evaluating dexmedetomidine in TAVR. A pairwise meta-analysis was conducted using risk ratios (RRs) with 95% confidence intervals (CIs). Statistical significance was defined as a two-sided P-value < 0.05. A random-effects model with restricted maximum likelihood (REML) estimation was applied to account for between-study heterogeneity. Heterogeneity was assessed using the Cochrane Q test and the I² statistic. Resultados e Conclusões: A total of 09 studies including 1,489 patients were analyzed, of whom 46.74% were male, with a mean age of 81.4 years. Dexmedetomidine was associated with a significant reduction in vasopressor use compared with other sedatives (RR 0.72; 95% CI 0.55–0.94; P = 0.02). There were no significant differences between groups in 30-day mortality (RR 1.02; 95% CI 0.48–2.20; I² = 0%), myocardial infarction (RR 0.75; 95% CI 0.11–5.21; I² = 0%), stroke (RR 1.83; 95% CI 0.39–8.61; I² = 12%), or their composite (RR 1.30; 95% CI 0.38–4.45; I² = 15%). Respiratory outcomes were similar, including overall complications (RR 0.97; 95% CI 0.63–1.49), hypoxemia (RR 1.12; 95% CI 0.43–2.93), and invasive ventilation (RR 2.33; 95% CI 0.45–12.02). No differences were observed in postoperative delirium (RR 0.72; 95% CI 0.26–1.99), sedation failure (RR 2.68; 95% CI 0.55–13.00), need for rescue medication (RR 10.55; 95% CI 0.31–358.75), or conversion to GA (RR 0.58; 95% CI 0.12–2.74). Conclusions: Dexmedetomidine-based sedation in TAVR is safe and associated with reduced vasopressor requirements without increasing major adverse cardiovascular or neurological events. These findings support its use as a hemodynamically favorable sedation strategy in TAVR, although further randomized evidence is needed to confirm its impact on clinically meaningful outcomes.

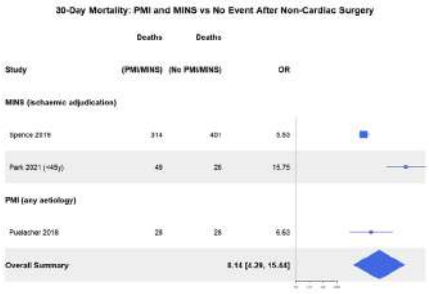
INTRAOPERATIVE HYPOTENSION AND MAJOR ADVERSE CARDIOVASCULAR EVENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

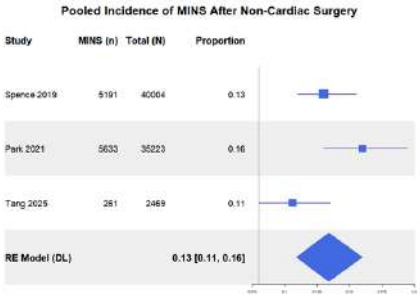
MARCOS PAULO JORGE DE SALES1; LOUISE ARAUJO JASSÉ SANTOS1; ANTONIO MARIA ZACARIAS ARAÚJO MONTEIRO1; LUIGGI SALGADO SANTA BRÍGIDA1; LAÍSE CASTRO WEIS1; GABRIEL SANTARÉM JORGE PINTO DOS REIS1; RAFAEL ARAÚJO DE BRITO NOBRE2; LETÍCIA SANFORD CARNEIRO COELHO1; RENATA GOMES DE ARAÚJO TEIXEIRA CYPRIANO3;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITÁRIO FIBRA (FACULDADE INTEGRADA BRASIL AMAZONIA) - BELÉM - PA - BRASIL; (3) UNIVERSIDADE DA AMAZONIA - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Cardiovascular events are leading causes of morbidity and mortality. Intraoperative hypotension (IOH) is defined as low blood pressure during surgery and is associated with clinically significant postoperative complications, including myocardial injury and major adverse cardiovascular events. Objetivos: To evaluate the association between intraoperative hypotension (IOH) and major adverse cardiovascular events (MACE). Métodos: This systematic review and meta-analysis were conducted per PRISMA and included observational and clinical studies. Literature searches were performed in PubMed, Google Scholar, and EBSCO using predefined terms related to intraoperative hypotension and major adverse cardiovascular events. Studies were screened by title and full text. Inclusion criteria comprised studies involving IOH, reporting MACE outcomes, conducted in surgical patients, and designed as observational studies or clinical trials. Exclusion criteria included studies without clinical outcomes, those focused on monitoring or prediction, non-cardiovascular outcomes, and reviews or protocols. After all screening stages, 13 studies were included. Data were extracted into Excel and analyzed using RevMan. Resultados e Conclusões: Intraoperative hypotension was consistently associated with increased risk of MACE (OR 1.21 [1.11–1.32]) and myocardial injury (OR 1.30 [1.09–1.54]), reinforcing its role as a modifiable perioperative target associated with adverse outcomes. The association with stroke was not statistically significant (OR 1.78 [0.69–4.60]), limited by few studies and wide confidence intervals. Duration-based analysis showed a statistically significant but modest association (OR 1.10 [1.01–1.19]), with substantial heterogeneity (I²=81%). Severity-based metrics demonstrated a stronger association (OR 3.52 [1.82–6.81]), though limited to a single study. Continuous exposure analyses showed that both duration and severity of IOH were associated with adverse outcomes, with severity emerging as the strongest predictor of risk. High heterogeneity – especially in duration-based analyses – likely reflects inconsistent definitions and patient variability, while the stronger effect of severity, despite limited data, underscores its relevance. These findings support stricter intraoperative blood pressure control as a potential strategy to reduce cardiovascular risk.



21791



PERIOPERATIVE MYOCARDIAL INJURY AND 30-DAY MORTALITY IN NON-ELDERLY ADULTS UNDERGOING NON-CARDIAC SURGERY: A SYSTEMATIC REVIEW AND META-ANALYSI

AMANDA ROCHA1; MARINA ISADORA LEMOS1; RODRIGO DIÓGENES MARTINS1; BRUNO CARAMELLI2;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) DEPARTAMENTO DE CARDIOLOGIA PEDIATRICA, FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO, INSTITUTO DO CORACAO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Perioperative myocardial injury (PMI) — defined either as any postoperative troponin elevation (broad PMI) or as ischaemia-confirmed elevation (MINS) — is the most frequent perioperative cardiovascular complication. Its incidence and prognostic impact in adults aged 12–64 years remain poorly characterised. Objetivos: To estimate the pooled incidence of PMI and MINS and their association with 30-day mortality in non-elderly adults undergoing non-cardiac surgery. Métodos: Systematic review and meta-analysis (PRISMA 2020; PROSPERO pre-registered). Searches in five databases and ClinicalTrials.gov yielded 1,560 records; after removing 335 duplicates, 1,225 were screened; 16 studies met inclusion criteria. Pooled MINS incidence was estimated using Freeman-Tukey double arcsine transformation (random-effects, DerSimonian-Laird). For 30-day mortality, Mantel-Haenszel random-effects was applied to three non-overlapping cohorts. Resultados e Conclusões: Pooled MINS incidence was 13.4% (95%CI 10.9–16.0%; I²=95%; n=77,696), though most contributing cohorts enrolled adults ≥45 years. The sole study restricted to adults under 45 years (Park 2021, SMC-TINCO registry; n=4,062) found MINS in 11.7% (475/4,062) — a population rarely screened in routine practice given assumed low cardiac risk. Within this subgroup, 30-day mortality was 10.3% with MINS (49/475) vs 0.7% without (26/3,587; adjusted HR 10.48; 95%CI 6.18–17.78), demonstrating that prognostic impact is preserved even in younger adults. Puelacher 2018 (n=2,018) was the sole study applying the broader PMI definition — any troponin elevation regardless of aetiology; the remaining three cohorts required ischaemic confirmation and thus report MINS. In Puelacher's cohort, 86% of PMI was cardiac in origin; 30-day mortality was 6.1% for cardiac vs 32.5% for extracardiac PMI (predominantly sepsis) — a descriptive finding illustrating distinct prognostic pathways, not included in the pooled estimate. Across three non-overlapping cohorts (n=45,083), both PMI and MINS were associated with an approximately 8-fold increase in 30-day mortality (OR 8.14; 95%CI 4.29–15.44; I²=88%). These findings challenge the assumption that non-elderly adults are low cardiac risk perioperatively and support systematic troponin monitoring in this population undergoing intermediate-to-high-risk non-cardiac surgery.

PREVALENCE OF CORONARY ARTERY DISEASE AND CARDIOVASCULAR RISK STRATIFICATION IN PRE-RENAL TRANSPLANT PATIENTS: ANALYSIS OF AN INSTITUTIONAL PROTOCOL

DANILO PAES DE SÁ MAGALHÃES1; GABRIELA EVANGELISTA DE CARVALHO PONTES1; MARIA EDUARDA RAMOS MAGALHÃES1; CAMILA ANTUNES MOURA1; DANIELA FANTATO1; CRISTIANO BERARDO CARNEIRO CUNHA1; GRACE FOLEY1; DAVI PAES DE SÁ MAGALHÃES1; DÉBORA LAÍS OLIVEIRA FERREIRA MORAES1; ERLEI BISPO1; VERONICA SOARES MONTEIRO1;

(1) INSTITUTO DE MEDICINA INTEGRAL PROFESSOR FERNANDO FIGUEIRA - IMIP - RECIFE - PE - BRASIL;

Introdução/Fundamentos: Patients with end-stage chronic kidney disease (CKD) carry a markedly elevated cardiovascular risk. Preoperative cardiac evaluation is critical for renal transplant candidates; however, the optimal risk stratification strategy remains debated. Objetivos: This study aimed to assess the prevalence of coronary artery disease (CAD) and the performance of an institutional risk stratification protocol in pre-renal transplant patients. Métodos: A cross-sectional, descriptive, and analytical study was conducted among 518 patients who underwent renal transplantation at Medical Institution of Reference in Northeast Brazil, between January 2022 and June 2024. Data were collected retrospectively. Univariate analyses were performed using Pearson's chi-square test or Fisher's exact test (significance level 5%). Resultados e Conclusões: The mean age was 46 years, and 67.4% were male. Only 8.5% had a documented preoperative cardiology consultation. Myocardial perfusion scintigraphy (MPS) was performed in 275 patients (53%), with abnormalities observed in 30%. Of these, 42.7% proceeded to cardiac catheterization, and CAD was confirmed in 19.5%. Overall, 47 patients underwent invasive stratification: CAD was confirmed in 22 (46.8%), and 7 (1.35% of total cohort) required percutaneous coronary intervention. Twelve-month post-transplant mortality was 13.3%, with only 7 cardiovascular deaths. Older age, male sex, diabetes, prior heart failure, prior stroke, and smoking were significantly associated with CAD. The prevalence of CAD was low (~4%) in this younger-than-average transplant cohort, with correspondingly low cardiovascular mortality. MPS demonstrated limited sensitivity for CAD detection in asymptomatic CKD patients, and a substantial proportion of patients underwent testing outside protocol indications. Refinement of institutional risk stratification criteria and prospective studies are warranted.

EFFECTS OF A RELAXATION PROTOCOL ON ANXIETY IN PATIENTS WITH HEART FAILURE

MARIANA BRAGA NETTO LIRA MARANHÃO LACERDA1; ISABELLA PINTO RIBEIRO CRUZ BARBOSA1; CLARISSA MARIA DUBEUX LOPES BARROS1; RAIANE LÚCIA CRUZ DE OLIVEIRA TORRES1; LEOPOLDO NELSON FERNANDES BARBOSA1;

(1) FPS - FACULDADE PERNAMBUCANA DE SAUDE - RECIFE - PE - BRASIL;

Introdução/Fundamentos: Heart Failure (HF) represents a global public health challenge, with an alarming and progressive rise in incidence. As the leading cause of death among heart diseases, it affects more than 23 million people worldwide, with a five-year survival rate after diagnosis estimated at just 35%. The diagnosis of HF is characterized by reduced blood flow through the heart, leading to debilitating symptoms that significantly impact patients' quality of life. Anxiety is a common condition among those affected, occurring in up to 45% of cases, and can worsen prognoses. Cognitive-behavioral therapy (CBT) has been effective in treating anxiety, with relaxation and mindfulness techniques demonstrating positive results. This study evaluated the effects of these techniques on anxiety in patients with HF, aiming to improve psychological well-being and disease prognosis. Objetivos: To evaluate the effectiveness of a relaxation protocol in reducing anxiety in hospitalized patients with heart failure. Métodos: A quasi-randomized clinical trial was conducted with 20 participants allocated into two groups: experimental (n=10) and control (n=10). The experimental group underwent eight individual relaxation sessions, while the control group only completed baseline and final assessments. Anxiety levels were measured using the Hamilton Anxiety Rating Scale (HAM-A). Resultados e Conclusões: The sample (n=20) consisted of two groups (experimental and control, n=10 each), with no significant difference at baseline regarding anxiety levels (p=0.65). The experimental group showed a significant reduction in anxiety scores after the intervention (22.1 ± 5.3 to 13.3 ± 1.7; p < 0.001; d = 2.05), with 100% of participants reclassified as having mild anxiety. In contrast, the control group maintained clinically relevant levels of anxiety, with no significant improvement. At the end of the study, a significant difference was observed between the groups (p < 0.001), with lower anxiety levels in the experimental group. These findings indicate that the relaxation protocol is effective in reducing anxiety in hospitalized patients with heart failure, representing a brief, low-cost intervention applicable to the hospital setting, with potential for integration into multidisciplinary care.

IMPACT OF PSYCHOLOGICAL INTERVENTIONS ON HARD CARDIOVASCULAR OUTCOMES ACCORDING TO THE UNDERLYING CARDIAC CONDITION: SYSTEMATIC REVIEW AND META-ANALYSIS

EDUARDO MACHADO LINS VASCO1; RODRIGO FON ALVES1; DAVID CALOMBÉ TENÓRIO FERRO DO AMARAL1; PEDRO ANTONIO ROCHA BARROS DE MENEZES1; IZADDORA SPOSITO LEÃO RAMOS REAL MARTINS2; LUCCA RIBEIRO DORIA1; RAPHAELA COSTA FERREIRA LEMOS1;

(1) CENTRO UNIVERSITARIO DE MACEIO - UNIMA / AFYA - MACEIO - AL - BRASIL; (2) FACULDADE DE MEDICINA DE OLINDA - OLINDA - PE - BRASIL;

Introdução/Fundamentos: Meta-analyses on psychological interventions in cardiology frequently pool heterogeneous populations, masking the true therapeutic effect in each specific clinical scenario. Objetivos: To evaluate the impact of psychological interventions on hard cardiovascular outcomes, stratifying clinical trials by patients' underlying cardiac condition. Métodos: This review followed PRISMA and Cochrane guidelines (PROSPERO: CRD420261370635), with a systematic search of PubMed, Embase, and Cochrane CENTRAL through April 2026, supplemented by manual reference tracking. We included randomized clinical trials comparing active psychological interventions to usual care, stratified into: Post-AMI/ACS, Heart Failure (HF), and Mixed Chronic Coronary Disease (CCD). Relative risk (RR) was calculated using a random-effects model (Mantel-Haenszel/DerSimonian-Laird) in R. Resultados e Conclusões: Twenty-five studies (N = 12,356) were included. Significant outcomes were concentrated in the Post-AMI/ACS scenario (N = 10,459): reduced angina (RR = 0.64; 95% CI [0.50–0.83]; p = 0.006) and recurrent AMI (RR = 0.75; 95% CI [0.57–1.00]; p = 0.048). Non-CBT psychotherapies showed the greatest reduction in reinfarction (RR = 0.33; 95% CI [0.14–0.80]; p = 0.003). No benefit was observed for cardiac mortality in Post-AMI/ACS (RR = 0.81; 95% CI [0.63–1.04]; I^2 = 14.0%), total rehospitalizations in HF (RR = 1.00; 95% CI [0.87–1.14]; I^2 = 0.0%), or cardiac mortality in Mixed CCD (RR = 0.72; 95% CI [0.16–3.20]; sparse data). Clinical stratification radically alters the interpretation of therapeutic efficacy. Psychological interventions reduce recurrent ischemic events exclusively in the Post-AMI/ACS scenario, with no impact on mortality or heart failure. Future guidelines should avoid indiscriminate pooling of distinct cardiovascular syndromes.

ASSOCIATION BETWEEN OBSTRUCTIVE SLEEP APNEA AND ATRIAL FIBRILLATION - IMPACT OF CPAP THERAPY ON ARRHYTHMIA RECURRENCE: A SYSTEMATIC REVIEW OF THE LITERATURE

ELIONAI FELIPE ROCHA DE LIMA SOUZA1; JONATHAS ADRIEL TAVARES AMARAL1; ANNA CHRISTINA LORENZONI FERREIRA2; LUCAS GABRIEL CARDOSO DE SOUZA1; ENRICO MAGELA BATALHA FALCAO2; JOÃO PAULO MONTEIRO RODRIGUES1; VICTOR PAMPLONA MENESCAL DE SOUZA1; DANGILLA RIBEIRO DOS SANTOS1; JOÃO LUCAS LALOR TAVARES1; ANA LUIZA NEPOMUCENO SAMPAIO1; JOÃO GABRIEL PORTILHO GOMES BRITO1; VIVIANE PATRÍCIA LOPES CARDOSO1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Atrial fibrillation (AF) and obstructive sleep apnea (OSA) coexist in up to 90% of cases, sharing mechanisms of atrial remodeling driven by hypoxemia and mechanical stress. Although Continuous Positive Airway Pressure (CPAP) is the standard treatment for OSA, its impact on AF recurrence remains controversial in the classical literature due to low adherence. In light of recent evidence (2025–2026) incorporating digital monitoring and long-term follow-up, an updated synthesis is warranted to validate the clinical benefit of this therapy on arrhythmic outcomes. Objetivos: To evaluate the impact of CPAP therapy on AF recurrence in patients with OSA undergoing cardioversion or ablation. Métodos: Following PRISMA guidelines, a systematic search was conducted in PubMed, Embase, Cochrane, Scopus, Web of Science, LILACS, and SciELO databases from January 2010 to February 2026. Clinical trials and cohort studies (population ≥18 years) were included, enrolling patients with OSA confirmed by polysomnography (Apnea–Hypopnea Index [AHI] ≥5) and documented AF. Study selection and data extraction were performed independently by two reviewers using Rayyan software, applying the PICO strategy to define eligibility. The primary outcome was post-intervention arrhythmic recurrence rate, comparing treated (CPAP) versus control groups. Resultados e Conclusões: Eight primary studies were included, totaling a sample of over 5,800 patients. The strength of this analysis lies in the integration of cutting-edge evidence (2025–2026), addressing gaps from previous meta-analyses. Data demonstrate that CPAP therapy acts as a critical modulator of atrial electrical stability; recent meta-analyses (Itaya et al., 2025) confirm an overall reduction in recurrence, while real-world studies (Varrias et al., 2026) and long-term follow-up data (Tanaka et al., 2025) show up to a 42% reduction in AF burden among adherent patients (use >4 h/night). Risk of bias ranged from low to moderate, with newer studies overcoming limitations of earlier research through remote digital monitoring. CPAP significantly reduces AF recurrence, provided that therapeutic adherence is maintained. OSA screening and remote adherence monitoring should be integrated into clinical management to optimize the success of arrhythmia therapies.

ASSOCIATION BETWEEN OBSTRUCTIVE SLEEP APNEA AND RISK OF MAJOR CARDIOVASCULAR EVENTS: A SYSTEMATIC REVIEW OF THE LITERATURE

AILAN CRISTIAN FERREIRA FREITAS1; EMILY NEGRÃO PAULO2; FLÁVIO LOBO ALTIERI3; BRENNO VINÍCIUS DE SOUZA ROCHA1;

(1) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Obstructive Sleep Apnea (OSA) is a highly prevalent and underdiagnosed condition characterized by recurrent upper airway obstruction during sleep, leading to intermittent hypoxia and sympathetic activation. Increasing evidence suggests a strong association between OSA and cardiovascular diseases, including Hypertension, Atrial Fibrillation, Myocardial Infarction and Stroke. However, the magnitude and consistency of this association across different populations remain to be fully established. Objetivos: To evaluate the association between obstructive sleep apnea and the risk of major adverse cardiovascular events (MACE) through a systematic review of the literature. Métodos: A systematic review was conducted according to PRISMA guidelines. A comprehensive search was performed in PubMed/MEDLINE, Embase, Scopus and Cochrane Library for studies published between 2005 and 2025. Search strategy included: “obstructive sleep apnea” AND “cardiovascular disease” OR “myocardial infarction” OR “stroke” OR “atrial fibrillation”. The inclusion criterias were: observational studies (cohort or case-control), adult population, diagnosis of OSA confirmed by polysomnography, report of cardiovascular outcomes. The exclusion criterias were: reviews, editorials or case reports, pediatric studies, absence of cardiovascular outcomes. Two independent reviewers performed study selection, data extraction and quality assessment. Data synthesis was qualitative due to heterogeneity in study design and outcome reporting. Resultados e Conclusões: A total of 1,040 studies were identified, with 20 studies included after full-text review, comprising over 1 million participants. Most studies demonstrated a significant association between OSA and increased cardiovascular risk. Patients with OSA showed higher incidence of hypertension and a 2–3-fold increased risk of atrial fibrillation. Additionally, moderate-to-severe OSA was associated with increased risk of myocardial infarction and stroke. Cohort studies consistently demonstrated higher rates of MACE among untreated OSA patients compared to controls. Pathophysiological mechanisms include intermittent hypoxia, oxidative stress, systemic inflammation and endothelial dysfunction. These findings support a strong and consistent association between OSA and major cardiovascular events, highlighting the importance of early diagnosis and management of this condition as a strategy to reduce cardiovascular risk.

16368

ASSOCIATION BETWEEN SHORT SLEEP DURATION AND ADVERSE CARDIOVASCULAR EVENTS: A SYSTEMATIC REVIEW OF COHORT STUDIES

YURI VICTOR CRUZ DE ARAÚJO1; LUIZA BEATRIZ DA SILVA MORAES2; SAULO CÂMARA MONTEIRO1; JÚLIA OLIVEIRA PIMENTEL1; ABNER DAVI COSTA DA ROCHA1; ANDRÉ SOUZA DE CARVALHO1; CARLA ANDREA AVELAR PIRES2;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Sleep plays a fundamental role in physiologic regulation and the maintenance of homeostasis. In this context, sleep disturbances, particularly short sleep duration, have been associated with clinically relevant effects on the cardiovascular system. Evidence suggests that individuals with reduced sleep duration are at increased risk of stroke, coronary artery disease, cardiovascular mortality, and major adverse cardiovascular events. Therefore, these conditions represent an important public health concern, with substantial implications for quality of life in the adult population. Objetivos: To evaluate the association between short sleep duration and the occurrence of cardiovascular outcomes in adults. Métodos: A systematic review was conducted in accordance with the PICO framework and PRISMA guidelines. The literature search was performed in the PubMed and SciELO databases using the descriptors “short sleep duration,” “sleep deprivation,” “cardiovascular events,” and “mortality,” combined with the Boolean operators AND/OR, and limited to studies published within the last five years. Observational studies assessing the association between short sleep duration and cardiovascular outcomes in adults were included. Duplicate studies, review articles, and studies that did not analyze cardiovascular outcomes were excluded. Study selection was performed independently by two independent reviewers, resulting in five studies included in the final analysis. Resultados e Conclusões: Five studies were included. Sleep duration was predominantly self-reported, with one study using accelerometry. Short sleep duration (≤5–6 h/day) was compared with adequate sleep (7–8 h/day). Outcomes included cardiovascular mortality, stroke, coronary artery disease, and major adverse cardiovascular events. Short sleep duration, particularly ≤5 h/day, was associated with increased risk, with hazard ratios ranging from 1.23 to 1.66. Higher risks of incident stroke—especially hemorrhagic—and coronary artery disease were also observed, with effect estimates up to 1.82. Associations at 6 h/day were less consistent. Younger and hypertensive individuals showed higher risk. Long sleep duration (≥8–9 h/day) was also associated with increased risk, suggesting a U-shaped relationship. Short sleep duration is a relevant and modifiable cardiovascular risk factor with implications for clinical practice and public health.

16440

ASSOCIATION OF OBSTRUCTIVE SLEEP APNEA WITH CARDIOVASCULAR OUTCOMES: SYSTEMATIC REVIEW AND META-ANALYSIS

LETICIA MENESES DOS SANTOS1; LAYSA MOREIRA PETERLE1; GABRIEL TOFONO VELOSO1; GUILHERME MOREIRA PIZETTA2;

(1) MULTIVIX - CACHOEIRO DE ITAPEMIRIM - ES - BRASIL; (2) UNIVERSIDADE VILA VELHA - VILA VELHA - ES - BRASIL;

Introdução/Fundamentos: Obstructive Sleep Apnea (OSA) is an independent risk factor for cardiovascular disease, mediated by intermittent hypoxia, sympathetic activation, oxidative stress, and systemic inflammation. Although Continuous Positive Airway Pressure (CPAP) is the standard treatment for moderate-to-severe OSA, its effect on major adverse cardiovascular events (MACE) remains controversial, particularly in non-sleepy patients. Objetivos: To evaluate the association between OSA and cardiovascular outcomes, assess the effect of CPAP therapy through meta-analysis, and explore potential modifiers such as treatment adherence and physiological phenotypes. Métodos: A systematic review and meta-analysis were conducted according to PRISMA guidelines. PubMed was searched for studies published between 2016–2026. Inclusion criteria comprised adult populations with OSA, CPAP intervention compared with usual care or no treatment, and reporting of MACE. After screening 388 records, 7 studies were included in the qualitative synthesis. For quantitative analysis, 3 randomized controlled trials (SAVE, ISAACC and RICCADSA) were selected. Hazard ratios (HR) were pooled using a random-effects model. Heterogeneity was assessed using I^2 statistics. Risk of bias in the included randomized trials was considered low to moderate based on Cochrane criteria. Resultados e Conclusões: The qualitative synthesis demonstrated a consistent association between OSA and increased risk of myocardial infarction (particularly nocturnal events), atrial and ventricular arrhythmias, and cardiac remodeling, with nocturnal hypoxia identified as a central mechanistic predictor. In the meta-analysis, CPAP therapy was not associated with a statistically significant reduction in MACE (HR 0.97; 95% CI 0.84–1.12), with low-to-moderate heterogeneity (I^2=30%). Overall, OSA is associated with increased cardiovascular risk; however, randomized evidence does not support a significant reduction in MACE with CPAP in unselected populations, particularly in non-sleepy patients. Secondary analyses suggest a potential benefit in patients with higher adherence (≥4 h/night), indicating a possible dose-response relationship. These findings support the hypothesis that treatment response may be modulated by adherence and individual physiological phenotypes.

CAFFEINE, ENERGY DRINK, AND STIMULANT CONSUMPTION AND ITS ASSOCIATION WITH AUTONOMIC DYSFUNCTION, SLEEP QUALITY, AND STRESS IN MEDICAL STUDENTS

JULIA VILELA BATTAGLIN KERKHOFF1; YASMIN VIEIRA TORRES GROSSE1; LUCAS DORTE MONTEIRO1; ISADORA VIEIRA TORRES GROSSE1; LARISSA SOARES LEITE1; CAMILA GODOY SABATINI1; RICARDO JOSÉ TOFANO1;

(1) UNIVERSIDADE DE MARÍLIA - MARÍLIA - SP - BRASIL;

Introdução/Fundamentos: The academic life of medical students requires a high cognitive and emotional load, leading many to consume stimulants such as caffeine, energy drinks, and psycho-stimulant medications in order to enhance focus and performance. Chronic use may alter the autonomic nervous system, impair sleep, and increase stress, although the long-term effects are still poorly understood. Objetivos: To evaluate the association between stimulant consumption (caffeine, energy drinks, medications) and symptoms of autonomic dysfunction, sleep quality, and perceived stress in medical students, using validated instruments. Métodos: Observational, cross-sectional, analytical study with 200 medical students (>18 years). Participants completed digital questionnaires containing sociodemographic data, patterns of stimulant consumption, and validated instruments: COMPASS-31 (autonomic dysfunction), PSQI (sleep quality), and PSS-10 (perceived stress). Descriptive analyses, correlations, and multiple linear regression were performed, considering levels of consumption and the outcomes studied. Resultados e Conclusões: A high prevalence of caffeine consumption was observed, mainly through coffee, occasional use of energy drinks, and infrequent use of pharmacological stimulants. Caffeine consumption showed a moderate negative association with sleep duration ($r = -0.32$; $p < 0.001$) and a low positive association with perceived stress ($r = 0.24$; $p < 0.01$). Multiple regression did not identify significant independent predictors of stress. The findings indicate that reduced sleep duration is the most consistent effect of caffeine consumption and may indirectly contribute to increased stress. The study reinforces the need for strategies that promote healthy habits, raising awareness among students about the impacts of stimulant use and the importance of sleep quality.

EARLY SUBCLINICAL CARDIOVASCULAR RISK DRIVEN BY SLEEP DEPRIVATION AND CIRCADIAN MISALIGNMENT IN YOUNG ADULTS

ANA LIZ LIMA BARRETO1; IGOR RAFAEL SANTOS LOPES1; KAWANNE ISABELLE DINIZ DAMASCENO1; LEOMAR GABRIEL SOUZA MAIA SANTOS RODRIGUES CAMPOS1; MARIA FERNANDA ALVES SÁ1; ROMERO HENRIQUE ALMEIDA BARBOSA1; MATHEUS RODRIGUES LOPES1;

(1) UNIVERSIDADE FEDERAL DO VALE DO SAO FRANCISCO - PAULO AFONSO - BA - BRASIL;

Introdução/Fundamentos: Modern lifestyles characterized by heavy technology use and stress have affected young adults' sleep patterns. While serious cardiovascular events generally happen later in life, early exposure to subclinical risk factors begins in youth. Recent updates from the American Heart Association, which incorporated sleep duration into the "Life's Essential 8," underscore the view that sleep disturbances are active causes rather than merely lifestyle markers. These disturbances activate pathophysiological processes, including sympathetic hyperactivity, dysregulation of the hypothalamic-pituitary-adrenal axis, and systemic inflammation. Objetivos: To analyze the association between sleep disorders and early cardiovascular risk markers, as well as the subsequent development of cardiovascular diseases, specifically in young adults. Métodos: Guided by the PRISMA framework and the PECO strategy. A systematic search was conducted in MEDLINE (via PubMed) and BVS (including LILACS and IBECS) databases for primary studies (2020–2025) evaluating young adults (18-40 years) exposed to sleep disturbances such as insomnia, obstructive sleep apnea, sleep deprivation, and circadian misalignment. Study selection was independently executed by two reviewers via the Rayyan platform, while risk of bias was appraised using the Joanna Briggs Institute (JBI) critical appraisal tools. Resultados e Conclusões: Eighteen studies were included in the synthesis. Evidence demonstrated that sleep deprivation, mild-to-moderate obstructive sleep apnea, and evening chronotypes each independently contribute to early subclinical cardiovascular changes. Notably, insufficient sleep correlates with increased central pulse pressure, greater arterial stiffness, and microvascular endothelial dysfunction. Both experimental and observational evidence indicate that losing sleep homeostasis causes direct vascular damage mainly through sustained sympathetic activation and an adverse cardiometabolic profile, including heightened insulin resistance. Unlike older populations, where cardiovascular risk factors are complicated by multiple chronic conditions, young adults experience direct and early vascular damage from poor sleep habits. Routine screening plays an important role in promoting good sleep hygiene and maintaining healthy circadian rhythms, especially for young people. Including these assessments in regular clinical visits can help catch and address underlying issues early, before overt cardiovascular disease manifests.

17506

EFFECTS OF NOCTURNAL RESPIRATORY INTERVENTIONS IN PATIENTS WITH COPD–OBSTRUCTIVE SLEEP APNEA OVERLAP SYNDROME: A SYSTEMATIC REVIEW OF CLINICAL AND CARDIOPULMONARY OUTCOMES

DAVI DE HOLANDA MARTINS ACSELRAD1; GUILHERME COSTA DINIZ1; MARIA EDUARDA TELMOS DE LIMA1; BIANCA SENA MACEDO1; LUCAS VITOR ARAGÃO MOREIRA1; CAMILA ALVES ROCHA1; NILCYELI LINHARES ARAGÃO1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Overlap syndrome between chronic obstructive pulmonary disease (COPD) and obstructive sleep apnea (OSA) is associated with worse outcomes, including more exacerbations, hospitalizations, and higher mortality than either condition alone. Intermittent hypoxia and systemic inflammation contribute to poorer prognosis. Positive airway pressure (PAP), especially continuous positive airway pressure (CPAP), is widely used to improve nocturnal oxygenation and reduce sleep-related respiratory events. Objetivos: To evaluate the effects of nocturnal respiratory interventions on clinical and cardiopulmonary outcomes in patients with COPD–OSA overlap syndrome. Métodos: A systematic review of PubMed, SciELO, Cochrane Library, and LILACS identified clinical trials and analytical observational studies published from 2019 to 2024 on therapeutic interventions in adults with COPD–OSA overlap syndrome. The review followed PRISMA and PICO. Outcomes included mortality, hospitalizations, COPD exacerbations, quality of life, nocturnal hypoxemia, blood gas parameters, and cardiovascular complications. Resultados e Conclusões: Three studies were included: one randomized trial and two retrospective observational studies, enrolling 79 to 269 adults. Interventions mainly involved PAP, especially CPAP, alone or combined with pulmonary rehabilitation. Overall, PAP was associated with fewer exacerbations and possible survival benefit. In one retrospective study, CPAP use, better lung function, and lower comorbidity burden independently predicted lower mortality, while poor adherence was linked to more exacerbations and worse outcomes. Another cohort found lower mortality and longer survival in overlap patients and in those prescribed home PAP after discharge, although this lost significance after multivariate adjustment. The randomized trial showed that PAP plus pulmonary rehabilitation improved six-minute walk distance, functional independence, dyspnea, anthropometric measures, and nocturnal oxygenation versus PAP alone, with no significant change in predicted FEV1%. Major cardiovascular outcomes were not robustly assessed. Overall, PAP-based therapies may improve relevant clinical outcomes, and pulmonary rehabilitation may add functional and nocturnal respiratory benefits. However, evidence remains limited by heterogeneity and the predominance of observational studies, supporting the need for larger randomized trials.

18364

IMPACT OF THE TREATMENT OF OBSTRUCTIVE SLEEP APNEA ON THE CLINICAL PROGRESSION OF HEART FAILURE

ARTUR FERRER GRIBEL1; INÁCIO KRAUSS DE MENEZES1; LETICIA BARROS DOS SANTOS LIMA1; VITOR MENDONÇA BARRETO1; ARTHUR MAGALHÃES RODRIGUES1; FELIPE FRANÇA CÂMARA1; MARCELLA NASCIMENTO ANDRADE1; MIRLA FEITOSA ROCHA1; GABRIELA SENA DE ANDRADE BARRETO1; BRUNA DE ANDRADE LIMA BARRETTO1; ANA MARIA BARRETTO LIMA1; ANA LUÍSA HARDMAN BARRETO1;

(1) UNIVERSIDADE TIRADENTES (UNIT) - ARACAJU - SE - BRASIL;

Introdução/Fundamentos: Obstructive sleep apnea (OSA) has a high prevalence among patients with heart failure (HF) and is associated with clinical deterioration, increased arrhythmias, and higher mortality. Its pathophysiology involves intermittent hypoxia, activation of the sympathetic nervous system, and intrathoracic pressure changes, contributing to cardiac overload. Despite this well-established association, the impact of different therapeutic strategies on cardiovascular outcomes remains controversial. Objetivos: To critically analyze the impact of OSA treatment on clinical, respiratory, and cardiovascular outcomes in patients with heart failure. Métodos: This is a systematic review based on 11 studies published over the last 8 years, including randomized clinical trials, meta-analyses, and systematic reviews. The search was conducted in databases such as PubMed and Scopus, including studies involving patients with HF and OSA. Interventions analyzed included continuous positive airway pressure (CPAP), automatic positive airway pressure (APAP), adaptive servo-ventilation (ASV), dapagliflozin, and neural stimulation therapies. Outcomes assessed included apnea-hypopnea index (AHI), left ventricular ejection fraction (LVEF), cardiac biomarkers, and quality of life. Resultados e Conclusões: CPAP improved oxygenation and reduced AHI, with modest benefits in ventricular function but no significant impact on major cardiovascular events. APAP improved functional capacity and cardiopulmonary performance. Adaptive servo-ventilation (ASV) showed superior efficacy in improving respiratory parameters, with greater reductions in AHI and improvements in oxygen saturation and LVEF; however, it did not demonstrate consistent prognostic benefit and may pose risks in specific HF subgroups. Dapagliflozin significantly reduced OSA severity and improved metabolic and inflammatory parameters. Neural stimulation therapies were effective in selected patients intolerant to CPAP. Despite consistent physiological benefits, the lack of robust impact on major cardiovascular outcomes highlights the need for individualized treatment and further long-term studies.

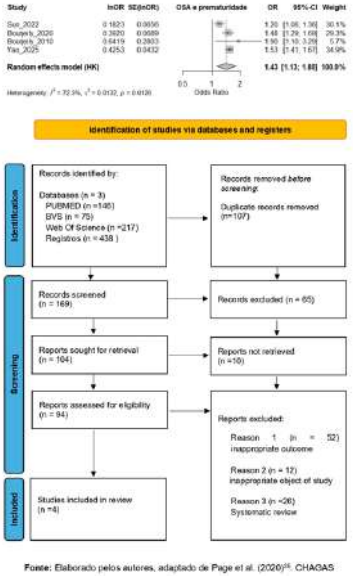
18296

NEUROVASCULAR AND FUNCTIONAL PARAMETERS IN PATIENTS WITH CONTROLLED HYPERTENSION AND OBSTRUCTIVE SLEEP APNEA: IMPLICATIONS FOR CARDIOVASCULAR RISK

ISABELA GIBIN LIMA1; GABRIELA MONTENEGRO RIBEIRO1; PABLO DE OLIVEIRA ANTUNES1; RENAN SEGALLA GUERRA2; MURILLO DE OLIVEIRA ANTUNES1;

(1) UNIVERSIDADE SÃO FRANCISCO - BRAGANÇA PAULISTA - SP - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Hypertension is a major risk factor for cardiovascular diseases and is strongly associated with endothelial dysfunction, arterial stiffness, and increased cardiovascular events. Obstructive sleep apnea (OSA) further contributes to cardiovascular risk through intermittent hypoxia, sympathetic overactivation, and systemic inflammation, leading to adverse neurovascular alterations. The coexistence of OSA and controlled hypertension may potentiate vascular dysfunction even in clinically stable patients. However, the impact of OSA severity on arterial stiffness and central hemodynamic parameters in this population remains insufficiently characterized. Understanding these interactions is essential for improving cardiovascular risk stratification and guiding early therapeutic interventions. Objetivos: To evaluate the association between obstructive sleep apnea severity and arterial stiffness in patients with controlled hypertension. To investigate the impact of OSA on central hemodynamic and neurovascular parameters. Métodos: A cross-sectional observational study was conducted including 29 patients with controlled hypertension (35–70 years) presenting sleep-related complaints. Obstructive sleep apnea (OSA) was diagnosed using type IV polysomnography, and patients were stratified according to the Oxygen Desaturation Index (ODI) into: control group (no OSA or mild OSA, ODI <15 events/hour) and moderate-to-severe OSA group (ODI ≥15 events/hour). Arterial stiffness was assessed by pulse wave velocity (PWV), and central hemodynamic parameters were obtained using a validated oscillometric method. Group comparisons were performed using Student's t-test and chi-square test. Statistical significance was set at p<0.05. The study was approved by a local Research Ethics Committee (protocol number: 93967125.0.0000.5514). Resultados e Conclusões: Patients with moderate-to-severe OSA (n=14) showed significantly higher PWV compared to controls (n=15) (8.1 ± 1.5 vs. 6.4 ± 1.2 m/s; p<0.03). Additionally, the OSA group presented a reduced cardiac index (1.9 ± 0.2 vs. 2.3 ± 0.2 L/min/m²; p<0.01). No significant differences were observed between moderate and severe OSA subgroups. Moderate-to-severe OSA is associated with increased arterial stiffness and reduced cardiac performance even in patients with controlled hypertension, indicating persistent subclinical cardiovascular risk. These findings reinforce the importance of systematic OSA screening and management as part of cardiovascular risk assessment.



18357

SLEEP DISORDERED BREATHING DURING PREGNANCY AND RISK OF PRETERM BIRTH: A SYSTEMATIC REVIEW WITH META ANALYSIS

HADASSA TONUSSI ROSSETTE DO VALLE1; LUCAS GABRIEL TAVARES DA COSTA2; LARA KETHELEN SILVA DE SOUSA2; ANA CLARA BARROS DE ANDRADE2; RACHEL TONUSSI ROSSETTE DO VALLE2; ADRIAN OLIVEIRA DOS SANTOS2; DANIELLE FERREIRA DO NASCIMENTO LINARD2; ARTHUR MACENO DA HORA PIRES2; GUILHERME VASCONCELOS NEGREIROS2; FRANCISCO NAILDO CARDOSO LEITÃO3; FRANCISCO SALATIEL CLEMENTE DE SOUZA3; JOSEANE ELZA TONUSSI MENDES2;

(1) AFYA FACULDADE CIENCIAS MEDICAS DE CRUZEIRO DO SUL - CRUZEIRO DO SUL - AC - BRASIL; (2) AFYA FACULDADE DE CIENCIAS MEDICAS DE CRUZEIRO DO SUL - CRUZEIRO DO SUL - AC - BRASIL; (3) UNIVERSIDADE FEDERAL DO ACRE - RIO BRANCO - AC - BRASIL;

Introdução/Fundamentos: Sleep disordered breathing during pregnancy has been increasingly associated with adverse obstetric outcomes, particularly preterm birth. Physiological changes that occur during pregnancy may favor the onset or worsening of these disorders. In addition, intermittent hypoxia, systemic inflammation, oxidative stress, and endothelial dysfunction may impair maternal cardiovascular adaptation and placental function, thereby contributing to preterm birth. However, the available evidence remains heterogeneous regarding both exposure definition and outcome assessment. Objetivos: To evaluate the pooled association between sleep disordered breathing during pregnancy and the risk of preterm birth. Métodos: A systematic review with meta analysis was conducted in accordance with the PRISMA 2020 statement. Observational studies evaluating sleep disordered breathing during pregnancy and preterm birth, and reporting adjusted measures of association, were included. Meta analysis was performed in R software using a random effects model, with pooled odds ratio and 95 % confidence interval. Heterogeneity was assessed using the I² statistic. Risk of bias was independently evaluated by two reviewers using the Newcastle Ottawa Scale for cohort and case control studies, and the Joanna Briggs Institute critical appraisal tool for cross sectional studies, when applicable. Resultados e Conclusões: The quantitative synthesis demonstrated a significant association between sleep disordered breathing during pregnancy and a higher likelihood of preterm birth, with a pooled odds ratio of 1.43 and a 95% confidence interval from 1.13 to 1.80. Substantial heterogeneity was observed across studies, with an I² of 72.3 % , suggesting relevant clinical and methodological variability. In the forest plot, most individual estimates remained on the side favoring increased risk of preterm birth among exposed pregnant women. Therefore, despite the elevated heterogeneity, the pooled effect remained statistically significant, indicating that sleep disordered breathing during pregnancy may represent an important risk factor for preterm birth.

SLEEP DISORDERS AND CARDIOVASCULAR MORTALITY: AN INTEGRATED ANALYSIS OF BIOLOGICAL AND SOCIAL DETERMINANTS

ISABELA CAMPOS MOTA1; GEORGE DE SARGES AZEVEDO2;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Sleep disorders have emerged as determinants of cardiovascular health, being associated with increased risk of cardiovascular disease and mortality. Evidence from cohort studies shows that insomnia symptoms, such as difficulty initiating or maintaining sleep and daytime dysfunction, are linked to a higher incidence of cardiovascular events, with a proportional effect according to symptom burden. In addition to biological mechanisms, such as sympathetic activation, inflammation, and metabolic alterations, social factors, including socioeconomic conditions and access to healthcare, influence this risk. Yet, the interaction between biological and social determinants in cardiovascular mortality remains poorly understood. Objetivos: To analyze the association between sleep disorders and cardiovascular mortality, identifying the main biological and social determinants involved, as well as their interaction in modulating cardiovascular risk. Métodos: Systematic review conducted according to PRISMA recommendations, with searches in PubMed, SciELO, and BVS using descriptors related to sleep disorders, cardiovascular mortality, and social determinants. Observational studies evaluating the association between sleep alterations and cardiovascular outcomes were included. Study selection was performed independently by two reviewers, with standardized data extraction and qualitative synthesis. Resultados e Conclusões: Five observational studies, predominantly large-scale cohorts, were included and showed a consistent association between sleep disorders and increased cardiovascular mortality. Insomnia symptoms and obstructive sleep apnea were associated with higher risk of cardiovascular events, with evidence of a dose–response relationship according to severity and number of symptoms. Mechanisms such as sympathetic activation, systemic inflammation, and metabolic dysfunction were implicated. Additionally, sociodemographic factors, including low income, lower educational level, and racial disparities, were associated with poorer sleep quality and higher cardiovascular risk, suggesting a synergistic effect between biological and social factors. Sleep disorders are independent determinants of cardiovascular mortality, resulting from the interaction between biological dysfunctions and social vulnerabilities. Their incorporation into clinical practice and public health strategies is essential to improve risk stratification and reduce inequalities in cardiovascular outcomes.

SLEEP DISORDERS AND CARDIOVASCULAR MORTALITY: DISTINCT CARDIOVASCULAR DISEASE PATTERNS ACROSS SLEEP DISORDER SUBTYPES IN A NATIONWIDE ANALYSIS

VICTOR SCHINAIDER GAIA DA CUNHA1; LETÍCIA MARTINS RAPOSO1; MATIAS BRITO FLORIANI1; PEDRO HENRIQUE FELTRAN COSTA1; FELIPE JETTAR GIANDALIA1; LUCAS SILVA DONATO DA CRUZ MONTEIRO1; PAULO HENRIQUE GODOY1;

(1) UNIVERSIDADE FEDERAL DO ESTADO DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Sleep disorders, including insomnia and obstructive sleep apnea (OSA), are established risk factors for cardiovascular disease (CVD). Although both are associated with multiple cardiovascular outcomes, their risk profiles may overlap. However, data on cardiovascular patterns across sleep disorder subtypes in mortality records remain limited. Objetivos: To assess the association between sleep disorders and cardiovascular mortality and to identify patterns of cardiovascular disease across sleep disorder subtypes in a population-based analysis. Métodos: Cross-sectional study using data from the Brazilian Mortality Information System (2000–2024), including deaths with any mention of sleep disorders and circulatory system diseases (ICD-10 Chapter IX). Sleep disorders were classified as OSA, insomnia, or other sleep disorders. Cardiovascular conditions included hypertension, acute coronary syndrome (ACS), chronic coronary disease (CCD), heart failure (HF), arrhythmias, pulmonary heart disease (PHD), other CVD, and cerebrovascular disease (CBVD). Cardiovascular conditions were not mutually exclusive and were defined by ≥1 ICD-10 code. Group comparisons were performed using Pearson's chi-squared test, with a significance level of 5%. Resultados e Conclusões: A total of 2,094 deaths were analyzed. OSA was the most frequent category (n=1,593), followed by insomnia (n=280) and other sleep disorders (n=221). Hypertension, ACS, and CCD were more frequent in insomnia compared with OSA and other sleep disorders (p<0.001). In contrast, HF, PHD, and CBVD were more prevalent in OSA than in insomnia and other sleep disorders (p≤0.002). No differences were observed for arrhythmias (p=0.128) or other CVD (p=0.986) (Table 1). These findings suggest that, despite overlapping cardiovascular risk profiles described in the literature, sleep disorder subtypes may exhibit distinct patterns of cardiovascular involvement in mortality data. Although limited by the use of secondary data, this heterogeneity may have implications for cardiovascular risk stratification.

Table 1. Comparative distribution of cardiovascular disease groups across sleep disorder categories in a national mortality dataset (Brazil, 2000–2024)

Cardiovascular disease groups	Overall N = 2,094[1]	Insomnia N = 280[1]	OSA N = 1,593[1]	Other sleep disorders N = 221[1]	p-value[2]
Hypertension	958 (45.7%)	186 (66.4%)	650 (40.8%)	122 (55.2%)	<0.001
Acute coronary syndrome	357 (17.0%)	106 (37.9%)	201 (12.6%)	50 (22.6%)	<0.001
Chronic coronary disease	156 (7.4%)	40 (14.3%)	101 (6.3%)	15 (6.8%)	<0.001
Cardiac arrhythmias	177 (8.5%)	15 (5.4%)	141 (8.9%)	21 (9.5%)	0.128
Heart failure	282 (13.5%)	21 (7.5%)	241 (15.1%)	20 (9.0%)	<0.001
Pulmonary heart disease	165 (7.9%)	4 (1.4%)	154 (9.7%)	7 (3.2%)	<0.001
Other cardiovascular diseases	86 (4.1%)	11 (3.9%)	66 (4.1%)	9 (4.1%)	0.986
Cerebrovascular disease	402 (19.2%)	45 (16.1%)	331 (20.8%)	26 (11.8%)	0.002

SLEEP DURATION IN ATHLETES WITH AND WITHOUT DISABILITIES: ASSOCIATIONS WITH TRAINING VOLUME AND SYMPTOMS OF PSYCHOLOGICAL DISTRESS

MANUELA LOBATO BARBOSA1; ISABELLA VIANA GOMES SCHETTINI1; BRUNO VALDIZAN PEREIRA RODRIGUES1; RAFAELA BONFIOLI COSTA1; LUCAS ROCHA VALLE1; ANA GABRIELY ROCHA DOS SANTOS2; MIRIAM RAQUEL MEIRA MAINENTI3; ANGELA NOGUEIRA NEVES3; MILENA SORIANO MARCOLINO1;

(1) SPORTS TRAINING CENTRE, UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (3) ESCOLA DE EDUCAÇÃO FÍSICA DO EXÉRCITO - ESEFEX - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Although athletes potentially require 9 to 10 hours of slee\33p per night for optimal recovery, many sleep less than 8 hours, which may be associated with higher levels of stress, anxiety and depression. In addition, higher training volume and intensity may impair sleep and exacerbate psychological distress in athletes with and without disabilities. Objetivos: To examine if the relationship between weekly training volume and depressive, anxiety, and stress symptoms in athletes with and without disabilities is mediated by sleep duration. Métodos: Cross-sectional study, including competitive athletes with and without physical disabilities, aged ≥12 years, from different sports modalities, recruited at multiple reference sports institutions in Brazil. Demographic data, self-reported average daily sleep duration and weekly training volume were obtained through a standardized questionnaire. Psychological distress assessment was performed using the Depression, Anxiety and Stress Scale - 21 (DASS-21). Mediation analyses were conducted using structural equation modeling in the total sample and stratified by disability status. Resultados e Conclusões: A total of 1,032 competitive athletes were included (median age 20 years; 66.4% men), of whom 158 (15.3%) had a disability. The median weekly training volume was 14 hours (interquartile range [IQR] 9.5-20.0), the median competitive training duration was 5 years (IQR 2.5-10.0, ranging from 0.5 to 48 years), and the median sleep duration was 7.0 hours (IQR 7.0-8.0, ranging from 3.0 to 12 hours). Longer sleep duration was associated with lower depression [β = −0.036 (−0.039 to −0.033)], anxiety [β = −0.032 (−0.036 to −0.029)], and stress symptoms [β = −0.081 (−0.084 to −0.079)]. Higher training volume was associated with lower depression [β = −0.009 (−0.014 to −0.004)], anxiety [β = −0.006 (−0.011 to −0.002)], and stress [β = −0.014 (−0.020 to −0.007)]. No significant indirect effects via sleep duration were observed. In stratified analyses, training volume predicted lower depression and stress among athletes without disabilities, whereas sleep duration predicted lower depression, anxiety, and stress among athletes with disabilities. Therefore, sleep duration did not mediate the association between training volume and psychological distress. Training volume and sleep duration showed independent associations with mental health outcomes, with distinct patterns according to disability status. The pictographic model of these associations is shown in Figure 1.

ASSOCIATION BETWEEN ANXIETY SYMPTOMS AND ENDOTHELIAL FUNCTION IN MEDICAL STUDENTS: EVIDENCE OF EARLY CARDIOVASCULAR RISK

MATHEUS NAKAZATO TINOCO1; LETICIA SILVA FLOR DOS SANTOS1; ISADORA DE SA GUIMARAES1; KELEN CAROLINA SILVA CRUZ1; PEDRO BASTOS DE MEDEIROS1; ANDRE MARQUES CASARSA1; SERGIO LUIZ SCHMIDT1; MATHEUS DA SILVA CARDOSO1; JOSÉ PEDRO BOAVENTURA BRAGA1; OLÍVIA ESPEZIM OTERO LACOSTE1; JULIO CESAR TOLENTINO JUNIOR1;

(1) HOSPITAL UNIVERSITARIO GAFFREE E GUINLE - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Anxiety disorders are highly prevalent among medical students and have been associated with increased cardiovascular risk. Endothelial dysfunction may represent an early pathophysiological mechanism linking anxiety to atherosclerosis, but this association remains poorly explored in young healthy populations. Objetivos: To evaluate the association between anxiety symptoms and endothelial function in medical students. Métodos: This cross-sectional study included 104 medical students aged ≥18 years, without prior clinical disease and with normal echocardiography and carotid Doppler. Endothelial function was assessed by brachial artery flow-mediated dilation (FMD), with dysfunction defined as FMD <10%. Anxiety symptoms were measured using the Generalized Anxiety Disorder 7-item scale (GAD-7), with scores >10 indicating positive screening. Statistical analyses included t-tests, linear and logistic regression, and bivariate correlation (SPSS 23®), adopting a significance level of 5%. Resultados e Conclusões: Mean age was 23.3±2.9 years, with equal sex distribution. Mean FMD was 11.9%, and endothelial dysfunction was present in 33.7% (n=35), with no association with age or sex. Positive screening for anxiety occurred in 38.5% and was more frequent in females (p<0.001). Higher GAD-7 scores were independently associated with endothelial dysfunction (OR=1.122; 95% CI: 1.028–1.224; p=0.01). Anxiety severity correlated inversely with FMD (r=−0.219; p=0.03). Anxiety symptoms were independently associated with impaired endothelial function, suggesting an early psychophysiological link to cardiovascular risk. These findings support integrating mental health assessment into early cardiovascular risk evaluation in young adults.

INNER PEACE AND LIFE PURPOSE ARE ASSOCIATED WITH ENDOTHELIAL FUNCTION IN HEALTHY ADULTS

LETICIA SILVA FLOR DOS SANTOS1; MATHEUS NAKAZATO TINOCO1; PEDRO BASTOS DE MEDEIROS1; ISADORA DE SA GUIMARAES1; KELEN CAROLINA SILVA CRUZ1; ANDRE MARQUES CASARSA1; SERGIO LUIZ SCHMIDT1; OLÍVIA ESPEZIM OTERO LACOSTE1; JOSÉ PEDRO BOAVENTURA BRAGA1; MATHEUS DA SILVA CARDOSO1; JULIO CESAR TOLENTINO JUNIOR1;

(1) HOSPITAL UNIVERSITARIO GAFFREE E GUINLE - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Endothelial dysfunction (ED) is an early marker of cardiovascular disease influenced by biological and psychosocial factors. While depression and anxiety contribute to vascular impairment, higher levels of inner peace and life purpose have been associated with reduced mortality in patients with cardiovascular disease. However, whether these dimensions are linked to vascular function in individuals without overt disease remains unclear. Objetivos: To investigate the association between inner peace and life purpose with endothelial function in clinically healthy adults. Métodos: In this cross-sectional study, 148 individuals aged 18–60 years were assessed using validated instruments. Inner peace and life purpose were evaluated using the FACIT-Sp. Depressive and anxiety symptoms were assessed using the PHQ-9 and GAD-7, respectively. Endothelial function was measured by brachial artery flow-mediated dilation (FMD). Multivariate logistic regression analyses were performed to identify independent predictors of endothelial dysfunction, controlling for mental health variables and cardiovascular risk factors. Discriminant analysis was used to determine which dimensions best distinguished vascular profiles. Resultados e Conclusões: Endothelial dysfunction was identified in 39.2% of participants. Inner peace and life purpose significantly distinguished individuals with and without endothelial dysfunction. Higher levels of these dimensions were associated with preserved endothelial function, independent of anxiety, depression, and conventional risk factors. In multivariate analysis, overall spiritual well-being remained inversely associated with endothelial dysfunction (OR=0.929; p=0.005), while anxiety (OR=2.551; p=0.035), depression (OR=3.740; p=0.038), and body mass index (OR=1.130; p=0.016) were positively associated. Inner peace and life purpose were independently associated with preserved endothelial function, suggesting a potential link between existential well-being and early vascular health, independent of depression and anxiety.

RELATIONSHIP BETWEEN INNER PEACE DIMENSION OF SPIRITUALITY AND BLOOD PRESSURE IN PATIENTS WITH RESISTANT HYPERTENSION

VICTÓRIA ENNE MAGALHÃES1; AMANDA BARBUDA HASSAN1; THOMÁS BARBOSA LEAL DE SOUZA1; JOÃO FELIPE ASSAD DUARTE1; VITÓRIA LUIZA LUDUGERIO SILVA1; JOÃO GABRIEL VALLAPERDE2; PEDRO BASTOS DE MEDEIROS3; ELIZABETH SILAID MUXFELDT1; JULIO CESAR TOLENTINO3; RICARDO BEDIRIAN1;

(1) IDOMED/ESTACIO - RIO DE JANEIRO - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (3) UNIRIO - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Resistant hypertension (RH) remains a therapeutic challenge despite optimized pharmacological treatment. Current evidence suggests that psychosocial and spiritual factors may influence neurohormonal mechanisms involved in blood pressure regulation. Among those, the “inner peace” dimension of spirituality, has been associated with better cardiovascular outcomes and may reduce blood pressure levels. Objetivos: Evaluate the correlation between inner peace dimension of spirituality and blood pressure levels in resistant hypertension. Métodos: This cross-sectional study included patients with resistant hypertension receiving optimized pharmacological therapy and followed at a specialized center. Patients with secondary hypertension or pseudoresistance were excluded. Data collection included 7-day home blood pressure monitoring (HBPM) using a validated device, sociodemographic variables, and assessment of the “peace” dimension of spirituality using the Functional Assessment of Chronic Illness Therapy – Spiritual Well-Being (FACIT-Sp) questionnaire. Statistical analysis was performed using SPSS version 26, applying simple and multiple linear regression models, with a significance level set at 5%. Resultados e Conclusões: 56 patients were evaluated, with a mean age of 56 years (range: 38–67), 66.1% female, and using an average of five antihypertensive medications. The peace score ranged from 5 to 16 points (mean: 11). A negative correlation was observed between peace and blood pressure measured by HBPM, both for overall systolic blood pressure (SBP) ($r = -0.397$; $p = 0.002$) and overall diastolic blood pressure (DBP) ($r = -0.383$; $p = 0.004$). Similar results were found for morning and afternoon/evening measurements. In multiple linear regression analysis adjusted for age, sex, and sedentary lifestyle, inner peace remained independently associated with SBP ($\beta = -0.389$; $p = 0.007$; $R^2 = 0.195$) and DBP ($\beta = -0.290$; $p = 0.039$; $R^2 = 0.214$). Each 1-point increase in the peace score was associated with an approximate reduction of 2.3 mmHg in overall SBP. Conclusions: Higher levels of inner peace were associated with lower blood pressure levels measured by HBPM in patients with RH, maintaining statistical significance after adjustment for clinical variables. These findings suggest that inner peace may act as a modulator of blood pressure control, reinforcing the importance of a biopsychosocial-spiritual approach in the management of resistant hypertension.

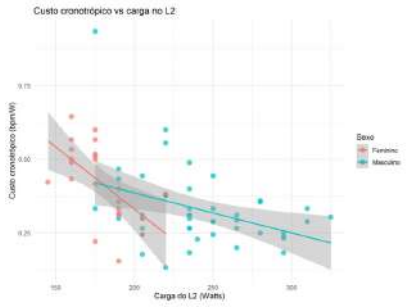
CARDIO-ONCOLOGY REHABILITATION: INTERVENTION STRATEGIES AND FUNCTIONAL ASSESSMENT IN PATIENTS WITH POST-CANCER CARDIOVASCULAR RISK

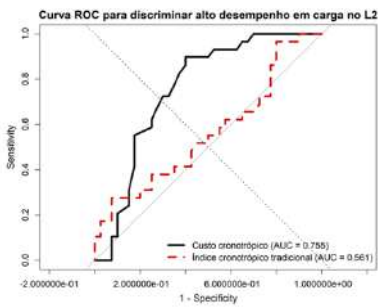
ALEX VIDAL CUSTÓDIO1; EDUARDA NOGUEIRA DE OLIVEIRA1; ANA CAROLINA VIDAL CUSTODIO DOS SANTOS2; GIULIA VAICBERG GISLER1; MARIA EDUARDA GUEDES1; FILIPE VIEIRA PANAR1; GABRIELI PORFIRIO MELO DA SILVA1; ANA CRISTINA RIVERA SALDANHA1; MARIANA CAROPRESE TOLEDO SANTOS1; EVERSON MONTEIRO FATIGATTI1; LAÍS DE SOUZA RODRIGUES1; MARIA APARECIDA DE ALMEIDA SOUZA RODRIGUES1;

(1) UNIVERSIDADE DE VASSOURAS (UNIVASSOURAS) - VASSOURAS - RJ - BRASIL; (2) CENTRO UNIVERSITÁRIO SERRA DOS ÓRGÃOS - TERESÓPOLIS - RJ - BRASIL;

Introdução/Fundamentos: Cardiotoxicity related to oncologic therapies remains an important determinant of morbidity and functional limitation among cancer survivors. Despite its prognostic relevance, structured cardiovascular prevention strategies are still underutilized. Cardio-oncology rehabilitation (COR), particularly in digital formats, emerges as a scalable intervention with potential disease-modifying effects. Objetivos: This study aims to evaluate the potential of cardio-oncology rehabilitation in modifying cardiovascular and functional outcomes in cancer patients. This is a systematic review based on the PICO strategy, conducted using the PubMed and Cochrane databases. Studies involving adult cancer patients undergoing structured COR (either in-person or via telerehabilitation), compared to usual care, were included. The outcomes assessed included left ventricular ejection fraction (LVEF), functional capacity (peak VO□), quality of life, adherence, safety, and cost-effectiveness. Métodos: Of the 31 studies identified, 7 were included, comprising randomized clinical trials and prospective studies, totaling approximately more than 1,000 patients. COR demonstrated consistent and clinically relevant benefits. In a randomized clinical trial, there was a significant attenuation in the decline of LVEF (−1.5% vs. a more pronounced decline in the control group; p=0.006), with no occurrence of significant cardiotoxicity. Telerehabilitation programs promoted a substantial increase in functional capacity (peak VO□: +3.66 vs. +1.09 mL/kg/min; absolute difference ~2.5 mL/kg/min; p=0.02), in addition to a marked improvement in quality of life (+16.25 vs. +1.04 points; p=0.03), as well as reductions in fatigue, anxiety symptoms, and sleep disturbances. Resultados e Conclusões: Adherence rates exceeded 100% in some protocols, with an excellent safety profile and no major adverse events reported. Cardio-oncology rehabilitation should be recognized as a high-impact intervention, capable of preserving ventricular function, improving functional capacity, and optimizing patient-centered outcomes. The incorporation of digital strategies significantly enhances its scalability without compromising efficacy or safety, consolidating its role as an essential component of contemporary oncologic care. In the era of prolonged cancer survival, cardio-oncology rehabilitation emerges as a powerful tool and should be incorporated into standard care plans.



18414



CHRONOTROPIC PHENOTYPING BETWEEN VENTILATORY THRESHOLDS: A DOMAIN-SPECIFIC HEART RATE-TO-POWER DESCRIPTOR OF SUBMAXIMAL CARDIOVASCULAR PERFORMANCE IN ENDURANCE ATHLETES

WAGNER ANTIDES PINA1; JADY BONARDI JOSÉ LIMA1; MARILIA DOS SANTOS ANDRADE1;

(1) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Conventional chronotropic metrics were developed for clinical populations and may not adequately characterize submaximal cardiovascular behavior in endurance athletes. The VT1–VT2 domain is a physiologically distinct interval in which performance depends on autonomic regulation, cardiovascular reserve, and metabolic stability. We therefore examined a heart rate-to-power ratio derived specifically from this domain as a threshold-oriented descriptor of submaximal cardiovascular response. Objetivos: To characterize the VT1–VT2 heart rate-to-power ratio in amateur triathletes, assess sex-related differences, examine its association with performance markers, and compare its discriminative performance with that of the traditional chronotropic index. Métodos: In this cross-sectional study, 69 amateur triathletes (46 men, 23 women; age 39.4 ± 9.7 years; VO□max 47.7 ± 7.7 mL·kg□¹·min□¹) underwent maximal cardiopulmonary exercise testing on a cycle ergometer. Ventilatory thresholds were determined by 2 independent blinded evaluators using standardized gas-exchange criteria. The VT1–VT2 heart rate-to-power ratio was calculated as (HRVT2 − HRVT1)/(PowerVT2 − PowerVT1) and expressed in beats per minute per watt. Associations were assessed by Spearman correlation and multivariable linear regression. Discriminative performance was evaluated by ROC analysis with DeLong comparison versus the traditional chronotropic index. Resultados e Conclusões: The mean VT1–VT2 ratio was 0.361 ± 0.137 bpm/W (median 0.333; IQR 0.267–0.433). Women showed significantly higher values than men (0.42 ± 0.13 vs 0.33 ± 0.13 bpm/W; p=0.002), whereas the traditional chronotropic index showed no sex-related difference (p=0.306). The VT1–VT2 ratio correlated inversely with power at VT2 (ρ=−0.546; p<0.001) and peak oxygen pulse (ρ=−0.493; p<0.001). For identifying athletes with above-median power at VT2, the VT1–VT2 ratio outperformed the traditional chronotropic index (AUC 0.755 vs 0.561; DeLong p=0.038), whereas neither metric discriminated dichotomized VO□max. These findings support the VT1–VT2 heart rate-to-power ratio as a sex-sensitive, threshold-oriented descriptor of submaximal cardiovascular performance with potential relevance for sports cardiology and cardiopulmonary phenotyping, refinement of CPET interpretation, and early identification of inefficient submaximal hemodynamic-autonomic responses.

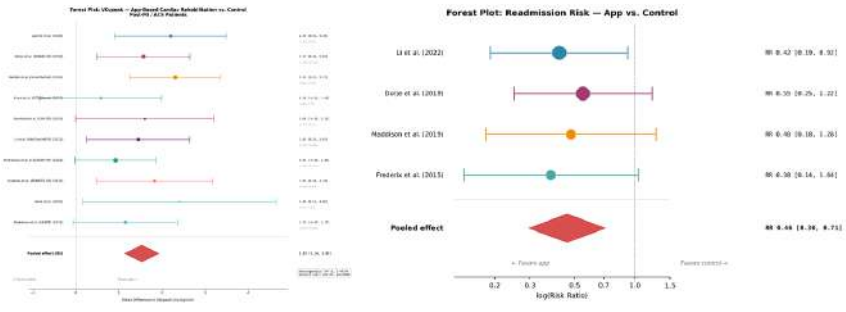
15548

ELECTROCARDIOGRAPHIC FINDINGS IN COMPETITIVE ATHLETES WITH AND WITHOUT DISABILITIES: A COMPARATIVE STUDY

MANUELA LOBATO BARBOSA1; HAROLDO CHRISTO ALEIXO1; ANA LAURA MOREIRA GERHARDT1; BRUNO VALDIZAN PEREIRA RODRIGUES1; RAFAELA BONFIOLI COSTA1; ANA CAROLINA DE ALMEIDA BASTOS1; JOÃO GABRIEL COUTO GONTIJO1; LAURA CARRARA RIBEIRO1; BIBIANA SARTORI CHAGAS2; MIRIAM RAQUEL MEIRA MAINENTI3; ANTONIO LUIZ PINHO RIBEIRO1; MILENA SORIANO MARCOLINO1;

(1) TELEHEALTH CENTER, UNIVERSITY HOSPITAL, UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) ESCOLA DE EDUCAÇÃO FÍSICA DO EXÉRCITO - RIO DE JANEIRO - RJ - BRASIL; (3) ESCOLA DE EDUCAÇÃO FÍSICA DO EXÉRCITO - ESEFEX - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Electrocardiographic (ECG) adaptations to intensive training are well described in able-bodied athletes but remain poorly characterized in athletes with physical disabilities, a population markedly underrepresented in sports cardiology research. Objetivos: To compare the prevalence of electrocardiographic findings between competitive athletes with and without physical disabilities. Métodos: Cross-sectional study, including competitive athletes ≥12 years, with and without physical disabilities, from different sports modalities, recruited at multiple reference sports institutions in Brazil. The ECG was performed at rest using TEB® equipment and analyzed by a sports cardiologist following standardized criteria. Categorical variables were compared using Chi-square or Fisher's exact test, and continuous variables using the Mann–Whitney U test. A two-sided significance level of 0.05 was adopted. Resultados e Conclusões: A total of 1,237 athletes were included (median age 19 [interquartile range 15-27], 67.4% men, 130 [10.5%] had physical disabilities). The weekly training load was significantly higher in athletes without physical disabilities compared to those with them (median: 14.5h vs. 11.0h, p<0.001), and only 7.5% of athletes with physical disabilities exceeded 20 hours per week, compared to 18.1% of the other group. Athletes with disabilities showed significantly lower prevalence of both sinus arrhythmia (4.6% vs. 22.5%, p<0.001) and sinus bradycardia (3.1% vs. 7.9%, p<0.005) compared to the one without disabilities. The percentages of other electrocardiographic findings were similar among athletes with and without physical disabilities, that being, respectively, 0.8% vs 1.0% for ventricular extrasystole, 1.5% vs 0.9% for supraventricular extrasystole, 0.8% vs 2.6% for first-degree atrioventricular block, 0.8% vs 0.5% for incomplete right bundle branch block, 1.5% vs 0.5% for complete right bundle branch block, 0.0% vs 0.3% for left bundle branch block, 0.8% vs 1.3% for wide QRS complex, 0.8% vs 0.8% for primary repolarization abnormalities and 6.2% vs 7.4% for early ventricular repolarization. Therefore, it can be observed that athletes with physical disabilities showed a lower prevalence of vagally mediated ECG findings, such as sinus bradycardia and sinus arrhythmia. These findings suggest that differences in autonomic adaptation, rather than global cardiac remodeling, may underlie the observed results, potentially influenced by lower training volume.



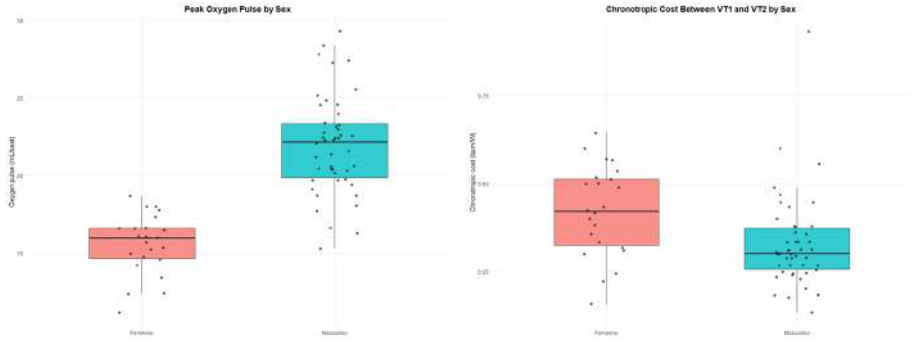
17460

MOBILE APP-BASED CARDIAC REHABILITATION AFTER ACUTE MYOCARDIAL INFARCTION/ACUTE CORONARY SYNDROME: A SYSTEMATIC REVIEW AND META-ANALYSIS

JAMILE TEREZA TEIXEIRA OLIVEIRA1; ANA CLARA LIBERALI SAWABINI1; EDUARDO ESCAÑO SALOMÃO GONÇALVES1; ARTHUR VILAR DE OLIVEIRA MALHEIROS1; CARLOS GUN1;

(1) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Cardiac rehabilitation (CR) after acute myocardial infarction (AMI) is a Class I recommendation and is associated with reduced mortality and recurrent cardiovascular events. However, adherence to center-based programs remains below 30% worldwide, mainly due to barriers such as cost, transportation difficulties, and limited access to specialized centers. In this context, mobile health (mHealth) technologies, especially smartphone applications, have emerged as a promising alternative for home-based CR, allowing individualized exercise prescription, remote monitoring, and continuous behavioral support. Objetivos: To evaluate, through a systematic review and meta-analysis, the efficacy of home-based CR delivered through mobile applications on functional capacity, hospital readmissions, and quality of life in post-AMI or acute coronary syndrome (ACS) patients, compared with center-based CR or usual care. Métodos: This systematic review was conducted according to PRISMA 2020 recommendations. PubMed/MEDLINE, Embase, Cochrane CENTRAL, Scopus, Web of Science, LILACS, and SciELO were searched from inception to March 2026. Randomized clinical trials involving adult post-AMI/ACS patients undergoing mobile app-based CR were included. Study selection was performed in two independent stages, with standardized data extraction and risk-of-bias assessment using the RoB 2 tool. Quantitative synthesis used the DerSimonian-Laird random-effects model, with mean difference (MD) and risk ratio (RR) calculations. Heterogeneity was assessed using the I² statistic. Resultados e Conclusões: The search identified 1,847 records, of which 10 randomized clinical trials were included (n = 1,193 patients from 10 countries). App-based CR demonstrated significant improvement in aerobic capacity (VO□peak: MD = 1.53 mL/kg/min; 95% CI: 1.14–1.92; p < 0.001; I² = 0%) and functional capacity (six-minute walk test: MD = 27.51 m; 95% CI: 16.88–38.15; p < 0.001), both exceeding thresholds of clinical relevance. A significant reduction in hospital readmissions was also observed (RR = 0.46; 95% CI: 0.30–0.71; p < 0.001), corresponding to a 54% risk reduction. The results showed high consistency across studies. Home-based CR delivered through mobile applications was associated with improved functional capacity and reduced hospital readmissions in post-AMI/ACS patients, reinforcing the potential of mHealth as a feasible, scalable, and potentially cost-effective alternative to expand access to CR.



19293

SEX-SPECIFIC CARDIOVASCULAR RESPONSE PHENOTYPES DURING INCREMENTAL EXERCISE IN TRIATHLETES

WAGNER ANTIDES RIBEIRO DE ALMEIDA PINA1; JADY BONARDI JOSE LIMA1; MARILIA DOS SANTOS ANDRADE1;

(1) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Sex-related differences in endurance performance are not explained solely by maximal aerobic capacity and may reflect distinct cardiovascular adjustment strategies during incremental exercise. Chronotropic cost and oxygen pulse may provide clinically relevant insight into sex-specific patterns of submaximal and late-exercise cardiovascular behavior. Objetivos: To investigate sex-specific cardiovascular response patterns during incremental cardiopulmonary exercise testing in amateur triathletes, with emphasis on chronotropic cost, oxygen pulse, and segmental oxygen pulse dynamics across ventilatory thresholds. Métodos: In this cross-sectional study, 69 amateur triathletes (46 men and 23 women) underwent maximal cardiopulmonary exercise testing on a cycle ergometer. Chronotropic cost between the first and second ventilatory thresholds was defined as the increase in heart rate divided by the increase in workload. Oxygen pulse was calculated at the first ventilatory threshold, second ventilatory threshold, and peak exercise as oxygen uptake divided by heart rate. Segmental oxygen pulse slopes and adapted metabolic-chronotropic coupling indices were derived from summarized test data. Between-sex comparisons were performed using Student's t test or Mann-Whitney test, as appropriate. Resultados e Conclusões: Women exhibited higher chronotropic cost between the first and second ventilatory thresholds than men (0.423 vs 0.330 bpm/W; p=0.0016), indicating greater heart rate recruitment per unit of workload. Men showed higher oxygen pulse at peak exercise (21.93 vs 15.56 mL/beat; p<0.001), at the first ventilatory threshold (18.77 vs 13.85 mL/beat; p<0.001), and at the second ventilatory threshold (20.04 vs 15.15 mL/beat; p<0.001). Men also demonstrated steeper oxygen pulse slopes from the first ventilatory threshold to peak exercise and from the second ventilatory threshold to peak exercise, suggesting greater late-exercise oxygen pulse augmentation. No significant sex differences were observed in adapted metabolic-chronotropic coupling indices. These findings support the presence of distinct sex-specific cardiovascular phenotypes during incremental exercise, with men showing a profile more consistent with greater stroke volume-related contribution and women demonstrating greater chronotropic dependence. This pattern may be relevant for sports cardiology, cardiopulmonary phenotyping, and sex-informed interpretation of exercise testing.

SUBSTANCE USE AMONG COMPETITIVE ATHLETES WITH AND WITHOUT DISABILITIES: A CROSS-SECTIONAL STUDY IN BRAZIL

ANA LAURA MOREIRA GERHARDT1; RAFAELA BONFIOLI COSTA1; ANA GABRIELY ROCHA DOS SANTOS2; ANGELA NOGUEIRA NEVES3; LETÍCIA VITORIA RAMOS DA CUNHA1; MÍRIAM RAQUEL MEIRA MAINENTI3; MILENA SORIANO MARCOLINO1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (3) ESCOLA DE EDUCAÇÃO FÍSICA DO EXÉRCITO - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Competitive sports are often associated with health benefits and improved physical conditioning. However, high-performance athletes may also engage in behaviors that negatively affect cardiovascular health and performance, including alcohol consumption and tobacco use. Although these substances are well recognized as modifiable cardiovascular risk factors in the general population, their use in competitive athletes remains understudied. Objetivos: To analyze the prevalence and patterns of alcohol consumption and smoking among competitive athletes with and without disabilities. Métodos: This cross-sectional study included competitive athletes aged □18 years from sports reference institutions in Brazil. Both able-bodied athletes and athletes with disabilities were eligible. Data were collected through face-to-face structured interviews using a standardized questionnaire covering sociodemographic characteristics, sports practice, and lifestyle behaviors. Tobacco and alcohol use were assessed in terms of frequency and quantity. Descriptive statistical analysis was performed. Resultados e Conclusões: Among 737 athletes included (median age 27 years [interquartile range - IQR 21-33]), 65.5% were men and 19.3% had a disability. Tobacco use was reported by 19 athletes (2.6%). Most smokers used hand-rolled cigarettes (n=12), followed by traditional cigarettes (n=6), and one athlete reported cannabis use. No use of electronic cigarettes was reported. Regarding the frequency of traditional cigarette use, 66.7% of all users had sporadic/low-use (1-5 cigarettes/week), while 16.7% had light (6-10 cigarettes/week) and 16.7% moderate (11-20 cigarettes/week) use. Regarding hand-rolled cigarette use, 90% of users had sporadic/low use, with 10% of users having light use. Regarding alcohol use, 106 athletes used it weekly (n=14.8%). Of these, 78.2% consumed up to 2 doses/week, 12.4% consumed 3-4 doses/week, 8.2% consumed 5-11 doses/week, and 1.2% consumed >12 doses per week. Alcohol and tobacco consumption are present among competitive athletes, inclçuding those with disabilities, although at a low prevalence when compared to the general population. Despite lower rates, these behaviors remain clinically relevant due to their potential negative impact on cardiovascular health and athletic performance. Therefore, initiatives and discussions on this topic should be established within the sporting environment to promote healthier habits among this group and minimize the deleterious effects mentioned before.

VENTILATORY EFFICIENCY (VE/VCO_2) AS A MARKER OF CARDIOVASCULAR INEFFICIENCY AND EXERCISE INTOLERANCE IN PATIENTS WITH PULMONARY HYPERTENSION.

MARIA EDUARDA ISALINO E SILVA1; JHENIFFER GIRELLI1; FILIPE DE MATOS SANCHEZ1; DANILO CORTOZI BERTON1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introdução/Fundamentos: Pulmonary hypertension is characterized by increased pulmonary vascular resistance, leading to right ventricular overload and impaired capillary perfusion, which results in ventilation/perfusion (V/Q) mismatch. In this context, the VE/VCO□ ratio, when associated with other variables such as peak VO□, acts as a marker of cardiorespiratory interaction and patients' functional limitation, reflecting not only ventilatory but also hemodynamic alterations. Objetivos: To evaluate the association between VE/VCO□ and exercise tolerance parameters in patients with pulmonary hypertension. Métodos: A retrospective cohort study based on the analysis of medical records of patients with pulmonary hypertension (groups 1 and 4) who underwent cardiopulmonary exercise testing and the 6-minute walk test. VE/VCO□ was the main variable, correlated with peak VO□ and distance in the test. Pearson's correlation was used, with a significance level of 5% ($p < 0.05$). The study was approved by the Institutional Research Ethics Committee (CEP). Resultados e Conclusões: A total of 123 patients diagnosed with pulmonary hypertension were included, with a mean age of 50.9 ± 16.4 years and a predominance of females (69.1%). The mean BMI was 27.8 ± 6.8 kg/m², with most patients in functional classes I–II (69.1%) according to the NYHA scale. The mean VE/VCO□ was 47.8 ± 11.2, while the mean peak VO□ was 1.08 ± 0.42 L/min. The mean distance in the 6-minute walk test was 401 ± 118 meters. A negative correlation was observed between VE/VCO□ and the distance in the 6-minute walk test ($r = -0.353$; $p = 0.003$), as well as with peak VO□ ($r = -0.434$; $p < 0.001$), indicating that patients with greater ventilatory inefficiency had worse functional performance. Thus, the increase in VE/VCO□ can be explained by ventilation/perfusion mismatch resulting from reduced effective pulmonary perfusion, leading to an increase in physiological dead space and a greater ventilatory requirement for carbon dioxide elimination. In addition, the limitation in the increase of cardiac output during exercise contributes to reduced oxygen delivery to tissues, which is reflected in decreased peak VO□ and lower exercise tolerance, demonstrated by the reduced distance walked in the 6-minute test. The significant association between VE/VCO□ and objective parameters, such as peak VO□ and distance in the 6-minute walk test, highlights its clinical utility as a noninvasive marker of disease severity and functional limitation.

: IL-1B EXPRESSION AND NF-KB ACTIVATION IN CARDIAC TISSUE IN FATAL CASES OF CHIKUNGUNYA INFECTION.

LARISSA ÁDILA DESIREÉ VIEIRA DE ANDRADE DUARTE1; BRUNA MARTYRES GUEIROS1; JUAREZ ANTÔNIO SIMÕES QUARESMA2; JORGE RODRIGUES DE SOUSA1; ORLANDO PEREIRA AMADOR NETO 2; ARNALDO JORGE MARTINS FILHO2; JULIANA MARINHO MELO2; JULIANE CORREA E CORREA2; MATHEUS DE CARVALHO ALVES1; GIOVANA SEIXAS DE MELO1; AYARA ALMEIDA SOUZA CABRAL1; PEDRO FERNANDO DA COSTA VASCONCELOS1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) INSTITUTO EVANDRO CHAGAS - IEC - ANANINDEUA - PA - BRASIL;

Introdução/Fundamentos: Chikungunya virus (CHIKV) infection can present with severe forms and cardiovascular involvement. The exacerbated inflammatory response plays a central role in this process, highlighting interleukin-1 (IL-1) and the transcription factor NF-κB, both fundamental in the regulation of pro-inflammatory genes. Objetivos: To evaluate IL-1 expression and NF-κB activation in the cardiac tissue of fatal CHIKV cases, investigating their association with myocardial damage. Métodos: Cardiac tissue samples from confirmed fatal CHIKV cases were analyzed by immunohistochemistry and/or molecular techniques to detect IL-1 and NF-κB. NF-κB activation was inferred by its nuclear localization, and the findings were correlated with histopathological alterations. Resultados e Conclusões: An increased expression of IL-1 and significant activation of NF-κB in the myocardium were observed, associated with the presence of an inflammatory infiltrate and alterations compatible with myocarditis. The activation of this pathway suggests amplification of the local inflammatory response, contributing to tissue damage. The elevation of IL-1 associated with NF-κB activation in cardiac tissue indicates a central role of this inflammatory pathway in the pathogenesis of myocardial injury in fatal CHIKV cases. These findings reinforce the relevance of inflammatory mechanisms in the severe evolution of the disease and highlight potential therapeutic targets.

AMAZONIAN PALM SPECIES EXHIBITS CARDIOPROTECTIVE EFFECTS AGAINST ISOPROTERENOL-INDUCED MYOCARDIAL INJURY

MARIA JULIA DE SENA LOPES1; ELLEN CAROLINE DA SILVA PENHA1; JHÔNATA COSTA MOURA1; JOÃO VICTOR CUNHA SILVA1; LARA LUIZA PITOMBEIRA ROCHA1; MARIA EDUARDA DE CASTRO PEREIRA1; BIANCA DE FÁTIMA ASSUNÇÃO SODRÉ1; MARIA CLARA SANTOS ARAUJO1; MATHEUS BASTOS VASCONCELOS1; ANDRESSA COELHO FERREIRA1; RAPHAEL FURTADO MARQUES1; RACHEL MELO RIBEIRO1;

(1) UNIVERSIDADE FEDERAL DO MARANHAO - SÃO LUIS - MA - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases represent a critical global challenge, with high morbidity and mortality linked to acute myocardial infarction (AMI). In parallel, the investigation of natural products has expanded, focusing on the antioxidant and anti-inflammatory properties of plant-derived bioactive compounds. Objetivos: To evaluate the cardioprotective potential of the hydroalcoholic extract of Syagrus cocoides almonds (SYA) in an experimental model of isoproterenol (ISO)-induced myocardial infarction in rats. Métodos: Male Wistar rats were used, distributed into Control, ISO, SYA 100 mg/kg, and SYA 300 mg/kg groups (n=8), subjected to oral pre-treatment for 15 days. On days 14 and 15, AMI was induced via subcutaneous administration of ISO (85 mg/kg). On day 16, biochemical and histopathological analyses were performed. Resultados e Conclusões: The ISO group exhibited intense leukocyte infiltration, marked myonecrosis, and extensive myocardial edema. Treatment with SYA (100 mg/kg) promoted a moderate reduction of these alterations, while the 300 mg/kg dose demonstrated superior efficacy, expressively mitigating edema and necrosis. Histologically, the ISO group presented significantly elevated injury scores compared to the other groups ($p < 0.05$), confirming the severity of tissue damage. AMI induction promoted a severe dyslipidemic profile, marked by elevated total cholesterol, LDL, triglycerides, and non-HDL, in addition to a discrete reduction in HDL. Pre-treatment with SYA (100 and 300 mg/kg) significantly attenuated these metabolic alterations. Both treatments substantially reduced triglycerides and non-HDL cholesterol, bringing lipid parameters closer to the values of the control group (Table 1). Furthermore, the ISO group presented a significant elevation in serum levels of urea, blood urea nitrogen (BUN), creatinine, and globulins, indicating metabolic and systemic impairment associated with myocardial injury. Treatment with S. cocoides was able to reverse these biochemical alterations, restoring values similar to those of the control group (Table 1). These findings demonstrate that Syagrus cocoides extract exerts potent cardioprotective and metabolic modulatory effects against ISO-induced myocardial injury, suggesting potential therapeutic application in the prophylaxis of cardiovascular damage.

ANALYSIS OF CARDIAC AND PULMONARY TISSUE OF RATS WITH PARKINSON'S DISEASE TREATED WITH MELATONIN AND PROGRESSIVE RESISTANCE EXERCISE

JOÃO MARCOS DA SILVA CARVALHO DE QUEIROZ1; CATHERINE LOUISE SEREJO GAMAS1; GUSTAVO SCHIAVONI DE ALMEIDA1; ANA LARA LEÃO ALMEIDA1; LAILA CRISTINA MOREIRA DAMÁZIO1;

(1) UNIVERSIDADE FEDERAL DE SÃO JOÃO DEL-REI - SÃO JOÃO DEL-REI - MG - BRASIL;

Introdução/Fundamentos: Parkinson's disease (PD) is a progressive neurodegenerative disorder that contributes to the manifestation of significant dysfunctions in the cardiovascular system, which impair respiratory capacity. Therefore, considering the relationship between reduced levels of melatonin (MLT) in individuals with PD and disease severity, as well as the potential of aerobic exercise in reducing the impacts of PD, it is suggested that the combination of these therapeutic approaches may induce functional and structural changes in the nervous system that are beneficial for mitigating the cardiorespiratory effects of PD. For this study, PD was induced in rats through the administration of the neurotoxin 6-hydroxydopamine (6-OHDA). Objetivos: To examine the impacts of high-intensity progressive resistance exercise combined with melatonin administration on the cardiorespiratory tissues of rats with 6-OHDA-induced PD. Métodos: This is an ex vivo experimental study using rats, divided into a control group (Sham) and a PD group treated with MLT and aerobic exercise in different combinations. The evaluated parameters included histomorphometric analysis of histological sections from heart and lung tissues. Data from this stage were statistically analyzed to compare findings between groups. Figure 1 legend. Photomicrograph of cardiac tissue section stained with H&E at 20× magnification. Resultados e Conclusões: No significant differences were observed in the number of cardiomyocytes in the left ventricle (p=0.0988; F=2.26). However, a significant difference was found in cardiomyocyte area (p<0.0001; F=28.63). Regarding pulmonary analysis, no significant differences were observed in the number of alveoli (F=1.59) or alveolar perimeter (p=0.56; F=0.73). Therefore, high-intensity progressive resistance exercise associated with melatonin administration promotes morphological adaptations favorable to the attenuation of cardiovascular alterations secondary to PD. However, the number of alveoli and alveolar perimeter were maintained, suggesting that PD induction does not cause detectable structural changes in the pulmonary parenchyma. Figure 2 legend. Mean cardiomyocyte area among the experimental groups.

BCG IMMUNE PRECONDITIONING ATTENUATES CARDIAC OXIDATIVE STRESS FOLLOWING EXPERIMENTAL ISCHEMIC STROKE IN RATS

VICTOR DUÍLIO ANTUNES MARAGNO1; KHIANY MATHIAS1; ISADORA BITTENCOURT BENEDET1; HENRIQUE FRAGNANI DA ROSA1; LARISSA CARVALHO CERETTA1; KETLYN ZANATTA MARQUES1; LUCAS PEREIRA BITENCOURT1; VITTORIO AUGUSTO CIMOLIM1; ISABELA MARCOMIN FIGUEIREDO1; LETICIA MACHADO MORETTI1; LIVIA PRESTES CESCONETO1; FABRICIA CARDOSO PETRONILHO1;

(1) UNESC - UNIVERSIDADE DO EXTREMO SUL CATARINENSE - CRICIUMA - SC - BRASIL;

Introdução/Fundamentos: Ischemic stroke triggers a systemic inflammatory response and oxidative stress that extend beyond the central nervous system, affecting peripheral organs such as the heart. Cardiac injury following cerebral ischemia has been increasingly recognized as part of the brain–heart interaction. Immunomodulatory strategies may represent a potential approach to mitigate these systemic consequences. Objetivos: To investigate whether immune preconditioning with the Bacillus Calmette–Guérin (BCG) vaccine can modulate cardiac oxidative stress in an experimental model of ischemic stroke. Métodos: Male Wistar rats were randomly assigned to four groups: Sham+Vehicle, Sham+BCG, MCAO+Vehicle, and MCAO+BCG. Animals received a subcutaneous injection of BCG (2×10^4 CFU) or saline solution 14 days before focal cerebral ischemia induced by middle cerebral artery occlusion (MCAO). Thirteen days after the procedure, animals were euthanized and cardiac tissue was collected for biochemical analyses of oxidative stress and inflammatory markers. Resultados e Conclusões: Ischemic stroke significantly increased myeloperoxidase (MPO) activity and protein carbonyl levels in cardiac tissue, indicating enhanced inflammation and oxidative damage. BCG preconditioning attenuated both markers, suggesting a protective systemic effect. No significant differences were observed in catalase (CAT), superoxide dismutase (SOD), or nitrite/nitrate levels among the groups. These findings indicate that BCG-induced immune preconditioning may reduce cardiac oxidative injury associated with ischemic stroke, highlighting the potential role of immunomodulation in mitigating cardiovascular complications secondary to cerebral ischemia.

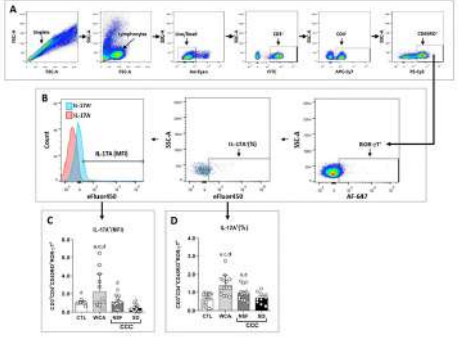
Caspase-1 activation and NALP1 expression in cardiac tissue in fatal cases of Chikungunya infection

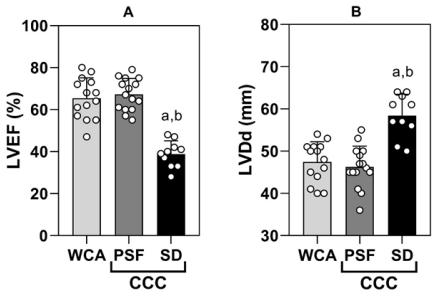
LARISSA ÁDILA DESIREÉ VIEIRA DE ANDRADE DUARTE1; BRUNA MARTYRES GUEIROS1; JUAREZ ANTÔNIO SIMÕES QUARESMA2; JORGE RODRIGUES DE SOUSA2; ORLANDO PEREIRA AMADOR NETO2; ARNALDO JORGE MARTINS FILHO2; JULIANA MARINHO MELO2; JULIANE CORREA E CORREA2; MATHEUS DE CARVALHO ALVES1; GIOVANA SEIXAS DE MELO1; MATHEUS PRADO DOS SANTOS1; PEDRO FERNANDO DA COSTA VASCONCELOS1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - Brasil; (2) INSTITUTO EVANDRO CHAGAS - IEC - ANANINDEUA - PA - Brasil;

Introdução/Fundamentos: Chikungunya virus (CHIKV) infection can evolve with severe manifestations, including cardiac involvement. Inflammasome activation has been implicated in the pathophysiology of exacerbated inflammation, highlighting the NALP1 complex and the Caspase-1 enzyme, which are responsible for the maturation of pro-inflammatory cytokines. Objetivos: To evaluate Caspase-1 activation and NALP1 expression in the cardiac tissue of fatal CHIKV cases and their association with inflammatory myocardial damage. Métodos: Cardiac tissue samples from confirmed fatal CHIKV cases were analyzed by immunohistochemical and/or molecular techniques to detect NALP1 and Caspase-1. The expression intensity was correlated with histopathological findings. Resultados e Conclusões: An increased expression of NALP1 and activation of Caspase-1 in the myocardium were observed, associated with the presence of an inflammatory infiltrate and alterations compatible with myocarditis. These findings suggest inflammasome activation, with consequent amplification of the local inflammatory response and potential induction of inflammatory cell death. The activation of the NALP1/Caspase-1 axis in cardiac tissue indicates a relevant role of the inflammasome in the pathogenesis of myocardial injury in fatal CHIKV cases. These results reinforce the importance of innate inflammatory pathways as potential therapeutic targets.



18865



CD4+TH17 CELLS PLAY A CRITICAL ROLE IN CONFERRING RESISTANCE TO TRYPANOSOMA CRUZI INFECTION WHILE ALSO DEMONSTRATING POTENTIAL IN MITIGATING THE DEVELOPMENT OF SEVERE CARDIAC COMPLICATIONS

JULIA KELLY CAMPOS1; MARIANA COSTA DUARTE1; ANA MARIA RAVENA SEVERINO CARVALHO1; MATHEUS RIBEEIRO ÁVILA1; LUCAS FRÓIS FERNANDES OLIVEIRA1; THIAGO MIRANDA DE SOUZA1; SANNY CRISTINA DE CASTRO FARIA1; DANIELLA CASTANHEIRA BARTHOLOMEU1; FERNANDA ALVARENGA CARDOSO MEDEIROS1; MANOEL OTÁVIO DA COSTA ROCHA1; HENRIQUE SILVEIRA COSTA2; DANIEL MENEZES- SOUZA1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DOS VALES JEQUITINHONHA E MUCURI - DIAMANTINA - MG - BRASIL;

Introdução/Fundamentos: Chagas disease (CD), caused by Trypanosoma cruzi, persists as a global health challenge characterized by a complex immunopathogenesis. CD4+ TH17 cells, producers of the pro-inflammatory cytokine IL-17A, have been implicated in various inflammatory and cardiac diseases, but their role in CD remains debated. Objetivos: This study investigated the role of TH17 IL-17A+ cells in Chagasic patients, focusing on their contribution to the immune response and cardiac protection. Métodos: Thus, we conducted an observational study, in which Chagasic patients were stratified according to cardiac function. TH17 IL-17A+ cell responses were evaluated, and IL-17A expression levels were correlated with echocardiographic parameters and intracellular parasite burden. Resultados e Conclusões: Our results demonstrated a distinct and potentially protective role for TH17 IL-17A+ cells in CD, particularly in the absence of dilated cardiomyopathy. In patients without systolic dysfunction, we observed an accentuated TH17 response, with elevated IL-17A expression, associated with favourable echocardiographic parameters, such as left ventricular ejection fraction (LVEF) and left ventricular end-diastolic diameter (LVDd). Furthermore, we observed an inverse correlation between IL-17A expression and intracellular parasite burden, suggesting a role for IL-17A in infection control. This study highlights the complex immunomodulatory role of TH17 cells in chronic Chagas cardiomyopathy (CCC). IL-17A may be a therapeutic target for preserving cardiac function and controlling parasite persistence in Chagasic patients, especially prior to the development of severe cardiac dysfunction.

DYNAMIC SYSTEMIC INFLAMMATORY RESPONSE IN ST-SEGMENT ELEVATION MYOCARDIAL INFARCTION: TEMPORAL BEHAVIOR OF HEMATOLOGICAL RATIOS AND THEIR CLINICAL ASSOCIATIONS

ANA PAULA DELUCA1; MILENA DAL WITT SOUZA1; LUISA HEINZEN CESCON1; EDUARDA ADAMCZEVSKI1; CAROLINE OLIVEIRA FISCHER-BACCA1; MARCELO VIER GAMBETTA1; SILVIA ROZAURIA FROES TONIAZZO1; CRISTINA BICHELS HEBEDA1;

(1) UNIDAVI - CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL;

Introdução/Fundamentos: ST-segment elevation myocardial infarction (STEMI) triggers a complex systemic inflammatory response driven by ischemic myocardial injury. Hematological ratios derived from routine blood counts have emerged as accessible inflammatory biomarkers; however, their temporal dynamics and clinical significance in the acute phase remain incompletely characterized. Objetivos: To evaluate systemic inflammatory activity through hematological ratios and C-reactive protein (CRP) in patients with STEMI, and to explore their temporal changes and clinical correlations. Métodos: This observational study included consecutive patients with STEMI undergoing primary percutaneous coronary intervention (PCI) admitted to a tertiary care center in southern Brazil. Neutrophil-to-lymphocyte ratio (NLR), lymphocyte-to-monocyte ratio (LMR), platelet-to-lymphocyte ratio (PLR), monocyte-to-lymphocyte ratio (MLR), neutrophil-to-monocyte ratio (NMR), Systemic Inflammation Response Index (SIRI), and Systemic Immune-Inflammation Index (SII) were assessed at admission and after 24 hours. SIRI and SII were calculated as (neutrophils × monocytes)/lymphocytes and (platelets × neutrophils)/lymphocytes. CRP levels were measured at both time points. Total ischemic time (Δ pain) was defined as the interval between symptom onset and percutaneous coronary intervention. Comparisons were performed using the Wilcoxon test and associations using Spearman's coefficient. Resultados e Conclusões: A total of 30 patients were included (mean age 57.5 ± 9.5 years; 73.3% male). LMR, MLR, and SIRI showed no significant variation over 24 hours. In contrast, NLR, PLR, NMR, and SII significantly decreased at 24 hours compared to admission ($p < 0.0001$), indicating early attenuation of inflammation. No difference in NLR was observed between patients with left ventricular ejection fraction > 40% and ≤ 40% ($p = 0.86$). Admission troponin moderately correlated with CRP at 24 hours ($r = 0.38$; $p = 0.037$). CRP levels at admission and 24 hours correlated with ischemic time ($r = 0.42$; $p = 0.022$ and $r = 0.37$; $p = 0.042$). CRP at 24 hours also correlated with monocyte count ($r = 0.43$; $p = 0.018$). These findings suggest that hematological ratios show early dynamic changes in STEMI, reflecting an acute inflammatory response with partial resolution within 24 hours. Although associated with myocardial injury and ischemic time, these markers were not related to short-term systolic dysfunction, limiting prognostic utility.

22004

EFFECTS OF ACUTE ANTIEPILEPTIC DRUG ADMINISTRATION ON CARDIAC STRUCTURE AND MORPHOMETRY

ROBERTA ALVES RAMOS1; LEONARDO PARREIRA SILVA NASCIMENTO1;

(1) UNIVERSIDADE DE RIBEIRAO PRETO - GUARUJA - SP - BRASIL;

Introdução/Fundamentos: Potassium (K+) channel opener drugs have traditionally been used in clinical practice as antihypertensive agents, and more recently, studies have demonstrated a significant anticonvulsant effect that appears superior to that of drugs conventionally used in the treatment of epilepsy. However, there are limited studies investigating the effects of potassium channel openers used as epilepsy treatment on the cardiac system. Objetivos: Therefore, the aim of this study is to evaluate the acute effects of antiepileptic drug administration on cardiac morphometry and structure in experimental models. Métodos: This quantitative and experimental study included 39 male Wistar rats allocated into three groups (n = 13): Negative Control, Positive Control, and Experimental. Following seizure induction with pentylenetetrazol (PTZ), the hearts were collected for histomorphometric analysis using light microscopy and hematoxylin–eosin staining. Resultados e Conclusões: The results demonstrated that the experimental group exhibited a significant increase in coronary vessel area (+126.2%) and vascular perimeter (+42.5%), suggesting a strong selective vascular relaxation effect on smooth muscle. In contrast, left ventricular and interventricular septal thickness remained stable across all groups, with variations below 5%, indicating the absence of immediate myocardial remodelling or cardiotoxicity. These findings suggest that acute administration of the investigated drug is associated with a favourable cardiovascular safety profile, promoting hemodynamic benefits through afterload reduction and improved coronary blood flow without compromising myocardial structural integrity in the anticonvulsant setting.

Table 1. Analysis of the Measurement of Cardiac Vessel Perimeter

Group	Mean ($\bar{X}$) (μm)	Standard deviation (SD)	Implication
Negative Control	120.72	34.00	Baseline for vascular tone
Positive Control	100.28	32.44	Mean is lower than that of the Negative Control, indicating absence of significant vasodilation or, in certain instances, slight vasoconstriction or minimal change
Experimental	172.04	37.76	Mean value is significantly higher than both the Negative Control and Positive Control, confirming strong vasodilation

Source. Authors' own elaboration.
Note. $\bar{X}$ = mean; SD = standard deviation; μm = micrometers.

Table 2. Analysis of the Measurement of Cardiac Vessel Areas

Group	Mean ($\bar{X}$) (μm²)	Standard deviation (SD)	Implication
Negative Control	911.96	622.18	Basal vascular lumen area
Positive Control	785.45	499.71	The mean value is lower than the Negative Control, confirming that there is no lumen enlargement
Experimental	2063.15	942.92	The mean is significantly higher than both the Negative Control and the Experimental group, exceeding twice their respective values

Source. Authors' own elaboration.
Note. $\bar{X}$ = mean; SD = standard deviation; μm² = square micrometers.

EFFECTS OF AEROBIC INTERVAL TRAINING ON ANTIOXIDANT ENZYMES AND REDOX STATE IN CARDIAC PATIENTS.

MIRELA PARISSA BONDAN MISAGHI1; RICARDO CLEMENTE ROSA1; ALESSANDRA BETINA GASTALDI1; GUSTAVO SCHUETZLER GOMES FERNANDES1; KARINE LOUIZE VINCENZI1; DANIELLE DIAS1; KLAUS JOHANN JACQUES SCHEBEK TEIXEIRA1; MANUELA KLEIN1; RAMON FERNANDES OLM1; DÉBORA DELWING-DAL MAGRO2; CARLA WERLANG-COELHO1; DANIELA DELWING-DE LIMA1;

(1) UNIVERSIDADE DA REGIAO DE JOINVILLE - JOINVILLE - SC - BRASIL; (2) FURB - BLUMENAU - SC - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases (CVDs) constitute the leading cause of morbidity and mortality worldwide and are closely associated with oxidative stress, characterized by an imbalance between reactive species and antioxidant defense systems. In this context, physical exercise has been widely adopted as a non-pharmacological therapeutic strategy, capable of promoting beneficial physiological adaptations, including modulation of the antioxidant defense system, particularly through the regulation of enzymes such as catalase, superoxide dismutase, and glutathione peroxidase. Objetivos: To evaluate the effects of aerobic interval training on cardiorespiratory fitness, redox status, and antioxidant enzyme activity in patients with cardiovascular disease. Métodos: The study protocol (CEP 4.479.472) was approved by the institutional ethics committee. A non-randomized clinical trial, with a quantitative approach, was conducted in a sample of 14 patients with cardiovascular disease of both sexes, aged 50 to 80 years, all of whom were enrolled in a cardiovascular rehabilitation program. The variables assessed included maximal oxygen consumption (VO□max), biomarkers of oxidative stress (thiobarbituric acid reactive substances, sulfhydryl content, and protein carbonyls), and antioxidant enzyme activities, including catalase, superoxide dismutase, and glutathione peroxidase. In addition, serum biochemical parameters were also analyzed. Participants were subjected to an aerobic interval training protocol. Resultados e Conclusões: A significant improvement in cardiorespiratory fitness was observed, as evidenced by increased VO□max, accompanied by favorable alterations in redox status, including a reduction in markers of oxidative damage and an increase in sulfhydryl levels. Notably, a significant increase in the activity of antioxidant enzymes —catalase, superoxide dismutase, and glutathione peroxidase— was observed, indicating adaptive upregulation of the antioxidant defense system in response to exercise stimulus. Additional benefits observed included improvements in the biochemical profile, particularly a reduction in serum triglyceride levels. It can be concluded that aerobic interval training promotes positive adaptations in cardiorespiratory fitness and redox balance, contributing to the modulation of oxidative stress through enhanced antioxidant enzymatic activity in patients with cardiovascular disease.

19368

ENDOTHELIAL DYSFUNCTION AND RISK OF MAJOR CARDIOVASCULAR EVENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF PROSPECTIVE STUDIES

GIOVANA CASAGRANDE DE ALENCAR1; POLIANA MARCELINO JOIA2; TAYNARA TAVARES DOS SANTOS2; THIAGO VITTOR SILVA FREITAS2; LUCAS MARINHO REIS DA CUNHA SILVA2; BRUNO DE FREITAS SILVA2; RAFAEL ALVES DE OLIVEIRA2; NILZA DE ALMEIDA NUNES2; GEOVANA ARAÚJO DA CRUZ2; AMANDA OLIVA SPAZIANI2;

(1) UNIVERSIDADE BRASIL - FERNANDÓPOLIS - MS - BRASIL; (2) UNIVERSIDADE BRASIL - FERNANDÓPOLIS - SP - BRASIL;

Introdução/Fundamentos: Endothelial dysfunction represents an early and central step in the pathophysiology of atherosclerosis, preceding clinical and structural manifestations of cardiovascular disease. Functional markers such as flow-mediated dilation (FMD) have been used as early indicators of risk; however, their predictive capacity on a large scale still requires further consolidation. Objetivos: To evaluate the association between endothelial dysfunction and the occurrence of major cardiovascular events in adults. Métodos: A systematic review and meta-analysis conducted according to PRISMA guidelines. PubMed, Embase, Scopus, and Web of Science databases were searched through January 2025. Prospective cohort studies assessing endothelial function using validated methods, including FMD, peripheral reactive hyperemia index, and endothelial biomarkers, with major cardiovascular outcomes (acute myocardial infarction, stroke, and cardiovascular mortality) were included. Methodological quality was assessed using the Newcastle-Ottawa Scale. Statistical analysis was performed using a random-effects model, with calculation of relative risk (RR) and 95% confidence intervals. Heterogeneity was assessed using the I^2 statistic, and publication bias was evaluated using funnel plots and Egger's test. Subgroup analyses were performed according to diagnostic method and population profile. Resultados e Conclusões: A total of 26 studies were included, comprising 1,532,780 individuals, with a mean follow-up of 7.1 years. Endothelial dysfunction was associated with a significant increase in the risk of major cardiovascular events (RR=1.49; 95% CI: 1.34–1.66; p<0.001). In subgroup analyses, individuals with reduced FMD showed higher risk (RR=1.58), especially in the presence of traditional risk factors. The association remained significant in populations without prior cardiovascular disease. Heterogeneity was moderate (I^2=51%), with no consistent evidence of publication bias. In summary, Endothelial dysfunction is independently associated with an increased risk of major cardiovascular events, highlighting its role as a relevant early marker in risk stratification. Its incorporation into clinical practice may enable early identification of high-risk individuals and guide more effective preventive interventions.

EVALUATION OF ALGINATE SCAFFOLD IMPLANTATION FOR MYOCARDIAL INFARCTION TREATMENT IN A RAT MODEL

FELIPE SANTANA LOBO1; RICARDO ABBUD TORRES XAVIER1; LUIZE KREMER GAMBA1; HÉLCIO GIFFHORN1; EDILAINE BRAGA DE SOUZA1; LUIZ NEVES NETO1; DANIELLE DE PAULA E SILVA CARNEIRO BASAGLIA1; JÚLIO CÉSAR FRANCISCO1; LUIZ CÉSAR GUARITA-SOUZA1;

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL;

Introdução/Fundamentos: Coronary artery disease remains a leading cause of global morbidity and mortality, and myocardial regeneration continues to be a challenge due to the limited efficacy of current therapies. In this context, the use of alginate scaffolds has emerged as a promising alternative to promote myocardial repair. Objetivos: To evaluate the impact of alginate scaffolds on ventricular function and remodeling in a rat model of myocardial infarction (MI). Métodos: Following approval by the Ethics Committee on Animal Use of the UFPR (Process: 23075.046582/2024-88), MI was induced in 20 male Wistar rats via coronary ligation. At 7 days post-MI (D7), left ventricular end-systolic volume (LVESV), end-diastolic volume (LVEDV), and ejection fraction (LVEF) were assessed via the Simpson's method. Survivors (n=19) were randomized into Control (untreated, n=10) or Alginate (3D-printed membrane, n=9) groups. Repeat echocardiography was performed 30 days post-MI (D30) using the same parameters. Resultados e Conclusões: Regarding LVEF, the Alginate group presented a mean of 59.1% at D30 compared to 44.4% in the Control (p=0.065). From D7 to D30, the Alginate group showed a 7.7% mean increase, whereas the Control decreased by 3.1% (p=0.095). Inter-group comparisons for LVESV and LVEDV did not reach statistical significance (p>0.05). However, intra-group analysis revealed a mean LVEDV increase of 102.6 mL (p=0.059) in the Control group versus 40.8 mL in the Alginate group (p=0.594). These data suggest that alginate treatment attenuated adverse ventricular remodeling by promoting volumetric stability and significant intra-group improvement in LVEF over 30 days (p=0.050).

EXPRESSION PROFILE OF ACP1, PTPN1, AND PTPN11 IN HEART FAILURE AND THEIR POTENTIAL AS TRANSLATIONAL BIOMARKERS

HELENA PANTELIOU LIMA-VALASSI1; NATHAN MIGNELLA GRECO1; FELIPE YUJI KOYAMA AZEKA1; ISADORA BIAZON DE SOUZA1; LARISSA MIKALAUSKAS1; ALEXANDER DE MORAES FRANKIW1; MARIA ALICE KAWASHITA DALLA VECCHIA1; EDIELLE DE SANT' ANNA MELO1; ALESSANDRA VALERIA DE SOUZA FARIA2;

(1) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL; (2) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Heart failure (HF) represents a complex syndrome associated with high mortality rates, marked by ventricular remodeling and the progressive loss of myocardial function. In recent years, protein phosphatases have gained prominence as essential regulators of cellular hypertrophy and regeneration, with the roles of ACP1, PTPN11, and PTPN1 being particularly relevant in these mechanisms. Objetivos: The present study evaluated the expression of these phosphatases in the myocardium and investigated their applicability as whole-blood biomarkers. Métodos: Using transcriptomic databases (NIH), we analyzed two cohorts: 1) 64 left ventricular biopsies (14 controls, 37 with dilated cardiomyopathy [DCM], and 13 with ischemic cardiomyopathy [ICM]); and 2) 944 whole-blood samples from patients with HF. Statistical analyses were performed using R and Jamovi software, employing ANOVA and Kruskal-Wallis tests, followed by Tukey and Games-Howell post-hoc tests, with adjustments for clinical and demographic factors. Resultados e Conclusões: Transcriptomic analysis showed that phosphatase expression is strongly modulated by cardiac pathophysiology and demographic variables. In ventricular tissue, PTPN1 behaved as an indicator of myocardial stress, exhibiting significantly elevated expression in both DCM (p=0.009) and ICM (p=0.0029). Conversely, ACP1 exhibited downregulation restricted to DCM (p=0.04), suggesting an etiology-dependent molecular profile. In the whole-blood validation stage (n=944), an evident sexual dimorphism in ACP1 expression was noted, with higher levels in females (p<0.001). Additionally, PTPN11 demonstrated sensitivity to aging, with reduced expression in the 70-79 age group when compared to the 50-59 (p=0.013) and 60-69 (p=0.045) age ranges. Thus, the measurement of PTPN1 and ACP1 indicates tissue impairment, while the peripheral detection of ACP1 and PTPN11 enables clinical stratification adjusted by sex and age.The findings demonstrate that PTPN1 and ACP1 phosphatases integrate a molecular signature intrinsic to cardiac remodeling in HF. The applicability of ACP1 and PTPN11 in whole blood confers high translational value to these markers, consolidating them as biomarkers influenced by demographic characteristics. This discriminatory capacity highlights the promising role of these enzymes in advancing precision medicine, paving the way for more assertive and individualized clinical monitoring of heart failure.

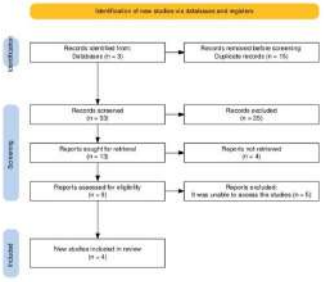
GENE EDITING AS A STRATEGY TO INCREASE THE EFFICACY OF MESENCHYMAL STEM CELLS IN MYOCARDIAL REGENERATION AFTER ISCHEMIA: A SYSTEMATIC REVIEW OF EXPERIMENTAL STUDIES

LUANA CARDOSO TAVARES1; JÚLIA OLIVEIRA PIMENTEL1; LUANA NÓBREGA DOS SANTOS1; EDSON GABRIEL SANTOS NASCIMENTO1; VITÓRIA CAMPOS CORDEIRO1; EVA LUDMILA DO SOCORRO DA CRUZ MARQUES1; GUILHERME HENRIQUE OLIVEIRA MOURA DA SILVA1; LUANA KAORI SAKAGUCHI SAKAMOTO1; LEONARDO GOUVÊA DE OLIVEIRA1; BIANCA LOBÃO GUTIERREZ1; RITA DE CÁSSIA SILVA DE OLIVEIRA1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Cardiac ischemia is an important factor in the aggravation of cardiovascular diseases and a relevant cause of mortality, due to the limited regeneration of the myocardium. Although mesenchymal stem cells (MSCs) have therapeutic potential, their poor survival in ischemic tissue reduces their effectiveness. The association with gene therapy emerges as a promising strategy to enhance cardiac regeneration. Objetivos: To compile data from the literature to evaluate the feasibility of engraftment of gene therapy-modified MSCs in myocardial tissue regeneration after ischemia. Métodos: Systematic review conducted according to the PRISMA protocol, including experimental studies in mice. The DeCS/MeSH descriptors were combined with the Boolean operators to compose the search strategy. The screening of articles was performed on the Rayyan platform, and the risk of bias was assessed using the SYRCLE protocol. Resultados e Conclusões: We included 4 studies in which different genetic modification strategies were evaluated. The first demonstrated that the addition of Interleukin (IL)-10 to MSCs increased cell survival, improved left ventricular ejection fraction (LVEF) and reduced fibrosis after ischemia. However, not all of them showed similar results. In the study with C-C Motif Chemokine Receptor 1 (CCR1) and C-X-C Motif Chemokine Receptor 2 (CXCR2) overexpression, there was no significant improvement in cardiomyocyte differentiation or proliferation, suggesting paracrine effects, and CXCR2 did not increase cell survival in relation to unmodified MSCs. The third study, with IL-7, also showed a reduction in fibrosis and an improvement in contractile function. Finally, the modification for stem cell factor (SCF) expression activated pathways associated with greater vascularization, lower fibrosis, and improved cardiac function. Risk of bias analysis showed high risk of bias in all studies. Thus, most techniques increased the survival of MSCs in ischemic tissue, except for those with CXCR2 overexpression. In addition, there was an increase in proangiogenic factors in most studies, with the exception of the IL-7 assay. Despite the promising results, the increased risk of bias in all studies indicates the need for more robust and methodologically improved research to evaluate the real contribution of gene therapy to MSC survival and post-ischemia cardiac remodeling.

Figure 1. Flow diagram of study screening and selection for sample inclusion.



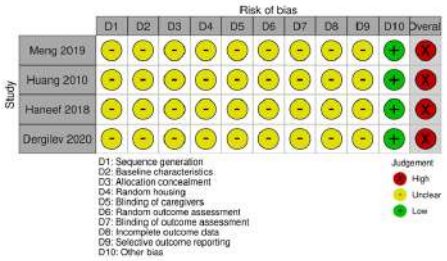


Figure 2. Assessment of the risk of bias using the SYRCLE tool.

GUT MICROBIOTA, LIPID METABOLISM AND HYPERTENSION: A COMPOSITIONAL AND FUNCTIONAL ANALYSIS

LISMAR DOS SANTOS SILVA JÚNIOR1; GABRIEL ARAÚJO RODRIGUES1; MANOLA DA CONCEIÇÃO KISTNER1; CAIO FELIPE SILVA SENA1; VITÓRIA CRISTINNE ALVES PERES1; JOSAFÁ ALMEIDA SOARES1; DANIELE SANTANA DE BRITO1; MARCELO AUGUSTO ROCHA CAVALCANTE1; ÍCARO SANTOS LOPES2; ARTUR TRANCOSO LOPO DE QUEIROZ2; DARIZY FLÁVIA SILVA1;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL; (2) FIOCRUZ - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Gut microbiota–host metabolic interactions play a critical role in cardiovascular regulation, modulating inflammation, energy homeostasis, and endothelial function. Microbial metabolites, including short-chain fatty acids (SCFAs), bile acids, and lipopolysaccharides (LPS), influence pathways such as PPAR signaling, lipid metabolism, and oxidative stress. However, whether arterial hypertension is associated with structural dysbiosis or functional alterations independent of microbial diversity remains unclear. Objetivos: To investigate gut microbiota composition and diversity in hypertensive individuals and evaluate associations between specific bacterial genera and lipid parameters compared to normotensive controls. Métodos: In this cross-sectional study, normotensive (NT, n=20) and hypertensive (HT, n=20) participants were analyzed. Fecal samples underwent 16S rRNA gene sequencing (V3–V4 region), processed using QIIME2. Alpha (Chao1, Shannon, Simpson, Faith's PD) and beta diversity (PhILR, PCoA) were assessed. Differential abundance was evaluated using DESeq2, and functional profiling was performed via KEGG. Spearman correlations were used to assess associations between microbial taxa and clinical parameters. Resultados e Conclusões: Results: No significant differences were observed in overall microbial diversity or composition between groups. However, hypertensive individuals showed increased abundance of CAG-873, Oribacterium, Succinivibrio, and Akkermansia, and reduced Lactobacillus. In normotensive individuals, Barnesiella and Phascolarctobacterium positively correlated with total cholesterol, while Fusicatenibacter negatively correlated with VLDL and triglycerides; these associations were absent in hypertensive subjects. In HT, vadinBE97 positively correlated with uric acid. Functional analysis revealed a predominance of upregulated pathways in HT (291 vs. 49 downregulated). Notably, pathways related to PPAR signaling, fatty acid metabolism, peroxisomal function, and oxidative phosphorylation were reduced in HT. Conclusion: Arterial hypertension was not associated with global microbial dysbiosis or reduced diversity but rather with shifts in specific bacterial taxa and functional reprogramming. The disruption of correlations between gut microbiota and lipid parameters observed in normotensive individuals, together with the downregulation of lipid-related metabolic pathways, suggests that impaired microbiota–lipid metabolism interactions may contribute to the pathophysiology of hypertension.

IMPAIRED BIOFILM FORMATION BY STAPHYLOCOCCUS AUREUS FROM HIV-INFECTED INDIVIDUALS: EVIDENCE OF REDUCED VIRULENCE ON MECHANICAL HEART VALVES

HENRIQUE AUGUSTO GUARESQUI1; PAULO EDUARDO GUARESQUI1; NÍCOLAS DE OLIVEIRA FRACAROLI1; PEDRO CAMPOS FERREIRA MENIN1; ANA CAROLINA DE SOUZA BRANDÃO1; RODRIGO MORAES1;

(1) ESCOLA SUPERIOR DE CIENCIAS DA SANTA CASA DE MISERICORDIA DE VITORIA - VITÓRIA - ES - BRASIL;

Introdução/Fundamentos: Biofilm formation by Staphylococcus aureus on prosthetic heart valves is a central mechanism in the pathogenesis of infective endocarditis, contributing to bacterial persistence and resistance to antimicrobial therapy. In individuals with HIV infection, the immunosuppressed state may influence host–pathogen interactions and potentially modify bacterial virulence profiles, including the biofilm formation capacity. Objetivos: To evaluate and compare the biofilm formation capacity of Staphylococcus aureus isolates obtained from the nasal microbiota of HIV-positive and HIV-negative individuals on mechanical heart valves. Métodos: This was an in vitro experimental study conducted using previously sterilized mechanical mitral valves. Staphylococcus aureus inocula were adjusted to 10^8 CFU/mL, followed by washing and centrifugation steps. The final bacterial suspension was added to a culture medium containing the prosthetic valve and incubated at 35°C for 24 and 72 hours. After incubation, non-adherent cells were removed, and the remaining biofilm was stained with crystal violet. Biofilm biomass was then detached by sonication and quantified by spectrophotometric analysis at 570 nm. The method was performed a total of eight times. In the HIV-positive group, it was conducted four times—two at 24 hours and two at 72 hours. The same protocol was applied to the HIV-negative group, also totaling four experiments, with two at 24 hours and two at 72 hours. Resultados e Conclusões: Isolates from HIV-negative individuals consistently demonstrated greater biofilm formation at both evaluated time points. At 24 hours, absorbance values were 0.188 and 0.162 in the HIV-negative group, compared to 0.072 and 0.084 in the HIV-positive group. At 72 hours, values reached 0.256 and 0.257 in the HIV-negative group and 0.104 and 0.081 in the HIV-positive group (Figure 1). Overall, isolates from HIV-positive patients exhibited an approximate 55% to 65% reduction in biofilm formation compared to controls, maintaining a consistent pattern across incubation periods. These findings suggest reduced biofilm-associated virulence among isolates from immunocompromised hosts. A possible explanation is that, in a more permissive host environment, there may be reduced selective pressure for the expression of virulence factors, resulting in diminished biofilm formation.

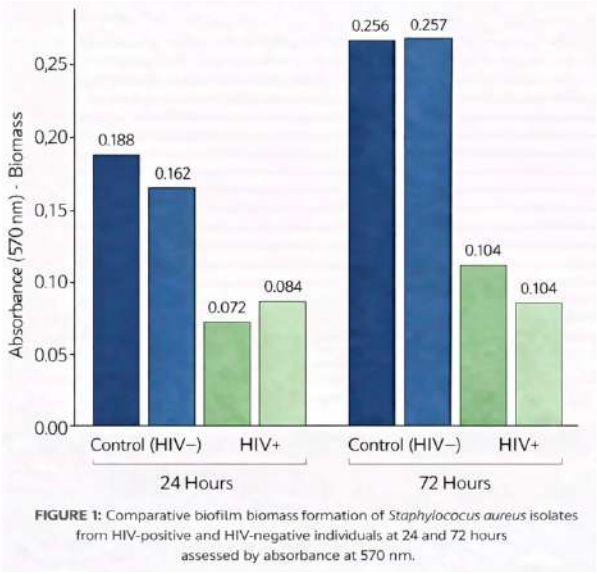

FIGURE 1: Comparative biofilm biomass formation of *Staphylococus aureus* isolates from HIV-positive and HIV-negative individuals at 24 and 72 hours assessed by absorbance at 570 nm.

IN SILICO SCREENING OF TRYPANOSOMA CRUZI CYSTEINE PROTEASES AS IMMUNOGENIC AND PHARMACOLOGICAL TARGETS

GUILHERME VIEIRA GONÇALVES1; RYAN EMILIANO DA SILVA1;

(1) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Chagas disease is a clinical condition still marked by deep biopsychosocial vulnerabilities. Although epidemiological indices have shown significant progress due to national initiatives, the disease remains a major challenge among parasitic infections. Therefore, biotechnological approaches investigating pharmacological targets and molecules with immunogenic potential are essential to amplify its therapeutic arsenal. Objetivos: This study aims to determine the viability of select peptide segments derived from cruzipain as potential immunogenic targets. To this end, these peptides were analyzed based on biochemical, conformational and stereoscopic criteria, generating protein fragments that were subsequently subjected to molecular docking simulations to identify new pharmacological targets with promising trypanocidal activity. Métodos: Nucleotide sequences of cruzipain (GenBank: UBT23809.1) were retrieved from the NCBI database, analyzed by homology and translated via BLAST algorithms. Later, the primary protein sequence underwent multiparametric analysis using ProtParam and ProSite, combining a series of eligibility criteria to identify candidate immunogens, including their probability of eliciting an immune response via MHC-I through Immune Epitope Database. Finally, the cysteine protease structure was modeled via I-TASSER and evaluated for its binding capacity to itraconazole using SwissDock. Resultados e Conclusões: Submission of the gene sequence to BLAST determined a 467-amino acid fragment with adequate solubility in the cellular environment, half-life (30 hours in vitro) and pI for prospective docking investigations. Next, the protein was analyzed under various other biochemical criteria, leading to the selection of VDWRARGAVTAVKD as a promising immunogenic peptide, with high probability of eliciting an MHC-I mediated immune response and satisfactory characteristics to serve as a vaccine target. Molecular docking evidenced ionic and hydrogen bonds, as well as hydrophobic interactions between the protease and itraconazole, with estimated affinity of -8.251 kcal/mol, showing high-intensity binding between the ligand and the target. In conclusion, these in silico findings suggest VDWRARGAVTAVKD as a viable immunogen candidate and support itraconazole repurposing as a promising strategy against Chagas disease. Such biotechnological approaches are crucial for developing more accessible and less toxic therapeutic interventions for this neglected pathology when compared to its usual therapeutic arsenal.

INFLUENCE OF RECOMBINANT METALLOPROTEINASE-2 ON AUTONOMIC AND SPONTANEOUS BAROREFLEX FUNCTION IN HEALTHY MICE

LÍVIA LÍVIA TRUFELI1; LAURA MOLEZINI1; ALEJANDRO FERRAZ PRADO2; ELEN RIZZI SANCHEZ3; CARLOS ALBERTO AGUIAR DA SILVA4; MARINA DE TOLEDO DURAND1;

(1) UNIVERSIDADE DE RIBEIRÃO PRETO - RIBEIRÃO PRETO - SP - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (3) UNVERSIDADE DE RIBEIRÃO PRETO - RIBEIRÃO PRETO - SP - BRASIL; (4) HOSPITAL DAS CLINICAS DA FACULDADE DE MEDICINA DE RIBEIRAO PRETO - USP - RIBEIRAO PRETO - SP - BRASIL;

Introdução/Fundamentos: The Baroreflex is responsible for controlling blood pressure (BP) by means of neural mechanisms via mechanoreceptors that change heart rate (HR) to maintain adequate BP levels. In cardiovascular diseases (CVD), there is a dysfunction of this system, associated with the presence of matrix metalloproteinase 2 (MMP-2), which are endopeptidases that destroy the extracellular matrix and generate cardiac remodeling. Objetivos: Thus, the objective of this study was to investigate the influence of recombinant MMP-2 on autonomic and spontaneous baroreflex function in healthy mice. Métodos: Male C57BL/6 (Wild Type) mice were used and divided into two groups: Control group (C, n=6), which received saline solution (i.p.), and MMP-2 group (M, n=5), which received 150 ng/g/day (i.p.) of recombinant MMP-2 for 4 weeks starting from the 7th week of life. After this period, the animals were anesthetized for cannulas implantation in the femoral artery and vein, and 24 hours after these procedures, baseline BP and HR were recorded with the animals unanesthetized for the evaluation of heart rate variability (HRV) and spontaneous baroreflex. Resultados e Conclusões: No significant differences were found in the spontaneous baroreflex gain parameters (5.0±0.67 vs. 4.9±0.58, p=0.7376) and in the Baroreflex Effectiveness Index (BEI) (0.046±0.004 vs. 0.039±0.004, p=0.2076), which illustrates the baroreflex's ability to respond adequately to BP variations. In the HRV analysis, no significant differences were observed between the groups in the time domain (RMSSD: 15.4±2.3 vs. 23.9±6.8, p=0.2362) and frequency domain parameters (high frequency – HF and low frequency – LF which relate to the parasympathetic and sympathetic autonomic nervous system, respectively LF/HF ratio: (0.35±0.14 vs. 0.42±0.14, p=0.7316). In conclusion, the administration of recombinant MMP-2 for 4 weeks does not interfere with the parameters of autonomic function and spontaneous baroreflex in healthy mice.

INTRACEREBROVENTRICULAR INFUSION OF ALAMANDINE-(1-5) REDUCES BLOOD PRESSURE AND IMPROVES BAROREFLEX IN SPONTANEOUSLY HYPERTENSIVE RATS (SHR)

GABRIELA COUTO ABRANTES RENNÓ1; KAMYLLE SILVA FERRAZ1; STHEFANIE CHAVEZ ALMEIDA GONÇALVES1; ANDREA SIQUEIRA HAIBARA1; ROBSON AUGUSTO SOUZA DOS SANTOS1; MARIA JOSÉ CAMPAGNOLE DOS SANTOS1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: It is well known that in the central nervous system, peptides of the renin-angiotensin system modulate autonomic and baroreflex activity, while angiotensin (Ang) II and Ang III reduce baroreflex sensitivity (BRS), Ang-(1-7) and alamandine (Ala) enhance it. We have recently shown that Ala-(1-5), a product of Ala, exerts vasodilatory and antihypertensive effects following intravenous administration. Objetivos: In the present study, we evaluated the cardiovascular effects and changes in BRS produced by intracerebroventricular (ICV) infusion of Ala-(1-5) in male and female spontaneously hypertensive rats (SHR). Métodos: SHR (3–4 months; n=5–6/group; IACUC protocol 120/2025) underwent stereotaxic implantation of a cannula into the lateral ventricle, under a mixture of ketamine (50 mg/kg) and xylazine (10 mg/kg) anesthesia. Seven days later, femoral artery and vein were cannulated for arterial pressure (AP) recording and drug administration, respectively. After 24 hours, AP was continuously recorded in conscious animals, with an initial 1-hour stabilization period for cardiovascular parameters. BRS was determined by the bradycardic response to increases in mean AP (MAP) before and 90 minutes after ICV infusion of Ala-(1-5) (4 µg/h). Resultados e Conclusões: In males, Ala-(1-5) infusion significantly reduced MAP by approximately 20 mmHg (155±6 vs. 175±6 mmHg; n=6), without altering baseline heart rate (HR; 327±11 vs. 328±11 bpm), and increased BRS by approximately 70% (0.81±0.08 vs. 0.48±0.08 ms/mmHg). Saline infusion (10 µL/h; n=4) did not alter MAP, HR, or BRS (0.50±0.14 ms/mmHg vs. 0.43±0.06 ms/mmHg). In females, the same infusion rate of Ala-(1-5) did not produce significant changes in MAP (152±7 vs. 162±9 mmHg; n=5), HR (370±10 vs. 342±12 bpm), or BRS (0.78±0.08 vs. 0.81±0.11 ms/mmHg). These findings demonstrate a central antihypertensive effect of Ala-(1-5) associated with improved baroreflex control in male SHR. Future studies should clarify whether the lack of response observed in females is solely attributable to the dose administered.

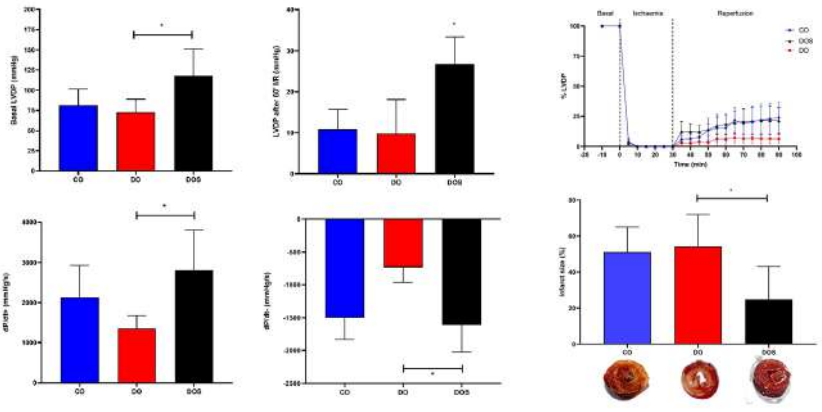
LOW HYDROSTATIC LOAD IN BATS: RESPIRATORY PUMP–FACILITATED CEREBRAL VENOUS RETURN AND POTENTIAL BRAIN PROTECTION STRATEGIES IN HUMANS

GIULIA FERREIRA DAMASCENO1; AKINORI CARDOZO NAGATO1;

(1) UFJF - JUIZ DE FORA - MG - BRASIL;



Introdução/Fundamentos: Trendelenburg positioning and other forms of body inversion, in which the head remains below heart level, increase cephalic venous pressure and intracranial pressure (ICP) in humans. In contrast, bats routinely rest upside down with apparent hemodynamic tolerance. Although circulation depends on multiple factors, hydrostatic pressure (HP) remains relevant. Because blood has an approximately constant density (1050–1060 kg/m³) and HP is proportional to the vertical height difference between two points (P=ρgh), body geometry may significantly influence cerebral perfusion and venous drainage. Objetivos: To analyze how the heart-to-head distance in bats, compared with humans, may explain tolerance to inverted posture through hydrostatic principles, and how these findings may inform human brain-protection strategies. Métodos: Comparative theoretical-anatomical study based on an integrative narrative review. PubMed, Scopus, and Google Scholar were searched using descriptors related to bats, body position, hydrostatic pressure, intracranial pressure, venous return, and comparative physiology. Heart-to-head distance was proportionally compared with axial trunk length (cranium to last vertebra). The main hydrostatic determinant was defined as the real vertical distance between heart and brain rather than total anatomical length. The approximation of 1 vertical cm = 0.77 mmHg was applied. Resultados e Conclusões: In humans, heart-to-head distance corresponds to approximately 45–57% of axial body length, whereas in bats it is estimated at 30–45%. In upright humans, the brain lies about 25–35 cm above the heart, implying a pressure reduction of 19–27 mmHg at cerebral level. During inversion, the head shifts below the heart, favoring increased cranial venous pressure and ICP. In resting inverted bats, the short cephalothoracic distance keeps the head only a few centimeters below the heart, producing a low hydrostatic increase of 2–5 mmHg that may facilitate cerebral venous return through the respiratory pump. Bat tolerance to inversion may be largely explained by the reduced vertical heart-to-brain distance, which limits arterial and venous hydrostatic effects. The resulting low hydrostatic load may also optimize venous drainage through thoracic respiratory mechanics. These concepts highlight the relevance of body geometry in cardiovascular physiology and may support novel postural, ventilatory, and circulatory strategies for human brain protection.

MATERNAL SEMAGLUTIDE INDUCES TRANSGENERATIONAL CARDIOPROTECTION: IMPROVED CARDIAC FUNCTION AND REDUCED INFARCT SIZE AFTER ISCHEMIA–REPERFUSION IN OFFSPRING

RAYNA LICAZALIO RIBEIRO1; WANDERSON DIAS DE ALMADA1; RAQUEL CARVALHO CASTIGLIONE1; SILVIO RODRIGUES MARQUES-NETO1;

(1) UNIVERSIDADE ESTADUAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Obesity is a chronic, multifactorial disease whose prevalence has increased by 105.93% in Brazil, elevating healthcare costs and the risk of non-communicable diseases, such as diabetes, hypertension, and cardiovascular events. This condition also increases susceptibility to ischemia-reperfusion (I/R) injury due to metabolic, inflammatory, and endothelial dysfunction. Semaglutide, a GLP-1 receptor agonist, promotes glycemic control and weight loss and may exert cardioprotective effects; however, its role in attenuating I/R injury is unclear. Objetivos: This study investigated the transgenerational cardioprotective effect of semaglutide administered exclusively to dams on myocardial function and infarct area in offspring subjected to an I/R injury model using isolated hearts. Métodos: Female rats were allocated to three groups: control offspring (CO, n = 4), diet offspring (DO, n = 5), and diet offspring treated with semaglutide (DOS, n = 4). Dams in the DO and DOS groups received a cafeteria diet from weaning through gestation, whereas semaglutide was administered only to the DOS dams during pregnancy and lactation. After weaning, DO and DOS offspring remained on a cafeteria diet for 12 weeks, whereas CO received a standard diet and vehicle. Cardiac function was assessed using the Langendorff system (30 min ischemia/60 min reperfusion), and left ventricular developed pressure (LVDP), myocardial contractility (dP/dt^+), and relaxation (dP/dt^-) were analyzed. The infarct area was determined using TTC staining. Resultados e Conclusões: The DOS group showed higher basal LVDP than the DO group ($p < 0.05$), indicating improved baseline ventricular function, and exhibited better recovery after reperfusion compared with CO and DO ($p < 0.05$), suggesting greater resistance to I/R injury. The dP/dt^+ was also higher in DOS than in DO ($p < 0.05$), reflecting enhanced systolic performance, while dP/dt^- was more negative ($p < 0.05$), indicating improved diastolic relaxation. The CO group presented intermediate values (Figure 1). In addition, infarct area was reduced in DOS compared to DO ($p < 0.05$), supporting a cardioprotective effect of maternal semaglutide; however, no difference was observed between DOS and CO (Figure 2). In conclusion, maternal semaglutide promoted a transgenerational cardioprotective effect, improving cardiac function after I/R and significantly reducing infarct size.

MILD HYPERHOMOCYSTEINEMIA INDUCES SEX-DEPENDENT CARDIAC INFLAMMATORY CHANGES IN AGED RATS: MODULATION BY SIMVASTATIN AND FOLIC ACID

VICTOR CAMARATTA DOSSIN BASTOS1; GUSTAVO RICARDO KRUPP PRAUCHNER1; LUCAS SCHERER LOUZADA1; BRUNO ALONSO ESTIVALLET1; ANGELA TEREZINHA DE SOUSA WYSE1;

(1) UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL;

Introdução/Fundamentos: Homocysteine (Hcy) is a non-proteinogenic amino acid derived from methionine metabolism. Normal plasma levels range from 5 to 15 µmol/L, and increases in these levels characterize Hyperhomocysteinemia (HHcy). Mild HHcy is described between 15 and 30 µmol/L, and is a known cardiovascular risk factor associated with aging and adverse cardiovascular outcomes through inflammatory processes. Folic acid (FA), a cofactor in Hcy metabolism, and simvastatin (SIM), a statin-class lipid-lowering drug, both with known anti-inflammatory properties, may exert protective effects against HHcy-induced alterations. Objetivos: Evaluate the impact of chronic mild HHcy on the expression of interleukins (IL1a, IL1b, IL6 and IL10) and Rela genes, as well as on cytosolic and nuclear NF-κB p65 protein levels, all involved in inflammatory pathways, in the myocardium of aged rats, and the cardioprotective effects of FA and SIM. Métodos: 365-day-old Wistar rats were administered Hcy (0.03 µmol/g, sc, twice daily) for 30 days to induce chronic mild HHcy. Post-euthanasia, myocardial slices were incubated with SIM (10 µM), FA (100 µM), or respective vehicles, for 60 min. Gene expression was quantified via RT-qPCR, and NF-κB p65 distribution was analyzed by Western blotting. Statistical analysis was performed using two-way ANOVA. (CEUA: 46247). Resultados e Conclusões: In males, HHcy upregulated IL1a, IL1b, and IL6 expression and downregulated IL10 ($p<0.05$). SIM treatment restored inflammatory marker levels, and FA exhibited a partial effect, reversing only IL1b upregulation ($p<0.05$). HHcy increased cytosolic NF-κB p65 in males ($p<0.05$) and both SIM and FA mitigated this cytosolic accumulation ($p<0.05$). HHcy-treated females exhibited reduced expression of IL1b and IL10, with increased IL6 levels ($p < 0.05$). SIM normalized IL1b and IL10 levels, and both SIM and FA attenuated IL6 expression ($p < 0.05$). HHcy upregulated Rela (mRNA) in females, which was reversed by FA and SIM ($p<0.05$). No changes were observed in NF-κB p65 protein content for HHcy-treated females ($p>0.05$). In conclusion, chronic mild HHcy alters the cardiac inflammatory profile of aged rats in a sex-specific manner. These findings suggest a pro-inflammatory environment that worsens age-related cardiac vulnerability. Consequently, pharmacological strategies targeting Hcy metabolism or its inflammatory signaling may represent viable pathways for reducing HHcy-associated cardiovascular risk. Funding: CNPq.

MORPHOMETRIC ANALYSIS OF THE LEFT MAIN CORONARY ARTERY BASED ON A CADAVERIC STUDY IN SOUTHERN BRAZIL: ASSOCIATIONS WITH CORONARY DOMINANCE AND BRANCHING PATTERN

ARTHUR SIMAS HEISSER1; PEDRO HERNANDEZ LOPES1; FRANK DE FAUSTO MUNIZ GUIMARÃES1; JÚLIA FEIJÓ BORBA1; MARIANA FONSECA SILVA1; EDUARDO KNECHT COLLETT1; CAETANO TODEO SEMINOTTI1; ESTEVAN KRUGER TRAMONTIN FERREIRA1; STHEFANY CRISTINA KRYCKI1; MATHEUS DA SILVA DO NASCIMENTO BORBA1; HENRIQUE SILVA LOVERA1; ANDREA OXLEY DA ROCHA1;

(1) UFCSPA - PORTO ALEGRE - RS - BRASIL;

Introdução/Fundamentos: The left main coronary artery (LMCA) supplies a substantial portion of the left ventricular myocardium through its major terminal branches, usually the left anterior descending and circumflex arteries. Because of its critical role in myocardial perfusion, the LMCA has major relevance in coronary angiography, percutaneous coronary intervention, coronary artery bypass grafting, and structural heart procedures. Anatomical variations involving LMCA length, diameter, coronary dominance, and branching pattern may influence catheter selection, stent sizing, surgical planning, and procedural risk. However, morphometric data remain limited in many populations, particularly in South America, where regional anatomical differences may exist. Cadaveric studies provide direct anatomical assessment and may complement imaging-based investigations. Therefore, further characterization of LMCA morphology in Southern Brazil may contribute to anatomical knowledge and clinical practice. Objetivos: To assess the prevalence of variations on the LMCA branching pattern in a Southern Brazilian population. As well as to investigate associations between different branching patterns. Métodos: This is an observational cadaveric study conducted with a sample of in-life donated bodies through an institutional body donation program. Whole cadavers and heart specimens were analyzed. Specimens with damaged coronary arteries were excluded. The LMCA branching patterns were noted and measurements of dominance, LMCA length (mm), diameter at its origin (mm), diameter at bifurcation (mm) and branching pattern were recorded. Resultados e Conclusões: A total of 40 hearts were analyzed. Mean LMCA length was 11.9 ± 4.13 mm (2.95–19.5 mm). Mean proximal diameter was 5.87 ± 1.28 mm, while mean distal diameter at the branching point was 5.25 ± 1.11 mm, corresponding to an average caliber reduction of 10.0%. No significant associations were found between coronary dominance and any of the morphometric variables analyzed. Similarly, the branching pattern was not associated with LMCA length or diameter. However, a statistically significant difference in caliber reduction was observed between branching patterns, with trifurcating LMCAs presenting a greater mean reduction compared to bifurcation specimens (17.43% vs. 7.85%). These findings remained significant when analyzed using Welch's t-test ($t = -2.86$, $p = 0.013$). The magnitude of the effect was large (pooled Cohen's $d = 1.06$; Hedges' $g = 1.03$), indicating a substantial difference between groups.

NON-ALCOHOLIC FATTY LIVER DISEASE AND RISK OF MAJOR CARDIOVASCULAR EVENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF PROSPECTIVE STUDIES

GIOVANA CASAGRANDE DE ALENCAR1; RAFAEL ALVES DE OLIVEIRA1; LAIS CATOZI BROGGIO1; NILZA DE ALMEIDA NUNES1; GEOVANA ARAÚJO DA CRUZ1; POLIANA MARCELINO JOIA1; TAYNARA TAVARES DOS SANTOS1; THIAGO VITTOR SILVA FREITAS1; LUCAS MARINHO REIS DA CUNHA SILVA1; BRUNO DE FREITAS SILVA1; AMANDA OLIVA SPAZIANI1;

(1) UNIVERSIDADE BRASIL - FERNANDÓPOLIS - SP - BRASIL;

Introdução/Fundamentos: Non-alcoholic fatty liver disease (NAFLD) has emerged as an important metabolic condition associated with insulin resistance, systemic inflammation, and endothelial dysfunction. Although often considered a liver disease, growing evidence indicates its strong association with cardiovascular outcomes, and it may represent an independent risk marker. Objetivos: To evaluate the association between non-alcoholic fatty liver disease and the occurrence of major cardiovascular events in adults. Métodos: A systematic review and meta-analysis conducted according to PRISMA guidelines. PubMed, Embase, Scopus, and Web of Science databases were searched up to January 2025. Prospective cohort studies evaluating NAFLD diagnosed by imaging (ultrasound, elastography, or magnetic resonance imaging) or clinical criteria, and its association with major cardiovascular outcomes (acute myocardial infarction, stroke, and cardiovascular mortality), were included. Methodological quality was assessed using the Newcastle–Ottawa Scale. Statistical analysis was performed using a random-effects model, with calculation of relative risk (RR) and 95% confidence intervals (95% CI). Heterogeneity was assessed using the I^2 index, and publication bias was evaluated by funnel plot and Egger's test. Subgroup analyses were conducted according to diagnostic method and presence of metabolic syndrome. Resultados e Conclusões: A total of 32 studies were included, comprising 2,214,560 individuals, with a mean follow-up of 7.3 years. The presence of NAFLD was associated with a significant increase in the risk of major cardiovascular events (RR=1.45; 95% CI: 1.32–1.59; p<0.001). In subgroup analyses, individuals with NAFLD associated with metabolic syndrome had a higher risk (RR=1.68), while the association remained significant even in the absence of advanced liver disease. Heterogeneity was moderate (I^2=54%), with no consistent evidence of publication bias. In summary, non-alcoholic fatty liver disease is independently associated with an increased risk of major cardiovascular events, reinforcing its role as a systemic risk marker. Early identification of this condition may contribute to integrated strategies for cardiovascular prevention and metabolic management.

OVARIAN HORMONES IN BLOOD PRESSURE CONTROL: EFFECTS OF OVARIECTOMY ON HYPERTENSION DEVELOPMENT IN FEMALE SPONTANEOUSLY HYPERTENSIVE RATS

MANUELA PARONETO ALENCAR DE SOUSA1; ALESSANDRA KOZORIS DIAS1; LUMA CAROLINA SANTOS DA SILVA1; RENATA MARIA LATARO1;

(1) UNIVERSIDADE FEDERAL DE SANTA CATARINA - FLORIANÓPOLIS - SC - BRASIL;

Introdução/Fundamentos: Hypertension is a multifactorial condition with sex-related differences in its pathophysiology. In this context, it is important to understand the role of ovarian hormones in the modulation of blood pressure and cardiovascular protection. Objetivos: To study the effect of ovariectomy (OVX) on the development of hypertension in female Spontaneously Hypertensive Rats (SHR) and its consequences on heart weight. Métodos: SHR and Wistar rats were used as hypertensive and normotensive models. OVX or sham surgery was performed at the 5th postnatal week (PNW), and the rats were randomized into Wistar, SHR, and SHR-OVX groups. The rats' body weight (BW) was monitored weekly and systolic blood pressure (SBP) was measured using tail cuff plethysmography at the 8th, 12th, 16th, and 20th PNW. The heart was collected after euthanasia at the 20th PNW. Data are presented as mean±SD. Resultados e Conclusões: Regarding BW, there was a significant main effect of strain (p<0.001) and time (p<0.001). Lower BW in SHR (p=0.025) and SHR-OVX (p=0.006) were observed only at 8 PNW (Wistar: 169.5±10.33; SHR: 145.87±19.62; SHR-OVX: 142.44±17.85 g). Two-way repeated measures ANOVA showed a significant main effect of strain (p<0,001) on SBP. Post hoc analysis revealed differences between groups at two specific time points. At 16 PNW, SBP was significantly higher in SHR compared to Wistar (Wistar: 120±10.3 vs. SHR: 156±17 mmHg; p<0.001), whereas at 20 PNW, both SHR (p=0.006) and SHR-OVX (p=0.011) exhibited significantly higher SBP compared to the Wistar (Wistar: 112±5.4; SHR: 144±17.6; SHR-OVX: 138±23.5mmHg). No difference in SBP was observed between SHR and SHR-OVX at any time point analyzed. Regarding relative heart weight, only strain had a significant effect (p=0.013), with higher values in SHR compared to Wistar, regardless of OVX (Wistar: 0.37±0.02; SHR:0.41±0.04; SHR-OVX: 0.46±0.13g). This study concludes that in female SHR, OVX at 5 PNW did not affect hypertension development, nor did it alter relative heart weight. These findings suggest that estradiol and progesterone may not play a major role in the development of hypertension in this model.

PROGNOSTIC IMPACT OF NEW PERSISTENT LEFT BUNDLE BRANCH BLOCK IN PATIENTS UNDERGOING AORTIC VALVE REPLACEMENT ACCORDING TO THE PROCEDURE PERFORMED: TRANSCATHETER AORTIC VALVE IMPLANTATION (TAVI).

DAIANA SU1; ANDRESSA APARECIDA DA SILVA2; LUCAS GABRIEL BATISTA GAUDENCIO3; EDUARDO LISTIK4; LARA DOS SANTOS AGUILAR3; MARIA EDUARDA COLLOSSAL CAMBRAIS4; ANDREA KARINA LAZCANO FERNANDEZ3; NATHÁLIA FOSSALUZA GONÇALVES5; RUY RIBEIRO CAMPOS JUNIOR4;

(1) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE CIDADE DE SÃO PAULO (UNICID) - SÃO PAULO - SP - BRASIL; (3) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL; (4) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL; (5) UNIP - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Left Bundle Branch Block (LBBB) causes ventricular dyssynchrony due to delayed or interrupted electrical conduction. Although Transcatheter Aortic Valve Implantation (TAVI) is an effective treatment for aortic stenosis, conduction disturbances such as persistent LBBB remain frequent complications, especially after the TAVI procedure. Objetivos: To evaluate the clinical impact of new persistent post-TAVI LBBB, analyzing its association with all-cause mortality, need for permanent pacemaker implantation, and worsening of left ventricular ejection fraction (LVEF). Métodos: The study followed the PRISMA 2020 guidelines, with searches conducted in PubMed and Embase via Parsifal, using a study selection performed independently by two reviewers. Funnel plots were used to assess publication bias. Observational studies evaluated using the Newcastle-Ottawa Scale were included, while pediatric and congenital heart disease patients were excluded. A random-effects meta-analysis (DerSimonian-Laird method) was performed, using RR for dichotomous outcomes, MD for LVEF, and I^2 to assess heterogeneity. Resultados e Conclusões: Six observational studies were included, totaling 3,340 patients undergoing TAVI, evaluating the impact of new persistent LBBB on clinical and functional outcomes. The meta-analysis demonstrated a 32% increase in long-term all-cause mortality (RR = 1.32), with 0% heterogeneity. There was a higher need for permanent pacemaker implantation in the LBBB group (RR = 3.05; $p < 0.001$). Impaired recovery of cardiac function after TAVI was also observed, with a reduction in LVEF ranging from 2.8% to 3.2% compared with controls. Additionally, a 37% increase in the risk of hospitalization for heart failure was identified (RR = 1.37). New persistent LBBB after TAVI is associated with an increased risk of all-cause mortality and need for permanent pacemaker implantation. Furthermore, it compromises long-term improvement in ejection fraction, suggesting the need for implantation strategies aimed at minimizing damage to the cardiac conduction system.

REPERCUSSIONS OF MESENCHYMAL STEM CELL THERAPY ON THE MECHANICAL PROPERTIES OF THE INFARCT SCAR

NATHALIA BOSCOLO BUFFONI1; EDNEI LUIZ ANTÔNIO1; IGHOR LUIZ AZEVEDO TEIXEIRA1; ANDRÉ RODRIGUES LOURENÇO DIAS1; GABRIEL MATHEUS DA SILVA BATISTA1; RODRIGO LABAT MARCOS2; JULIANA MENTZINGER3; NATALIA GALITO ROCHA AYRES3; ANDREY JORGE SERRA1;

(1) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (3) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL;

Introdução/Fundamentos: Myocardial infarction affects thousands of people worldwide each year, reducing the quality of life and life expectancy of survivors and increasing healthcare costs. Myocardial cell death due to ischemia promotes cardiac remodeling and collagen deposition at the site of injury, predisposing patients to heart failure, expansion of necrosis, aneurysms, and ventricular rupture, which may lead to death. Due to these complications, studies have emerged using mesenchymal stem cells in cardiac tissue; however, little is known about the mechanical impact and the structural and functional abnormalities of the infarcted area following the injection of these cells. This is the objective of the present study. Objetivos: The present study aims to analyze the impact of the therapeutic use of adipose tissue-derived mesenchymal stem cells on the mechanical properties of the infarct scar. Métodos: The study was approved by the research ethics committee of UNIFESP (No. 9220050424). Twelve-week-old Fischer rats were infarcted by coronary occlusion. After 28 days, an echocardiogram was performed to confirm the presence of infarction, and the animals were randomly assigned to receive intramyocardial injection of sterile saline (MC) or ADMSC. After 48 hours, the rats were euthanized for scar extraction and storage at −80°C for up to five days. The samples were thawed, fixed in steel rings, and subjected to tension on a loading platform to record maximum tensile strength (Fmax) and maximum deformation capacity (Dmax) of the material. Scar stiffness was defined by the tangent of the angle formed in the linear region of the stress–strain curve. Pro–matrix metalloproteinase-2 (pro-MMP-2) and matrix metalloproteinase-2 (MMP-2) activity were measured by zymography. Data were analyzed using a paired t-test ($p \leq 0.05$) and expressed as mean ± standard error. Resultados e Conclusões: Fmax (MC: 5.1 ± 1.8; ADMSC: 4.6 ± 1.5) and Dmax (MC: 2 ± 0.8; ADMSC: 2.3 ± 0.7) values were not significantly different between the MC and ADMSC groups. The tangent values (MC: 1.02 ± 0.36; ADMSC: 0.84 ± 0.08) and maximum deformation (MC: 1.98 ± 0.34; ADMSC: 2.19 ± 0.21) were also not significantly different between groups. Pro-MMP-2 (MC: 4 ± 0.2; ADMSC: 4 ± 0.5; a.u.) and MMP-2 (MC: 3 ± 0.1; ADMSC: 3 ± 0.2; a.u.) levels were likewise not altered by cell therapy. In summary, ADMSCs do not modify the strength, deformation capacity, or stiffness of the infarct scar.

SARCOPENIA AND THE RISK OF MAJOR CARDIOVASCULAR EVENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF POPULATION-BASED STUDIES

GIOVANA CASAGRANDE DE ALENCAR1; JULIA FERNANDES DE CARLI1; POLIANA MARCELINO JOIA1; TAYNARA TAVARES DOS SANTOS1; THIAGO VITTOR SILVA FREITAS1; LUCAS MARINHO REIS DA CUNHA SILVA1; BRUNO DE FREITAS SILVA1; LAIS CATOZI BROGGIO1; NILZA DE ALMEIDA NUNES1; GEOVANA ARAÚJO DA CRUZ1; AMANDA OLIVA SPAZIANI2;

(1) UNIVERSIDADE BRASIL - FERNANDÓPOLIS - SP - BRASIL; (2) UNIVERSIDADE BRASIL - FERNANDOPÓLIS - SP - BRASIL;

Introdução/Fundamentos: Sarcopenia, characterized by the progressive loss of muscle mass and function, has been recognized as a systemic condition associated with chronic inflammation, insulin resistance, and metabolic dysfunction. Recent evidence suggests its relationship with cardiovascular outcomes; however, the magnitude of this association has not yet been fully established. Objetivos: To evaluate the association between sarcopenia and the occurrence of major cardiovascular events in adults. Métodos: A systematic review and meta-analysis were conducted in accordance with PRISMA guidelines. PubMed, Embase, Scopus, and Web of Science databases were searched up to January 2025. Prospective cohort studies evaluating sarcopenia defined by clinical criteria, anthropometric measures, or imaging methods (DEXA, bioimpedance), and its association with major cardiovascular events (myocardial infarction, stroke, and cardiovascular mortality) were included. Methodological quality was assessed using the Newcastle-Ottawa Scale. Statistical analysis was performed using a random-effects model, with calculation of relative risk (RR) and 95% confidence intervals. Heterogeneity was assessed using the I^2 index, and publication bias was evaluated through funnel plot and Egger's test. Subgroup analyses were conducted according to diagnostic method and age group. Resultados e Conclusões: A total of 29 studies were included, comprising 1,764,320 individuals, with a mean follow-up of 6.5 years. The presence of sarcopenia was associated with a significant increase in the risk of major cardiovascular events (RR=1.51; 95% CI: 1.36–1.67; p<0.001). In subgroup analyses, the risk was higher in older adults (RR=1.62) and in individuals with metabolic comorbidities. Studies using imaging-based methods demonstrated a stronger association. Heterogeneity was moderate (I^2=55%), with no relevant evidence of publication bias. In summary, sarcopenia is independently associated with an increased risk of major cardiovascular events, reinforcing its relevance as a systemic risk marker. Early identification of this condition may contribute to integrated preventive strategies, including nutritional interventions and physical rehabilitation.

SCREENING FOR OBSTRUCTIVE SLEEP APNEA IN THE BRAZILIAN UNIFIED HEALTH SYSTEM USING SIMULTANEOUS MULTIMODAL HOME POLYSOMNOGRAPHY AND HOLTER MONITORING: FEASIBILITY AND ASSOCIATION BETWEEN OXYGEN DESATURATION INDEX AND CARDIAC ARRHYTHMIAS.

ISABELA MARIA SANTOS1; IVY KIEMLE TRINDADE-SUEDAM2; SERGIO HENRIQUE KIEMLE TRINDADE1;

(1) FACULDADE DE MEDICINA UNIVERSIDADE DE SÃO PAULO - USP - BAURU - SP - BRASIL; (2) FACULDADE DE ODONTOLOGIA DE BAURU DA UNIVERSIDADE DE SÃO PAULO - BAURU - SP - BRASIL;

Introdução/Fundamentos: Obstructive Sleep Apnea (OSA) is highly prevalent and has a substantial cardiovascular impact, yet it remains widely underdiagnosed within the Brazilian Unified Health System (SUS). The association between intermittent hypoxia and cardiac arrhythmias highlights the need for accessible and integrated diagnostic strategies. Objetivos: To evaluate the correlation between the Oxygen Desaturation Index (ODI) and cardiac arrhythmias, as well as to assess the feasibility of simultaneous multimodal home portable polysomnography and 24-hour Holter monitoring in a cardiology outpatient clinic within the SUS. Métodos: This cross-sectional observational study was conducted between March 2021 and January 2022 and included adult patients referred for 24-hour Holter monitoring at a secondary care service within the SUS. The Berlin Questionnaire and the Epworth Sleepiness Scale were administered. Participants underwent simultaneous monitoring with Holter and multimodal home portable polysomnography. OSA was defined as an ODI >5 events/hour. Resultados e Conclusões: Of the 69 enrolled patients, 58 successfully completed the protocol. The prevalence of OSA was 70.7%, with 31% of cases classified as moderate or severe. Patients presenting supraventricular tachycardia or non-sustained ventricular tachycardia showed significantly higher ODI values compared with those without these arrhythmias (22.6 vs. 10.6 events/hour; p=0.015). A significant correlation was also observed between ODI and premature ventricular contractions (PVCs). The rate of inadequate examinations was 16.4%, predominantly related to operational difficulties with the mobile application. Patients followed in a cardiology outpatient clinic within the SUS showed a high prevalence of OSA. Higher levels of nocturnal oxygen desaturation were associated with greater cardiac electrical instability. The simultaneous use of home portable polysomnography and Holter monitoring proved feasible within the SUS and may represent a promising strategy to expand integrated screening between sleep medicine and cardiology.

SEX-DEPENDENT IMPACT OF MILD HYPERHOMOCYSTEINEMIA ON REDOX BALANCE IN CARDIAC TISSUE OF WISTAR RATS AND THE PROTECTIVE EFFECTS OF FOLIC ACID AND SIMVASTATIN

LUCAS SCHERER LOUZADA1; GUSTAVO RICARDO KRUPP PRAUCHNER1; VICTOR CAMARATTA DOSSIN BASTOS1; BRUNO ALONSO ESTIVALLET1; ANGELA TEREZINHA DE SOUZA WYSE1;

(1) UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL;

Introdução/Fundamentos: Homocysteine (Hcy) is a non-proteinogenic sulfur containing amino acid derived from methionine metabolism. Normal plasma homocysteine levels range between 5–15 µmol/L, but may increase due to dietary and genetic factors, causing hyperhomocysteinemia (HHcy). Plasma levels between 15–30 µmol/L characterize mild HHcy and have been linked with cardiovascular damage via oxidative stress. In this context, Simvastatin (SIM) and Folic Acid (FA) may modulate these pathways due to their antioxidant effects. Objetivos: To evaluate chronic mild HHcy on oxidative stress and the potential protective effects of SIM and FA in ex vivo cardiac tissue slices from aged male and female Wistar rats. Métodos: Wistar rats (365 post natal days) received Hcy (0.03 µmol/g, sc, twice daily) in the treated group and an equivalent volume of saline in the control group for 30 days. After euthanasia, hearts were sliced using a McIlwain Tissue Chopper and incubated with SIM (10 µM, 90 min) or FA (100 µM, 60 min), or respective controls, followed by biochemical analyses. Statistical analysis was performed using two-way ANOVA (CEUA: 46247). Resultados e Conclusões: In males, Hcy increased reactive oxygen species (ROS) levels and lipid peroxidation (TBARS assay) compared to control (p<0.05), also increasing As a compensatory response, Catalase (CAT) activity (p<0.05) FA and SIM reversed the increase in ROS, TBARS and CAT observed (p<0.05). Hcy reduced cytosolic and nuclear protein content of Nrf2 (p<0.05), both restored with FA and SIM. In females, Hcy reduced nitrite levels and Glutathione Peroxidase (GPx) activity (p<0.05). FA and SIM normalized nitrite levels (p<0.05), and SIM restored GPx activity (p<0.05). No alterations were observed for Nrf2 protein content in females treated with Hcy (p>0.05). Regarding Superoxide Dismutase (SOD), although Hcy did not alter its activity, SIM increased enzyme activity in both sexes (p<0.05). Conclusion: Mild HHcy shows potential to promote oxidative imbalance in cardiac tissue in a sex-dependent manner, associated with cellular damage. This cardiotoxic damage may be related to the pathophysiology leading to dysfunctions characteristic of heart failure, such as fibrosis and remodeling. In this regard, FA and SIM demonstrated antioxidant potential by reversing redox imbalance pathways, supporting further investigation into cardioprotective drugs targeting antioxidant mechanisms. Supported by CNPQ.

SEXUAL DIMORPHISM IN ADIPONECTIN AND LEPTIN RESPONSE TO WEIGHT GAIN: EVIDENCE OF CARDIOMETABOLIC PROTECTION IN WOMEN

PAULO VICTOR BARBOSA1; MARCELLA AUGUSTA FELCI DEMARQUE1; LAISA FRANCIELE GONÇALVES DUTRA1; ANA CLARA FREITAS CARVALHO DE OLIVEIRA1; MARIA CECÍLIA DIAS DE OLIVEIRA1; JUAN PEDRO UPEGUI PASSOS1; YASMIM FIGUEIREDO ROSA1; PEDRO HENRIQUE ZAMPIER DE OLIVEIRA1; MARIANA MACEDO DE ALMEIDA1; THIAGO VINICIUS AVILA1;

(1) UFJF - JUIZ DE FORA - MG - BRASIL;

Introdução/Fundamentos: The Adiponectin/Leptin (A/L) ratio reflects the balance between adiponectin (anti-inflammatory, cardioprotective) and leptin (pro-inflammatory). Although women have higher leptin levels, the dynamic behavior of these markers across progressive weight gain and their sex differences have gained increasing interest for early cardiovascular risk stratification. Objetivos: To evaluate sex differences in serum levels of leptin, adiponectin, and the A/L ratio in lean, overweight, and obese individuals, investigating the existence of a cardiometabolic protection pattern associated with sex. Métodos: This cross-sectional study included 100 participants (47 men, 53 women) recruited at two university hospitals, stratified by BMI into 3 groups: lean (M11/F24), overweight (M20/F13), and obese (M16/F16). Leptin (pg/mL) and adiponectin (ng/mL) were measured by ELISA, and the A/L ratio was calculated. Data were expressed as median (IQR) for leptin and adiponectin, and as mean±SD for fold change. For median-based variables, comparisons used Mann-Whitney (2 groups) and Kruskal-Wallis (3 groups). For fold decrease, we used Student's t-test (2 groups) and ANOVA followed by Newman-Keuls post-hoc (3 groups). A p-value <0.05 was considered statistically significant. Resultados e Conclusões: Leptin was significantly higher in lean women. In both sexes, leptin increased from overweight onward; however, in women, levels stabilized in obesity, whereas men showed a progressive increase. Adiponectin decreased by 34% in obese men compared to lean (median 1405, IQR 1154 vs. 2140, IQR 1136 ng/mL) but remained stable in women across all BMI categories. Interestingly, lean men started with a higher A/L ratio. However, the fold decrease of the A/L ratio was markedly greater in obese men (0.057±0.029) than in obese women (0.514±0.133), representing a 94% vs. 49% reduction from lean controls, respectively. These data demonstrate clear sexual dimorphism in adipokine responses to weight gain. Women reveal remarkable cardiometabolic resilience of adipose tissue: stable adiponectin levels and stabilized leptin in obesity. Men, in contrast, lose adiponectin protection and show progressive leptin elevation when becoming obese. These findings indicate that: (1) male obesity represents a critical point of cardiometabolic protection loss; (2) women are metabolically more resilient to weight gain; and (3) A/L ratio cutoffs for cardiovascular risk should be sex specific.

Figure 1. Sex-specific changes in serum leptin, adiponectin, and the adiponectin/leptin (A/L) ratio across BMI categories

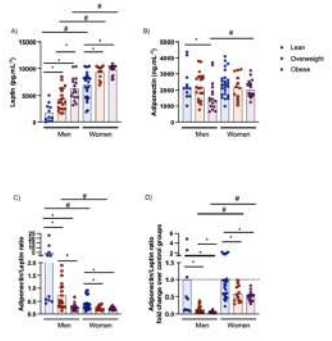

Figure 1. Serum levels of (a) leptin (pg/mL), (b) adiponectin (ng/mL), (c) adiponectin/leptin (A/L) ratio, and (d) adiponectin fold change relative to lean controls in men and women stratified by BMI category (lean, overweight, obese). Data are presented as median [IQR] for (a), (b), (c) and as mean ± SD for (d). *p < 0.05 compared to lean controls within the same sex; #p < 0.05 between sexes within the same BMI category.

Table 1. Demographic and clinical characteristics of the study population stratified by BMI category and sex

Demographic and clinical features	Eutrophic			Overweight			Obese		
	Women (n=24) 68,57 %	Men (n=11) 31,43 %	P, X²	Women (n=13) 39,39 %	Men (n=20) 60,61 %	P, X²	Women (n=16) 50,00%	Men (n=16) 50,00%	P, X²
Age (mean±SE)	39±3	50±4	0,06	49±3	51±3	0,63	50±3	51±3	0,83

SUBCLINICAL INFLAMMATION AND RISK OF MAJOR CARDIOVASCULAR EVENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS BASED ON HIGH-SENSITIVITY C-REACTIVE PROTEIN.

GIOVANA CASAGRANDE DE ALENCAR1; JULIA FERNANDES DE CARLI1; LAIS CATOZI BROGGIO1; POLIANA MARCELINO JOIA2; TAYNARA TAVARES DOS SANTOS1; THIAGO VITTOR SILVA FREITAS1; LUCAS MARINHO REIS DA CUNHA SILVA1; BRUNO DE FREITAS SILVA1; RAFAEL ALVES DE OLIVEIRA1; AMANDA OLIVA SPANZINI1;

(1) UNIVERSIDADE BRASIL - FERNANDÓPOLIS - SP - BRASIL; (2) UNIVERSIDADE BRASIL - FERNANDÓPOLIS - MS - BRASIL;

Introdução/Fundamentos: Subclinical inflammation plays a central role in the pathophysiology of atherosclerosis, influencing processes from plaque formation to its destabilization. High-sensitivity C-reactive protein (hs-CRP) has been widely studied as an inflammatory marker; however, its applicability as an independent predictor of cardiovascular risk remains under debate, especially in populations without established disease. Objetivos: To evaluate the association between elevated hs-CRP levels and the occurrence of major cardiovascular events, including acute myocardial infarction, stroke, and cardiovascular mortality Métodos: A systematic review and meta-analysis conducted according to PRISMA guidelines. PubMed, Embase, Scopus, and Web of Science databases were searched through January 2025. Prospective cohort studies assessing baseline hs-CRP levels and their relationship with cardiovascular outcomes were included. Methodological quality was assessed using the Newcastle-Ottawa Scale. Statistical analysis was performed using a random-effects model, with calculation of relative risk (RR) and 95% confidence intervals. Heterogeneity was assessed using the I^2 statistic, and publication bias was evaluated using funnel plots and Egger's test. Subgroup analyses were performed according to hs-CRP levels, presence of prior cardiovascular disease, and follow-up duration. Resultados e Conclusões: A total of 41 studies were included, comprising 2,356,890 individuals followed for a mean period of 6.8 years. Elevated hs-CRP levels were significantly associated with an increased risk of major cardiovascular events (RR=1.58; 95% CI: 1.44–1.73; $p<0.001$). In subgroup analyses, individuals with hs-CRP >3 mg/L showed a higher risk (RR=1.83; 95% CI: 1.62–2.07). In populations without prior cardiovascular disease, the risk remained significant (RR=1.37; 95% CI: 1.22–1.53), suggesting an independent role of the marker. Heterogeneity was moderate (I^2=56%), with no consistent evidence of publication bias. In summary, Elevated hs-CRP levels are consistently associated with an increased risk of major cardiovascular events, independent of traditional risk factors. These findings reinforce the role of subclinical inflammation in risk stratification and suggest that incorporating hs-CRP into clinical practice may contribute to the early identification of high-risk individuals and guide more effective preventive strategies.

TELECARDIOLOGY AS A STRATEGY TO IMPROVE ACCESS TO CARDIOVASCULAR CARE IN REGIONS FAR FROM MAJOR URBAN CENTERS.

MIRELLA LIMA FONTENELE1; MELISSA SOARES MEDEIROS1; ISABELLA SILVA FEITOSA1; SABRINA SILVA BEZERRA1; DAVI GONÇALVES ARAÚJO1; BRENDA JALES GOLIGNAC1; AMANDA COSTA ELOI1; ANA LARISSA CARVALHO GOMES1; GIOVANA SIEBRA OLIVEIRA1; MARIA CLARA VALENTE OLIVEIRA1; MILENA COSTA CARDOSO1; ENZO ZONARY ALENCAR DE OLIVEIRA1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases are among the leading causes of hospitalization and death in Brazil. In this context, the electrocardiogram (ECG) is a fundamental test, widely available in primary care and emergency services, helping in the identification of several cardiac conditions. However, its usefulness depends on adequate interpretation, which may be limited by the high concentration of specialists in major urban centers. According to the Federal Council of Medicine (2026), in the state of Ceará, in the capital there are 3.19 specialists per thousand inhabitants, while in the countryside this number is 0.43 per thousand inhabitants. Thus, telecardiology, through tele-ECG, emerges as a strategy to expand access to diagnosis, especially in regions distant from urban centers. Objetivos: To evaluate indicators related to access to cardiovascular diagnosis through telecardiology in regions far from major urban centers. Métodos: An observational, retrospective, and descriptive study, based on the analysis of data from a telecardiology service in the public health system of Ceará. Electrocardiograms (ECGs) sent for remote reporting from June 2024 to December 2025 were included. Data were obtained from the Business Intelligence (BI) system of the Health Department of the State of Ceará (SESA). Indicators related to the expansion of access to diagnosis were examined by a descriptive statistical analysis, using frequency calculations. The study ensured data anonymization, in accordance with ethical principles. Resultados e Conclusões: Results: During the analyzed period, a total of 6,269 exams were performed, mainly from Maracanaú (51.75%), Russas (28.6%), and Limoeiro do Norte (5.74%), and others (13.91%), regions located in the countryside or metropolitan area of Ceará, which are more distant from well-known specialist centers. An aggregate of 5,102 (81.38%) were requested by nurses and 785 by others who are not physicians (12.52%), showing that, even without a specialist, access to the exam was still possible. Of the total requested exams, 6,081 (97%) received a response, evidencing the increased access to cardiovascular diagnosis. Conclusion: Telecardiology has proven effective in expanding access to cardiovascular diagnosis in regions far from major centers. The high exam volume, reporting rates, and the possibility of requests by non-physician professionals reinforce its role as a clinical support tool. Thus, tele-ECG helps reduce healthcare access inequalities and improves care resolvability.

THE UNDERRECOGNIZED ILE127VAL VARIANT OF TRANSTHYRETIN AMYLOIDOSIS: CLINICAL AND CARDIAC INSIGHTS FROM A RETROSPECTIVE COHORT

GABRIEL DE SOUZA SANTOS PEREIRA1; TONNISON DE OLIVEIRA SILVA1; LUÍSA MARTINEZ1; ENZO RODRIGUES1; ELLEN BEATRIZ MENEZES1; LUÍS EDUARDO FONTELES RITT1;

(1) ESCOLA BAHIANA DE MEDICINA E SAUDE PUBLICA (EBMSP) - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Amyloidosis is a disease characterized by the deposition of abnormal proteins, it can be classified as either systemic or localized. When it affects the heart, it is called cardiac amyloidosis, often caused by the deposition of light chain proteins (AL) or transthyretin (TTR). The main focus of this study, is particularly the Ile127Val variant. Although other variants of amyloidosis due to TTR accumulation, such as Val50Met and Val142Ile, are well described, the genetic variant Ile127Val is still under-researched, especially regarding its clinical behavior and cardiac involvement. Objetivos: The study aims to evaluate the demographic, clinical, and cardiac characteristics of patients with familial amyloidosis (Ile127Val variant) in a real-world cohort. contributing to improved recognition and management of the disease. Métodos: A retrospective observational cohort study was conducted, analyzing data from 2018 to 2023. A convenience sample was used, including 19 patients diagnosed with familial amyloidosis (Ile127Val variant). Data were collected from electronic medical records using the Smart system and analyzed with SPSS version 14. Variables were categorized into demographic, clinical, and cardiac examination groups. Descriptive statistics were applied, with qualitative variables expressed as absolute (n) and relative (%) frequencies. For quantitative variables, measures of central tendency (mean and median) and dispersion (standard deviation and interquartile range) were used. The study was self-funded by the researchers, with no conflicts of interest declared, and was approved by an institutional Ethics Committee. Resultados e Conclusões: Results: ATTRv Ile127Val primarily manifests in brown-skinned women over 40 years old, with a family history of amyloidosis. Regarding presentation patterns, 9 patients (47.4%) had heart disease and peripheral nervous system involvement was observed in 100% of patients, all presenting with polyneuropathy. The most significant cardiac findings on echocardiogram were Left Ventricular Hypertrophy (LVH) and septal thickening, observed in 11 (57.9%) and 8 (42.1%) patients, respectively. Conclusion: The Ile127Val variant demonstrates a mixed phenotype of transthyretin amyloidosis, with predominance of neurological manifestations. Cardiac involvement, characterized by an infiltrative pattern, tends to occur in later stages, potentially delaying diagnosis

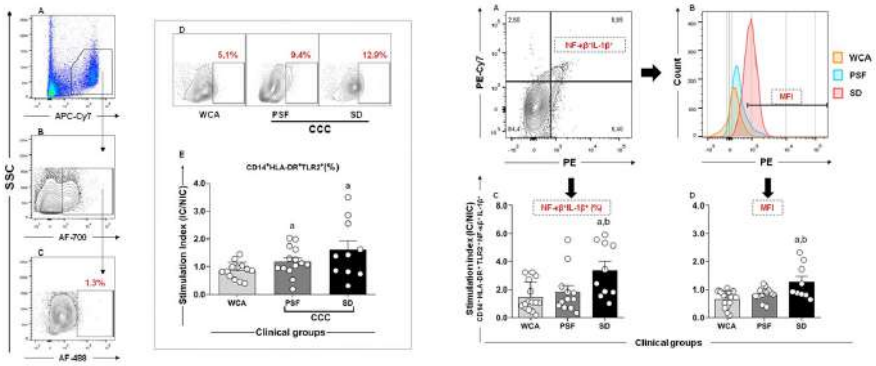
TRANSCRIPTOMIC AND PROTEIN INTERACTION NETWORK ANALYSIS REVEALS A POTENTIAL THERAPEUTIC TARGET IN AORTIC STENOSIS BEYOND TAVI

ISABELLA GOMES ANCINELLO1; ULYSSES CAVALCANTI1; ALINE ZANIN ZOUVI1; ANA LAURA BRILL THUM1; GABRIEL MELO ROTH DE OLIVEIRA1; GABRIELA CARMINATI LIN01; GABRIELLE DAMIANI BRUN1; MANUELA TIMM1; MARIA CLARA REIMANN1; MARINA DALL'AGNOL REDEL1; NATHÁLIA POZZOBON BRUM1; NATASHA MALGAREZI2;

(1) UNISINOS - SÃO LEOPOLDO - RS - BRASIL; (2) UFCSPA - PORTO ALEGRE - RS - BRASIL;

Introdução/Fundamentos: There is still no pharmacological treatments that slow aortic stenosis (AS) progression or replace valve replacement (VR). Randomized controlled trials have demonstrated that calcification-targeting and lipid-lowering therapies don't prevent progression or VR need. In this context,transcriptomic and bioinformatics approaches may identify new gene expression patterns. Our study delineated molecular signatures and genetic associations, highlighting potential non-invasive therapeutic targets for AS. Objetivos: Investigate the differences in the gene expression patterns between casecontrol relative to aortic valvulopathies and perform bioinformatic analysis of enrichment and clusterization in the protein-protein interaction(PPI) networks produced from it. Métodos: The dataset used in this research was GSE153555 (GEO) and patients were divided into three groups: normal, Severe Aortic Stenosis (AS) and Severe Aortic Insufficiency (AI). The expression profiles analysis was performed by GEO2R program and the log2fold change results were exported from the VennDiagram for analysis. The PPI network, clusterization and functional enrichments analysis were performed using STRING v12 software. Resultados e Conclusões: The positive values of log2fold change indicates a overexpression in the respective genes, this analysis shown 259 genes overexpress when comparing normal vs severe AI patients, 374 genes overexpress when comparing normal vs Severe AS and only 2 genes (KCNA5 e TP53I11) were overexpressed in both comparisons (normal vs severe AI and normal vs Severe AS). This two genes were used to produced the PPI network in String generating 102 nodes and 1643 edges, the clusterization was performed using kmeans clustering and resulted in 3 different clusters: (I) containing 78 genes, (II) containing 15 genes and (III) containing only 9 genes. The enrichment analyses were performed in all clusters and the (I) had the most correlation with cardiac alterations in the analysis, as one of the most central genes in this cluster was KCNA5. The identification of KCNA5 as a hub gene in aortic valve diseases extends its relevance beyond atrial fibrillation, where it modulates voltage-gated potassium channels, influencing action potential and refractory period. These in silico results highlight this mechanism as a promising target for drug repurposing, offering a potential non-surgical approach to AS and AI and suggesting a possible shift in clinical management.



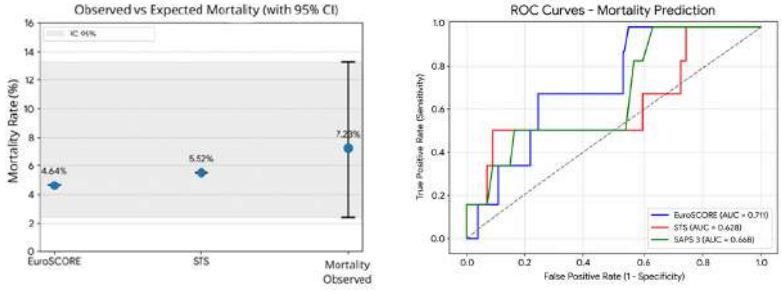
18033

TRYPANOSOMA CRUZI TRYPOMASTIGOTE INFECTION DRIVES TLR2-NF-KSS-IL-1SS AXIS ACTIVATION ASSOCIATED WITH SYSTOLIC DYSFUNCTION IN CHRONIC CHAGAS CARDIOMYOPATHY

JULIA KELLY CAMPOS1; MARIANA COSTA DUARTE1; ANA MARIA RAVENA SEVERINO CARVALHO1; MATHEUS RIBEIRO ÁVILA1; LUCAS FRÓIS FERNANDES DE OLIVEIRA1; SANNY CRISTINA DE CASTRO FARIA1; NAIANDA REZENDE RIBEIRO1; SCARLETH SILVA COSTA1; DANIELLA CASTANHEIRA BARTHOLOMEU1; HENRIQUE SILVEIRA COSTA2; MANOEL OTÁVIO DA COSTA ROCHA1; DANIEL MENEZES- SOUZA1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DOS VALES JEQUITINHONHA E MUCURI - DIAMANTINA - MG - BRASIL;

Introdução/Fundamentos: Chagas disease (CD), caused by the protozoan Trypanosoma cruzi, affects millions worldwide, with a high prevalence in Latin America, representing a significant public health burden. The transition from the asymptomatic acute phase to the chronic stage, where about 30% of individuals develop cardiomyopathy, poses a scientific challenge. Objetivos: This study explored the role of Toll-like receptor 2 (TLR2) and interleukin-1β (IL-1β) in the pathogenesis of systolic dysfunction in chronic Chagas cardiomyopathy (CCC). Métodos: Through flow cytometry analysis of CD14 + HLA-DR+ cells, after trypomastigote infection assays, we observed higher TLR2 expression and activation in patients with preserved systolic function and systolic dysfunction (SD) compared to those without cardiac abnormalities. Resultados e Conclusões: Notably, patients with SD exhibited higher percentages of NF-κβ + IL-1β+ cells and of mean fluorescence intensity of IL-1β in CD14 + HLA-DR + TLR2 + NF-κβ+ cells. A significant negative correlation was observed between left ventricular ejection fraction and IL-1β expression. These findings suggest that higher TLR2-mediated IL-1β production, likely through NF-κβ activation, plays a critical role in the development of systolic dysfunction in CCC. This study provides clinical evidence supporting the TLR2-NF-κβ-IL-1β axis as a potential therapeutic target for mitigating cardiac damage in CCC, considering the progression to chronic and symptomatic cases.



17027

VALIDATION OF EUROSCORE II, STS, AND SAPS 3 SCORES FOR MORTALITY PREDICTION IN VALVULAR CARDIAC SURGERY AND MYOCARDIAL REVASCULARIZATION IN A BRAZILIAN PUBLIC UNIVERSITY HOSPITAL

LOUISE WEBSTER COSTA CRUZ1; JAQUELINE LEITE TANIGUCHI1; JULIA MENDES CAMPOS1; CHRISTIAN TREVISAN1; BEATRIZ ARCHEGAS1; GUSTAVO GUSTAVO LENCI MARQUES1;

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases remain the leading cause of mortality worldwide, accounting for approximately 31% of global deaths and more than 30% of national deaths. In the context of cardiac surgery, adequate risk stratification is essential to estimate mortality and complications, guide clinical decision-making, and optimize hospital resources. Scores such as EuroSCORE II, STS Score, and SAPS 3 are widely used internationally; however, their applicability in Brazilian populations, particularly in public healthcare settings, still requires local validation. Objetivos: To evaluate the performance of EuroSCORE II, STS, and SAPS 3 in predicting in-hospital mortality among patients undergoing valvular and coronary artery bypass graft (CABG) surgery at a Brazilian public university hospital, analyzing model calibration and discrimination. Métodos: This retrospective observational study included 83 patients who underwent cardiac surgery with complete data available for score calculation. Continuous variables were expressed as mean ± standard deviation or median (interquartile range), and categorical variables as absolute and relative frequencies. Calibration was assessed using the Observed/Expected (O/E) ratio with 95% confidence interval (95% CI), considering good calibration when the CI included 1.0. Discrimination was evaluated using receiver operating characteristic (ROC) curves and the area under the curve (AUC). A significance level of 5% was adopted. Resultados e Conclusões: Mean age was 62.7±9.6 years, and 61.4% were male. Hypertension was the most prevalent comorbidity(73.5%), followed by dyslipidemia(43.4%) and diabetes(38.6%). Emergency surgeries accounted for 55.4%. In-hospital mortality was 7.23%. EuroSCORE II predicted a mean mortality of 4.64% (O/E = 1.56; 95% CI: 0.70-3.47) and STS predicted 5.52% (O/E = 1.31; 95% CI: 0.59-2.91), showing acceptable calibration despite underestimating absolute mortality. EuroSCORE II had the best discrimination (AUC = 0.711), followed by SAPS 3 (AUC = 0.668) and STS (AUC = 0.628). For secondary outcomes, prolonged mechanical ventilation (>24 hours) occurred in 26.76% of patients, exceeding the 12.32% predicted by STS. Prolonged ICU stay (>14 days) was lower than estimated (7.41% vs. 20.60%). EuroSCORE II demonstrated superior performance in predicting in-hospital mortality after cardiac surgery in a Brazilian public hospital, showing adequate calibration and moderate discrimination. STS and SAPS 3 provided complementary but lower discriminatory accuracy.

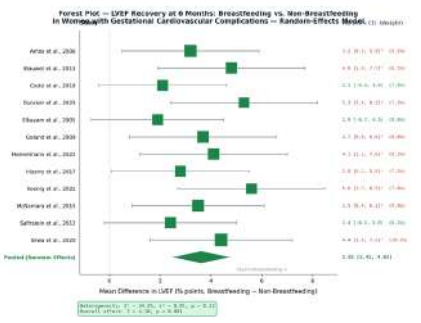
ADVERSE PREGNANCY OUTCOMES AND LONG-TERM RISK OF ATRIAL FIBRILLATION: A SYSTEMATIC-REVIEW AND META-ANALYSIS

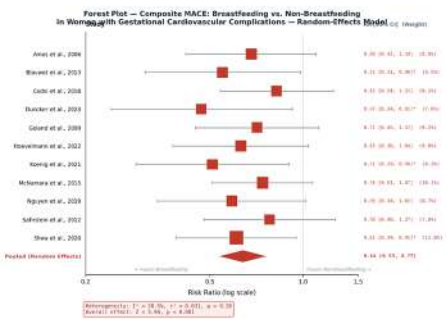
KAROLINA GUEDES AMORIM1; ANTÔNIO LACERDA CAVALCANTI NETO1; DAVI ALBUQUERQUE MADRUGA1; LUCAS CHIANCA TEOTÔNIO NÓBREGA DE PONTES2; MARIA EDUARDA MARINHO SILVA1; MARCO ANTONIO PANET DE VIVO BARROS1; LAURA DIAS DE SOUZA1; MATEUS COSTA SANTOS2; MARCELO DANTAS TAVARES DE MELO1;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (2) UNIVERSIDADE FEDERAL DE CAMPINA GRANDE - UFCG - CAMPINA GRANDE - PB - BRASIL;

Introdução/Fundamentos: Adverse pregnancy outcomes (APOs) are established female-specific cardiovascular risk factors, yet their association with incident atrial fibrillation (AF) – the most prevalent sustained cardiac arrhythmia – remains unclear. Obstetric history is absent from current AF risk stratification models, representing a critical gap in sex-specific cardiovascular prevention. Objetivos: To estimate the association between individual APO subtypes and long-term risk of incident AF in women without prior AF diagnosis. Métodos: A systematic review and meta-analysis was conducted according to PRISMA guidelines. Observational cohort and registry-based studies reporting hazard ratios (HR) for incident AF after APOs were eligible. Random-effects models (REML) were applied across pre-specified exposure subgroups. Heterogeneity was assessed using I^2, Cochran's Q, and prediction intervals (PI). Sensitivity analyses employed a leave-one-out approach. Exploratory meta-regression tested follow-up duration and FA diagnostic method as heterogeneity moderators. Resultados e Conclusões: Sixteen observational studies were included, comprising 12.813.579 women, of whom 1.520.140 (11.9%) had adverse pregnancy outcomes. Preeclampsia was associated with increased incident AF risk (HR 1.46; 95% CI 1.30-1.65; I^2=80%), with a prediction interval above unity (95% PI: 1.01-2.12). Hypertensive disorders of pregnancy showed a similar association (HR 1.48; 95% CI 1.25-1.75; I^2=79.3%); leave-one-out analysis identified a single influential study as the primary driver of heterogeneity in this subgroup, with I^2 reducing to 0% upon its exclusion while the pooled estimate remained significant (HR 1.41; 95% CI 1.31-1.52). Gestational hypertension was also significantly associated with AF (HR 1.38; 95% CI 1.19-1.59; I^2=70%). Gestational diabetes mellitus (HR 1.20; 95% CI 1.03-1.39; I^2=72%) and preterm birth (HR 1.28; 95% CI 1.06-1.55; I^2=86%) were additionally significant, though prediction intervals crossed unity for both. Exploratory meta-regression identified no significant moderator of the association between preeclampsia and AF. In this meta-analysis, adverse pregnancy outcomes were consistently linked to an increased long-term risk of incident AF, with the strongest associations observed for hypertensive disorders of pregnancy and preeclampsia. These findings suggest that obstetric history may be relevant to AF risk assessment in women, though prospective studies are needed to clarify the independence and clinical utility of these associations.



19305



BREASTFEEDING AND POSTPARTUM CARDIOVASCULAR RECOVERY IN WOMEN WITH GESTATIONAL CARDIOVASCULAR COMPLICATIONS: IMPACT ON LEFT VENTRICULAR FUNCTION AND MAJOR ADVERSE CARDIOVASCULAR EVENTS — A SYSTEMATIC REVIEW AND META-ANALYSIS

EDUARDO ESCAÑO SALOMÃO GONÇALVES1; YASMIN SILVA MILAGRES1; MATHEUS LORICCHIO ALEXANDRE1; ANA CLARA LIBERALI SAWABINI1; JAMILE TEREZA TEIXEIRA OLIVEIRA1; MANUELA SILVA LEME DEL MONACO1; LUCAS VASQUEZ CEVALLOS1; CARLOS GUN2;

(1) UNIVERSIDADE DE SANTO AMARO - SÃO PAULO - SP - BRASIL; (2) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Women with gestational cardiovascular complications—such as peripartum cardiomyopathy (PPCM) and hypertensive disorders—are often advised against breastfeeding due to potential medication risks. However, lactation may offer long-term cardiovascular protection. No systematic synthesis has yet evaluated its impact on cardiac recovery specifically in this high-risk population. Objetivos: To systematically review and meta-analyze the effect of breastfeeding on (1) left ventricular ejection fraction (LVEF) recovery at 6 months postpartum and (2) composite major adverse cardiovascular events (MACE) incidence in women with gestational cardiovascular complications, comparing those who breastfed versus those who did not. Métodos: Systematic review following PRISMA 2020 guidelines, searching PubMed/MEDLINE, Embase, Cochrane CENTRAL, LILACS, Web of Science, and CINAHL from inception to March 2026. Observational studies and clinical trials evaluating postpartum cardiovascular outcomes in women with PPCM, HDP, or structural heart disease, stratified by breastfeeding status, were included. Random-effects meta-analysis (DerSimonian-Laird) calculated pooled mean differences (MD) for LVEF and pooled risk ratios (RR) for MACE with 95% CI. Quality assessed by NOS. Resultados e Conclusões: Twelve studies (n = 3,218 women with gestational cardiovascular complications; 1,687 breastfed and 1,531 non-breastfed) met inclusion criteria. Meta-analysis demonstrated that breastfeeding was associated with significantly greater LVEF recovery at 6 months postpartum (MD = +3.62 percentage points; 95% CI: 2.41-4.83; p < 0.001; I-squared = 34.2%). Additionally, breastfeeding was associated with a significant 36% reduction in composite MACE risk (RR = 0.64; 95% CI: 0.53-0.77; p < 0.001; I-squared = 28.5%). Subgroup analysis in PPCM women showed an even more pronounced benefit (LVEF MD = +5.1 points; MACE RR = 0.52). Breastfeeding is associated with significantly superior cardiovascular recovery in women with gestational cardiac complications, both in ventricular function and adverse event reduction. These findings challenge the current practice of discouraging lactation in this population and support reassessment of the cardiovascular risk-benefit balance of breastfeeding, with direct implications for postpartum management guidelines in obstetric cardiology.

20167

CARDIOVASCULAR RISK AND ASSISTED REPRODUCTION IN LESBIAN WOMEN IN BRAZIL: REGIONAL INEQUALITIES AND EPIDEMIOLOGICAL PROFILE

BEATRIZ DE LIMA VITORIO FERREIRA1; FLAVIA BEATRIZ DO CARMO MOREIRA2; EVELIN GABRIELLY DE VARGAS3; MARCOS AURÉLIO FONSECA MEDEIROS1; JOSIANE DE SOUZA BEZERRA3; LORENA DE OLIVEIRA BARRETO1; YRIANA RAMOS DE LIMA1; LUANA TABOSA DE CARVALHO1; CAMYLLA LEITE MEDEIROS DO NASCIMENTO1; VALESKA TAVARES DA SILVA RORIS RODRIGUEZ SCAVARDA DO CARMO3;

(1) UNIFACISA - CAMPINA GRANDE - PB - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - RJ - BRASIL; (3) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: The expansion of assisted reproduction (AR) techniques, including intrauterine insemination, in vitro fertilization, and the ROPA method, has increased reproductive possibilities for female same-sex couples. However, significant gaps persist regarding the cardiovascular health of this population, which may be exposed to a higher burden of cardiometabolic risk factors and structural barriers to healthcare access. Objetivos: This study aims to evaluate the relationship between access to AR and cardiovascular health indicators in lesbian women in Brazil, considering clinical, sociodemographic, and regional disparities. Métodos: An ecological, retrospective epidemiological study was conducted using secondary data from DATASUS, IBGE, the National Health Survey (PNS), CNES, and SisEmbrio/ANVISA. The study covered the period from 2014 to 2024. Variables analyzed included AR availability and utilization, cardiovascular risk factors, hospitalizations, and mortality in women aged 20–49 years. Absolute and relative frequencies, rates, time-series analyses, thematic maps, and Pearson's correlation were employed for data analysis. Resultados e Conclusões: Between 2015 and 2025, a total of 5,792 hospitalizations for female infertility related to AR were recorded in the Brazilian public health system. Most occurred in the Southeast (53.4%), with the lowest proportion in the North (3.2%). Public AR availability remained restricted to fewer than 10 states, indicating significant regional care gaps, particularly in the North and Midwest. Female same-sex marriages increased by more than 200% between 2013 and 2022, mainly in the Southeast and South, without proportional expansion in AR services. In the Northeast, cardiovascular hospitalizations among women aged 20–49 years increased after 2019, mainly due to hypertension, stroke, and heart failure. States with higher AR rates showed lower mean cardiovascular mortality ($r = -0.41$; $p < 0.05$). The 2019 National Health Survey showed high rates of obesity, physical inactivity, smoking, and low screening adherence among lesbian women. Public AR availability in Brazil remains limited and uneven, with regional barriers that may disproportionately affect this population, highlighting the need for screening, prevention, equitable AR expansion, improved data systems, and inclusive care guidelines.

CARDIOVASCULAR-RENAL-METABOLIC SYNDROME AND MORTALITY IN NON-OBSTRUCTIVE CORONARY ARTERY DISEASE: PROGNOSTIC IMPACT OF DIABETES IN WOMEN

DAVI PARAGUASSU MARTINS1; MARIA EDUARDA BERGAMO2; JOAO CRUZ1; FRANCISCO DE LA PUENTE1; ANTÔNIO DE PÁDUA MANSUR2;

(1) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: In non-obstructive coronary artery disease (NOCA), the absence of significant epicardial stenosis shifts the prognostic focus to structural, functional, and systemic mechanisms. In this context, interactions among left ventricular remodeling, renal dysfunction, and metabolic disorders reflect activation of common pathways, including chronic inflammation, oxidative stress, and endothelial dysfunction, that together comprise the cardiovascular-renal-metabolic syndrome (CRMS). Understanding these interactions, particularly by sex, is fundamental for risk stratification and clinical management. Objetivos: To determine the main predictors of mortality in patients with NOCA, with emphasis on sex differences. Métodos: Observational study of 716 patients with NOCA confirmed by coronary angiography, stratified by sex and clinical stage (survivors and non-survivors). Clinical variables, comorbidities, laboratory tests, echocardiographic parameters, and renal function were examined. Multivariate Cox regression models were constructed for the total population and for each sex. Resultados e Conclusões: Death was associated with advanced age and the most severe markers of CRMS, including lower left ventricular ejection fraction (LVEF), higher left ventricular mass index (LVMI), and worse renal function. Kaplan-Meier curves showed that diabetes significantly affects mortality only in females (p=0.022) (Figure). In the overall multivariate analysis, myocardial infarction (HR 1.010; 95% CI: 1.007–1.013), creatinine clearance <60 mL/min (HR 2.272; 95% CI: 1.852–2.786), age (HR 1.021; 95% CI: 1.011–1.031), and diabetes mellitus (HR 1.414; 95% CI: 1.160–1.724) were independent predictors of death. Among men, creatinine clearance <60 mL/min (HR 2.380; 95% CI: 1.750–3.145), LVEF (HR 0.978; 95% CI: 0.968–0.989), and LVMI (HR 1.008; 95% CI: 1.003–1.012) were associated with mortality. In women, LVMI (HR 1.012; 95% CI: 1.008–1.016), creatinine clearance <60 mL/min (HR 2.328; 95% CI: 1.746–3.104), and diabetes mellitus (HR 1.455; 95% CI: 1.096–1.932) were the main independent determinants.In patients with NOCA, diabetes mellitus acts as a critical and sex-specific determinant of mortality, being an independent predictor of death exclusively in women. In these patients, diabetes is the central axis of the CRMS, increasing systemic vulnerability and the risk of death. These results reinforce the need for preventive strategies and personalized therapy specifically for the management of diabetes in the female population with NOCA.

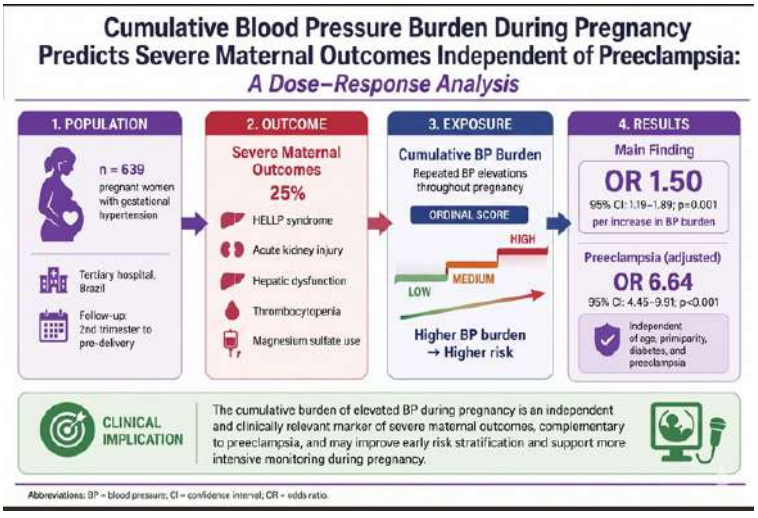
COMBINED USE IN POSTMENOPAUSE: SYNERGISTIC EFFECTS BETWEEN GLP-1 RECEPTOR AGONISTS AND MENOPAUSAL HORMONE THERAPY (MHT)

ANA LUIZA BARBOSA1; ELIÉZER MENEZES VIERA1; ALINE EVANGELISTA SANTIAGO1;

(1) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL;



Introdução/Fundamentos: Postmenopausal women experience increased cardiometabolic risk related to estrogen deficiency, adverse fat redistribution, and greater insulin resistance. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) improve weight, glycemic control, and cardiovascular risk markers. However, it remains uncertain whether these effects are modified by menopausal hormone therapy (MHT), including route of administration and timing relative to menopause, highlighting an important gap in current evidence. Objetivos: To evaluate whether the clinical effects of GLP-1 RAs differ according to MHT use and time since menopause, focusing on cardiometabolic outcomes. Métodos: Systematic review following PRISMA guidelines was conducted using PubMed, Embase, and the Cochrane Library. Two independent reviewers screened titles, abstracts, and full texts, with disagreements resolved by a third reviewer. Most studies were excluded for not assessing concomitant GLP-1 RA and MHT use or for being narrative reviews, reflecting the scarcity of randomized trials. Studies including postmenopausal women treated with GLP-1 RAs alone or combined with MHT were included. Primary outcomes were changes in body weight, body mass index (BMI), and body composition. Secondary outcomes included glycemic control, lipid profile, cardiovascular risk markers, quality of life, and adverse events; randomized cardiovascular outcome data were limited. Resultados e Conclusões: R: Three retrospective cohorts published in 2024, totaling 119,817 participants (all from the United States), met the inclusion criteria. Studies evaluated transitions between BMI categories and percentage of total body weight loss (TBWL%). One study reported an 8% transition from obesity to overweight or normal BMI among GLP-1 analog users. Two studies showed greater TBWL% in women receiving concomitant MHT compared with non-users (17% vs 14% and 16% vs 12%). Combined GLP-1 RA and MHT therapy was consistently associated with greater weight reduction, suggesting additive or synergistic metabolic effects. Data on glycemic control, lipids, and cardiovascular biomarkers were limited but suggested improvement, without increased serious adverse events. C: GLP-1 RAs reduce weight and BMI in postmenopausal women. Concomitant MHT may enhance these effects and improve cardiometabolic risk modulation. However, current evidence is observational, and prospective randomized trials are needed to confirm causality and guide clinical practice.

19894

CUMULATIVE BLOOD PRESSURE BURDEN DURING PREGNANCY PREDICTS SEVERE MATERNAL OUTCOMES INDEPENDENT OF PREECLAMPSIA: A DOSE–RESPONSE ANALYSIS

MARESSA DE JESUS MOREIRA1; LUANA ARAÚJO MACEDO SCALIA1; MARIA BEATRIZ GUIMARÃES RAPONI1; MARIANA TORREGLOSA RUIZ2; VALÉRIA NASSER FIGUEIREDO1;

(1) UNIVERSIDADE FEDERAL DE UBERLÂNDIA - UBERLÂNDIA - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DO TRIANGULO MINEIRO - UBERABA - MG - BRASIL;

Introdução/Fundamentos: Hypertension during pregnancy is a major contributor to maternal morbidity and mortality. However, the cumulative burden of elevated blood pressure (BP) throughout gestation remains poorly characterized as a marker of maternal risk beyond preeclampsia. Objetivos: To evaluate the association between cumulative BP burden during pregnancy and severe maternal outcomes, and to investigate the presence of a dose–response relationship independent of preeclampsia. Métodos: This retrospective cohort included 639 pregnant women with gestational hypertension followed at a tertiary hospital in Brazil. Women aged ≥18 years were monitored from the second trimester to the pre-delivery period. Data were obtained from electronic medical records. The exposure was the cumulative burden of elevated BP episodes across pregnancy, derived from repeated measurements in routine care and analyzed as an ordinal score. The outcome was a composite of severe maternal complications, including HELLP syndrome, acute kidney injury, impaired liver function, thrombocytopenia, severe hypertension and use of magnesium sulfate. Multivariable logistic regression was used to estimate odds ratios (ORs) and 95% confidence intervals (CIs), adjusting for age, primiparity, diabetes, and preeclampsia. Resultados e Conclusões: Among the 639 women, 25% developed severe maternal complications. A graded increase in risk was observed with increasing BP burden, indicating a dose–response relationship. Each increment in BP burden was associated with a 50% increase in the risk of severe maternal outcomes (OR=1.50; 95% CI: 1.19–1.89; p=0.001), independent of covariates. Preeclampsia remained strongly associated with the outcome (OR=6.64; 95% CI: 4.45–9.91; p<0.001). The cumulative burden of elevated BP during pregnancy, capturing longitudinal BP patterns, is an independent and clinically relevant marker of severe maternal outcomes, complementary to preeclampsia, and may improve early risk stratification and support more intensive monitoring during pregnancy.

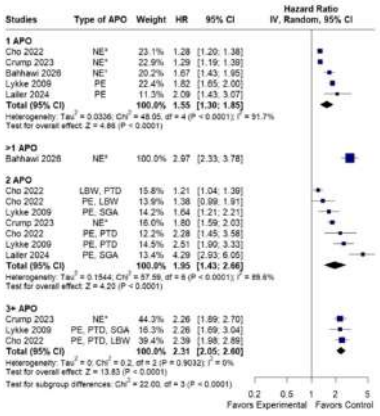
CUMULATIVE IMPACT OF MULTIPLE ADVERSE PREGNANCY OUTCOMES ON LONG-TERM STROKE AND ISCHEMIC HEART DISEASE RISK: A SYSTEMATIC REVIEW AND META-ANALYSIS.

CAIO TEOTONIO DE OLIVEIRA1; ANNA JULIA ANDRINO SCHNEIDER1; ARTHUR MENDES BENEVIDES MEDEIROS1; DUSTIN ANDREI MESQUITA BARBOSA1; HEITOR GONDIM BRAGA1; REBECA MOURA ALVES1; MARIA LUIZA CARVALHO MAGALHÃES1; SAAD LAHLOU1;

(1) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Adverse pregnancy outcomes (APOs), such as preeclampsia and preterm delivery, are established risk enhancers for cardiovascular disease (CVD). Current clinical guidelines acknowledge the impact of isolated APOs, but there is a lack of quantified evidence about the cumulative effect of multiple APOs occurring in the same pregnancy. Understanding this relationship is critical for refining long-term risk stratification and primary prevention strategies for women. Objetivos: To quantify the dose-response relationship between the number of APOs and the long-term risk of ischemic heart disease (IHD) and stroke. Métodos: A meta-analysis and systematic review using retrospective and prospective cohorts was conducted following Cochrane guidelines. A systematic search of Embase, Pubmed and the Cochrane database was made for studies having multiple APOs and future IHD and/or stroke. Hazard ratios (HR) were pooled using random-effects models, comparing pregnancies with APOs to those without. Resultados e Conclusões: Full-text of 26 articles was analysed and five studies (N=6,096,351) from Sweden, Denmark, France, Wales and Korea with a median follow-up of 10.5 years were included in the final analysis. Meta-analysis demonstrated a graded increase in IHD risk, for 1, 2 and 3+ APOs, respectively (hazard ratio [HR] 1.55;95% confidence interval [CI] 1.30-1.85;p<0.0001;I²=91.7%), (HR 1.95;95%CI 1.43-2.66;p<0.0001;I²=89.6%), and (HR 2.31;95%CI 2.05-2.60;p<0.0001;I²=0%). Furthermore, 4 studies provided data regarding cumulative APO burden for stroke risk, showing for 1, 2 and 3+ APOs, respectively (HR 1.37;95%CI 1.22-1.55;p<0.0001;I²=71.9%), (HR 1.75;95%CI 1.36-2.24;p<0.0001;I²=80%), and (HR 1.99;95%CI 1.35-2.94;p=0.0005; I²=77.8%). Despite substantial heterogeneity in most APO categories, the direction of effect was consistent among all studies. A clear dose-response relationship exists between the number of APOs and long-term IHD and stroke risk. Women with 3+ APOs face more than double the risk of IHD with remarkable consistency across populations (I²=0%). These findings support incorporation of cumulative obstetric history in IHD risk calculators to trigger early, targeted primary prevention.

Figure 1: Forest plot showing the meta-analysis of ischemic heart disease.



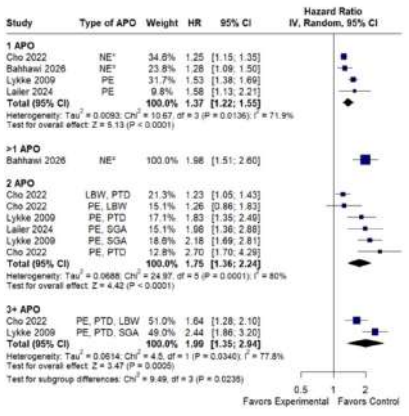


Figure 2: Forest plot showing the meta-analysis of the risk of stroke.

ECLAMPSIA-RELATED HOSPITALIZATIONS AND LETHALITY IN BRAZIL (2018–2024): A NATIONAL COMPARISON OF THE PRE-, DURING, AND POST-PANDEMIC PERIODS.

GABRIEL PETECK1; LETICIA SANTANA POPADIUK1; EDUARDA TORMEM GIROTTO1; MARIA LUISA MAFFIOLETTI1; GLAUCO WILLIAM DE OLIVEIRA TRAMUJAS1; GISELLE CAVALI DA COSTA RAITZ1;

(1) UNIVERSIDADE ESTADUAL DO CENTRO OESTE - GUARAPAVA - PR - BRASIL;

Introdução/Fundamentos: Eclampsia is a hypertensive emergency in pregnancy and a major cardio-obstetric cause of maternal morbidity and lethality. During the COVID-19 pandemic, beyond cardiovascular stress due to the pathophysiology of SARS-CoV-2, disruptions in prenatal care and healthcare access may have delayed recognition and management of preeclampsia, potentially increasing severe maternal outcomes. Evaluating temporal and epidemiological patterns may help identify vulnerable groups and guide cardiovascular and obstetric risk surveillance. Objetivos: To describe the epidemiological profile of eclampsia-related hospitalizations and lethality in Brazil from 2018 to 2024, comparing pre-, intra-, and post-pandemic periods. Métodos: Cross-sectional study using secondary national data from SIH/SUS (hospitalizations) and SIM (deaths) for ICD-10 code O15 (eclampsia), from 2018 to 2024. In-hospital case fatality rate was estimated by dividing deaths by hospitalizations. Temporal comparisons were performed between pre-pandemic (2018–2019), intra-pandemic (2020–2022), and post-pandemic (2023–2024) periods using the Two-Proportion Z-test ($p < 0.05$). Resultados e Conclusões: Between 2018 and 2024, Brazil recorded 10,170 eclampsia-related hospitalizations and 951 deaths, corresponding to an overall in-hospital case fatality rate of 10.69%. This ratio increased from 9.27% in 2018–2019 to 10.70% in 2020–2022, a 15.4% relative increase (p=0.042), then declined to 7.5% in 2023–2024 (p<0.0001 vs. 2020–2022), representing a 30.1% reduction. Most deaths occurred among women aged 30–39 years (40.9%; n=389) and 20–29 years (35.4%; n=337), totaling 76.3%. Lethality was higher in the 30–39 group resulting in 40,9% (Z=2.45; p=0.014). Regarding ethnicity, Women of mixed race (Pardo) accounted for 57.2% of deaths (n=544), a higher burden compared to White women (22.9%; n=218; Z=15.24; p<0.001). The Northeast concentrated the highest lethality burden (39.3%). A 42.5% decline in hospitalizations occurred in the Northeast, while the Southeast showed a 12.5% increase, suggesting regional differences in access, detection, or referral. The increase in case fatality during the pandemic likely reflects delayed diagnosis, reduced prenatal surveillance, and limited access to specialized care, while the post-pandemic decline may indicate recovery of healthcare services. Eclampsia remains a major cause of maternal morbidity and mortality in Brazil, requiring improved prenatal surveillance and cardiovascular care.

19516

EFFECTS OF MENOPAUSAL HORMONE THERAPY ON HEART FAILURE OUTCOMES: A SYSTEMATIC REVIEW

ANA CLARA LIBERALI SAWABINI1; KELVIN HENRIQUE VILALVA2; DANIEL BRANCO DE ARAUJO2;

(1) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL; (2) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Heart failure (HF) is a highly prevalent syndrome with significant morbidity and mortality, particularly among women, in whom the preserved ejection fraction phenotype predominates. The menopausal transition, characterized by estrogen deficiency, is associated with adverse metabolic and cardiovascular changes, increasing HF risk. The role of menopausal hormone therapy (MHT) in modifying HF outcomes remains controversial. Objetivos: To evaluate the effects of MHT on heart failure–related outcomes in peri- and postmenopausal women. Métodos: A systematic review was conducted according to PRISMA guidelines and Cochrane recommendations. Searches were performed in PubMed, Embase, Scopus, and Cochrane Library (2000–2025), using MeSH and Emtree terms related to menopause, hormone therapy, and heart failure (Table 1). Eligible studies followed PICOS criteria: peri- or postmenopausal women (Population), systemic MHT (Intervention), placebo or no therapy (Comparison), and HF-related outcomes including incidence, hospitalization, and mortality (Outcomes). Randomized controlled trials and observational studies were included. Study selection was performed independently by two reviewers, with disagreements resolved by consensus. Data extraction included study design, population characteristics, type and route of MHT, follow-up, and outcomes. Risk of bias was assessed using RoB 2, and overall quality of evidence using the GRADE approach. Resultados e Conclusões: A total of 1,943 records were identified, and 10 studies met eligibility criteria (Table 2). Significant heterogeneity was observed regarding study design, population characteristics, and hormonal regimens. Large randomized clinical trials consistently demonstrated a neutral effect of menopausal hormone therapy (MHT) on heart failure incidence and hospitalization. In contrast, observational studies and secondary analyses suggested potential benefits, including reduced mortality and improvement in diastolic function. These discrepancies may be explained by differences in patient profiles, timing of therapy initiation, and type of hormonal formulation. Overall, current high-quality evidence indicates a predominantly neutral effect of MHT on heart failure outcomes, with no consistent benefit in hard clinical endpoints. Therefore, MHT should not be used for cardiovascular prevention, and its indication must remain individualized, further studies needed to identify subgroups that may benefit, particularly considering timing of initiation and patient risk profile.

EFFICACY AND SAFETY OF STATINS IN PREVENTING CARDIOTOXICITY IN WOMEN WITH BREAST CANCER: A SYSTEMATIC REVIEW OF CLINICAL TRIALS.

BIANCA BIANCA ANDRADE1; MARIA ANTONIA LINARD MACÊDO1; LORENNA NASCIMENTO BEZERRA DA ROCHA1; DAISY MENEZES DANTAS1; MARIA OLÍVIA EMÍDIO DOS SANTOS1; LAYLLA MOREIRA CIDRÃO BEZERRA1; LARHA JÚLIA CRUZ PORTELA1; LARAH FERREIRA SANTOS1; GIOVANA MAMEDE CASTRO1; VITÓRIA AGNES RODRIGUES MOREIRA1; PAULA ANALY FELIX DA SIVA1; ISAURA ELAINE GONÇALVES MOREIRA1;

(1) UFC - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Breast cancer chemotherapy, specifically anthracyclines and trastuzumab, increases cardiotoxicity risk, impacting patient survival and quality of life. Consequently, statins are being investigated for their anti-inflammatory and antioxidant properties to mitigate therapy-related cardiac damage. Objetivos: To evaluate, through a systematic review of clinical trials, the efficacy and safety of statins in preventing cardiotoxicity in women undergoing treatment for breast cancer. Métodos: A systematic review was conducted following PRISMA guidelines across PubMed, LILACS, and Scopus databases. Randomized controlled trials (RCTs) published in the last 10 years analyzing the efficacy and safety of statins in the prevention of cardiotoxicity in women with breast cancer were included. Study selection and data extraction were performed independently by three reviewers and the risk of bias was assessed using the Cochrane Risk of Bias 2 (RoB 2) tool. Resultados e Conclusões: The analysis of 3 RCTs, involving 210 female patients with breast cancer undergoing anthracycline-based regimens, demonstrated significant efficacy in the prophylactic use of statins to reduce chemotherapy-induced cardiotoxicity in patients with cardiovascular risk. One of the trials evaluated, comprising a population with moderate to high cardiovascular risk, showed the maintenance of higher levels of Left Ventricular Ejection Fraction (LVEF) after 6 months in the intervention group (56.22%) compared to the control group (52.92%), p=0.008. The study conducted with low cardiovascular risk patients showed an absence of significant benefit for the same analyzed period. Regarding the safety of prophylactic therapy, the studies showed a low incidence of adverse events. Biochemical monitoring showed no significant findings. In the cardiovascular risk trial, 5% of the intervention group developed myalgia and 1.8% had elevated transaminases, though both were statistically insignificant (p>0.05). In breast cancer patients undergoing cardiotoxic chemotherapy, prophylactic statins significantly reduced cardiotoxicity, particularly in moderate-to-high cardiovascular risk subgroups. While LVEF was preserved in these higher-risk patients compared to controls, no significant benefit was observed in low-risk patients. Given the low incidence of adverse events, these findings support individualized preventive strategies based on baseline cardiovascular risk.

ENDOMETRIOSIS AS A MARKER OF CARDIOVASCULAR RISK: A SYSTEMATIC REVIEW

ANA FLAVIA MIRANDA LIMA1; ISABELA DO NASCIMENTO OLIVEIRA1; KARINA RIGUE SHIMBA1; LUIZA TAPIA DALL AGNOL1; BEATRIZ ALVES CARDOSO1; MARESSA REIS1; JULIA LANG LOPES GAGLIARDI PALERMO1; CAROLINE RIBEIRO BACALHAU1; VICTORIA GIMENES DE CASTRO1; ISABELLA LEAL ALONSO1; IRVING GABRIEL ARAUJO BISPO1;

(1) UNIVERSIDADE MUNICIPAL DE SAO CAETANO DO SUL - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Endometriosis is a chronic, estrogen-dependent, inflammatory gynecological disease affecting 10% of women. It is associated with an increased risk of cardiovascular disease due to chronic inflammation and increased atherosclerotic risk. Objetivos: In this context, the present study aimed to investigate the association between endometriosis and the risk of cardiovascular diseases in women. The guiding question was: “Is there an association with increased cardiovascular risk in patients with endometriosis?” Métodos: This study is a systematic review following the PRISMA flow diagram. A search was conducted in the PubMed database using the previously defined descriptors. A total of 99 articles were identified, of which 7 were duplicates and 4 were excluded, resulting in 95 articles for initial screening. Article selection was performed using the Rayyan application, with blinded assessment by three researchers. Duplicate studies, reviews, meta-analyses, editorials, letters to the editor, and case reports were excluded. Observational studies and clinical trials evaluating women with confirmed endometriosis associated with cardiovascular outcomes were included. The search identified 99 articles, of which 95 were selected for screening after removal of duplicates and initial exclusions. At the end, 9 studies were included in the review. Resultados e Conclusões: The results demonstrated a consistent association between endometriosis and increased cardiovascular risk. Women with the condition showed higher incidence of acute myocardial infarction (HR≈1.4–1.6; p<0.05), stroke (HR≈1.2–1.3; p<0.05), hypertension (OR≈1.3–1.5; p<0.05), arrhythmias, and heart failure (HR≈1.2–1.4; p<0.05). Alterations in metabolic and inflammatory markers were also observed, including increased LDL (↑10–20%; p<0.05), triglycerides (↑15–25%; p<0.05), C-reactive protein (↑30–50%; p<0.01), and homocysteine (↑10–15%; p<0.05), as well as reduced folate and vitamin B6 (↓10–20%; p<0.05). These findings indicate increased cardiovascular risk and a pro-atherogenic profile associated with endometriosis. Endometriosis is associated with increased cardiovascular risk, requiring follow-up similar to that of high-risk patients, highlighting the importance of early diagnosis and control of modifiable risk factors.

GESTATIONAL DIABETES MELLITUS AND MATERNAL CARDIOMETABOLIC REMODELING: DIASTOLIC DYSFUNCTION, MYOCARDIAL STRAIN IMPAIRMENT, AND THE METABOLIC-CARDIOVASCULAR SYNDROME — A SYSTEMATIC REVIEW AND META-ANALYSIS

EDUARDO ESCAÑO SALOMÃO GONÇALVES1; YASMIN SILVA MILAGRES1; MATHEUS LORICCHIO ALEXANDRE1; JAMILE TEREZA TEIXEIRA OLIVEIRA1; ANA CLARA LIBERALI SAWABINI1; LUCAS VASQUEZ CEVALLOS1; MANUELA LEME DEL MONACO SILVA1; CARLOS GUN2;

(1) UNIVERSIDADE DE SANTO AMARO - SÃO PAULO - SP - BRASIL; (2) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Gestational diabetes mellitus (GDM) affects up to 18% of pregnancies and is an independent risk factor for maternal cardiovascular disease. While the link to type 2 diabetes is clear, specific cardiac changes—such as diastolic dysfunction and myocardial strain impairment—remain poorly synthesized. This represents a critical gap in cardio-obstetric knowledge regarding the metabolic-cardiovascular syndrome. Objetivos: To meta-analyze maternal echocardiographic changes (E/e’ ratio, global longitudinal strain [GLS], and left ventricular mass [LVMi]) in GDM pregnancies compared to normoglycemic controls. Métodos: Systematic review per PRISMA guidelines across PubMed, Embase, Cochrane, LILACS, and Web of Science (inception to March 2026). Studies comparing echocardiographic parameters in GDM vs. controls were included. Random-effects meta-analysis (DerSimonian-Laird) calculated pooled mean differences (MD) with 95% confidence intervals (CI). Quality was assessed via Newcastle-Ottawa Scale. Resultados e Conclusões: Twelve studies (n = 2,847 pregnant women; 1,412 with GDM and 1,435 controls) met inclusion criteria. Meta-analysis demonstrated that GDM pregnancies had significantly higher E/e’ ratios compared to controls (MD = 1.38; 95% CI: 1.04-1.72; p < 0.001; I-squared = 42.3%), indicating subclinical diastolic impairment. Absolute GLS was significantly reduced in the GDM group (MD = 1.24 percentage points; 95% CI: 0.95-1.53; p < 0.001; I-squared = 38.7%), suggesting subclinical systolic dysfunction detected by speckle tracking. LVMi showed a trend toward elevation in the GDM group (MD = 4.2 g/m-squared; 95% CI: 1.8-6.6; p = 0.001). Subgroup analysis revealed that GDM pregnancies with concomitant metabolic syndrome (obesity + insulin resistance + dyslipidemia) showed greater GLS impairment compared to isolated GDM. GDM is associated with significant changes in maternal diastolic function and myocardial strain, consistent with adverse cardiometabolic remodeling. These findings support that advanced echocardiographic assessment — including GLS by speckle tracking — should be integrated into cardiovascular follow-up of GDM pregnancies, particularly those with metabolic syndrome components. GDM pregnancy represents a window of opportunity for early identification of women at elevated cardiovascular risk.

HYPERTENSION IN PREGNANCY AND ITS ASSOCIATION WITH DEPRESSION THROUGHOUT LIFE

JOSÉ MARQUES NETO1; REJANE MACEDO SOUSA1; SYSSI A MARQUES2; TANIA MARIA ARAUJO3; ROSANE HARTER GRIEP1;

(1) CENTRO UNIVERSITARIO UNIDOMPEDRO - SALVADOR - BA - BRASIL; (2) HOSPITAL - SALVADOR - BA - BRASIL; (3) UNIVERSIDADE ESTADUAL DE FEIRA DE SANTANA - FEIRA DE SANTANA - BA - BRASIL;

Introdução/Fundamentos: “There is no health without mental health”, according to the international call to action by the WHO. About 14% of the global disease burden, largely due to depression. Psychosocial risk factors in the workplace can be a determining factor in maintaining health. The association between hypertensive disorders of pregnancy (HDP), such as pre-eclampsia, and long-term risk of depression remains underexplored, despite shared mechanisms including angiogenic biomarkers and oxidative stress. Objetivos: This study aimed to assess women who had hypertension during pregnancy and their risk of developing depression over their lifetime among public service employees participating in ELSA-Brasil, a multicenter study on chronic diseases in adults conducted by public institutions of education and research in six Brazilian capitals. Métodos: This was a cross-sectional study, in which a sample of 6.559 female workers was evaluated. Psychosocial factors in the workplace were measured using the Job Stress Scale (JSS) and analyzed within the framework of the Demand-Control Model (DCM). Depressive symptoms were assessed using the Clinical Interview Schedule–Revised (CIS-R). Statistical analysis was conducted in multiple stages: crude prevalence ratios (PR) were estimated, establishing the relationship between occupational stressors and depression. Poisson regression with robust variance adjusted the PRs for sociodemographic factors. Model fit was verified using the Hosmer-Lemeshow test and the ROC curve. Resultados e Conclusões: Women with hypertension during pregnancy had a significantly higher prevalence of depressive episodes (PR = 1.62; 95% CI: 1.23–2.14; p<0,01), representing a 62% increased risk compared to those without HDP. This risk magnitude is comparable to that observed for myocardial infarction and stroke in women with gestational hypertension. No significant effect modification was found for social support in the DCM. Hypertensive disorders of pregnancy are associated with increased lifetime risk of depression, comparable to major cardiovascular outcomes. Integrating psychosocial interventions into non-communicable disease management is essential. Mental health awareness must be embedded in health system planning, particularly in developing countries.

HYPERTENSIVE DISORDERS IN PREGNANCY AMONG WOMEN WITH GESTATIONAL DIABETES MELLITUS AT A BRAZILIAN REFERENCE CENTER

MARIA RITA LEITE MONTEIRO HASBUN1; LUÍS OTÁVIO SAMPAIO FAÇANHA2; CAUAN MIRANDA MATEUS1; GUILHERME NOBRE NOGUEIRA1; SAMUEL LUCAS ALMEIDA DA SILVA1; PEDRO HENRIQUE TAUFIC MONTEIRO HASBUN1; GABRIEL YGOR MACHADO NUNES3; LIA DE VASCONCELOS BARREIRA CARVALHO3; TAÍSSA MARIA CAVALCANTE MAGALHÃES3; CRISTINA FIGUEIREDO SAMPAIO FAÇANHA2;

(1) UFC - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (3) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Hypertensive disorders in pregnancy (HDP) are related to increased morbimortality outcomes for mothers and their newborns. When presented with gestational diabetes (GD), these risks of adverse outcomes may be enhanced. Objetivos: To evaluate the prevalence of HDP among women with GD and its influence in clinical presentations and outcomes of both mother and newborn. Métodos: Prospective Cohort study examining patients with GD (WHO 2013) from 2nd to 3rd trimester of pregnancy attending a public health care facility in northeast Brazil. Sociodemographic, clinical and obstetric data were obtained through interviews, structured questionnaires and chart reviews. The hypertensive group includes patients diagnosed before pregnancy and during pregnancy. The pregnancy outcomes were collected at the follow-up visit after delivery, with the sources of information being the mother’s discharge report, the live birth certificate, and the newborn’s vaccination card. P>0.05 was considered significant. Data was analyzed using SPSS, v23. The study was approved by the local Ethics Committee, approval number 6.195.677. Resultados e Conclusões: Out of 362 patients with GD, aged 33+-5.6 years old, 73 (20.1%) presented HDP (12,4% diagnosed before 20th week). Patients with HDP were older (P<0.01), had similar education level (P=0.34) and stable marital status. Before pregnancy, they had higher pre-gestational BMI (P<0.001), higher prevalence obesity (P<0.001), higher parity (P=0.06) and more prevalent history of abortion (P=0.02). Maternal blood glucose levels in the OGTT or glycaemic control by HbA1C were statistically similar between the groups, but HDP patients showed a greater need for pharmacological treatment to control diabetes (p<0.01). Regarding pregnancy outcomes, data from 293 deliveries and 287 newborns were evaluated (Table 2). There was no difference in average birth weight and pre-term delivery, but the HDP group had shorter duration of pregnancy (p<0.01), higher frequency of preeclampsia (P<0.001) and a greater need for neonatal ICU admission(P=0.02). Postpartum glucose tolerance was reassessed in 152 patients. Diabetes was diagnosed in 9.4% of the patients, with similar numbers among the groups. However, we observed that the mean fasting glucose was higher in HDP patients(fasting glucose = 94.8 mg/dl versus 87.6 mg/dl, P=0.01). These findings highlight the critical need for preventive interventions during pregnancy and careful postpartum follow-up, which may contribute to maternal and fetal long-term health.

TABLE 1: Clinical and obstetric characteristics of patients with gestational diabetes mellitus according to the presence hypertensive disorders in pregnancy (HDP)

	TOTAL	No-HD	HD	p-Value
N(%)	362	287 (70.3%)	73 (20.1%)

Introdução/Fundamentos: Premature menopause, defined as the cessation of ovarian function before the age of 45, is associated with an increased cardiovascular risk, largely driven by prolonged estrogen deficiency. In this context, menopausal hormone therapy (MHT), when initiated early, has been proposed as a potential risk-modifying strategy through its effects on endothelial function and atherosclerotic progression. Objetivos: In light of these considerations, this study aims to evaluate the impact of MHT on cardiovascular markers in women with premature menopause. Métodos: To this end, a systematic review was conducted in accordance with PRISMA recommendations, encompassing the stages of identification, screening, eligibility, and inclusion. Initially, a structured search was performed in PubMed, Cochrane Library, Embase, and Scopus using descriptors and related terms for premature menopause, hormone therapy, and cardiovascular markers, combined with Boolean operators. Subsequently, randomized controlled trials and observational studies were included, involving women with premature menopause (<45 years) receiving early-initiated MHT, compared with late initiation or no therapy. Accordingly, case reports, case series, reviews, and studies with insufficient data were excluded. Resultados e Conclusões: Following eligibility assessment, nine studies evaluating subclinical cardiovascular outcomes were included. Consistently, the absence of MHT was associated with greater progression of aortic valve calcification, whereas its use was independently associated with slower progression. Additionally, a lower prevalence of carotid plaques was observed among estrogen users. From a functional perspective, early MHT was associated with improved left ventricular diastolic function and reduced blood pressure in hypertensive women. In parallel, reductions in endothelial and thrombotic biomarkers were observed, along with improvements in lipid profile. However, no significant changes in arterial stiffness were detected in the short term. Overall, these findings suggest that early initiation of MHT is associated with favorable subclinical cardiovascular effects; nevertheless, methodological heterogeneity limits causal inference

IMPACT OF SEX ON OUTCOMES IN PATIENTS WITH REFRACTORY HYPERTENSION: A RETROSPECTIVE LONGITUDINAL STUDY.

TAREK CASTRO FAYYAT1; THIAGO ARTIOLI2; EIJI TAIRA3; MANUELA DRIGO DE ALMEIDA3; ANTONIO LAURINAVICIUS2; MÁRCIO GONÇALVES SOUSA2; FERNANDO YUE CESENA2;

(1) UNIVERSIDADE POSITIVO - CURITIBA - PR - BRASIL; (2) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (3) FACULDADE DE CIENCIAS MEDICAS DA SANTA CASA DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Refractory hypertension (RefHTN) represents a severe phenotype of hypertension (HTN) with high cardiovascular risk. Women have a lower prevalence of HTN for a given age stratum and better blood pressure (BP) control compared to men. However, sex differences among patients with RefHTN remain poorly understood. Objetivos: To evaluate the influence of sex on BP control, target organ damage, and clinical outcomes in patients with RefHTN. Métodos: This was a single-center, retrospective, longitudinal cohort study conducted in a public tertiary hypertension outpatient clinic. We included patients who attended the service from 2021 to 2025 with RefHTN defined as office BP ≥140/90 mmHg and 24h ambulatory BP ≥130/80 mmHg, taking at least 5 classes of antihypertensive medication. BP control at follow-up was defined as 24h ambulatory systolic BP (SBP) <130 mmHg and diastolic BP <80 mmHg. Patients with signs of poor medical adherence or secondary hypertension were excluded from the study. The associations between sex and changes in 24h ambulatory SBP (delta SBP), BP control, and outcomes, as well as estimated marginal means, were evaluated by multivariable linear and logistic regression models. Resultados e Conclusões: We analyzed 180 patients (mean age 62.6±11.4 years, 76% female, 29% with Stages 3 or 4 chronic kidney disease [CKD], 61% with left ventricular hypertrophy [LVH] at baseline), with a median follow-up of 3.6 (interquartile range 2.6-4.3) years. In analyses adjusted for age, baseline 24h SBP, and follow-up time, sex was not significantly associated with delta SBP. However, estimated marginal means of delta SBP increased with age and were numerically lower in females than in males (11.0 [95% CI: 8.1 to 13.8] mmHg vs 13.5 [95% CI: 8.2 to 18.7] mmHg at the mean age of 63 years, (Figure 1A). In multiadjusted analyses, sex, was not significantly associated with a higher chance of BP control at follow-up, but the estimated probability of BP control was numerically lower in females than males (0.23 [95% CI: 0.16 to 0.32] vs 0.28 [95% CI: 0.16 to 0.45]) for patients at the mean age of 63 years (Figure 1B). After adjustment for age and baseline outcome values, sex was not associated with LVH, CKD, or abnormal urine albumin-creatine ratio at follow-up (Table 1). In this predominantly female RefHTN cohort, women did not show better BP control or a more favorable profile of HTN-mediated organ damage compared to men, contrasting with known sex differences in other HTN scenarios.

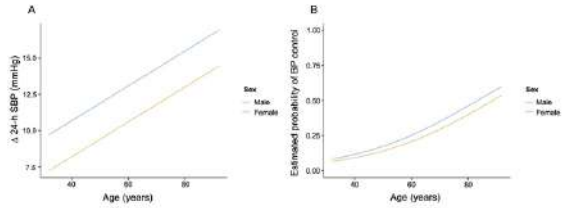

Figure 1. Estimated marginal means of delta 24h SBP (A) and estimated probability of BP control at follow-up (B), according to age and sex.

Table 1. Outcomes during follow-up according to sex

Outcome during follow-up	Frequency		Adjusted OR (female vs male)	95% CI	p-value
	Female	Male			
Clinical event	11 (8.1%)	2 (4.5%)	1.82	0.39 to 8.56	0.45
LVH	40 (55.6%)	8 (38.1%)	1.40	0.45 to 4.32	0.56
CKD	63 (46.3%)	23 (52.3%)	0.82	0.33 to 2.07	0.68
Abnormal uACR	54 (40.3%)	16 (39.0%)	1.17	0.48 to 2.83	0.73

Values are presented as n (%). ORs were adjusted for age, follow-up time and baseline values of each outcome (LVH, eGFR, and uACR). Incident events: acute coronary syndrome (ACS); stroke or transient ischemic attack (TIA); myocardial revascularization; hospitalization for heart failure; all-cause mortality. LVH: left ventricular mass index (LVMI) >115 g/m² in men and >95 g/m² in women. CKD: estimated glomerular filtration rate (eGFR, CKD-EPI) <60 mL/min/1.73 m². Abnormal uACR: urine albumin-to-creatinine ratio >30 mg/g.

MATERNAL ATOPIC DISEASES AND RISK OF HYPERTENSIVE DISORDERS OF PREGNANCY: A SYSTEMATIC REVIEW

GIOVANNA SACRAMENTO SLUZEK FACCIOLI1; CLARA QUARESMA VIEIRA1; ISABELLY CRISTINA HAUBERT MOREIRA1; MARIA ANTÔNIA BONATTO1; LUANA ELIAS HABR1; VIVIANE BATISTA DE MAGALHÃES PEREIRA1;

(1) UNIVERSIDADE EVANGELICA DE GOIAS - UNIEVANGELICA - ANÁPOLIS - GO - BRASIL;

Introdução/Fundamentos: Hypertensive disorders of pregnancy (HDP), including gestational hypertension and preeclampsia, remain leading causes of maternal morbidity and mortality worldwide. Emerging evidence suggests that the inflammatory and immunological profile associated with maternal atopic diseases may contribute to endothelial dysfunction and abnormal placentation. Objetivos: To evaluate the association between maternal atopic diseases (asthma, allergic rhinitis, and eczema) and the risk of developing gestational hypertension and preeclampsia. Métodos: This systematic review was conducted according to the PECO framework and reported following PRISMA guidelines. Searches were performed in PubMed, Web of Science, LILACS, and BVS databases. Observational studies and randomized controlled trials published within the last six years, in English, Portuguese, or Spanish, with sample sizes greater than 10 participants were included. Reviews, meta-analyses, editorials, case reports, and studies involving pediatric populations were excluded. The quality of evidence for clinical outcomes was assessed using the GRADE system. Resultados e Conclusões: Of 288 identified studies, 9 were included in the qualitative synthesis, demonstrating moderate to high quality of evidence. Maternal asthma emerged as the main risk factor, increasing the likelihood of preeclampsia by 20% to 30%, particularly in cases of severe or uncontrolled disease. Shared gene expression signatures (e.g., CXCL10 and ARG1) and elevated IgE levels were identified as potential biomarkers of risk. Maternal atopy, especially active asthma, appears to be an independent risk factor for HDP. Adequate control of allergic inflammation may play a key role in reducing adverse obstetric outcomes.

Article Title	Author and Year	Study Design	Sample Size / Population	Key Findings	GRADE Evidence Level
Association between asthma and hypertensive disorders of pregnancy	Maisán et al. (2023)	Secondary analysis of a prospective cohort (nuMom2b)	8,741 nulliparous individuals (1,521 with asthma)	Asthma was associated with a significantly higher risk of HDP (aOR: 1.23) and preeclampsia (aOR: 1.21). Active asthma (medication use) increased the risk of preeclampsia to aOR 1.27.	LOW ⊕⊕◯◯
Association of Maternal Asthma and Total Serum IgE levels with Obstetric Complications	Murata et al. (2020)	Prospective birth cohort (JECS)	77,131 women with singleton live births	Pregnant women with asthma and high IgE levels (>331 IU/mL) had a higher risk of HDP (aOR 1.33). Total IgE serves as a useful prognostic biomarker.	MODERATE ⊕⊕⊕◯ (Upgrade: dose-response gradient)
Asthma and risk of adverse pregnancy outcomes: A Mendelian randomization study	Han et al. (2024)	Mendelian Randomization (UVMR and MVMR)	GWAS data (UK Biobank and FinnGen)	Confirmed genetic links between asthma, abortion, and gestational diabetes. Did not confirm a direct causal genetic correlation with preeclampsia (p=0.297).	LOW ⊕⊕◯◯
Early pregnancy transcriptome signatures of preeclampsia: from peripheral blood to placenta	Yadama et al. (2026)	Nested case-control (transcriptome study)	157 pregnant women (discovery) plus replication cohorts	Identified genetic signatures and common inflammatory pathways (genes: CXCL10 and ARG1) shared between maternal asthma and preeclampsia.	LOW ⊕⊕◯◯
Effect of asthma exacerbation during pregnancy in women with asthma	Abdullah et al. (2026)	Longitudinal population cohort	103,424 pregnancies in women with asthma	Asthma exacerbation increased the odds of preeclampsia by 30% (OR 1.30) and pregnancy-induced hypertension by 17% (OR 1.17).	LOW ⊕⊕◯◯
Effects of Pregnancy-Onset Asthma on Perinatal Outcomes	Gu et al. (2024)	Retrospective cohort	336 pregnant women with asthma (36 pregnancy-onset)	Severe exacerbation was a strong independent risk factor for gestational hypertension and preeclampsia (aOR: 3.58).	MODERATE⊕⊕⊕◯ (Upgrade: magnitude of effect)
Maternal and perinatal outcomes of asthma exacerbation in a Chinese population	Li et al. (2024)	Retrospective cohort	226 patients with asthma (195 with exacerbations)	Women with exacerbation had an HDP risk of 12.4% vs 3.5% in those without. Exacerbation was an independent risk factor (aOR 3.35).	MODERATE ⊕⊕⊕◯ (Upgrade: magnitude of effect)
Pregestational maternal risk factors for preterm and term preeclampsia	Sande et al. (2023)	National population cohort	1,044,860 births registered in Norway	Confirmed asthma as a risk factor for both preterm preeclampsia (RPR 1.20) and term preeclampsia (RPR 1.29).	LOW ⊕⊕◯◯
Pregnancy Outcomes among Women with Intermittent Asthma	Chaiprom et al. (2021)	Retrospective cohort	364 cases of intermittent asthma and 3,640 controls	Controlled intermittent asthma did not increase the risk of preeclampsia or adverse outcomes; the risk is concentrated in cases with active attacks.	LOW ⊕⊕◯◯

MATERNAL MORTALITY DUE TO HYPERTENSIVE DISORDERS IN BRAZIL: TEMPORAL TRENDS AND REGIONAL INEQUALITIES (2010–2024)

STEPHANIE VITORIA RODRIGUES MENDES RHEIO1; GUSTAVO FRANCISCO SANTOS DA SILVA1; STÉPHANIE SAMPAIO DALLAGNOL1; RAFAEL VIEIRA LOPES1; CARLOS DENILSON SILVA SOARES1; GUILHERME AUGUSTO GUIMARÃES RESENDE1; MARIA CLARA DE MATTOS MIRA1; CAIO AUGUSTO FREITAS BIZERRA1; GIOVANI BONASSOLI FERNANDES1; EDUARDA NASCIMENTO BEGALLE1; LETICIA LIMA PINHEIRO1; ROGERIO TOSHIRO PASSOS OKAWA1;

(1) UNIVERSIDADE ESTADUAL DE MARINGA - MARINGÁ - PR - BRASIL;

Introdução/Fundamentos: Hypertensive disorders of pregnancy are among the leading causes of maternal mortality worldwide and represent major cardiovascular complications, reflecting endothelial dysfunction and long-term risk. Despite advances in care, maternal mortality remains unevenly distributed, particularly in low- and middle-income settings. In Brazil, regional disparities in healthcare access and socioeconomic conditions may contribute to unequal outcomes, but nationwide temporal analyses integrating cardiovascular and structural determinants remain limited. Objetivos: To analyze temporal trends in maternal mortality due to hypertensive disorders in Brazil and to evaluate regional inequalities in relation to socioeconomic development. Métodos: Ecological time-series study using national data from SIM and SINASC (2010–2024). Maternal deaths due to hypertensive disorders (ICD-10 O10–O16) were analyzed. The maternal mortality ratio (MMR) per 100,000 live births was calculated. Temporal trends were assessed using Prais–Winsten regression, estimating annual percent change (APC) and 95% confidence intervals. Regional averages were calculated, and the Human Development Index (HDI) was used as a socioeconomic indicator. Resultados e Conclusões: A total of 5,197 maternal deaths due to hypertensive disorders and 42,053,253 live births were recorded, corresponding to an MMR of 12.36 per 100,000 live births. Temporal analysis showed a non-significant downward trend (APC -0.41% per year; 95% CI -1.07 to +0.26; p=0.204), indicating relative stability. Marked regional disparities were observed. The highest mortality rates occurred in the Northeast (17.21/100,000) and North (15.19/100,000), while the lowest were in the South (7.03/100,000) and Southeast (10.42/100,000), representing a 2.45-fold difference. Regions with lower HDI values consistently showed higher mortality rates, supporting the influence of socioeconomic factors. Maternal mortality due to hypertensive disorders remained stable in Brazil, but with substantial regional inequalities. The coexistence of stable national trends with pronounced regional disparities suggests that aggregate indicators may obscure critical inequities in maternal outcomes. The association between lower socioeconomic development and higher mortality reinforces the role of structural determinants. Targeted strategies integrating obstetric and cardiovascular care are essential to reduce preventable maternal deaths

Introdução/Fundamentos: Cardiovascular disease is the leading cause of maternal mortality in developed countries and is increasing in middle-income settings due to advanced maternal age and comorbidities. In this context, cardio-obstetrics has emerged as a multidisciplinary model associated with improved maternal and perinatal outcomes. Objetivos: To evaluate the impact of multidisciplinary cardio-obstetric care on maternal outcomes in pregnant women with cardiovascular disease, as well as to identify the main cardiovascular and obstetric complications associated with pregnancy in this population and the barriers to effective implementation of this care model. Métodos: A systematic review was conducted according to PRISMA guidelines. Searches were performed in PubMed, Cochrane Library, and LILACS, including primary studies from the last five years in English, Portuguese, or Spanish. Studies involving pregnant women with cardiovascular disease receiving multidisciplinary care and reporting at least one relevant maternal outcome were included. After screening and eligibility assessment, 16 studies were selected. Resultados e Conclusões: Pregnant women with cardiovascular disease showed a high incidence of adverse events, particularly heart failure (up to 41.1% in patients with pulmonary hypertension), thromboembolic events (up to 13.1%), and high rates of preterm birth (≈42.3%). Maternal mortality ranged from 0% to 8.5%, reflecting disparities across healthcare settings. Advanced maternal age, hypertensive disorders, and complex heart disease (WHO classes III–IV) were associated with worse prognosis. Multidisciplinary care was consistently associated with improved outcomes, including therapeutic success rates of up to 96.2%, improved preconception planning, and reduced severe complications. However, its implementation remains heterogeneous due to structural barriers, unequal access to specialized centers, and gaps in professional training. Pregnant women with cardiovascular disease represent a high-risk group with a significant burden of morbidity and mortality. Multidisciplinary cardio-obstetric care plays a central role in improving maternal outcomes by promoting integrated and individualized management throughout the pregnancy–puerperal cycle. Expanding access to specialized care, adapting strategies to different healthcare contexts, and conducting further prospective studies are essential to strengthen the evidence and support broader implementation of this care model.

POLYCYSTIC OVARY SYNDROME AS A RISK FACTOR FOR ACUTE MYOCARDIAL INFARCTION: A SYSTEMATIC REVIEW

ALINE PASQUINI SANTOS1; FERNANDO SILVA GALVÃO2; TATIANE CARINTA DE SOUZA2; ANA LUÍSA VICENTE MENDES2; ISABELA MARTINS MULLER2; PAULO JOSÉ MATNI DOS SANTOS2; THIAGO AUGUSTO HENDERSON MONTEIRO2; NEY PEREIRA CARNEIRO DOS SANTOS2;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - RO - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Polycystic ovary syndrome (PCOS) is the most common endocrine disorder in women of reproductive age. Its pathophysiology involves hyperandrogenism, ovulatory dysfunction, and insulin resistance. PCOS is associated with a higher risk of cardiovascular diseases, such as acute myocardial infarction (AMI), since hyperinsulinemia contributes to obesity, glucose intolerance, and endothelial dysfunction. However, the scientific literature presents variations regarding this risk, as well as its manifestation in different phenotypes and age groups. Objectives: This study aims to analyze the risk of myocardial infarction in women with PCOS. Objetivos: This study aims to analyze the risk of myocardial infarction in women with PCOS. Métodos: This review was conducted in accordance with the PRISMA guidelines, registered on the PROSPERO platform under number CRD420261386778. A search was performed in the PubMed, Scopus, and Web of Science databases using the descriptors “Polycystic Ovary Syndrome,” “Myocardial Infarction,” and “Risk” between 2006 and 2026. The identified studies were exported to Rayyan, where they were screened by title and abstract. Duplicate studies, those unavailable in full text, or those unrelated to the topic were excluded. The risk of bias was assessed using the Newcastle-Ottawa Scale (NOS), and the certainty of evidence was assessed using the GRADE system. Resultados e Conclusões: The search resulted in 294 articles, of which 8 were selected, totaling a sample of over 2.7 million women. The NOS assessment indicated high methodological rigor (scores of 5 to 9; average of 6.8). The certainty of the evidence, according to GRADE, was moderate. Dwivedi et al. (2023), Berni et al. (2021), and Okoroh et al. (2016) demonstrated a positive association between PCOS and MI risk, with Dwivedi reporting an OR of 1.30. Zhao et al. (2024) highlighted that this vulnerability persists in young, non-obese women. In contrast, Ollila et al. (2023), Forslund et al. (2022), and Iftikhar et al. (2013) did not observe an increased risk of MI, while Schmidt et al. (2011) indicated that the metabolic risk profile in pre-menopause did not result in an increase in this event in post-menopause.
The data show that PCOS is a risk marker for MI, although it did not translate into deaths in post-menopausal women, but it reinforces the need to integrate PCOS into cardiovascular stratification protocols to mitigate the risk of early MI in this population.

PRE-ECLAMPSIA AS A PREDICTOR OF CARDIOVASCULAR EVENTS IN BRAZILIAN WOMEN: A PROJECTION BASED ON INTERNATIONAL EVIDENCE

ANA CAROLINA AMARAL CARNEIRO1; LUIZ GUSTAVO VILHENA PEREIRA1; MARIANA TOMÁS MARDEGAM1; GUILHERME AUGUSTO GUIMARÃES RESENDE1; MARIA CLARA DE MATTOS MIRA1; BRUNA SAYURI MATSUMURA KANASHIRO1; STEPHANIE VITORIA RODRIGUES MENDES RHEIO1; JENNIFFER AZOVEDI CARNEIRO2; PHELIPE AZOVEDI CARNEIRO3; MATHEUS HENRIQUE ARRUDA BELTRAME1; ROGERIO TOSHIRO PASSOS OKAWA1;

(1) UNIVERSIDADE ESTADUAL DE MARINGA - MARINGÁ - PR - BRASIL; (2) CENTRO UNIVERSITARIO UNICESUMAR - MARINGA - PR - BRASIL; (3) CENTRO UNIVERSITÁRIO INGÁ - MARINGÁ - PR - BRASIL;

Introdução/Fundamentos: Pre-eclampsia (PE) is a well-documented risk factor for future cardiovascular (CV) disease internationally. However, its magnitude remains unknown in the Brazilian context. Under this rationale, the present study proposes a statistical projection of CV events attributable to PE in Brazilian women in light of the international meta-analysis by Inversetti et al., 2024. Objetivos: This projection aims to estimate the Population Attributable Fraction (PAF) and the absolute number of CV events attributable to PE in Brazilian women over the last decade (2015–2024), in order to estimate the relevance of this association and highlight its importance. Métodos: The central reference is the meta-analysis by Inversetti et al. 2024, selected through a systematized search of PubMed/MEDLINE (AMSTAR-2 criteria), for extraction of Relative Risks (RR) between PE and CV death (RR: 2.08), heart failure (HF) (RR: 2.47), and acute myocardial infarction (AMI) (RR: 1.75). A clinical latency interval of 1 to 16 years was established between gestational exposure (PE) and the occurrence of CV events, based on the weighted mean follow-up time from the meta-analysis. For the national projection, data from SINASC and SIH/DATASUS were used, cross-referencing the mean age at PE diagnosis in Brazil (26.5 years) with the latency period to define the target population age range (30–59 years) at the time of the outcome. The time window was adjusted for latency and data availability: exposure (PE-related hospitalizations) between 2008–2014 was analyzed to project CV outcomes occurring from 2015 to 2024. The calculated prevalence of PE during the initial period resulted in 2.65%, and finally, the PAF was estimated to assess the impact of PE on CV events in Brazilian women. Resultados e Conclusões: Based on these data, an estimated 18,972 CV events (95% CI: 12,463–26,895; combined PAF: 3.07%) are attributable to a prior history of PE. Of these, 7,087 CV disease deaths (95% CI: 4,640–9,993; PAF: 2.78%), 4,222 AMI-related hospitalizations (95% CI: 3,103–5,561; PAF: 2.68%), and 7,663 HF-related hospitalizations (95% CI: 4,720–11,341; PAF: 3.75%). It is concluded that approximately 1 in every 33 CV events (95% CI: 1 in every 23 to 1 in every 50) in Brazilian women aged 30–59 years over the last decade may be attributable to prior PE. These findings support the recognition of PE as a female-specific CV risk factor and underscore the urgent need for post-gestational CV prevention and surveillance strategies in Brazil.

SEX DIFFERENCES IN HOSPITAL MORBIDITY AND CASE FATALITY FROM ACUTE MYOCARDIAL INFARCTION IN BRAZIL (2015–2024): EVIDENCE OF PERSISTENT HEALTHCARE INEQUITIES

ANNE KAROLINNE GOMES DAS MERCÊS1; FERNANDA SANTOS DA ANUNCIAÇÃO1; MANOEL LOUZADO BARRETO NETO1; CAIO CEZAR FERREIRA FRAGA1; ANA SAMIRY DA SILVA GOMES1; JOSÉ BESSA JÚNIOR1; VICTOR RIBEIRO CUNHA1; VINICIUS OLIVEIRA DE MELO1; MARLENE VELOZO PIMENTEL NETA1; RAFAEL QUINTO DE SOUZA1; MILENA GONZALES LAMARCA1; HELEN EDUARDA MACHADO DOS SANTOS DE JESUS1;

(1) UNIVERSIDADE ESTADUAL DE FEIRA DE SANTANA - FEIRA DE SANTANA - BA - BRASIL;

Introdução/Fundamentos: Acute Myocardial Infarction remains one of the leading causes of cardiovascular morbidity and mortality in Brazil, representing a substantial burden on the public health system. Evidence indicates relevant sex-based differences in clinical presentation and prognosis, with women showing poorer hospital outcomes despite a lower incidence of events. This phenomenon may reflect inequalities in clinical recognition, atypical presentations, and delays in the initiation of reperfusion therapies. Objetivos: To analyze sex differences in hospital morbidity and in-hospital mortality due to Acute Myocardial Infarction in Brazil between 2015 and 2024, as well as their temporal trends. Métodos: This was a descriptive epidemiological time-series study using data from the Hospital Information System of the Brazilian Unified Health System (SIH/SUS). Hospital admissions and deaths due to Acute Myocardial Infarction (ICD-10: I21) were analyzed according to sex. In-hospital mortality rates were calculated as the ratio between deaths and hospital admissions ×100. Descriptive statistics and temporal trend assessment were performed. Resultados e Conclusões: During the study period, 1,358,587 hospital admissions and 130,155 deaths due to Acute Myocardial Infarction were recorded in Brazil. A 78.7% increase in hospital admissions was observed, rising from 101,208 in 2015 to 180,876 in 2024. Men accounted for 63.5% of hospital admissions (863,663), while women represented 36.5% (494,924). Regarding deaths, 72,980 occurred among men and 57,175 among women. Despite the higher absolute number of events among men, women presented higher in-hospital mortality rates (11.6% vs. 8.5%), indicating proportionally worse outcomes in this group. These findings suggest persistent healthcare inequities in the management of myocardial infarction among women, possibly associated with lower diagnostic suspicion, atypical clinical presentations, and delays in reperfusion therapy. The results demonstrate a consistent disparity in hospital outcomes by sex, with poorer prognosis among women hospitalized for myocardial infarction. These findings reinforce the need for strategies aimed at earlier recognition of myocardial infarction in women and reduction of barriers to timely and qualified cardiovascular care.

SUBCLINICAL CAROTID ATHEROSCLEROSIS AND CORPORAL ADIPOSITY IN POSTMENOPAUSAL WOMEN WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

CLARA DA COSTA MARRUCHO1; JENAINE ROSA GODINHO1; LIVIA PETRI MANEA1; MONICA SUZARTH RAMOS1; ANA CAROLINA DA SILVA GUIMARÃES1; CAMILA MENDES PEIXOTO1; RENATA PEREIRA MARTINS BARROSO1; CARLOS ROBERTO MORAES DE ANDRADE JUNIOR1; LUIS GUILLERMO COCA VELARDE1; MARIA AUXILIADORA NOGUEIRA SAAD1; PRISCILLA POLLO FLORES1; DÉBORA VIEIRA SOARES1;

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL;

Introdução/Fundamentos: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most prevalent chronic liver disease worldwide and is closely linked to increased cardiovascular risk. Women with MASLD represent an underexplored population, and hormonal transitions, particularly menopause, may amplify cardiometabolic vulnerability by promoting visceral adiposity, dyslipidemia, and a pro-atherogenic state. Sex-specific data on subclinical carotid atherosclerosis and visceral adiposity in this population remain scarce. Objetivos: This study aimed to describe the frequency of carotid plaques, carotid intima-media thickness (cIMT) abnormalities, fat mass, and visceral adiposity in postmenopausal women with MASLD. Métodos: This observational, cross-sectional study with prospective data collection was conducted between April 2022 and December 2025. It received prior approval by the Institutional Research Ethics Committee. The study included only postmenopausal women with MASLD who had not received estrogen therapy. Liver steatosis and fibrosis were assessed via ultrasound and liver elastography, respectively. Carotid atherosclerosis was examined through carotid ultrasound, cIMT measurements, and Vascular Age. Quantitative assessment of fat mass was performed using anthropometric measurements and dual-energy X-ray absorptiometry (DXA), including fat mass index (FMI = total fat mass kg/height m²), abdominal visceral adipose tissue (VAT, cm³), and android-to-gynoid (A/G) percent fat ratio. Data are presented as mean ± standard deviation (SD) or median (Interquartile Range, p25–p75) as appropriate. Resultados e Conclusões: Among the 84 women, carotid plaques were observed in 26.2%. Vascular age was markedly elevated compared to chronological age (72.5 ± 23.9 vs. 66.0 ± 8.2 years), indicating early vascular aging in this population and 34.5% had a cIMT value above the 75th percentile. The frequency of obesity (BMI > 30 kg/m²), high fat mass percentage (>40%), and A/G >1 was 60.7%, 78.6%, and 85.7%, respectively. The population data are described in Table 1. Postmenopausal women with MASLD presented high rates of subclinical carotid atherosclerosis, early vascular aging, and android fat distribution, with fat mass percentage notably increased. These findings highlight the cardiometabolic burden in postmenopausal women with MASLD and support the integration of adiposity distribution assessment and carotid evaluation into cardiovascular risk stratification in this population.

ACUTE CORONARY SYNDROME AND PERIPHERAL ARTERIAL OCCLUSION SECONDARY TO RIGHT NATIVE CORONARY SINUS THROMBOSIS

MARCELA DO NASCIMENTO MONTEIRO[1]; MARIA EDUARDA RUVIARO SANTOS[2]; ROMUALDO BOLZANI DOS SANTOS[3]; NICOLÁS NAVARRO STILER[1]; LUCAS VERARDO LOPES[1]; GABRIELA LARIÇA RAUBER WEISS[1]; ALICE WACHHOLZ DAL RI[1]; LETÍCIA GUIMARÃES LORENZON[1]; LUZIA CONZ AGOSTINETTO[1]; RENATA GUIZOLFI FERREIRA[1]; MILENA ISABELI BRUN[1]; NÁGILA SIMON ZIEBELL[4];

(1) UNIVERSIDADE FRANCISCANA - SANTA MARIA - RS - Brasil; (2) UNIVERSIDADE DE PASSO FUNDO - PASSO FUNDO - RS - BRASIL; (3) HEMOCOR-HCAA - SANTA MARIA - RS - BRASIL; (4) UNIVERSIDADE FEDERAL DE SANTA MARIA - SANTA MARIA - RS - BRASIL;

Introduction: Sinus of Valsalva thrombosis is a rare presentation and is scarcely described in the literature. Possible etiological factors include hypercoagulability, structural abnormalities, congenital conditions, inflammatory processes of the aorta, procedure-related complications, and idiopathic cases. The most frequent clinical presentations are myocardial infarction and systemic embolization. The cusp most commonly involved is the non-coronary sinus and less frequently the right. A high index of suspicion is required, especially in cases of infarction in the absence of obstructive coronary artery disease. Case Description: A 60-year-old female patient sought medical attention due to precordial pain. The electrocardiogram showed ST-segment elevation in the inferior wall and right-sided leads, and she was transferred for primary angioplasty. During catheterization, coronary arteries without stenoses were observed, along with a thrombus in the right coronary sinus, extending to the proximal and mid segments of the right coronary artery (figure 1). During the procedure, she presented ventricular fibrillation, promptly reverted, followed by progressive hemodynamic instability. Tirofiban associated with heparin was administered, and thrombectomy with an aspiration catheter was performed. A significant amount of thrombotic material was retrieved (figure 2), restoring coronary flow, however, a large amount of thrombus persisted in the right coronary sinus. Arterial Doppler revealed acute arterial occlusion of the left lower limb. Embolectomy was performed at the level of the left iliac artery using a Fogarty catheter. The patient evolved with progressive hemodynamic deterioration, refractory shock, multiple organ dysfunction, and death. Conclusions: Thrombosis in the sinus of Valsalva represents an uncommon cause of systemic embolism. When manifested as an acute coronary syndrome, it constitutes an important therapeutic dilemma, as selective coronary catheterization may dislodge the thrombus, resulting in systemic embolization with potentially catastrophic consequences. Thrombosis in a native aortic valve is an uncommon diagnosis with an estimated in-hospital mortality of 20%. The ideal treatment remains uncertain due to the scarcity of studies. Surgical thrombectomy and antithrombotic therapy are available options. Depending on the clinical presentation, surgical risk, and embolization potential, surgical exploration of the aortic valve may be considered.

ANOMALOUS LEFT CORONARY ARTERY FROM THE PULMONARY ARTERY (ALCAPA) IN A 64-YEAR-OLD PATIENT: A DIAGNOSTIC CHALLENGE

GABRIEL SIQUEIRA HANKE[1]; THIAGO LIMA CAVALCANTE[2]; GABRIEL HENRIQUE ZIMERMANN DOS SANTOS[1]; MICHELLY CRUVINEL DAL PAI SANDRI[2]; LUIS HENRIQUE DE GODOI MACHADO[2]; THÁBATA THALITA DE SOUSA SILVEIRA TIMERMANN[2]; KIELLA DE LIMA TAVARES DA SILVA[2]; CARLOS ALBERTO KENJI NAKASHIMA[2]; DALTON BERTOLIM PRÉCOMA[2];

(1) FACULDADES PEQUENO PRINCIPE - CURITIBA - PR - BRASIL; (2) SOCIEDADE HOSPITALAR ANGELINA CARON - CURITIBA - PR - BRASIL;

Introduction: ALCAPA, or Bland–White–Garland syndrome, is a rare congenital coronary anomaly (~1:300,000 live births), with high infant mortality if untreated. Adult survival is uncommon and depends on collateral circulation from the right coronary artery (RCA). Case Description: A 64-year-old woman presented with acute constrictive chest pain and exertional dyspnea. Her history included hypertension and obesity. She received acetylsalicylic acid and clopidogrel for suspected acute coronary syndrome, with partial relief. She was hemodynamically stable, and physical examination was unremarkable. Electrocardiography showed subendocardial ischemia in anterolateral leads and signs of prior inferoseptal infarction. Troponin levels were elevated (54,102–822,90 ng/mL). Coronary angiography revealed a dominant RCA with a dilated posterior descending branch supplying collaterals to the left coronary system, without obstructive lesions. The left coronary artery was not visualized from the aortic root, and a fistulous connection to the pulmonary artery was suspected. Coronary computed tomography angiography confirmed ALCAPA, demonstrating anomalous origin of the left main coronary artery from the pulmonary trunk with extensive collateral circulation. Myocardial perfusion scintigraphy demonstrated mild-to-moderate transient hypoperfusion in the anterior, anterolateral, and basal segments of the left ventricle during stress, with a left ventricular ejection fraction of 58% under stress conditions and rest. Given the high surgical risk, optimized medical therapy was chosen. Conclusions: This case highlights the central role of multimodality imaging in diagnosing ALCAPA in adulthood when angiography is inconclusive. Coronary computed tomography and myocardial perfusion imaging defined anatomy and ischemia, guiding clinical decision-making. Imaging findings supported a tailored, non-surgical approach in a high-risk patient.

Atypical Presentation of Acute Myocardial Infarction in a Young Patient Secondary to Blunt Sports Trauma

MARCO ANTÔNIO PANET DE VIVO BARROS[1]; MARCO ANTÔNIO DE VIVO BARROS[1]; GUSTAVO SOARES FERNANDES[1]; THIAGO LISBOA LOPES[1]; JOAO VICTOR DE OLIVEIRA RAMOS[1]; PABLO OLIVEIRA CORDEIRO[1]; JOAO RICARDO CAVALCANTI DO NASCIMENTO[1]; GIOVANNA DE SOUSA OLIVEIRA[1]; ERIKA ALVES DA SILVA[1]; EMMILY NEVES DE ARAUJO PEREIRA[1]; DAVI ALBUQUERQUE MADRUGA[1];

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - Brasil;

Introduction: Acute myocardial infarction (AMI) secondary to blunt chest trauma is rare, and its sequelae remain poorly explored. Distinct from the usual atherosclerotic etiology, an AMI is reported in a young athlete without cardiovascular risk factors. The clinical presentation was notable for atypical and delayed symptoms. This case highlights the need to consider AMI in chest trauma despite delayed onset. Furthermore, it underscores the therapeutic dilemma between conservative antithrombotic management and percutaneous intervention. Case Description: A 27-year-old male amateur athlete with no cardiovascular risk factors or illicit drug use sustained a high-impact blunt anterior chest trauma at 3:00 PM during an American football match. He remained active in the game until 5:00 PM. At night, during postprandial rest, he developed sudden severe precordial pain, diaphoresis, and nausea. He presented to the emergency department hemodynamically stable: BP 120/70 mmHg, HR 75 bpm, and SpO2 98%. The electrocardiogram revealed hyperacute T waves in V2-V5. He received ASA 300 mg, clopidogrel 600 mg, and subcutaneous enoxaparin 60 mg prior to referral for primary angioplasty. Coronary angiography (5-hour ischemia time) demonstrated a patent left anterior descending artery with a proximal intraluminal filling defect suggestive of a thrombus, and a coronary tree free of atherosclerosis. A conservative approach with full anticoagulation was chosen. Ten days later, repeat angiography revealed complete thrombus resolution and no atherosclerotic lesions. Left ventriculography measured an ejection fraction (EF) of 43.7%. The patient was discharged on an ACE inhibitor, beta-blocker, antiplatelet therapy, and a statin. Cardiac magnetic resonance performed six months later evidenced a 19% myocardial fibrosis mass and an EF recovery to 49%. Conclusions: This case illustrates the diagnostic challenge of coronary syndromes triggered by sports-related impacts, in which severe blunt force causes endothelial injury and disruption of the arterial muscular layer, leading to subsequent thrombosis and occlusion. It emphasizes the need for high clinical suspicion in the emergency setting, even in young patients who are asymptomatic in the immediate post-trauma period and lack atherosclerotic risk, making an initial ECG indispensable. Furthermore, conservative antithrombotic management proved safe and effective for thrombus resolution, ensuring partial recovery of ventricular function.

IMPORTANCE OF ENDOTYPE CLASSIFICATION IN PATIENTS WITH ANGINA/ISCHEMIA WITHOUT SIGNIFICANT CORONARY OBSTRUCTION

LAYSE DIÓGENES LIMA[1]; JOÃO MACEDO NETO[1]; SARAH MENDES CAVALCANTE[1]; JOÃO FERRIERA MARINHO[1]; ARTUR VASQUES FARIAS[1]; DAVI PONTE PIERRE[1]; JARDEL MACHADO CORDEIRO[1]; TIAGO MOURA FAÇANHA[1]; NICOLE AIRES PERAZOLO[1]; YNGRID BEZERRA MATSUNOBU[1]; MAYRA DIÓGENES LIMA[2]; MATEUS PAIVA FEITOSA[2];

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (2) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introduction: Angina and ischemia without obstructive coronary arteries (ANOCA/INOCA) represent a growing and non-benign clinical challenge. The pathophysiology involves coronary alterations such as microvascular dysfunction, epicardial or microvascular spasm and endothelial dysfunction. Invasive coronary functional assessment, perfusion positron emission tomography (PET), stress cardiac magnetic resonance imaging and acetylcholine testing allow identification of pathophysiological endotypes, enabling personalized management and symptomatic improvement. Case Description: Case description 1 71-year-old female, with chronic obstructive pulmonary disease, hypothyroidism and dyslipidemia. Two years ago, she presented angina, diaphoresis and dyspnea. Submaximal exercise stress test was negative for myocardial ischemia; myocardial scintigraphy showed apical ischemia of the left ventricle with preserved ejection fraction; coronary angiography revealed no lesions. Due to unavailability of acetylcholine testing, clinical diagnosis of INOCA was established. Beta-blocker therapy improved symptoms. Case description 2 67-year-old female, hypertensive and dyslipidemic, with anginal chest pain. Positive exercise stress test and coronary computed tomography angiography (CCTA) suggested moderate lesion in the left anterior descending artery (LAD). Cardiac catheterization confirmed 50% eccentric lesion in the mid LAD. Functional assessment showed resting full-cycle ratio (uFR) negative for ischemia, indicating obstruction was not the main cause of mismatch; microvascular resistance index (MR) was positive, confirming microvascular dysfunction. Beta-blocker therapy improved angina. Case description 3 61-year-old male, hypertensive, dyslipidemic, with family history of coronary artery disease. Presented atypical chest pain. Myocardial scintigraphy showed ischemia in the anterior and inferolateral walls; CCTA revealed mild calcified plaques in the LAD and the circumflex artery (CX); catheterization confirmed mild non-obstructive plaques. Functional assessment showed resting full-cycle ratio (uFR) negative in both arteries (0.98 LAD, 0.97 CX), but microvascular resistance index (MR) was 251 (reference up to 250). Beta-blocker therapy improved symptoms. Conclusions: ANOCA/INOCA requires a comprehensive and individualized approach guided by endotypes. Complementary methods and coronary functional assessment are essential to define phenotype, improving quality of life and overall cardiovascular risk.

MYOCARDIAL ISCHEMIA WITH NON-OBSTRUCTIVE CORONARY ARTERIES (INOCA) ASSOCIATED WITH CORONARY-CAVITARY MICROFISTULAS IN A PATIENT WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A CASE REPORT

SARAH MENDES CAVALCANTE[1]; JOÃO DA SILVA FERREIRA MARINHO[1]; IAN SANTOS ALENCAR OLIVEIRA[1]; JARDEL BRASIL MACHADO CORDEIRO[1]; ISRAEL NASCIMENTO COUTINHO COSTA[1]; TIAGO MOURA FAÇANHA[1]; LAYSE DIÓGENES BRAGA LIMA[1]; EDUARDO CRUZ LOPES[1]; ANTONIO ARAGÃO XEREZ JUNIOR[1]; NICOLE AIRES PERAZOLO[1]; MAYRA DIÓGENES BRAGA LIMA[2]; MATEUS PAIVA MARQUES FEITOSA[2];

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (2) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introduction: Ischemia with non-obstructive coronary arteries (INOCA) is a frequently underdiagnosed condition, affecting approximately 50–70% of those with angina undergoing coronary angiography. Coronary-cavitary microfistulas, although rare, may contribute to ischemia through a coronary steal mechanism. This report describes a case of chest pain with findings of myocardial ischemia in a patient with systemic lupus erythematosus (SLE) and non-obstructive coronary arteries. Case Description: A 54-year-old woman with a diagnosis of SLE and hypertension, on olmesartan/amlodipine (40/5 mg), naltrexone 1.5 mg, duloxetine 30 mg, and metoprolol 25 mg/day, was admitted for progressive chest pain. She reported an episode of chest pain three years earlier, when she underwent coronary angiography that showed no obstructive lesions but identified coronary-cavitary microfistulas, complicated by an anaphylactic reaction to contrast. Symptoms recurred with progressive worsening over the past two months, characterized by constrictive chest pain on minimal exertion and at rest, radiating to the back and left arm, associated with dyspnea and diaphoresis. Exercise stress testing showed chest pain on exertion with ST-segment depression in V5–V6. Myocardial perfusion scintigraphy revealed stress-induced ischemia in the posterior wall of the left ventricle, with preserved function. Laboratory tests were unremarkable, and troponin was negative. Due to persistent symptoms a coronary angiography was repeated, not demonstrating significant obstructive coronary lesions. Post-procedural analysis using artificial intelligence showed uFR of 0.93 in the left anterior descending artery (reference >0.80) and an index of microcirculatory resistance (MR) of 315 mmHg·s/m, suggestive of microvascular dysfunction (values >250 mmHg·s/m), likely related to coronary-cavitary microfistulas. The patient remained hemodynamically stable. Beta-blocker therapy was maintained, and she was discharged with outpatient follow-up. Conclusions: This case reinforces the importance of recognizing INOCA as a cause of chest pain, particularly in patients with inflammatory conditions such as SLE. It highlights the need for investigation beyond coronary angiography for accurate diagnosis and management.

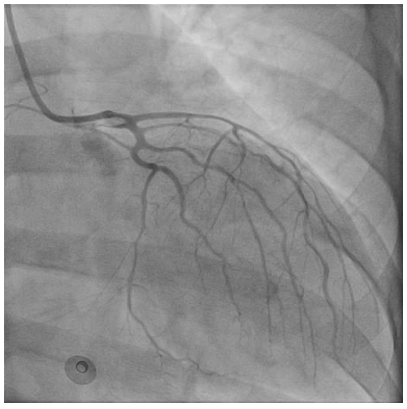
PERCUTANEOUS CLOSURE OF A LARGE POST-INFARCTION VENTRICULAR SEPTAL DEFECT: FROM CARDIOGENIC SHOCK AND ACUTE RENAL FAILURE TO HEMODYNAMIC OPTIMIZATION

CAIO MOREIRA SALGUEIRO[1]; NATHÁLIA SALIM SAUD[1]; NOEMI ROCÍO ANDRADE ALBAN[2]; CARLOS DANIEL LUCIO LÓPEZ[2]; ANTHONY JOSUÉ LUCIO LÓPEZ[2]; LEONARDO ANDRADE CACERES[2]; ARIEL IVAN MENA AMALUIZA[2]; WOLNEY DE ANDRADE MARTINS[1]; MARCOS MERULA DE ALMEIDA[1];

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (2) UNIVERISADE TECNICA DE AMBATO - ECUADOR;



Introduction: Ventricular Septal Defect (VSD) is a devastating mechanical complication of acute myocardial infarction. Despite the reduction in its incidence due to primary reperfusion therapies, it still carries high mortality. The managenement of low cardiac output and severe pulmonary hypertension is important to prognostic. Case Description: A male patient with anterior ST-elevation myocardial infarction underwent thrombolysis with alteplase within the 12-hour window, following with a stent in the anterior coronary. Ten days post-procedure, he presented with severe anasarca and dyspnea. With a loud holosystolic murmur, loudest at the left lower sternal border on cardiac auscultation.. Echocardiography confirmed a large 4-cm VSD and a Pulmonary Artery Systolic Pressure (PASP) of 80 mmHg. A pulmonary artery catheter was inserted, showing a baseline Cardiac Index of 1.3 L/min/m². Pharmacological optimization was initiated with milrinone (inodilator) and sodium nitroprusside (vasodilator) to reduce systemic vascular resistance and left-to-right shunting. The strategy resulted in a significant hemodynamic shift: Cardiac Output rose from 1.3 to 2.9 L/min, and PASP dropped to 42 mmHg. With improved renal perfusion and aggressive diuretic therapy. Consequently, serum creatinine decreased from 4.2 mg/dL to 1.3 mg/dL over six days. Following clinical and hemodynamic stabilization, the patient underwent successful percutaneous VSD closure without complications. Conclusions: The “standard” murmur of an acquired VSD is holosystolic because the pressure gradient between the left and right ventricles persists throughout the entire contraction phase. In this case, the severity of the shunt led to “congestive” acute renal failure (cardiorenal syndrome type 1), which was reversed not by volume, but by optimizing forward flow and reducing afterload. The use of milrinone and nitroprusside was pivotal to “pre-condition” the pulmonary vascular bed and the right ventricle before the percutaneous intervention. The 10-day delay from the MI likely allowed for some degree of myocardial fibrosis at the edges of the defect, facilitating the anchoring of the percutaneous device.This case illustrates that even large post-infarction VSDs associated with severe pulmonary hypertension and multisystemic dysfunction can be successfully managed. Hemodynamic monitoring and aggressive pharmacological optimization are essential to bridge these high-risk patients to definitive percutaneous therapy.

PERIPARTUM SPONTANEOUS CORONARY ARTERY DISSECTION WITH MULTIVESSEL INVOLVEMENT PRESENTING AS ANTEROLATERAL STEMI, SEVERE LV DYSFUNCTION, APICAL THROMBUS, AND EPISTENOCARDIAC PERICARDITIS: A CASE REPORT

MARINA ISADORA DE ANDRADE LEMOS[1]; AMANDA ROCHA MORAES RIBEIRO[1]; RODRIGO DIÓGENES MARTINS[1]; AMANDA GRIPPA PIFFER[1]; EUTRÓPIO LUIZ BRANDÃO JUNIOR[1]; LUCIANO MOREIRA BARACIOLI[1]; FELIPE GALLEGO LIMA[1]; ROBERTO ROCHA CORREA VEIGA GIRALDEZ[1]; MATHEUS CARVALHO ALVES NOGUEIRA[1];

(1) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL;

Introduction: Spontaneous coronary artery dissection (SCAD) is a non-atherosclerotic separation of the coronary artery wall creating a false lumen that compromises the true lumen. It accounts for up to 35% of acute coronary syndromes in women under 50 and is strongly associated with the peripartum period, yet remains underrecognized. Case Description: A 30-year-old woman (G3P3A0, vaginal delivery 15 days ago, no comorbidities) sought care with chest pain, Killip I. ECG showed ST elevation in DI, aVL, and V2 with reciprocal depression in DIII. After receiving aspirin and clopidogrel (300 mg each) at the referring hospital, she was transferred to a tertiary center where she had a urgent coronary angiography the following day, revealing type 2 spontaneous dissection of the LAD at mid-1/3, diagonal branches (Dg1, Dg2), circumflex (Cx), marginal branches (MgE1-3), and posterior ventricular branch of the RCA, without obstructive lesions. Echocardiography on that same day showed LVEF 35% with akinesis of the anterior wall, apex, and mid-anterolateral segment; eight days later, LVEF was 29%, with eccentric LV hypertrophy, moderate-to-severe mitral regurgitation, and pericardial effusion - sign of pericarditis epistenocardica. Cardiac MRI performed 13 days after initial presentation confirmed LVEF of 30%, transmural late gadolinium enhancement across anteroseptal, anterior, anterolateral, inferoseptal, and apical segments, microvascular obstruction, and a 9mm apical LV thrombus. Coronary CTA corroborated diffuse luminal reduction in LAD and Cx from the ostium with pericoronary fat attenuation. Calcium score was zero. Given the LV thrombus, dual antiplatelet therapy was replaced at discharge by rivaroxaban for 6 months — a clinically relevant decision, since antiplatelet choice (aspirin, clopidogrel, or dual) remains contested in uncomplicated SCAD. Heart failure therapy, statin, and colchicine (pericarditis epistenocardica) were also prescribed. A follow-up echocardiogram two months later showed partial LVEF recovery to 36%. Conclusions: This case illustrates the complexity of peripartum SCAD presenting as a severe anterolateral STEMI with multivessel involvement, severe LV dysfunction, apical thrombus, and pericarditis. The LV thrombus determined an anticoagulation-based strategy, bypassing the contested debate on antiplatelet therapy in SCAD. Conservative management achieved partial LVEF recovery so far. High clinical suspicion is essential in young postpartum women with acute coronary syndrome (ACS).

ACUTE TYPE A AORTIC DISSECTION OF A YOUNG MALE ULTRAMARATHON RUNNER DURING AN INTENSE RUNNING SESSION – AN ATYPICAL PRESENTATION OF A FIRST CASE REPORT IN LITERATURE.

ALÉSSIA ALENCAR ARARIPE GURGEL[1]; MARIA LUIZA REIS SARAIVA FALCAO[2]; JOSE CARLOS JUCA POMPEU NETO[2]; ISABELLA FEITOSA PITA ULISSES[2]; NICOLAS ALMEIDA FERREIRA BARREIRA[3]; CAUÊ BARROS DE SOUSA NOBRE[3]; FRANCISCA GRAZYELE CARDOSO BEZERRA SOARES[3]; FRANCISCO ERIVALDO JORGE SILVA[3]; HILANE SNILLE DINIZ SANTOS[3]; FRANCISCO SAMUEL RODRIGUES DIAS[3]; JOAO LUIZ ALENCAR ARARIPE FALCAO[3]; SANDRA NIVEA REIS SARAIVA FALCAO[2];

(1) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (3) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL;

Introduction: Introduction: Acute type A aortic dissection is a clinical emergency that usually presents with tearing chest pain and hemodynamic instability. The immediate mortality is as high as 1%/hour over the first several hours, making early diagnosis and treatment critical for survival. High index of clinical suspicion is important as delay in diagnosis can have dreadful consequences. Aortic dissection in athletes was reported but is rare and often associated with weightlifting. Otherwise, a high prevalence of ascending aorta dilation in competitive endurance athletes has been reported - possibly related to a long-term increased stroke volume. Case Description: Case report: A 40-year-old male ultramarathon runner developed Type A aortic dissection during an intense running session. He presented dizziness associated with an intense mandibular pain during intense running. Pain relieved after resting for 5 minutes. He ran a 40-minute treadmill recovery session next day and a 26km long run workout 3 days after, without symptoms. During a weightlifting exercise, 5 days after, he reported a short duration light mandibular pain - wearable watch data in Figure 1. He looked for medical attention. He was asymptomatic and physical examination was unremarkable: normal heart sounds, symmetric pulses, blood pressure 90x60mmHg, heart rate 48bpm. EKG: sinus bradycardia. A cardiac CT to discard coronary heart disease was performed in the next day. It was diagnosed a type A aortic dissection that started beside left coronary ostium and caused a discrete compression of initial portion of left main (Figure 2-A). There was an associated 5.6cm diameter ascending aortic aneurysm. Aortic valve was spared. Dissection extended to the initial portion of iliac arteries. No major aortic branch was occluded (Figure 2-B). An urgent open surgical to replace the diseased ascending aorta with a 26mm Dacron graft was performed. After a hospital stay of 6 days, patient was discharged. Genetic profile was negative for Marfan and Loeys-Dietz syndrome. Conclusions: Conclusions: We report, to the best of our knowledge, the first case of a type A acute aortic dissection in a young male ultramarathon runner during an intense training session. Clinical course followed an atypical presentation. It's remarkable that initial pain was completely relieved after 5-minute rest and that patient ran 26km without symptoms 3 days after dissection. Preparticipation screening for ascending aorta aneurysm may be relevant for endurance runners.

AORTIC COARCTATION ASSOCIATED WITH A RUPTURED MIDDLE CEREBRAL ARTERY ANEURYSM IN AN ADOLESCENT. A CASE REPORT

KAIO VINICIUS CAMPOS MARQUES[1]; PAULA SANTIAGO TEIXEIRA[1]; ANA CAROLINA SANTOS COUTINHO[1]; BRENO VINICIUS DOS SANTOS PINTO[1]; ANDRE KENZO ARAGAKI[1]; GUILHERME BOALENTO FIGUEIREDO[1]; LUIZ FILIPE XIMENES DA SILVA[1]; KIMBERLY MARIA BENTES VIANA[1]; HEIGLON ESTEVÃO BONELLA DENTI[1]; GUSTAVO ROCHA FEITOSA SANTOS[1]; ADRIANO CAIXETA[2]; CELIA MARIA CAMELO SILVA[2];

(1) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL;

Introduction: Aortic coarctation (CoA) Eventually remains undiagnosed until adolescence or adulthood, presenting only after severe, potentially life-threatening complications. Intracranial aneurysms and subarachnoid hemorrhage (SAH) are well-recognized, yet rare, associations. We present a case of previously undiagnosed aortic coarctation revealed by the rupture of a middle cerebral artery aneurysm in an adolescent. Case Description: A previously healthy 15-year-old male was admitted with sudden-onset headache and lower-limb weakness during physical activity. Cerebral angiography revealed subarachnoid hemorrhage due to a ruptured, 6 mm saccular aneurysm of the left middle cerebral artery. Aortography performed during the diagnostic workup revealed severe aortic coarctation with reversed flow in the left vertebral artery, suggesting significant collateral circulation. The patient underwent successful endovascular embolization of the cerebral aneurysm without complications. Following neurological stabilization, a cardiologic evaluation confirmed severe coarctation of the aorta (CoA), with a peak gradient of 56 mmHg, as well as a bicuspid aortic valve without functional impairment. During the same hospitalization, the coarctation was successfully treated percutaneously using a covered stent. The procedure achieved complete angiographic success with a reduction in the trans-stenotic gradient from 34 mmHg to 0 mmHg. At follow-up, the patient remains asymptomatic with normal blood pressure and symmetric peripheral pulses. Conclusions: This case highlights the rare presentation of previously asymptomatic aortic coarctation, which was diagnosed following the rupture of an intracranial aneurysm. The case reinforces the well-established association between coarctation of the aorta (CoA) and cerebral aneurysms, emphasizing the need for a high index of suspicion. A staged, multidisciplinary endovascular approach addressing both the cerebral and aortic lesions proved safe and effective.

Patent Foramen Ovale and Paradoxical Embolism Complicated by Confirmed Chronic Thromboembolic Pulmonary Hypertension: A Therapeutic Dilemma Between Embolic Risk and Right Ventricular Overload

GABRIEL DE REZENDE TEIXEIRA BEDIM JANA[1]; DANILO CALIARI[2]; ALICE VIÇOSI SILVA[2]; JOÃO PEDRO REZENDE SOBREIRA[3]; MARCELO SANTOS POLIDO FABRI[2]; ESTHER VESCOVI MARTINS COUTINHO[2]; GABRIEL CAMPOS PEREIRA[2]; LUCAS LOPES NETTO[2]; YURI FRANÇA CALMON DE AZEVEDO[2]; LIZANDRA ZANETTI MIRANDA[2]; FERNANDO LUIZ TORRES GOMES[2]; PEDRO HENRIQUE DE MORAES CELLIA[2];

(1) UNIVERSIDADE FEDERAL DO ESPIRITO SANTO - VITÓRIA - RJ - Brasil; (2) UNIVERSIDADE FEDERAL DO ESPIRITO SANTO - VITÓRIA - ES - Brasil; (3) HOSPITAL ESTADUAL JAYME SANTOS NEVES - VITÓRIA - ES - Brasil;

Introduction: Patent foramen ovale (PFO) is a residual interatrial communication present in 14.7–31.3% of adults. Paradoxical embolism through a PFO is a well-established mechanism for cryptogenic stroke and transient ischemic attack (TIA). The simultaneous occurrence of systemic ischemic events and chronic pulmonary thromboembolism (CPTE) represents a highly complex clinical scenario, as the management of one condition often conflicts with the hemodynamic requirements of the other. Case Description: A 47-year-old woman with hypertension presented in 2023 with a transient focal neurological deficit, consistent with a TIA. Initial investigation revealed a PFO with a 5 mm opening and a 10 mm tunnel. Subsequent imaging confirmed left popliteal deep vein thrombosis and right common and internal carotid artery obstruction, supporting a diagnosis of paradoxical embolism. During follow-up, the patient developed right ventricular (RV) dilation and hypokinesia, with an estimated pulmonary artery systolic pressure (PASP) of 60 mmHg.An initial chest CT angiography (CTA) was negative for acute pulmonary thromboembolism. However, subsequent chest CT findings showed chronic lesions suggestive of CPTE, leading to the clinical suspicion of chronic thromboembolic pulmonary hypertension (CTEPH). Based on this suspicion, percutaneous PFO closure was deferred, as the defect could serve as a necessary “pop-off” valve for the right ventricle. The patient remained on anticoagulation while awaiting definitive hemodynamic assessment. Right heart catheterization subsequently confirmed severe pre-capillary pulmonary hypertension, revealing a mean pulmonary artery pressure (mPAP) of 46 mmHg, a pulmonary capillary wedge pressure (PCWP) of 11 mmHg, and a pulmonary vascular resistance (PVR) of 5.4 Wood units. Pulmonary arteriography definitively identified bilateral chronic thromboembolic disease with occlusions, webs, and stenoses. The procedure also confirmed the PFO with an absence of a spontaneous shunt (Qp/Qs 1.02). Conclusions: This case highlights the importance of maintaining high clinical suspicion for CTEPH in PFO patients with unexplained RV dysfunction. The decision to postpone PFO closure, although it prolonged the risk of systemic embolism, was validated by the invasive confirmation of severe pulmonary hypertension. This chronological management underscores the necessity of a multidisciplinary approach and definitive hemodynamic stratification before considering structural interventions in complex embolic scenarios.

PHEOCHROMOCYTOMA-INDUCED TAKOTSUBO SYNDROME PRESENTING AS CARDIOGENIC SHOCK AND ST-ELEVATION MYOCARDIAL INFARCTION MIMIC: A CASE REPORT

VICTOR SORANZO VERDI[1]; MARIA LUIZA STANGHERLIN[1]; GUSTAVO SKONETZKY[1]; TIAGO VICTOR VENDRUSCULO[1]; ISADORA COMINETTI BIGOLIN[1]; FERNANDA VICTOR PUNGAN[1]; SOFIA MANN ZATTI[1]; LEONARDO ROSSNER WBATUBA[1]; ANTONELA FEDERLE OMIZZOLO[1]; LUIZA BARCELOS FABONATTO[1]; ITAMAR LUÍS GONÇALVES[1]; VITOR BONIATTI NEVES[2];

(1) UNIVERSIDADE REGIONAL INTEGRADA DO ALTO URUGUAI E DAS MISSÕES - URI / ERECHIM - ERECHIM - RS - BRASIL; (2) HOSPITAL SÃO LUCAS DA PUCRS - PORTO ALEGRE - RS - BRASIL;

Introduction: Takotsubo syndrome (TTS) is an acute stress-induced cardiomyopathy characterized by transient left ventricular dysfunction, often mimicking acute myocardial infarction. Pheochromocytoma is a rare catecholamine-secreting tumor and an uncommon trigger of TTS, frequently associated with severe clinical presentations, including cardiogenic shock. Case Description: A 60-year-old woman with long-standing refractory hypertension presented with acute dyspnea and hemodynamic instability. Initial electrocardiogram showed supraventricular tachycardia (Figure 1), successfully reverted with adenosine. Shortly thereafter, she developed cardiac arrest with pulseless electrical activity, requiring resuscitation and mechanical ventilation. Computed tomography angiography ruled out aortic dissection. During intensive care unit stay, she experienced recurrent cardiac arrest. A subsequent electrocardiogram demonstrated anterior ST-segment elevation, raising suspicion for acute myocardial infarction. However, coronary angiography revealed no obstructive coronary artery disease, with apical ballooning and a left ventricular ejection fraction of approximately 20%. Given the clinical context, secondary causes were investigated. Laboratory evaluation revealed markedly elevated metanephrine and normetanephrine levels (532 pg/mL and 3413 pg/mL, respectively). Follow-up echocardiography on day five showed rapid recovery of ventricular function (left ventricular ejection fraction >50%), consistent with Takotsubo syndrome. Conclusions: Pheochromocytoma-induced Takotsubo syndrome is a reversible yet life-threatening condition that may mimic ST-elevation myocardial infarction and cardiogenic shock. In patients with unexplained hemodynamic collapse and non-obstructive coronary arteries, catecholamine excess should be actively considered. Early recognition is essential to guide appropriate management and improve clinical outcomes.

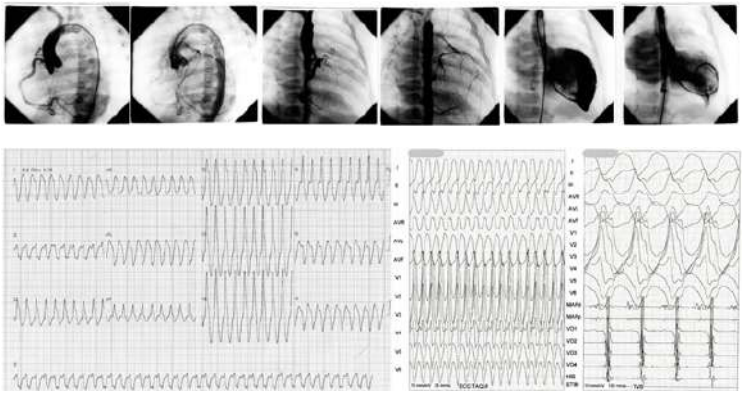
USE OF CONTRAST PERICARDIOGRAPHY IN SUPERIOR VENA CAVA PERFORATION: A CASE REPORT

FERNANDO VIEIRA BRANDALISE[1]; ARTHUR KLIPPEL TONET[2]; JOÃO HENRIQUE STRAPASSON[2]; MARINA VECINI TESSARI[2]; IÁDINE ANDREIS DE OLIVEIRA[2]; JOÃO BERNARDO FABRIS[2]; OTÁVIO REIS BOF[2]; CAROLINA FILIPPIS FOCHESATO[3]; RONALD PAULO PINTO ZART[2]; JORGE JERRY BUSTAMANTE BUSTAMANTE[4]; LETICIA CASTRO BECKER[4];

(1) CENTRO UNIVERSITARIO DA SERRA GAUCHA - CAXIAS DO SUL - RS - BRASIL; (2) CENTRO UNIVERSITÁRIO DA SERRA GAÚCHA - CAXIAS DO SUL - RS - BRASIL; (3) UNIVERSIDADE DE CAXIAS DO SUL - CAXIAS DO SUL - RS - BRASIL; (4) HOSPITAL VIRVI RAMOS - CAXIAS DO SUL - RS - BRASIL;

Introduction: A 52-year-old male, presented with Chronic Kidney Disease (CKD) in dialysis since September 2023, also presents with urethral obstruction secondary to colon neoplasm. In January 2024, a tunneled hemodialysis catheter (Permcath) was placed following the removal of a previous hemodialysis catheter. During insertion of the Permcath via the Right Subclavian Vein, a Superior Vena Cava (SVC) perforation occurred, leading to intra pericardial hemorrhage and cardiac tamponade. Subsequently, the patient developed severe hypotension (blood pressure 48/28 mmHg) and oxygen desaturation while still in the Intensive Care Unit (ICU). Given the clinical presentation, a norepinephrine infusion was initiated at 30 mL/h, in an attempt to achieve hemodynamic stabilization. The cardiovascular surgery team conducted a Contrast Pericardiography (CPCG) in the ICU, which revealed the Permcath in contact with the intrapericardial space, as well as hematic hyperdensities in the pericardium and mediastinum. This allowed for the localization of the SVC perforation and identified the communication between the Permcath and the water-seal chest tube that controlled the shock. Consequently, the patient was taken to the operating room for a Sternotomy to remove the Permcath and perform an SVC Venorrhaphy. Case Description: CPCG is an uncommon procedure, as it has been replaced by non-invasive methods such as Echocardiography and Computed Tomography (CT), due to risks associated with the puncture. However, it remains relevant in specific clinical scenarios that require a more detailed assessment of the pericardial cavity, as in the case described, being essential for a prompt diagnosis. The procedure involves the introduction of contrast into the pericardial cavity, which can be negative (pneumopericardiography, using air, carbon dioxide, or nitrous oxide) or positive (water-soluble iodinated contrast), followed by radiography. As demonstrated by Cohn et al., CPCG allows for the assessment of pericardial surfaces, identification of masses, effusions, adhesions and thickenings. In this case, positive pericardiography was used, enabling the precise identification of the Permcath's path and confirmation of the pericardial sac invasion. Conclusions: Contrast Pericardiography is a procedure that has fallen into disuse, yet it remains fundamental for diagnoses involving the pericardial cavity. The clinical presentation described emphasizes the current importance of this examination in ensuring early and accurate diagnosis.

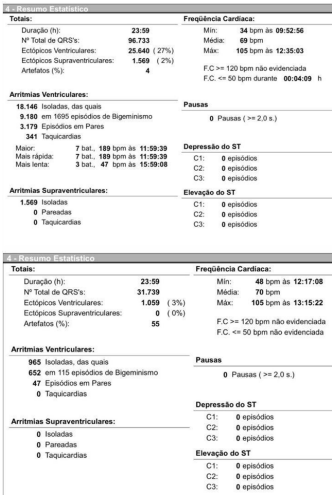


14766

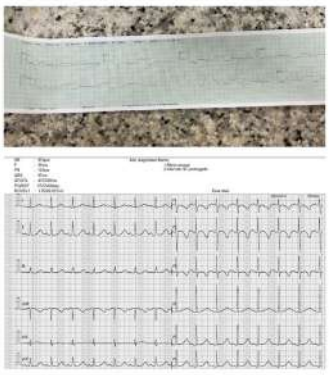
CASE REPORT OF BLAND-WHITE-GARLAND SYNDROME PROGRESSING TO VENTRICULAR TACHYCARDIA AND IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR (ICD) IMPLANTATION IN A YOUNG PATIENT

MARIANA OLIVEIRA GUIMARÃES[1]; VINÍCIUS MUNUTE DESIDÉRIO[2]; ANDRÉ MESSIAS GUIMARÃES[3];

(1) UNIVERSIDADE DE RIBEIRÃO PRETO- UNAERP - RIBEIRÃO PRETO - SP - BRASIL; (2) FACULDADE DE MEDICINA DE SÃO JOSÉ DO RIO PRETO- FAMERP - SÃO JOSÉ DO RIO PRETO - SP - BRASIL; (3) UNIVERSIDADE FEDERAL DO TRIANGULO MINEIRO - UBERABA - MG - BRASIL;



Introduction: Bland-White-Garland syndrome, a rare congenital heart disease characterized by anomalous origin of the left coronary artery (LCA) from the pulmonary trunk (PT). It results in hypoperfusion of the left chambers and myocardial ischemia. It has an incidence of 1:300,000 live births (0.5% of congenital heart diseases) and a mortality rate of 90%. This report highlights its association with significant late arrhythmic events. Case Description: Male, 4 months old, born in Sertãozinho-SP. Pregnancy and delivery without complications. Presented with crying and sweating during feeding, and physical exam revealed a cardiac murmur due to mitral regurgitation (MR). The electrocardiogram (ECG) during crying showed ST segment depression. Echocardiogram reported marked dilation of left chambers, moderate/severe MR and ejection fraction (EF) of 46%. Cardiac catheterization showed marked dilation of the left ventricle (LV), diffuse hypocontractility of the anterolateral wall, dilation of the right coronary artery and retrograde filling of the LCA originating from the PT. Scintigraphy showed fibrosis of the anterior LV wall. Surgical correction was performed with LCA translocation to the aorta. At 8 months, EF increased to 80%, confirming procedural success. The patient remained under cardiologic follow-up with preserved EF and no exercise-induced ischemia. At 16 years old, he presented palpitations, dizziness and dyspnea during boxing training. ECG showed monomorphic ventricular tachycardia (VT) with right bundle branch block morphology, reverted by electrical cardioversion. Etiological investigation with cardiac magnetic resonance showed thinning of the anterior apical wall, suggesting VT origin. Coronary CT angiography showed LCA anastomosis without stenosis. Electrophysiological study (EPS) induced VT by stimulation of the fibrotic area (pace mapping), confirming its origin. Ablation of the arrhythmogenic focus was attempted without success, and an implantable cardioverter-defibrillator (ICD) was indicated. The patient is currently 32 years old, with two events successfully reverted by the device. Conclusions: This case highlights the rarity of therapeutic success in Bland-White-Garland syndrome associated with late arrhythmic manifestations. It emphasizes the need for long-term clinical follow-up after surgical correction due to the risk of late arrhythmias. The report has informed consent, ensuring anonymity and confidentiality.



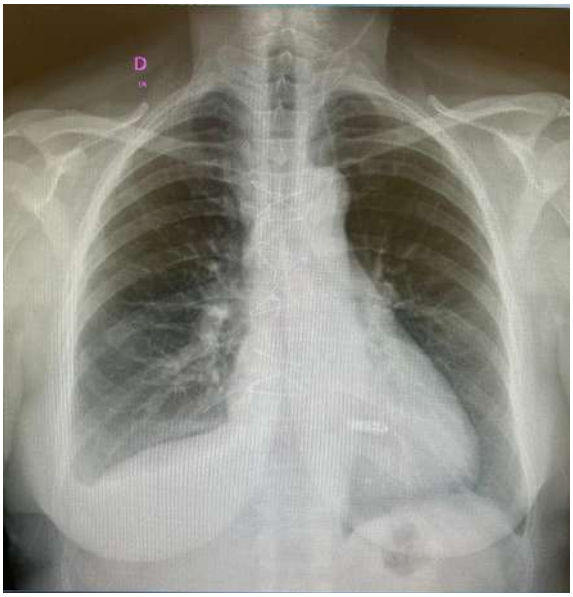
18986

CATHETER ABLATION OF LEFT VENTRICULAR SUMMIT PVC IN REFRACTORY ELECTRICAL STORM IN CONGENITAL LONG QT SYNDROME - A CASE REPORT

GUILHERME BORGES MORAIS[1]; BRUNA LISBOA VERGARA[1]; DANIELLE CAVALCANTE MONTEIRO[1]; ALBERT DICKSON FILHO[1]; JOSE HUMBERTO RODRIGUES JUNIOR[1]; JULIO CESAR SOUSA[1];

(1) UFRN - NATAL - RN - BRASIL;

Introduction: Long QT Syndrome (LQTS) is an inherited channelopathy characterized by QT interval prolongation and increased risk of malignant ventricular arrhythmias, particularly Torsades de Pointes (TdP), which may lead to syncope and sudden cardiac death. Standard therapy is based on beta-blockers (BB), with implantable cardioverter-defibrillator (ICD) in selected cases. However, some patients develop refractory TdP, progressing to electrical storm. In this context, additional strategies such as cardiac sympathetic denervation and catheter ablation of triggering premature ventricular complexes (PVCs) may be required. Case Description: We report the case of a previously healthy 9-year-old male who experienced syncopal episode without prodromes in April 2025 after emotional stress. In November 2025, he was found unconscious with myoclonic movements. At an emergency unit, he was diagnosed with cardiac arrest in polymorphic ventricular tachycardia consistent with TdP, reverted after chest compressions and six defibrillation shocks. He was admitted the following day. Admission electrocardiogram showed corrected QT interval (QTc) of 650 ms, suggestive of LQTS type 1. Transthoracic echocardiography revealed left ventricular ejection fraction of 42%. The patient continued to have multiple daily self-terminating TdP episodes despite high-dose propranolol (5 mg/kg). A temporary pacemaker was implanted without success. Due to refractory arrhythmia, right stellate ganglion block followed by bilateral thoracic sympathectomy was performed, with partial reduction of events. A 24-hour Holter revealed more than 25,000 polymorphic PVCs and frequent TdP episodes up to seven beats, with repetitive triggering pattern. The patient underwent electrophysiological study, which identified PVC originating from the left ventricular summit, successfully treated with radiofrequency catheter ablation. Post-ablation Holter monitoring demonstrated significant reduction in PVC burden (1,059 beats) and no further TdP episodes. Cardiac magnetic resonance imaging showed no structural heart disease. The patient subsequently underwent subcutaneous ICD implantation for secondary prevention and was discharged on beta-blocker therapy and magnesium supplementation. During follow-up, QTc decreased to 520 ms, and genetic testing is pending. Conclusions: This case highlights challenges of managing electrical storm in congenital LQTS. Favorable response to catheter ablation of triggering PVCs underscores its potential role in refractory cases.



19274

RECURRENT PACEMAKER POCKET INFECTIONS MANAGED WITH LEADLESS PACEMAKER IMPLANTATION: A CASE REPORT

PEDRO NUNES HUMMES[1]; BERNARDO ROMAGNA BERTO[1]; ARTHUR MENEZES SCHMITZ[1]; ARTHUR LEIRIA MÜLLER[1]; LORENZO MAGNUS SOTILLE[1]; GABRIEL SILVA SARKIS[1]; ISABELA GIACOMINI SAUERESSIG[1]; THIAGO BONATTO ARLAQUE[1]; LAURA ROSSI DE CASTRO[1]; ANA CAROLINA ZAFFARI VITORELLO[1]; DANIELA GALON CARNIEL[1]; MATHEUS DE AZEVEDO LÜDTKE[1];

(1) PUCRS - PORTO ALEGRE - RS - BRASIL;

Introduction: Pacemaker (PM)-related infection is an uncommon complication (0.8–5.7%), but remains a significant clinical challenge, due to its association with increased morbidity, repeated hospitalizations, and healthcare costs. The most common source of infection is perioperative contamination by skin-colonizing bacteria. Despite adherence to guideline recommendations, including complete device removal and appropriate antimicrobial therapy, conventional transvenous systems may still carry a risk of recurrent infection, particularly in patients with a history of prior device infection. In this context, leadless pacemakers have emerged as an important alternative, as they eliminate the need for a subcutaneous pocket and transvenous leads, thereby reducing potential sites for bacterial colonization. Consequently, leadless systems may be considered in patients at high risk of reinfection, especially those with recurrent PM infections. Case Description: A 63-year-old female patient with second-degree atrioventricular block (Mobitz II) underwent pacemaker implantation in January 2023. In January 2024, she was admitted with a pacemaker pocket infection; the generator and all transvenous leads were removed, and, after appropriate antimicrobial therapy, a new pacemaker was implanted on the contralateral side. In April 2024, she returned with inflammatory signs at the initial pocket site, requiring surgical debridement. Culture results were positive for Staphylococcus warneri. In March 2025, she was readmitted with swelling at the current pacemaker pocket, which had been evolving over the previous 15 days, without fever or other systemic symptoms. Ultrasound examination revealed a fluid collection of approximately 20 mL in the generator region. Further evaluation with 18F-FDG PET/CT demonstrated hypermetabolic activity within the collection, extending along the leads up to their insertion near the subclavian vein, confirming the diagnosis of pacemaker system infection. Drainage was performed, yielding purulent material. Given the history of recurrent infections involving multiple sites, implantation of a leadless pacemaker was indicated. Conclusions: This case underscores that, in patients with recurrent PM infections, conventional reimplantation strategies may be insufficient. Early consideration of leadless pacing systems should be part of the therapeutic decision-making process, particularly in those at high risk for reinfection.

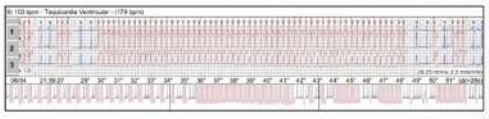
TRAUMATIC TOTAL ATRIOVENTRICULAR BLOCK IN THE EMERGENCY DEPARTMENT: THE IMPORTANCE OF EXPECTANT MANAGEMENT GIVEN ITS TRANSITORY NATURE

CAIO MOREIRA SALGUEIRO[1]; NATHÁLIA SALIM SAUD[1]; NOEMI ROCÍO ANDRADE ALBAN[2]; LEONARDO ANDRADE CACERES[2]; CARLOS DANIEL LUCIO LÓPEZ[2]; ANTHONY JOSUÉ LUCIO LÓPEZ[2]; ARIEL IVAN MENA AMALUIZA[2]; WOLNEY DE ANDRADE MARTINS[1]; MARCOS MERULA DE ALMEIDA[1];

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (2) UNIVERSIDADE TECNICA DE AMBATO - ECUADOR;



Introduction: Total atrioventricular block (TAVB) resulting from blunt chest trauma is a rare manifestation of myocardial contusion. In motor vehicle accidents involving sudden deceleration, the conduction system may suffer direct injury. The clinical challenge lies in differentiating the need for definitive intervention from spontaneous functional recovery, thereby avoiding unnecessary invasive procedures in patients who are frequently young. Case Description: A 28-year-old male was admitted to the emergency department following a high-energy frontal collision. He was hemodynamically stable, complaining of mild retrosternal pain. The initial ECG revealed TAVB with a junctional escape rhythm, narrow QRS complex, and a heart rate of 38 bpm. Myocardial necrosis markers (Troponin I) showed a slight elevation. The echocardiogram ruled out ventricular dysfunction or acute valvular lesions. The clinical team opted for continuous monitoring in the coronary care unit with bedside transcutaneous pacemaker support (on standby). After 48 hours of observation and hemodynamic stability, the patient experienced spontaneous reversal to sinus rhythm, with 1:1 AV conduction and a normal PR interval. He was discharged without sequelae after 5 days. Conclusions: Discussion: The pathophysiology of traumatic TAVB involves edema, hematoma, or hemorrhage in the AV node or the Bundle of His. Literature emphasizes the transient and benign nature of these cases, with most reverting within 7 days as the inflammatory process resolves. According to SBC, ESC, and AHA/ACC guidelines, conduction disorders associated with potentially reversible causes (such as acute trauma) require expectant management. Permanent pacemaker implantation should only be considered after an observation period of 5 to 7 days if there is no recovery of the conduction system. The priority in the acute phase is rigorous monitoring of rhythm and hemodynamic status, reserving artificial pacing only for symptomatic or unstable cases. Conclusion: Post-traumatic TAVB is frequently reversible. Recognizing its transitory nature and adhering to guideline-recommended timelines for definitive pacing are crucial for safe and conservative management, prioritizing active surveillance over early intervention.

ANTHRACYCLINE CARDIOTOXICITY MIMICKING ARRHYTHMOGENIC CARDIOMYOPATHY: A CASE REPORT

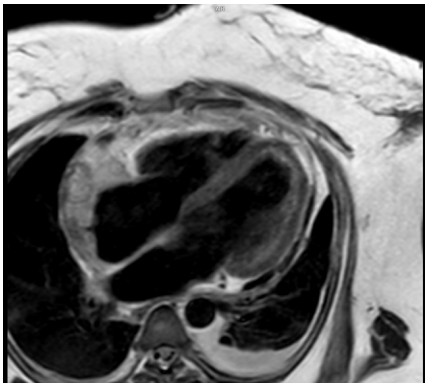
ISABELLA FRANÇA OLIVEIRA AVILA[1]; ANA JÚLIA CAMPOS QUEIROZ[1]; MIGUEL BIZINOTTO CORREA XAVIER[1]; FELIPE SOUTO GONÇALVES LIMA[1]; ISABELI AMORIM OFUGI[1]; PABLO SOUZA LINHARES[1];

(1) UNIVERSIDADE DE UBERABA - UBERABA - MG - BRASIL;

Holter tracing demonstrating sustained monomorphic ventricular tachycardia

Variable	Initial Holter	Post-treatment Holter
Mean heart rate	94 bpm	Bradycardic tendency
Supraventricular ectopy	512 isolated SVEs	Rare isolated SVEs
Ventricular ectopy	84,974 monomorphic PVCs	Absent
Ventricular tachycardia	13,210 episodes	Absent
Non-sustained VT	Present	Absent
Supraventricular tachycardia	1 episode	4 episodes
Maximum heart rate	167 bpm	120 bpm
QTc interval	Within normal range	Prolonged (479 ms)

Comparison of Holter Findings Before and After Treatment



Introduction: Anthracyclines remain among the main chemotherapeutic agents used in solid and hematologic malignancies; however, they are associated with significant cardiotoxic potential. Anthracycline-induced myocardial injury may range from subclinical ventricular dysfunction to heart failure and severe cardiovascular events. Diagnosis may be particularly challenging in predominantly electrical presentations, since electrocardiographic abnormalities can precede ventricular dysfunction detectable by conventional imaging modalities. Case Description: A 69-year-old woman with no previous cardiovascular disease was referred for preoperative cardiologic evaluation after completing 12 cycles of doxorubicin-based chemotherapy for malignancy treatment. She remained asymptomatic from a cardiovascular standpoint. Transthoracic echocardiography demonstrated preserved left ventricular ejection fraction (56%), grade I diastolic dysfunction, moderate left atrial enlargement, and mild aortic regurgitation, without significant structural abnormalities. Coronary angiography showed no obstructive coronary lesions. Twenty-four-hour Holter monitoring revealed ectopic atrial rhythm, mean heart rate of 94 bpm, 512 isolated supraventricular ectopic beats, a high burden of monomorphic ventricular ectopy (84,974 premature ventricular contractions), and one episode of non-sustained ventricular tachycardia lasting three beats. Amiodarone 200 mg every 8 hours was initiated for seven days. Repeated Holter monitoring demonstrated complete suppression of ventricular ectopy, heart rate tendency toward bradycardia, rare isolated supraventricular ectopy, four episodes of supraventricular tachycardia with maximum heart rate of 120 bpm, and QTc prolongation (mean 479 ms). After exclusion of coronary artery disease and structural cardiomyopathies, anthracycline-induced cardiotoxicity with predominantly arrhythmogenic presentation was considered the most likely diagnosis. The patient remains asymptomatic during outpatient follow-up. Conclusions: This case highlights an atypical presentation of anthracycline cardiotoxicity characterized by severe ventricular arrhythmias despite preserved ventricular function, mimicking arrhythmogenic cardiomyopathy. Early recognition of predominantly electrical manifestations enabled appropriate treatment and complete arrhythmia control, reinforcing the importance of electrocardiographic surveillance in patients exposed to anthracyclines, even with preserved left ventricular ejection fraction.

DIFFERENTIAL DIAGNOSIS OF PERICARDIAL EFFUSION IN A YOUNG PATIENT: PRIMARY CARDIAC EPITHELIOID ANGIOSARCOMA MIMICKING TUBERCULOUS PERICARDITIS

MARIA ISABELLE SOUZA VIEIRA DE MELO[1]; ANA AMÉLIA OLIVEIRA GARCEZ VIEIRA[2]; ANA JÚLIA MATOS DE ANDRADE[1]; MARIA LUÍSA DIAS FONTES[1]; RENATA REIS SOBRAL[1]; ROBERTO CINTRA DE AZEVEDO ARAGÃO[3]; ERYCA VANESSA SANTOS DE JESUS[3]; WILSON OLIVEIRA FELIX[3]; MARÍLIA PRUDENTE MENEZES[3];

(1) UNIVERSIDADE TIRADENTES (UNIT) - ARACAJU - SE - BRASIL; (2) CENTRO UNIVERSITARIO UNIDOMPEDRO - SALVADOR - BA - BRASIL; (3) HOSPITAL SAO LUCAS - ARACAJU - SE - BRASIL;

Introduction: Pericardial effusion (PE) consists of fluid accumulation between the visceral and parietal pericardium. In Western nations, the most common etiology is acute idiopathic or viral pericarditis, whereas in developing countries tuberculosis (TB) accounts for more than 70% of the cases. Primary cardiac neoplasms are rare causes of PE, representing 0.001% to 0.007% of cases. Among these, angiosarcoma stands out as the most aggressive and fatal malignant cardiac neoplasm, with infiltrative characteristics and early metastases, which makes its diagnosis and treatment challenging in clinical practice. Case Description: Female patient, 33 years old, no comorbidities, admitted with dyspnea and chest pain for 9 days. Admission echocardiogram demonstrated significant diffuse PE (up to 39 mm), with incipient signs of hemodynamic repercussion (plethoric vena cava and mild right ventricular diastolic collapse), and preserved biventricular systolic function. She was submitted to pericardiocentesis, whose pericardial fluid analysis indicated an exudate (pH 8, proteins 7g/dL, glucose 25mg/dL, leukocytes 4,980 [67% lymphocytes], RBCs 2,296,000). Serologies and autoimmune panel were normal; rapid molecular test for TB in the fluid was positive (traces), initiating the RIPE regimen. Cardiac magnetic resonance imaging evidenced diffuse pericardial thickening and an irregular nodular formation adjacent to the visceral pericardium in the right atrium topography, with peripheral enhancement and intermediate T2 signal, corresponding to organized pericardial hematoma or neoplastic involvement. The primary oncological screening was negative. With hemodynamic worsening, surgery was indicated for hemorrhagic PE drainage, partial tumor resection and patch placement (on direct inspection: tumor invading the right atrium and right ventricular outflow tract). Anatomopathological examination confirmed primary cardiac epithelioid angiosarcoma. The RIPE regimen was suspended and chemotherapy initiated, with clinical improvement and hospital discharge. Conclusions: Pericardial effusion has a wide range of etiologies with frequently overlapping clinical presentations. Among the possibilities, angiosarcoma stands out, a rare primary cardiac neoplasm of high lethality if not addressed early. Thus, an assertive and comprehensive diagnostic investigation regarding differential diagnoses is fundamental, especially in the young population, aiming to change the natural history of the disease and achieve a more favorable prognosis.

15807

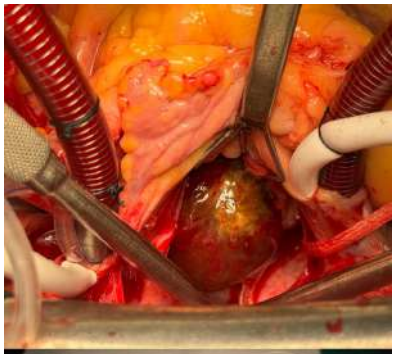
HYPERTENSIVE-ENDOTHELIAL ENCEPHALOPATHY IN PEDIATRIC ACUTE MYELOID LEUKEMIA: TOXIC-METABOLIC BRAIN INJURY AS A CARDIOVASCULAR EMERGENCY — A CARDIO-ONCOLOGY CASE REPORT

FABIO GUIMARAES SILVEIRA[1]; KELLY LYRA PAIVA[2];

(1) UNIVERSIDADE SALGADO DE OLIVEIRA - SAO GONCALO - RJ - BRASIL; (2) HOSPITAL DA CRIANÇA PRONTOBABY - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Chemotherapy-induced toxic-metabolic encephalopathy represents a cardiovascular emergency when triggered by the convergence of endothelial injury, acute arterial hypertension, and severe electrolyte disturbances. In pediatric oncohematology, intensive chemotherapy establishes a pathogenic substrate through direct vascular toxicity and systemic inflammatory activation. High-dose cytarabine induces cerebral endothelial dysfunction and disrupts cerebrovascular autoregulation. Hypertension occurs in 59% of children during induction chemotherapy, while electrolyte disturbances amplify cardiovascular risk. These overlapping mechanisms produce acute neurological deterioration that requires urgent cardiovascular management. The syndrome shares pathophysiological features with posterior reversible encephalopathy syndrome but may present with atypical imaging findings. Case Description: A 13-year-old male with high-risk hyperleukocytic myelomonocytic acute myeloid leukemia developed progressive neurological deterioration following high-dose cytarabine chemotherapy: tonic-clonic seizure, transient aphasia, bilateral visual loss, vertical nystagmus, papilledema, and pre-macular hemorrhage. Arterial hypertension was documented alongside simultaneous hyponatremia, hypokalemia, and hypomagnesemia. Cranial computed tomography was unremarkable on two occasions. Brain magnetic resonance imaging demonstrated diffuse signal abnormalities in bilateral nucleocapsular regions with restricted diffusion, consistent with toxic metabolic encephalopathy. Early cardiovascular management was implemented as the primary therapeutic strategy: gradual blood pressure reduction with angiotensin- converting enzyme inhibitor targeting 10-15% mean arterial pressure decrease within 24 hours, dual antiepileptic therapy, and aggressive intravenous electrolyte replacement for three concurrent disturbances. Continuous electroencephalography confirmed absence of epileptiform activity. At four weeks, complete visual recovery, aphasia resolution, marked nystagmus reduction, and serial electroencephalography normalization were achieved with complete hematological recovery. Conclusions: Toxic-metabolic encephalopathy is a cardiovascular emergency in pediatric oncology. The substrate is cardiovascular: autoregulation failure, hypertension, endothelial injury, and electrolyte disturbances. Blood pressure and electrolyte monitoring are essential. Cardiovascular management determines outcome.

19412



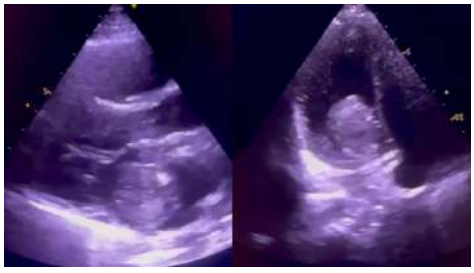
LEFT ATRIAL MYXOMA ASSOCIATED WITH A CORONARY FISTULA ARISING FROM AN ATRIAL BRANCH OF THE CIRCUMFLEX ARTERY AND THE POSTERIOR VENTRICULAR CORONARY ARTERY: A CASE REPORT

DAVID EVANGELISTA BARROS DE OLIVEIRA[1]; NICOLE AIRES PERAZOLO[2]; ISADORA MÔNICA PONTE DE OLIVEIRA[1]; DENYSE DE OLIVEIRA MORAES SAUNDERS[1]; MARIANNE MENDES PINTO[1]; MARIA EDUARDA BORGES LINHARES[3]; BIANCA ARAGÃO DE OLIVEIRA[4]; VITOR TEIXEIRA BOSCOV[1]; CARLOS GUSTAVO ALVES LEITÃO[1]; JULIA ALENCAR MENDONÇA PIMENTA FREITAS[2]; ADRIANO SIQUEIRA DOS SANTOS[5]; FRANCISCO DANIEL DE SOUSA[5];

(1) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (3) UNIVERSIDADE CHRISTUS - FORATLEZA - CE - BRASIL; (4) UNICHRISTUS - FORTALEZA - CE - BRASIL; (5) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introduction: Myxoma is the most common benign primary cardiac tumor, although rare, with a predilection for the left atrium. Its clinical presentation is heterogeneous and may include constitutional symptoms, embolic phenomena, and intracardiac obstruction. Tumor neovascularization with arteriocavitary fistulas is an angiographic finding present in 33% of cases, with the left circumflex artery frequently described as the feeding vessel. However, involvement of the posterior coronary artery is uncommon and of relevant anatomical and clinical interest. Case Description: A 64-year-old woman with a history of systemic arterial hypertension, insulin-treated diabetes mellitus, and dyslipidemia was admitted after recurrent episodes of constrictive chest pain and dyspnea at rest, lasting 10 to 20 minutes, over approximately one month. Transthoracic echocardiography demonstrated a mobile nodular mass attached to the interatrial septum in the left atrium, measuring 5.6 × 2.7 cm, suggestive of myxoma. A repeat echocardiogram confirmed preserved left ventricular ejection fraction, mild chamber remodeling, and an intracavitary left atrial structure protruding through the mitral valve, with a mean transmitral gradient of 5 mmHg, consistent with functional obstructive hemodynamic impact. Coronary angiography showed no significant obstructive coronary lesions; however, it demonstrated a coronary fistula arising from an atrial branch of the circumflex artery and from the posterior ventricular coronary artery supplying the atrial mass, characterizing tumor vascularization. The patient underwent surgical resection of the left atrial myxoma combined with ligation of the coronary fistula, with good postoperative recovery. Conclusions: This case demonstrates an uncommon presentation of left atrial myxoma due to tumor vascularization through a coronary fistula, without concomitant obstructive coronary artery disease. Echocardiography was essential for the initial diagnosis and for demonstrating the hemodynamic impact, whereas coronary angiography provided important anatomical definition for surgical planning. Surgical treatment was effective, with a favorable postoperative outcome.

21042



PRIMARY CARDIAC OSTEOSARCOMA WITH CEREBRAL METASTASIS AND RECURRENCES IN AN ADOLESCENT: A CASE REPORT

MATHEUS ANDRÉ LOBO[1]; JULIA WESGUEBER FELIX[2]; BIANCA SILVEIRA ABREU[3]; LINA ALESSANDRA MIURA[3]; MARIA COSTA SERFATY[3]; ROMULO GUIMARÃES ALMEIDA[3]; FABRICIO CARON[3]; MARITZA XAVIER ANZANELLO[3]; GUSTAVO RODRIGUES[3]; ROBERTO MAX LOPES[3]; DEBORAH FERREIRA[3]; DENOEL MARCELINO OLIVEIRA[3];

(1) UNIVERSIDADE UNIGRANRIO AFYA - RIO DE JANEIRO - RJ - BRASIL; (2) IDOMED/ESTACIO - RIO DE JANEIRO - RJ - BRASIL; (3) HOSPITAL UNIMED FERJ - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Primary cardiac tumors are uncommon, they can be benign (75%) or malignant (25%). Malignant cardiac neoplasms are rare, aggressive, infiltrative, and highly metastatic. Primary cardiac osteosarcoma is a rarer subtype of cardiac sarcomas, representing 3–9% of cases, and has a poor prognosis. Cerebral metastases and remission-recurrence dynamics in young patients pose significant clinical challenges. This case describes a rare, complex evolution, emphasizing vigilance and a multidisciplinary approach. Case Description: A 14-year-old male, previously healthy. He presented with prolonged cough, progressing to respiratory discomfort and ICU admission for extensive pneumonia and pleural effusion. Echocardiogram revealed a voluminous left atrial mass mobilizing into the left ventricle, which we thought was a myxoma. He underwent left atrial tumor resection, posterior mitral annuloplasty, mitral cleft closure, and thymectomy on April 23, 2025 (105 min cardiopulmonary bypass, 95 min circulatory arrest). Cranial tomography showed ischemic areas without neurological manifestations, and he was discharged 8 days post-admission. Immunohistochemistry confirmed high-grade osteoblastic osteosarcoma with smooth muscle differentiation (SATB2+, Desmin D33+, high Ki-67). Post-discharge,hospitalizations were limited to chemotherapy and for oncological examinations. Methotrexate and leucovorin were used in July 2025. In September, doxorubicin and cisplatin were administered, associated with ondansetron, carvedilol, and furosemide for symptom relief. Subsequently, 8 cycles of etoposide and ifosfamide were performed, associated with mesna, ondansetron, dexamethasone, furosemide, and carvedilol.Initial complete remission was followed by cardiac recurrence and a 0.8 cm frontal cerebral metastasis, plus ischemic lacunar infarcts, after three months. Subsequent radio and chemotherapy achieved another remission. One year post-surgery, he experienced a convulsive episode, recovering without sequelae, leading to hospital monitoring and therapeutic adjustment. Conclusions: This case illustrates the highly aggressive nature of primary cardiac osteosarcoma, with cerebral metastasis, ischemic events, and recurrence-remission patterns despite intensive treatment. A late convulsive crisis reinforces the need for rigorous neurological follow-up. Complex management requires an individualized, continuous therapeutic strategy to optimize treatment and patient quality of life.

18268

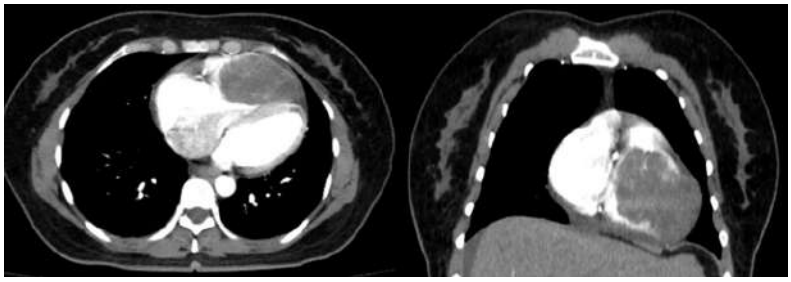
RIGHT-SIDED HEART FAILURE DUE TO PULMONARY HYPERTENSION ASSOCIATED WITH METASTATIC PANCREATIC NEUROENDOCRINE NEOPLASM: A CASE REPORT

LAURA FORTES RUHLING[1]; RENATO ASSMANN MACCARI[1]; JULIA POHREN REIS[1]; VALENTINA NICOLINI CASTRO[1]; LAHRA MUNIZ COUTO DE BRAGA[1]; CATARINA HAUSER SCHMITZ[1]; JULIA REI PIRES[2]; ARTHUR INEU FIGUEIREDO[1]; GUSTAVO CHATKIN[1];

(1) PUCRS - PORTO ALEGRE - RS - BRASIL; (2) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction: Right heart failure can result from multiple etiologies, with pulmonary hypertension being a relevant cause. Identifying etiology is essential for therapeutic definition. The association with malignant neoplasms is rare and represents a diagnostic challenge. We report a case of right heart failure attributed to pulmonary hypertension associated with metastatic pancreatic neuroendocrine neoplasia. Case Description: A 37-year-old male patient presented to the emergency department after developing dyspnea on effort, fatigue, weight loss and ascites. Regarding his past medical history, he had been diagnosed with hypertension at age 35, denied smoking and alcohol consumption. He presented with pulmonary hypertension (PASP 77 mmHg and pulmonary artery trunk with a 3.7 cm caliber) with dilation of the right chambers and right ventricular systolic dysfunction on echocardiography, in addition to elevated NT-proBNP. Right heart catheterization was performed, which showed pre-capillary hypertension. Investigation revealed multiple liver metastases and a mass in the head of the pancreas, confirming metastatic pancreatic neuroendocrine neoplasia. It is worth pointing out that the 24-hour urinary 5-HIAA level was normal in two measurements and there was no right valvular heart disease, ruling out classic carcinoid syndrome. The right heart failure was attributed to pulmonary hypertension associated with the neoplasm, possibly through microvascular mechanisms, after excluding other causes, including Budd-Chiari syndrome and liver cirrhosis (portopulmonary hypertension). The patient's right heart failure improved clinically after oncological treatment. Conclusions: This case stands out due to the multidisciplinary approach involved in a situation of oncological symptomatology that began with cardiopulmonary manifestations, products of right heart failure caused by pulmonary hypertension. Possible mechanisms explaining the association between cancer and the condition include carcinoid heart disease and pulmonary tumor thrombotic microangiopathy. Metastatic pancreatic neuroendocrine neoplasia is a rare malignant neoplasm, representing less than 5% of pancreatic tumors. The late onset of symptoms can also lead to late diagnosis of the disease. It is important to consider neoplasms as causes of pulmonary hypertension and heart failure when the pathophysiological origin is not elucidated.

19636



SUPRAVENTRICULAR TACHYCARDIA AS THE INITIAL PRESENTATION OF A PRIMARY RIGHT VENTRICULAR CARDIAC SARCOMA: A CASE REPORT

BRUNO ALBERTO MENDOZA-NIETO[1]; JOSÉ ANTONIO CITALÁN-JIMÉNEZ[2];

(1) HOSPITAL SAO LUCAS - MEXICO; (2) HOS - MEXICO;

Introduction: Primary cardiac sarcomas are rare malignant tumours whose presentation depends mainly on location and haemodynamic impact. Right-sided masses are diagnostically challenging and often require multimodality imaging. We report a young woman whose first manifestation was new-onset supraventricular tachycardia. Case Description: A 38-year-old woman with no prior structural heart disease presented with progressive exertional dyspnoea, palpitations, and diaphoresis. Electrocardiography showed regular narrow-complex supraventricular tachycardia at 166 b.p.m. without haemodynamic instability. Sinus rhythm was restored with adenosine and amiodarone. Because symptoms persisted, transthoracic echocardiography was performed and revealed a large infiltrative right ventricular mass causing right ventricular outflow tract obstruction, severe tricuspid regurgitation, right-sided chamber dilatation, and right ventricular systolic dysfunction. Contrast-enhanced computed tomography demonstrated a 50 × 74 mm right ventricular mass with enhancement and small pericardial effusion. Cardiac magnetic resonance confirmed a 61 × 39 × 52 mm heterogeneous mass attached to the apical anterior right ventricular wall, with loss of interface with adjacent structures, severe outflow obstruction, severe tricuspid regurgitation, right ventricular ejection fraction of 25%, and mild pericardial effusion. Endomyocardial biopsy demonstrated a low-grade primary intracardiac sarcoma. After multidisciplinary discussion, the patient was referred for oncological care and systemic chemotherapy with doxorubicin. Conclusions: New-onset supraventricular tachycardia may be the first sign of a major structural cardiac lesion, including primary cardiac sarcoma. In patients with new supraventricular arrhythmia and progressive dyspnoea, structural heart disease should be actively investigated. Multimodality imaging is essential, but histopathological confirmation remains required for definitive diagnosis.

“DRY” CONSTRICTIVE PERICARDITIS: AN UNUSUAL PRESENTATION OF METASTATIC INVASIVE LOBULAR BREAST CARCINOMA

GIOVANA AJNHORN MATTIELLO[1]; ISABELA CARVALHAL[1]; SOFIA PICARELLI DANZMANN[1]; JOÃO FELIPE FOSCARIN PEDROSO BASEGGIO[2]; ANDRÉ FAY[2]; LUIS FELIPE SILVA SMIDT[2]; PRISCILA SILVA[2];

(1) PUCRS - PORTO ALEGRE - RS - BRASIL; (2) UFCSPA - PORTO ALEGRE - RS - BRASIL;

Introduction: Pericardial involvement occurs in 5-15% of advanced malignancies, typically presenting as effusion. Invasive lobular carcinoma (ILC) is distinguished by its unique metastatic tropism to atypical sites; however, pericardial metastasis from ILC presenting as diffuse infiltrative pericardial thickening with constrictive physiology without significant effusion is an exceptionally rare and diagnostically challenging manifestation. Case Description: A female patient diagnosed with invasive lobular breast carcinoma (ER+, PR+, HER2 2+/3+) presented ten years later systemic recurrence. PET-CT revealed an extensive soft tissue mass in the left flank, multiple osseous metastases with fracture risk, and left pleural effusion. Biopsy confirmed metastatic lobular carcinoma (HR+, HER2 1+, Ki-67 25%), and first-line treatment with ribociclib and fulvestrant was initiated, achieving metabolic response in bone and soft tissue lesions. However, the patient developed progressive dyspnea; transthoracic echocardiography demonstrated no pericardial effusion but rather diffuse pericardial thickening with signs of restrictive ventricular filling, predominantly affecting the right ventricle, along with significant inferior vena cava dilatation. Cardiac magnetic resonance imaging confirmed marked infiltrative thickening of the pericardial layers (up to 1.9 cm adjacent to the right ventricular lateral wall), restrictive diastolic physiology with interventricular septal flattening, and right ventricular lateral and inferior wall hypokinesis. The patient underwent left video-assisted thoracoscopic pleuroscopy with talc pleurodesis and pericardial and pleural biopsy, which confirmed metastatic lobular breast carcinoma in the pericardium (ER−, PR−, HER2−). Progressive clinical deterioration followed, characterized by overt right-sided heart failure, marked by jugular venous distension, peripheral edema, and congestive hepatopathy, confirming the hemodynamics of rigid constrictive pericarditis. Diuretic therapy with furosemide was initiated with good clinical response. Treatment was transitioned to carboplatin-based chemotherapy with favorable initial response. Conclusions: This case illustrates an atypical presentation of malignant pericardial disease. Notably, the receptor discordance between the primary tumor and the pericardial metastasis further highlights the biological complexity of ILC, underscoring the importance of multimodal cardiac imaging and immunohistochemical reassessment in guiding treatment decisions.

ARRHYTHMOGENIC CARDIOMYOPATHY RELATED TO A PATHOGENIC VARIANT OF DSG2 WITH "MYOCARDITIS-LIKE" PRESENTATION: DIAGNOSTIC AND THERAPEUTIC CHALLENGES

CAMILE RAMOS RIBEIRO[1]; PEDRO BÚRIGO COSTA[2]; LUANA RIBEIRO MORAES[2]; LUIZ GUSTAVO SOUZA CARDOZO[2]; ISABELA BARBOSA MACHADO[1]; GUILHERME GABRIEL MARTINI[1]; LUANA DANCONA BACKER[1]; RONALDO LAITART[1]; GABRIELA DA ROSA RIBEIRO[1]; LUIZA MEDEIROS NUNES[1]; MANUELA MENEGOTTO WERDINE SALOMON[1]; GUSTAVO HENRIQUE BREGAGNOLLO[3];

(1) UNIVERSIDADE DO SUL DE SANTA CATARINA - PALHOÇA - SC - BRASIL; (2) HOSPITAL SOS CÁRDIO - FLORIANÓPOLIS - SC - BRASIL; (3) INSTITUTO DE CARDIOLOGIA DE SANTA CATARINA - FLORIANÓPOLIS - SC - BRASIL;

Introduction: Arrhythmogenic cardiomyopathy (ACM) is a genetic disease defined by fibrofatty replacement of the myocardium and an increased risk of ventricular arrhythmias and sudden death. Variants in desmosomal genes, including DSG2, are associated with heterogeneous phenotypes and inflammatory episodes referred to as "myocarditis-like." These episodes present with chest pain and elevated troponin levels in the absence of coronary artery disease, representing a significant diagnostic challenge and a potential marker of disease progression. Case Description: A 22-year-old female presented to the emergency with chest pain radiating to the jaw and left upper limb. She reported an episode of syncope following orthostatism three days prior to hospitalization. Since then, she had experienced recurrent dizziness, especially with postural exertion. She has a positive family history for arrhythmogenic cardiomyopathy, with a brother who has presented myocarditis-like episodes and angina. On admission, laboratory tests showed elevated troponin with dynamic pattern, peaking at 12,000. The electrocardiogram revealed sinus rhythm, heart rate of 72 bpm, and T-wave inversion from V1 to V4. The patient was admitted to the intensive care unit, with significant improvement in angina following nitrate administration, although the dizziness persisted. Holter monitoring revealed 2% ventricular extrasystoles and 4 paired episodes. Cardiac magnetic resonance imaging was consistent with biventricular perimyocarditis. Prior genetic testing (2022) identified a pathogenic DSG2 variant, strongly associated with the arrhythmogenic disease. Thus, the main diagnostic hypothesis was a myocarditis-like flare secondary to biventricular arrhythmogenic cardiomyopathy with vasospastic angina. Pulse therapy and corticosteroid treatment were initiated, along with calcium channel blockers and nitrates. The patient showed clinical improvement and declining troponin levels, reaching 50 ng/mL (reference value <57), at the time of discharge. Conclusions: DSG2-related arrhythmogenic cardiomyopathy poses a diagnostic challenge due to its phenotypic variability. Early genetic testing is essential for diagnosis, risk stratification, and targeted therapy, especially to prevent heart failure and ventricular arrhythmias. In a myocarditis-like presentation, which may reflect an inflammatory phenotype associated with disease progression, immunosuppression emerges as a potentially outcome-modifying strategy.

21458

CARVAJAL SYNDROME DUE TO DESMOPLAKIN CARDIOMYOPATHY IN A FAMILY DIAGNOSED THROUGH CASCADE GENETIC SCREENING

MARCELA VASCONCELOS MONTENEGRO[1]; NATÁLIA QUINTELLA SANGIORGI OLIVETTI[2]; MARIA ELISA LUCENA SALES DE MELO ASSUNÇÃO[3]; TAYNE FERNANDA LEMOS DA SILVA[4]; LUCIANA SACILOTTO[2]; BIANCA DOMIT WERNER LINNENKAMP[2]; SARA RODRIGUES CORDEIRO DA SILVA[3]; GIOVANNA NAPOLITANO PEREIRA RIBEIRO[2]; DIOGO COUTINHO SUASSUNA[3]; AFONSO LUIZ TAVARES DE ALBUQUERQUE[3]; JOSÉ EDUARDO KRIEGER[2]; SILVIA MARINHO MARTINS[3];

(1) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (3) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL; (4) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction: Carvajal syndrome is a rare cardiocutaneous disorder with autosomal recessive inheritance characterized by dilated cardiomyopathy, congenital woolly hair, and palmoplantar keratoderma. It is associated with biallelic variants in the desmoplaquin (DSP) gene and can lead to severe heart failure (HF) with high morbidity and mortality even in the first years of life. Case Description: Index case was a male, born at term with no prenatal abnormalities, presenting with dilated cardiomyopathy (DCM), woolly hair and palmoplantar keratoderma. At age 3, he developed HF symptoms. Echocardiogram at that time showed dilated left chambers, left ventricular (LV) dysfunction, LV ejection fraction of 30%, mild mitral and tricuspid regurgitation, and a normal right ventricle. Symptoms progressed, leading to a heart transplant at age 5; pathological examination of the explanted heart revealed idiopathic dilated cardiomyopathy and extensive interstitial fibrosis. In family history, both siblings had DCM in the first decade of life (aged 6 and 5), they evolved to severe symptoms of HF and died as a result of cardiogenic shock, before any genetic testing could be performed. Their ancestry was marked by consanguinity, as his parents were first cousins. Genetic testing (whole-exome sequencing) was performed, revealing a homozygous variant in the DSP gene (NM 004415.4:c.4849:p.Gln1617Ter) classified as likely pathogenic. Sanger family sequencing for cascade screening revealed both parents carried the familial variant in heterozygous state. Additional screening was performed in 10 relatives and identified 3 heterozygotes (mean age 44.7 years, 33% male). All heterozygotes underwent electrocardiogram (EKG), echocardiograms and Holter monitoring due to the risk of autosomal dominant DSP-related arrhythmogenic cardiomyopathy. In two of them, all exams were normal, but the other relative with a positive genetic test showed frequent ventricular arrhythmia on Holter and EKG with inverted T wave in leads V1-V3, fulfilling the diagnostic criteria for arrhythmogenic cardiomyopathy. Conclusions: A challenging case highlighting the severity of Carvajal syndrome in a family with a history of DCM in children, underscoring the importance of genetic testing for diagnosis and cascade screening to identify at-risk family members.

FIRST REPORT OF GLYCOGEN STORAGE DISEASE TYPE IB DUE TO A SLC37A4 GENE VARIANT WITH ECOCHARDIOGRAPHIC ABNORMALITIES IN A YOUNG ADULT

VITOR CHAVANTE SILVA[1]; LOUISE MARIA DIAS CORTEZ BRAGA[1]; LUIS FELIPE DE LUCENA FABRÍCIO[1]; JOÃO GUILHERME FONTENELE GAMA[1]; CARLOS VINICIUS DE SOUZA FELIPE[1]; DANIEL BEZERRA BRAGA[1]; RENATA ANGÉLICA GOMES BORGES[1]; TIAGO ALVES DE MENDONÇA[1]; IAN ROCHA DE FARIAS[1]; GUSTAVO HENRIQUE FONTENELE GAMA[1]; FABIO MASTROCOLA[1];

(1) UNIVERSIDADE FEDERAL DO RIO GRANDE DO NORTE - NATAL - RN - BRASIL;

Introduction: Glycogen Storage Diseases (GSD) comprise a heterogeneous group of rare inborn errors of metabolism, presenting with fasting hypoglycemia, cardiomyopathy and neutropenia. Regarding Cardiac involvement, certain GSD variants can manifest concentric hypertrophy, mimicking restrictive cardiomyopathy phenotypes. This makes differential diagnosis an essential step for treatment. While tissue hyper-reflectivity and concentric hypertrophy are well-documented particularly in subtypes III and IV, GSD type Ib has no previous report of cardiac involvement in the literature. The findings of this case demonstrate hyper-reflectivity and eccentric hypertrophy in this form of the disease, revealing a potentially underdiagnosed manifestation in the current medical literature. Case Description: A 39-year-old male patient, diagnosed with Glycogen Storage Disease type Ib since childhood. The diagnosis was confirmed by biopsy and genetic testing, presented with the pathogenic variant rs3130453 in the SLC37A4 gene. The condition has progressed to chronic liver disease (Child-Pugh A5) with associated portal hypertension. In 2025, following a suspected transient ischemic attack (TIA), a cardiological investigation revealed significant structural findings. The transthoracic Echocardiogram demonstrated eccentric left ventricular hypertrophy (mass: 137g/m2) and myocardial hyper-reflectivity pattern suggestive of infiltration or storage. Left ventricular diastolic dysfunction (E/E': 16) was also one of the findings. The systolic function was slightly reduced (LVEF: 47%, via Simpson method), with a significant reduction in Global Longitudinal Strain (GLS: 10%). The electrocardiogram revealed left ventricular overload and supra supraventricular extrasystoles. GSD type Ib typically presents with severe hypoglycemia, neutropenia and inflammatory bowel disease. The presence of eccentric hypertrophy and hyper-reflectivity are atypical findings for the Ib variant, suggesting that the myocardium might serve as a direct site for glycogen deposition in this particular mutation. Conclusions: The cardiac involvement evidenced by hyper-reflectivity and eccentric hypertrophy supports the hypothesis of direct myocardial glycogen deposition, a cardiac manifestation that remains undocumented in the literature concerning the SLC37A4 variant. In this clinical context, establishing an etiological diagnosis and identifying the specific mutation are essencial to ensure effective therapeutic approach for the patient.

UNDERSTANDING THE MYH7 GENE AS A CAUSE OF HYPERTROPHIC CARDIOMYOPATHY THROUGH ITS CARRIERS: A CASE SERIES.

ARTHUR SANTOS DE OLIVEIRA PESSOA[1]; LARYSSA TEIXEIRA OTONI[1]; ISABELLE LUTTERBACH LUTTERBACH ERTHAL[1]; JOÃO PEDRO ROZENTAL RODRIGUES ROZENTAL RODRIGUES[1]; CACILDA ANDRADE DE SÁ[1]; BEATRIZ DE PAIVA ABRAHÃO DOS SANTOS[1]; MARIA AUGUSTA DE MENDONÇA LIMA[1]; DIANE MICHELA NERY HENRIQUE[1]; ARISE GARCIA DE SIQUEIRA GALIL[1];

(1) UNIVERSIDADE FEDERAL DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL;

Introduction: Hypertrophic cardiomyopathy (HCM) is one of the most common inherited heart diseases, and more than 50% of cases show a tendency towards familial aggregation. The myosin heavy chain 7 (MYH7) gene is a sarcomeric gene that encodes the myosin heavy chain (myosin-7), correlating with HCM or dilated HCM and skeletal myopathy. Carriers of the MYH7 variant are diagnosed between 31 and 40 years of age, with moderate hypertrophy and fibrosis (higher concentration in the anterior and inferior septum of the basal and medial regions), representing a moderate risk of sudden cardiac death. Objective: To analyze the clinical characteristics and complementary examination findings of carriers of the MYH7 variant related to cardiomyopathy and its supposed “red flags”. Methods: This was a descriptive and retrospective observational study (case series) conducted in an outpatient clinic of a university hospital dedicated to monitoring patients with HCM, from January 2025 to January 2026. Case Description: It was 211 patients records from the period were retrospectively evaluated, with information regarding genetic test results. Of these, 8 patients were found to have the pathogenic MYH7 variant, with 1 excluded (no information in the record). The remaining patients were predominantly female (71.42%); aged 48.66 ± 3.05 years; white (42.85%); sedentary (71.42%); hypertensive (85.71%); and had heart failure or previous arrhythmia (71.42%). Symptoms of altered sensitivity and motor function (42.85%) and dysautonomia (hypotension, 85.71%). Systolic blood pressure, 110±17.32 mmHg; heart rate, 86±22.51 bpm. Electrocardiogram: sinus rhythm, 42.85%; pacemaker, 57.14%. Transthoracic echocardiogram: left atrium, 45.23±3.05 mm; interventricular septum, 13.33±10.11 mm; left ventricular (LV) posterior wall, 9±2.65 mm; LV ejection fraction, 38±15.71%; systolic dysfunction, 57.14%; moderate to severe diastolic dysfunction, 42.85%. Presence of trabeculations in the left ventricle (28.57%) and diagnosis of non-compaction myocardium (14.28%). Cardiac magnetic resonance imaging is in progress. Conclusions: In this case series, a relatively young age range was observed for the numerous cardiological conditions detected, including severe arrhythmias requiring pacemakers and frequent autonomic symptoms. The trabeculations observed on TTE, despite not being considered a marker of the disease, represent a relevant phenotypic finding within the spectrum of the pathology.

ACQUIRED GERBODE DEFECT IN THE CONTEXT OF ENDOCARDITIS: A RARE POST-SURGICAL COMPLICATION OF VALVE REPLACEMENT

LUIZA LETTI FERRONATTO[1]; JOVENIL DAMACENO ROSA JÚNIOR[2]; NATHALIA CAETANO LOBO[2]; FERNANDA GARCIA FLEURY[2]; ITIEL DE SOUZA AQUINO[2]; SYLVIA BEATRIZ DE VASCONCELLOS CAVALCANTI VALENTE[2]; PEDRO ENZO CAMARGO LUZ[1]; MATHEUS LUAN QUEIROZ ALVES DA CUNHA[2];

(1) UNICEUB - BRASÍLIA - DF - BRASIL; (2) HOSPITAL DE BASE DO DISTRITO FEDERAL - BRASÍLIA - DF - BRASIL;

Introduction: The Gerbode defect is a rare abnormal communication between the left ventricle (LV) and right atrium (RA), resulting in an intracardiac shunt. This condition occurs due to the apical insertion of the tricuspid valve relative to the mitral valve. With a prevalence below 1%, its origin can be congenital or acquired (resulting from processes that damage the septum, such as trauma, myocardial infarction, surgical iatrogenesis, or endocarditis). Diagnosis is challenging, as high-velocity shunts are often misinterpreted as pulmonary hypertension or functional tricuspid regurgitation (TR). While transthoracic echocardiography is the screening tool, transesophageal echocardiography (TEE) is definitive for identifying flow origin and complications such as abscesses. Case Description: A 58-year-old female with rheumatoid arthritis, paroxysmal atrial fibrillation, hypothyroidism, and dyslipidemia underwent aortic and mitral valve replacement in 2024 for rheumatic mixed valve disease. The procedure included aortic root enlargement and left atrial appendage exclusion. Eight months later, she presented with progressive dyspnea. TEE revealed a mitral annular aneurysm in the posteroseptal region (18x21mm), with a wall discontinuity leading to a fistulous tract (5mm ostium). Predominantly systolic flow was observed between the LV and RA, characterizing a Type I (supravalvular/direct) Gerbode defect secondary to a perivalvular abscess. The exam detailed torrential TR due to coaptation failure (vena contracta 9.4mm; effective regurgitant orifice area 1.3cm²; regurgitant volume 138ml/beat), with systolic hepatic vein flow reversal and a pulmonary artery systolic pressure of 41 mmHg (underestimated due to the severity of the valvular failure). Marked right chamber dilation, ascites, and bilateral pleural effusion were observed. Given the diagnosis of infective endocarditis complicated by an intracardiac fistula, the patient remained hospitalized for antibiotic therapy pending surgical reintervention for valve replacement and defect repair. Conclusions: This case highlights the diagnostic complexity of the Gerbode defect in patients with prosthetic valves and endocarditis. Differentiating LV-RA shunts from massive TR is vital, as both cause right heart overload. A multimodal approach was decisive in identifying the septal abscess as the cause of the fistula. Clinical suspicion remains paramount for atypical murmurs or refractory heart failure post-surgery to ensure timely diagnosis and appropriate management.

COMPLICATED PROSTHETIC INFECTIVE ENDOCARDITIS WITH PERIVALVULAR AND PERIAORTIC ABSCESSES AND STERNAL FISTULA

GIULI DE FIGUEIRÊDO TEIXEIRA[1]; GIOVANNA TEIXEIRA GUEDES MEIRELES[1]; ANA CLARA DE MELO GUILHERME[1]; LÍVIA BONAPARTE LINHARES[1]; LETÍCIA DE SOUSA GUERIN TEIXEIRA[2]; ANA CAROLINA DOS SANTOS ARAUJO[2]; BIANCA DE ARAGÃO OLIVEIRA[2]; JOSÉ THIEFESON SERPA DA SILVA[2]; ALESSANDRA EDNA TEÓFILO LEMOS[2]; CARLOS JOSÉ MOTA DE LIMA[2];

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (2) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introduction: Prosthetic infective endocarditis (PIE) is a complication following valve replacement, characterized by high mortality and diagnostic and therapeutic complexity. Progression to periaortic collections and mediastinal fistulization is a rare manifestation, associated with significant tissue destruction and the need for complex surgical reinterventions. Case Description: A 59-year-old male patient with a surgical repair of an ascending aortic aneurysm associated with aortic and mitral valve replacement with biological prostheses on January 17, 2024. Presented with an abscess in the anterior cervical region, near the sternal furcula, associated with episodes of spontaneous cutaneous drainage since January 2026. In April 2026, he developed fever and chills, associated with an ulcerated lesion in the sternal furcula region with drainage of purulent secretion; empirical antimicrobial treatment with meropenem, vancomycin, and gentamicin was initiated, based on suspicion of infective endocarditis. Transesophageal echocardiography revealed a biological mitral prosthesis with multiple heterogeneous, mobile masses, the largest measuring 11 × 6.6 mm, consistent with vegetations, with no bioprosthesis dysfunction; A normally functioning aortic bioprosthetic valve was noted; a hyperechoic structure adjacent to the aortic valve apparatus, measuring 29 × 22 mm at its greatest diameters, was observed, suggestive of an abscess. A Dacron prosthesis positioned within the aortic lumen was visualized; an extensive infectious collection was evident adjacent to the aortic wall. Chest CT angiography confirmed the presence of hypodense material surrounding the aortic lumen, with soft tissue density (30 HU), suggestive of a thick collection with a maximum diameter of up to 10.2 cm; at the level of the 3rd costal arch, a disruption in continuity between the mediastinal collection and the subcutaneous tissue can be identified. Conclusions: This case illustrates the high severity of prosthetic infective endocarditis with perianular extension, periaortic abscess, and mediastinal fistulization in a patient with aortic and valvular prostheses, presenting a scenario of high clinical and surgical complexity. Cardiovascular imaging methods were fundamental for diagnosis and treatment planning, reinforcing the importance of multimodal imaging in invasive prosthetic endocarditis.

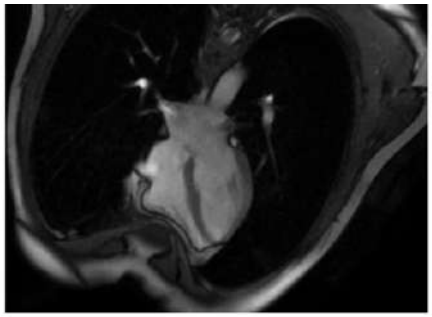
DYNAMIC FUNCTIONAL ATRIAL MITRAL REGURGITATION UNMASKED BY EXERCISE IN A PATIENT PREVIOUSLY DIAGNOSED WITH HFPEF

BETINA FOSSATI CHISTÉ FLORIAN[1]; ISABELLA RONCHETTI MARTINS XAVIER[1]; JÚLIA PEREIRA AVILA[1]; SOFIA ZONTA BISCHOFF[1]; PEDRO CAMPANEL BERTOLETTI[1]; ANDREI SILVA RECKZIEGEL[1]; DIEGO LUAN DA CRUZ ARAÚJO[1]; LUCAS DE OLIVEIRA SCHIRMER[1]; JORDANA SCHMALZ[2]; MARCELO HAERTEL MIGLIORANZA[2]; TIAGO HANSEL BASILE VIGIL[2]; PAULO MACIEL RINALDI[2];

(1) UNISINOS - SÃO LEOPOLDO - RS - BRASIL; (2) ECOHAERTEL DIAGNÓSTICO CARDIOVASCULAR, HOSPITAL MÃE DE DEUS - PORTO ALEGRE - RS - BRASIL;

Introduction: Heart failure with preserved ejection fraction (HFpEF) is a heterogeneous syndrome and often poses a diagnostic challenge. Exercise stress echocardiography is an important tool not only for diagnosing this condition but also for identifying underlying pathophysiological mechanisms that may not be evident at rest, including dynamic valvular disease. Case Description: MMS, a 76-year-old woman with hypertension, presented with progressive worsening of functional class over the past year (currently NYHA class III). She had been clinically diagnosed with HFpEF and remained symptomatic despite optimized treatment with an SGLT2 inhibitor and diuretics. Cardiac magnetic resonance imaging with pharmacological stress was negative for ischemia or infiltrative disease. Resting echocardiography showed a left ventricle with preserved dimensions and function (ejection fraction 71%), left atrial enlargement (indexed volume 44.7 mL/m²), and mild mitral regurgitation (effective regurgitant orifice area 13 mm²; regurgitant volume 21.5 mL per beat). Diastolic dysfunction with borderline filling pressures (septal E/e' 17; mean 13) and an estimated pulmonary artery systolic pressure (PASP) of 29 mmHg were also observed. She underwent exercise stress echocardiography on a cycle ergometer (Astrand protocol), which was terminated early due to severe dyspnea during stage 2 (50 W, 3:58 min, VO□ 8.6 mL/kg/min, 2.4 METs). At peak exercise, there was a marked increase in mitral regurgitation, which became significant, with a broad jet reaching the roof of the left atrium and extending into the pulmonary veins. This was accompanied by a significant increase in filling pressures (septal E/e' 30; mean 19) and PASP (65 mmHg), as well as subclinical pulmonary congestion detected by lung ultrasound (score 16/40). These findings led to a revised diagnosis of dynamic functional atrial mitral regurgitation, explaining the patient's reduced exercise tolerance. The patient is currently undergoing cardiopulmonary rehabilitation and is being evaluated by the heart team for therapeutic decision-making. Conclusions: This case highlights the value of physical stress echocardiography in evaluating patients with suspected HFpEF, allowing for objective assessment of functional limitation and identification of underlying dynamic mechanisms, such as functional atrial mitral regurgitation.



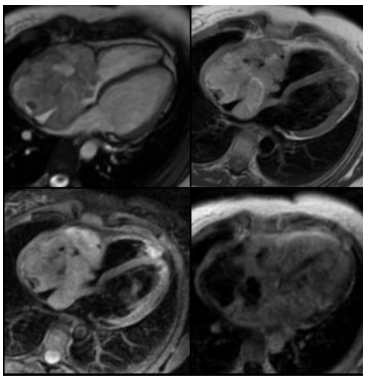
15124

BEYOND VALVULAR AND AORTIC ANOMALIES: A CASE REPORT OF ARRHYTHMOGENIC RIGHT VENTRICULAR DYSPLASIA IN A YOUNG WOMAN WITH TURNER SYNDROME.

ANNA JÚLIA ANDRINO SCHNEIDER[1]; EDUARDO ARRAIS ROCHA[2]; CARLOS HENRIQUE PAIVA GRANGEIRO[2]; DANIELLE DE SOUZA BESSA[2]; CARLA ANTONIA FERREIRA DE ALMEIDA VIEIRA[2]; EVELINE GADELHA PEREIRA FONTENELE[2];

(1) UFC - FORTALEZA - CE - BRASIL; (2) HOSPITAL UNIVERSITARIO WALTER CANTIDIO - FORTALEZA - CE - BRASIL;

Introduction: Turner Syndrome (TS) is a genetic condition resulting from total or partial loss of an X chromosome. The diagnosis is suspected in women with short stature or delayed puberty and confirmed by karyotyping. Congenital anomalies, such as bicuspid aortic valve and aortic coarctation, and hypertension (HT) contribute to a reduction in life expectancy of approximately 10 years due to cardiovascular (CV) death. Arrhythmogenic right ventricular dysplasia (ARVD) is a rare, progressive genetic disease characterized by the replacement of heart muscle with adipose and fibrous tissue and is one of the causes of severe arrhythmias and sudden death in young people. In this report, we will describe the unreported association of ARVD and TS. Case Description: A 35-year-old woman has been under follow-up since the age of 10 for short stature (height SDS −3.7) and hypergonadotrophic hypogonadism. TS was confirmed by 45,X [30] karyotype. The initial CV evaluation by echocardiogram was normal. At age 21, HT was diagnosed and controlled with losartan and propranolol. Magnetic resonance angiocardiography (MRA) was performed to assess pregnancy risk. MRA revealed dyskinesia of the posterobasal wall of the right ventricle with reduced ejection fraction and areas suggestive of myocardial fibrosis, consistent with ARVD. The electrocardiogram showed sinus rhythm, negative T wave from V1 to V5, and incomplete right bundle branch block. The exercise stress test was normal and the 24-hour Holter monitoring revealed rare supraventricular extrasystoles and no ventricular arrhythmias. The patient was advised to engage in moderate physical activity while monitoring her heart rate to 110 bpm, to continue taking propranolol and losartan, and to undergo regular cardiological follow-up. Conclusions: The diagnosis of ARVD requires integration of clinical data and imaging studies, particularly MRA, to assess of ventricular morphology and function. To date, 15 autosomal genes have been implicated in ARVD and alterations in genes on the X chromosome may modulate the expression of autosomal genes involved in the regulation of cardiac ion channels. To our knowledge, there are no previous reports in the literature of an association between ARVD and TS. This case illustrates the importance of MRA in CV evaluation in patients with TS.



Picture 1: Magnetic resonance angiography (MRA) applied to the morphofunctional characterization of the heart and thoracic aorta.

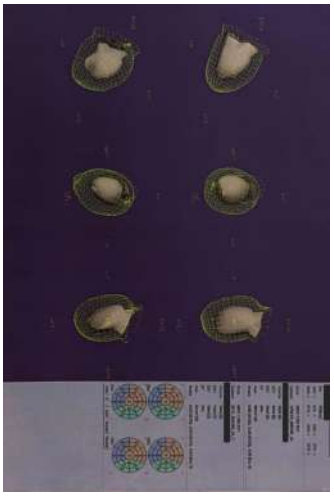
GIANT CARDIAC ANGIOSARCOMA IN A PUERPERAL WOMAN: A CASE REPORT

JOSÉ GUILHERME PINHATTI CARRASCO[1]; DANIEL COSTA GONÇALVES DO VALE[1]; ISABELA PONTES SERRA[1]; IGOR HENRIQUE RIGOTTO ALTOÉ[1]; LUCAS ALMEIDA GOMES[1]; AILTON FERNANDES JUNIOR[1]; MARCOS BORGES MACHADO[1]; AFONSO AKIO SHIOZAKIE[1];

(1) UNIVERSIDADE ESTADUAL DE MARINGA - MARINGÁ - PR - BRASIL;



Introduction: Primary cardiac tumors are rare, with most being benign, particularly myxomas. Cardiac angiosarcoma is an uncommon malignant neoplasm of endothelial origin, characterized by aggressive behavior and a high metastatic potential. Its occurrence during the puerperium is exceedingly rare, with only a few cases reported in the literature, making early diagnosis and appropriate management particularly challenging. A case of giant cardiac angiosarcoma in a puerperal patient is presented, emphasizing diagnostic challenges, therapeutic strategies, and key clinical aspects. Case Description: A 28-year-old woman presented with progressive dyspnea during the third trimester of pregnancy. Transthoracic echocardiography revealed a right atrial mass, initially suspected to be a cardiac myxoma. A joint decision was made to defer further investigation until after delivery. In the immediate puerperium, the patient experienced clinical deterioration with worsening dyspnea. Cardiac magnetic resonance imaging demonstrated a large right atrial mass with an estimated volume of 258 mL (Image 1). A percutaneous biopsy via the superior vena cava was performed, and histopathological analysis confirmed cardiac angiosarcoma. Systemic chemotherapy with doxorubicin was initiated, resulting in approximately 70% tumor reduction on follow-up imaging (Image 2). However, after five months of treatment, significant left ventricular systolic dysfunction developed, with a decline in ejection fraction from 64% to 35%, consistent with chemotherapy-induced cardiotoxicity. Consequently, the treatment regimen was switched to paclitaxel, with poor therapeutic response and subsequent metastatic progression, predominantly involving the liver. Due to progressive hepatic failure associated with heart failure, death occurred approximately 11 months after the definitive diagnosis. Conclusions: This case highlights not only an extremely rare condition but also underscores the diagnostic challenges imposed by physiological changes during pregnancy and the puerperium. Furthermore, it emphasizes the importance of close monitoring for chemotherapy-induced cardiotoxicity, which may significantly impact prognosis and survival, as illustrated in the present case.

LATE MYOCARDIAL ISCHEMIA AFTER TAKEUCHI REPAIR FOR ALCAPA: SYNERGISTIC EFFECT OF TUNNEL STENOSIS AND CORONARY STEAL FROM AN AORTO-PULMONARY FISTULA

FRANCISCO CAMARA RAPOSO ANDRADE[1]; MURILO HENRIQUE DE LUCENA PINZON[1]; ARTHUR ANDRADE LACET FLORENCIO[1]; DEBORA REIS DE ALMEIDA BRAGA[1]; BIANCA COUTINHO MUNIZ[2]; LUIS FELIPE BRITO DE MEDEIROS[1]; LUCIANA RAPOSO ANDRADE[2]; JESSICA CAROLYNE ALVES DA SILVA[3];

(1) HOSPITAL DAS CLINICAS - RECIFE - PE - BRASIL; (2) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL; (3) INSTITUTO DE MEDICINA INTEGRAL PROFESSOR FERNANDO FIGUEIRA - IMIP - RECIFE - PE - BRASIL;

Introduction: Anomalous origin of the left coronary artery from the pulmonary artery (ALCAPA) is a rare congenital anomaly requiring early surgical correction. The Takeuchi procedure remains an alternative when direct reimplantation is not feasible, but late complications may arise. The integrated hemodynamic consequences of these complications are of key interest. Case Description: A 10-year-old girl with ALCAPA repaired in infancy using the Takeuchi technique presented with chest pain. Myocardial perfusion imaging revealed moderate reversible ischemia involving the anterior, anterolateral, and inferior walls, despite preserved left ventricular function and a normal exercise stress test. Transthoracic echocardiography demonstrated moderate supravalvular pulmonary stenosis. Coronary computed tomography angiography and invasive coronary angiography identified significant tunnel stenosis, a hypoplastic and poorly opacified left coronary system, extensive collateralization from the right coronary artery, and contrast passage into the pulmonary artery consistent with an aorto-pulmonary fistula. These findings indicated a complex interplay between reduced antegrade coronary flow and coronary steal physiology. The patient underwent surgical correction of the fistula and pulmonary artery reconstruction, with favorable early postoperative evolution. Conclusions: This case illustrates a dual and synergistic mechanism of late myocardial ischemia after Takeuchi repair, combining structural obstruction and hemodynamic diversion of coronary flow. It emphasizes the critical role of multimodality imaging in detecting clinically relevant ischemia and supports the need for lifelong surveillance in this population.

15892

ATYPICAL HEPATIC PRESENTATION OF FAMILIAL HYPOBETALIPOPROTEINEMIA DETECTED AFTER TWIN DEATH: IMPLICATIONS FOR CARDIOVASCULAR AND METABOLIC RISK

RAFAELA MARQUES MÜLLER PESSÔA[1]; FELIPE FONTES BATISTA DE SOUZA[1]; CATARINA MARQUES MÜLLER PESSÔA[1]; RODRIGO NASCIMBENE SILVA[1]; ELAINE DOS REIS COUTINHO[1];

(1) PONTIFÍCIA UNIVERSIDADE CATÓLICA DE CAMPINAS - CAMPINAS - SP - BRASIL;

Introduction: Familial hypobetalipoproteinemia (FHBL) is a rare genetic disorder characterized by markedly reduced LDL-cholesterol and apolipoprotein B levels. Although often considered cardioprotective, FHBL may be associated with hepatic steatosis and progressive liver disease, posing diagnostic and management challenges. Case Description: A 29-year-old asymptomatic woman was referred to cardiology due to extremely low LDL-cholesterol identified during family screening after the death of her monozygotic twin sister from advanced cryptogenic liver disease following two failed liver transplants. She had no cardiovascular disease, diabetes, obesity, or alcohol misuse. Laboratory evaluation revealed profound hypolipidemia (LDL-C 4 mg/dL, ApoB <40 mg/dL) with mild transaminase elevation. Abdominal MRI showed moderate hepatic steatosis, and liver biopsy demonstrated chronic active hepatitis with fibrotic changes. Genetic analysis identified two heterozygous APOB variants in trans, confirming FHBL. The patient remains under multidisciplinary care, receiving fat-soluble vitamin supplementation and metabolic monitoring. Low-dose GLP-1 receptor agonist therapy was initiated to address hepatic steatosis, with follow-up elastography planned. Conclusions: This case highlights that extremely low LDL-cholesterol is not always benign and may indicate underlying genetic disorders with significant hepatic involvement. FHBL should be considered in patients with unexplained hypolipidemia. The challenge lies in balancing cardiovascular protection with the risk of progressive liver disease and defining optimal management strategies.

CARDIOVASCULAR EVENTS FOLLOWING COVID-19 VACCINATION: A CASE REPORT

LARISSA LAURETTO[1]; PEDRO HENRIQUE BATISTA CARLOS[1]; ANA CAROLINE DIAS[1]; MARIA OLIVIA DE OLIVEIRA FUTURO RODRIGUES[1]; ARTHUR VILAR DE OLIVEIRA MALHEIROS[2]; JOSÉ LUIZ AMURATTI GONÇALVES[1];

(1) UNIVERSIDADE DO OESTE PAULISTA - UNOESTE - PRESIDENTE PRUDENTE - SP - BRASIL; (2) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL;

Introduction: Myocarditis is an inflammatory infiltrate in the myocardium that damages cardiomyocytes in a non-ischemic manner and may have an infectious or non-infectious cause. Following vaccination against SARS-CoV-2, rare cases of myocarditis associated with mRNA vaccines have been reported, primarily in young men. Thus, this study reports the case of a young, healthy male patient who experienced two episodes of myocarditis following administration of the mRNA vaccine against SARS-CoV-2. Case Description: A 19-year-old male patient, previously healthy, was hospitalized in September 2021 with constricting retrosternal pain. Forty-one days earlier, he had received the first dose of the mRNA vaccine against COVID-19. Laboratory tests revealed a significant elevation in markers of myocardial necrosis, such as troponin I at 8.73 ng/ml and CK-MB at 120.60 U/L, as well as an increase in C-reactive protein. Cardiac magnetic resonance imaging demonstrated late enhancement with a non-ischemic pattern, suggestive of myocarditis. The patient underwent medical treatment with a favorable outcome. Approximately two months later, following the second vaccine dose, he presented with a new episode of chest pain associated with ST-segment elevation on the electrocardiogram. A new MRI revealed progression of areas of late enhancement consistent with myocardial inflammation. Management included anti-inflammatory drugs, a beta-blocker and colchicine, with progressive clinical improvement. During four years of outpatient follow-up, the patient remains asymptomatic, with preserved ventricular function and normal laboratory results. Conclusions: This report describes a case of recurrent myocarditis associated with COVID-19 vaccination in a young patient. Although events of this nature are rare, such recognition is important for appropriate diagnosis and management. However, current evidence demonstrates that the benefits of vaccination far outweigh the potential risks, remaining one of the main strategies for public health protection.

ERUPTIVE XANTHOMA IN A PATIENT WITH METABOLIC DISORDER: A CASE REPORT

GABRIEL JARDIM VARGAS[1]; JULIO COUTINHO VARGAS[2]; BARBARA GARCIA[1]; CARLA REJANE CANEDA JARDIM VARGAS[3];

(1) UNIVERSIDADE LUTERANA DO BRASIL- ULBRA - CANOAS - RS - BRASIL; (2) HOSPITAL SANTA CASA DE CARIDADE DE BAGÉ - BAGÉ - RS - BRASIL; (3) UNIPAMPA - DOM PEDRITO - RS - BRASIL;

Introduction: Xanthomas are skin lesions from lipid accumulation in macrophages, signaling metabolic disorders. Eruptive xanthomas arise when triglycerides exceed 3,000 mg/dl, linked to hyperlipoproteinemia and diabetes. They appear as yellow papules on extensor surfaces and can cause pain or pruritus. Their clinical value lies in signaling acute pancreatitis risk, allowing for early diagnosis and dyslipidemia management. Case Description: A male patient, 44 years old, presents with a complaint of yellowish, occasionally suppurative lesions on the elbows for several years, which evolve in outbreaks when overindulging in fatty and carbohydrate-rich foods and decrease when following a diet. He reported having type 2 Diabetes Mellitus (DM), under regular treatment with Metformin 1g twice daily. In his family history, he mentioned a mother with DM, a father who died of Acute Coronary Syndrome at age 73, and a sister who died young from sudden death. Upon inspection, he presented multiple papular and papulo-nodular lesions, either isolated or coalescing into plaques, with an erythematous-yellowish coloration, located on the extensor surfaces of the upper and lower limbs. No other particularities were noted. Laboratory tests revealed: Fasting glucose 281 mg/dl (Reference Value (RV) >99 mg/dl), Total cholesterol 717 mg/dl (RV >190 mg/dl), Triglycerides 3473 mg/dl (RV >150 mg/dl), and Uric acid 15.2 mg/dl (RV >7.2 mg/dl). Others were unremarkable. The anatomopathological study of a skin lesion biopsy (skin and hypodermis of the left knee) showed morphological findings suggestive of xanthoma, confirming the clinical diagnosis of tuberous xanthoma associated with hyperlipoproteinemia, aggravated by the association with DM; treatment for dyslipidemia and DM was then initiated. Thirty days after diagnostic confirmation, the patient returned to the office with regression of the lesions and laboratory tests within normal limits. Conclusions: This case illustrates the significance of xanthomas as cutaneous markers of severe metabolic disorders. The exuberance of the lesions, coupled with critical triglyceride and glucose levels, reinforces the interdependence between Diabetes Mellitus management and lipid metabolism. The rapid clinical and laboratory response following therapeutic intervention underscores that early diagnosis, based on dermatological inspection, is decisive in mitigating acute risks (such as pancreatitis) and reducing long-term cardiovascular risk, proving essential for a favorable patient prognosis.

FAMILIAL EXTREME HYPOCHOLESTEROLEMIA AND EARLY ISCHEMIC STROKE: A CLINICAL PARADOX IN CARDIOVASCULAR PREVENTION

NESTOR SOUSA JUNIOR[1]; BÁRBARA BEATRIZ GARCIA KIPPER FEITOZA[1]; GIULIANA TONOLLI FERRATO[1]; VANESSA MAYARA SOUZA SILVA MARTINS[1]; LARA MONTEIRO DE QUEIROZ RAVAZZI[1];

(1) UNIMAX - CENTRO UNIVERSITÁRIO MAX PLANCK - INDAIATUBA - SP - BRASIL;

Introduction: Familial Hypobetalipoproteinemia (FHBL) is a rare genetic dyslipidemia characterized by residual levels of LDL-cholesterol, theoretically conferring protection against atherosclerosis. The occurrence of severe ischemic events in these individuals challenges classical cardiovascular risk stratification. We report a case of early ischemic stroke in a patient with an FHBL phenotype, identified through cascade screening in Primary Health Care. Case Description: A 49-year-old male presented with a history of two early ischemic strokes (the first at age 40 and a cerebellar event at age 47, leaving him with residual dyslalia). He has a high cardiometabolic risk profile due to systemic arterial hypertension, insulin-dependent type 2 diabetes mellitus, smoking, and obesity. Despite being on a minimal dose of simvastatin, his lipid profile revealed extreme hypocholesterolemia with an LDL-cholesterol of 20 mg/dL, an atypical pattern strongly suggestive of a primary dyslipidemia. The etiological investigation ruled out cardioembolism, as both the echocardiogram and the 24-hour Holter monitor were unremarkable. Brain Magnetic Resonance Angiography (MRA) demonstrated microangiopathy and supratentorial ischemic lacunae, without large vessel occlusion. During family cascade screening, three sisters presented with LDL-cholesterol levels between 32 and 38 mg/dL in the absence of lipid-lowering therapy, all remaining free of cardiovascular events. The mother (with a history of hemorrhagic stroke) and the remaining three siblings showed lipid profiles without a protective pattern. Clinical screening validated the familial phenotypic aggregation, even though genetic confirmation is unavailable within the Brazilian public health system (SUS). Conclusions: A clinical paradox is evident: while relatives with the extreme hypocholesterolemia phenotype maintain atherosclerotic protection, the index patient suffered recurrent early ischemic events. The pathophysiological hypothesis assumes that chronic microvascular endothelial injury, induced by severe blood pressure and glycemic decompensation, overcame the hypolipidemic protection, leading to a lacunar rather than atherothrombotic etiology. Innate protection from low LDL-cholesterol does not waive the strict control of other risk factors for effective secondary prevention. This report highlights the importance of clinical investigation in Primary Health Care for managing cardiovascular risk.

19175

ST-SEGMENT ELEVATION MYOCARDIAL INFARCTION IN A TESTOSTERONE USER

VITÓRIA CHIES COLASSIOL[1]; MARIANA MONT'SERRAT FUSO PRUDENTE[1]; MÁRIO WIEHE[1]; RICARDO CZARNOBAI SOCCOL[1];

(1) PUCRS - PORTO ALEGRE - RS - BRASIL;

Introduction: The use of anabolic-androgenic steroids without clinical indication and without medical supervision has increased substantially, particularly for aesthetic purposes. This practice is associated with an elevated cardiovascular risk, even among previously healthy individuals. Synthetic testosterone derivatives have been implicated in deleterious pathophysiological mechanisms, including endothelial dysfunction and the promotion of a prothrombotic state. This state is characterized by increased platelet aggregability, favoring thrombus formation and the occurrence of acute cardiovascular events such as myocardial infarction. Case Description: A 45-year-old male, previously healthy and with no known cardiovascular risk factors, had been using testosterone for aesthetic purposes for two years. He presented with chest pain, and an electrocardiogram revealed ST-segment elevation in the anterior wall. Following the diagnosis of ST-segment elevation myocardial infarction (STEMI), dual antiplatelet therapy was initiated with a loading dose, and the patient was referred to the hemodynamics unit. Coronary angiography revealed total thrombotic occlusion of the proximal segment of the left anterior descending artery. The patient underwent percutaneous coronary intervention with stent implantation, achieving restoration of TIMI 3 flow. Laboratory findings showed markedly elevated cardiac biomarkers, with troponin levels exceeding 30,000 pg/mL. During hospitalization, the patient remained hemodynamically stable, although persistent electrocardiographic changes compatible with electrically inactive areas in the anteroseptal and high anterolateral walls were observed. Transthoracic echocardiography performed prior to discharge demonstrated a left ventricular ejection fraction of 41%, with hypokinesia of the apical, mid-anterior, and anteroseptal segments. The patient was discharged on guideline-directed medical therapy for secondary prevention and reduction of cardiovascular morbimortality: dual antiplatelet therapy, a high-intensity statin, a beta-blocker, and an angiotensin-converting enzyme inhibitor, with subsequent clinical improvement. Conclusions: This case illustrates and highlights the thrombogenic potential of testosterone as a precipitating factor for cardiovascular events in individuals without traditional risk factors. Furthermore, the absence of obstructive atherosclerotic plaques following recanalization suggests a thrombotic mechanism determined by the use of androgenic steroids.

17513

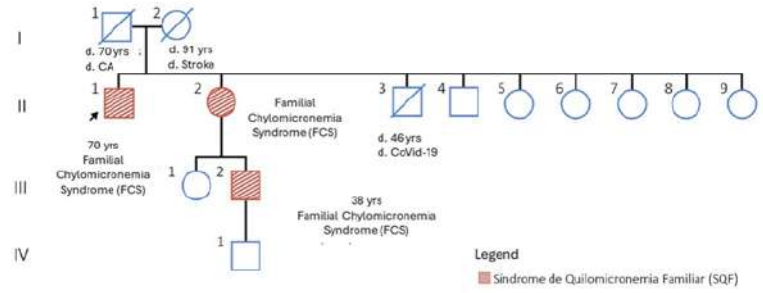
TWO-DECADE FOLLOW-UP OF ATHEROSCLEROSIS ASSOCIATED WITH HOMOZYGOUS MTHFR C677T MUTATION AND HYPERHOMOCYSTEINEMIA IN A YOUNG PATIENT

PEDRO HENRIQUE MENDONÇA CARVALLHO MADEIRA[1]; IVAN LUCAS PICONE BORGES DOS ANJOS[2]; LAIS DE SOUZA RODRIGUES[3]; LIVIA LIBERATA BARBOSA BANDEIRA[4]; ANA CAROLINA PORTO DA HORA[1]; CAIO TEIXEIRA DOS SANTOS[5]; MARIA APARECIDA DE ALMEIDA SOUZA RODRIGUES[3]; ALEXANDRE AUGUSTUS BRITO DE ARAGÃO[1]; IVANA PICONE BORGES DE ARAGÃO[1];

(1) FACULDADE DE CIENCIAS MEDICAS DE MARICA - MARICÁ - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (3) UNIVERSIDADE DE VASSOURAS (UNIVASSOURAS) - VASSOURAS - RJ - BRASIL; (4) NORFOLK AND NORWICH UNIVERSITY HOSPITAL, UNIVERSITY OF EAST ANGLIA - UNITED KINGDOM; (5) HOSPITAL UNIVERSITARIO PEDRO ERNESTO - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Homocysteine is an intermediate amino acid in methionine metabolism whose plasma accumulation, known as hyperhomocysteinemia (Hhcy), is associated with increased cardiovascular risk. Although hyperhomocysteinemia has been associated with increased cardiovascular risk, the clinical relevance of MTHFR mutations and the long-term benefit of targeted vitamin supplementation remain debated. Genetic alterations, such as mutations in the methylenetetrahydrofolate reductase (MTHFR) gene, may elevate serum homocysteine levels and contribute to thrombotic, atherosclerotic, and neurological events, particularly in young individuals.The aim of this study was to report the clinical case of a patient with hyperhomocysteinemia due to a homozygous MTHFR gene mutation associated with cardiovascular and cerebrovascular disease with extended longitudinal follow-up. Case Description: A 65-year-old male suffered an ischemic stroke at age 45 due to left vertebral artery dissection and acute thrombosis, resulting in persistent visual deficits and vertigo. Initial risk factors included hypertension and dyslipidemia, yet the event's precocity prompted an etiological screening that identified hyperhomocysteinemia (16.6 µmol/L) and a homozygous MTHFR C677T mutation. Treatment was established with folic acid, B-complex vitamins, statins, and antiplatelet therapy. In 2017, a brief period of non-adherence to vitamin supplementation led to a homocysteine rebound, directly coinciding with subclinical atherosclerotic progression: imaging revealed a new carotid fibrolipid plaque and an increase in the coronary calcium score (CAC). Strict reintroduction of folic acid stabilized these findings. Between 2013 and 2025, longitudinal follow-up showed no myocardial ischemia or ventricular dysfunction. Coronary CTA and Doppler ultrasound of the carotids and lower limbs confirmed stable, mild-to-moderate obstructions with preserved distal triphasic flow. During this 12-year monitoring period, the CAC score remained between 450 and 749, with no new ischemic events recorded. Conclusions: MTHFR-related hyperhomocysteinemia is a critical driver of early-onset atherosclerosis. Sustained vitamin therapy and rigorous monitoring are essential to halt disease progression and prevent recurrent macrovascular events over decades. The association between folic acid interruption and plaque progression underscores homocysteine as a modifiable driver of atherosclerosis, requiring strict biochemical adherence for long-term stabilization.

17089



VOLANESORSEN FOR FAMILIAL CHYLOMICRONEMIA SYNDROME: THERAPEUTIC DISPARITIES AND CLINICAL RESPONSE IN A FAMILY LINEAGE — A CASE REPORT

MANNOELA BECKER GENZ[1]; EMÍLIO HIDEYUKI MORIGUICHI[1];

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction: Familial Chylomicronemia Syndrome (FCS) is a rare genetic disorder causing severe, persistent hypertriglyceridemia (HTG) due to defects in the lipoprotein lipase (LPL) pathway or its cofactors. Lack of LPL activity impairs triglyceride (TG) breakdown, so chylomicrons (CM) remain in plasma even after fasting. HTG carries a high risk of recurrent acute pancreatitis. Conventional therapies – diet, fibrates, and omega-3s – often fail to control TG levels in genetically affected patients. Targeted inhibition of apolipoprotein C-III (ApoC3), such as with volanesorsen, offers sustained TG reduction. Case Description: This report describes two siblings with the same compound heterozygous variants in APOA5 (Figure 1), associated with type V hyperlipoproteinemia and recurrent pancreatitis. Patient II.1: Male, 68 years, critical lipids despite gemfibrozil and simvastatin: TG 2,620 mg/dL; total cholesterol 345 mg/dL; HDL 26 mg/dL. Genetic testing confirmed type V hyperlipoproteinemia and found APOA5 variants: c.758T>C (likely pathogenic) and c.490G>C (Variant of Unknown Significance). Volanesorsen was requested from the public health system (SUS), leading to a significant reduction in TG. Patient II.2: Sister, 65 years, HTG 530 mg/dL and a pancreatitis episode. Genetic studies showed the same diagnosis. She awaits volanesorsen. Patient III.2: Son of II.2, 38 years. Asymptomatic despite no medication. TG: 924 mg/dL; total cholesterol: 282 mg/dL; HDL: 34 mg/dL. Submitted to genetic panel to assess pathogenic variants. Conclusions: Both siblings had severe HTG despite optimized therapy, highlighting the limits of conventional strategies for genetic cases. Compound heterozygous APOA5 variants likely contributed to severe disease, as such genotypes often yield more serious phenotypes. The siblings' contrasting outcomes showed that volanesorsen provided robust TG control, reducing patient II.1's risk of acute pancreatitis.

LATE PRESENTATION OF ALCAPA SYNDROME: DIAGNOSIS AT 32 YEARS AND FAVORABLE POSTOPERATIVE EVOLUTION

RODRIGO ALEXANDRE SANTOS DE JESUS[1]; INGRID GONÇALVES SIQUEIRA BROWN[1]; ALEXANDRE DO COUTO CHAGAS DE GOES[1]; TATIANA REGINA AMARAL[1]; GIULIA HONÓRIO PADIGLIONE TEXEIRA[2]; MARCIA CRYSTINA DE MIRANDA GUIMARÃES[1]; LUAN ALVIM MOREIRA[1]; ROBERTA DO CARMO LOPES[1]; DIOGO MOREIRA THOMAZ PEREIRA[1]; RAFAEL RABISCHOFFSKY[3]; THAISSA MONTEIRO[4]; ARNALDO RABISCHOFFSKY[3];

(1) UNIVERSIDADE CASTELO BRANCO - RIO DE JANEIRO - RJ - BRASIL; (2) UNIVERSIDADE UNIGRANRIO AFYA - RIO DE JANEIRO - RJ - BRASIL; (3) HOSPITAL PRO CARDIACO - RIO DE JANEIRO - RJ - BRASIL; (4) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Anomalous Left Coronary Artery from the Pulmonary Artery (ALCAPA) is a rare congenital heart defect (estimated incidence 1:300,000 live births) in which the left coronary artery originates from the pulmonary artery. Clinical presentation ranges from severe heart failure in infancy to oligosymptomatic forms in adulthood, depending on collateral circulation. Survival into the third decade without surgical correction is exceptional, underscoring the clinical relevance of this case. Case Description: A male patient with a prenatal diagnosis of unspecified congenital heart disease was treated with hydrochlorothiazide and digoxin until age 13, then discharged from cardiology follow-up. He remained asymptomatic for 19 years, including during military service. At 32 years, he developed recurrent symptoms, including precordial pain, frequent extrasystoles, and exertional fatigue. On May 1, 2013, echocardiography revealed mild left ventricular and atrial dilation, preserved systolic function with grade II diastolic dysfunction, apical hypokinesia, dilation of the right coronary artery, reverse turbulent flow in the anterior descending artery, and mild mitral regurgitation. Computed tomography confirmed anomalous origin of the left coronary artery from the pulmonary artery, an extensive collateral network, right coronary artery hypertrophy, and apical anterior subendocardial hypoperfusion with spherical remodeling of the left ventricle. On May 27, 2013, he underwent surgical correction via median thoracotomy with cardiopulmonary bypass and normothermic cardioplegia. Coronary translocation was performed by excising the coronary ostium from a posterolateral right position and reimplanting it end-to-side into the aortic coronary sinus. The pulmonary artery was reconstructed using bovine pericardium. Postoperative course was satisfactory, with adequate hemodynamic recovery. At present, 12 years after surgery, the patient is asymptomatic and studying Medicine, demonstrating excellent quality of life and full social reintegration. Conclusions: This case highlights the adaptive capacity of the coronary system through collateral circulation, allowing prolonged survival in uncorrected ALCAPA. The late diagnosis at 32 years and favorable postoperative course following coronary translocation underscore the importance of maintaining clinical suspicion in young adults with atypical cardiovascular symptoms. Direct reimplantation proved effective even in late presentations, providing an excellent long-term prognosis.

PORCELAIN LEFT ATRIUM AS A LIMITING FACTOR FOR SURGERY IN SEVERE MITRAL STENOSIS

GIOVANA AJNHORN MATTIELLO[1]; RICARDO MEDEIROS PIANTÁ[1]; ISABELA CARVALHAL[1]; VICTORIA BORQUES SANTANA[1]; RICARDO NUNES QUINEPER[1]; AMABILE RIBEIRO OLIVEIRA[1]; THAIS SOARES FERREIRA[1]; RAYSON BELLOS SILVA[1]; VITOR AUGUSTO CIOQUETTA[1]; ARTHUR MENEZES SCHIMITZ[1]; EDUARDO STEFFEN COMASSETTO[1]; AMANDA RIVA ROHERS[1];

(1) PUCRS - PORTO ALEGRE - RS - BRASIL;

Introduction: Rheumatic mitral stenosis remains a major cause of structural valvular heart disease that in advanced stages may progress to extensive left atrial calcification, known as 'porcelain left atrium', a rare condition (estimated prevalence of 0.8-2.2%) that increases surgical risk and influences treatment strategy. We report a case of a patient with severe rheumatic mitral stenosis complicated by porcelain left atrium, precluding surgical intervention. Case Description: A 64-year-old male with a history of severe rheumatic mitral stenosis, chronic atrial fibrillation, and stable coronary artery disease was on Losartan (50 mg twice daily), Atenolol (25 mg twice daily), Warfarin, and Omeprazole (20 mg/day). The patient presented with dyspnea on mild-to-moderate exertion and episodes of seizures. Transthoracic echocardiography demonstrated a mitral valve with typical features of chronic rheumatic heart disease (valve area 1.17 cm² by planimetry; mean gradient 14 mmHg). There was marked left atrial enlargement (left atrial diameter = 5.8 cm; left ventricular ejection fraction = 50%) associated with atrial fibrillation, as well as pulmonary hypertension (estimated pulmonary artery systolic pressure 46 mmHg) and right ventricular dysfunction involvement with functional tricuspid regurgitation (reduced TAPSE - 16 mm). In correlation with exertional dyspnea, these findings supported an indication for mitral valve intervention. Pre-procedural cardiac catheterization revealed calcification requiring further evaluation.The chest computed tomography revealed an enlarged left atrium with extensive diffuse laminar calcifications involving its walls, with sparing of the interatrial septum and left atrial appendage, along with calcific involvement of the mitral leaflets, findings consistent with porcelain left atrium. Surgical intervention would necessitate left atriotomy through extensively calcified tissue. Therefore, surgical intervention was contraindicated given the anticipated high perioperative morbidity and mortality, and the patient was managed with optimized medical therapy. Conclusions: The presence of a porcelain left atrium is a clinically significant finding that limits conventional surgical approaches due to elevated operative risk of cardioembolic events and increased susceptibility to atrial arrhythmias. This case underscores the essential role of multimodality imaging in risk stratification and demonstrates how specific anatomical features critically influence therapeutic decision-making.

ACUTE PEDIATRIC CHAGAS DISEASE ASSOCIATED WITH CARDIOGENIC SHOCK AND SEVERE BIVENTRICULAR DYSFUNCTION: A CASE REPORT

KAROLINA DO ESPIRITO SANTO PINGARILHO[1]; DANIELLE MARIA MARTINS CARNEIRO[1]; LUIZ FELIPE SOUZA VIDAL[1]; GRETA EVELIN DA SILVA MOTA[1]; ANA FLAVIA FURTADO TELES[1]; ROGER VIANNA HÜHN[1]; ISABELA DE CÁSSIA BAYMA CRAVO[2]; GABRIELA PIXUNA DIAS[1]; ÁLVARO ALBERTO DE OLIVEIRA TAVARES[1];

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARA / FAMED - BELÉM - PA - BRASIL;

Introduction: Chagas Disease is an infection caused by Trypanosoma cruzi and may present with severe cardiac involvement, especially during the acute phase. Case Description: A previously healthy 4-year-old male patient from Belém was admitted in September 2025 with persistent fever for one week, abdominal distension, and severe cardiovascular impairment. Initial evaluation revealed a large pericardial effusion causing ventricular filling restriction and low cardiac output, requiring surgical drainage and admission to the pediatric intensive care unit. There was a relevant epidemiological history of a family member presenting with febrile illness and cardiopathy leading to death without a definitive diagnosis. During hospitalization, the patient developed cardiogenic shock, severe heart failure, and required vasoactive drugs. Serial echocardiograms demonstrated significant biventricular systolic dysfunction, with a lowest ejection fraction of 20%. On September 18, 2025, the second thick blood smear confirmed acute Chagas disease, and benznidazole therapy previously initiated was maintained. The patient experienced a critical clinical course, including cardiorespiratory arrest, dialysis-dependent renal failure, sepsis, and prolonged mechanical ventilation. Severe gastrointestinal complications developed, including cecal perforation, requiring ileoappendicocectomy and terminal ileostomy. Multiple antimicrobial and antifungal regimens, prolonged intensive support, and tracheostomy were necessary. Despite the initial severity, there was progressive recovery of cardiac function, with improvement of the ejection fraction to 60% by December 2025. Significant sequelae persisted, including severe malnutrition, neurological abnormalities compatible with leukoaraiosis and diffuse cerebral volume loss, as well as inferior vena cava thrombosis. The child was discharged from the hospital and remains under follow-up with cardiology, pediatrics, and infectious disease specialists. Conclusions: Acute Chagas Disease in childhood may present with a fulminant course, especially when associated with severe myocarditis and hemodynamic instability. This case highlights the importance of early recognition in endemic areas when febrile syndromes are associated with cardiac manifestations. The rapid progression to heart failure and multisystem dysfunction demonstrates the high severity of acute Trypanosoma cruzi infection, reinforcing the need for early intensive and multidisciplinary management.

ALCAPA SYNDROME IN ADULT: LATE PRESENTATION OF A RARE CONGENITAL HEART DISEASE

JOÃO VITOR JACOBSEN RAMOS[1]; RAMONA DUTRA ULIANA[1]; JULIA GAVA TOLENTINO[1]; JOAO PAULO MOULIN AUAD[1]; MARCIO VINICIUS NARDE ANGELI[1]; MARIA EDUARDA VICHI GOMES VIANA[1]; MARIANA OLIVEIRA RONCATO[1]; GUILHERME FREITAS FERNANDES OLIVEIRA[1]; LUCAS CRESPO BARROS[1]; LUIZ FERNANDO MACHADO BARBOSA[1]; ROBERTO RAMOS BARBOSA[1];

(1) ESCOLA SUPERIOR DE CIENCIAS DA SANTA CASA DE MISERICORDIA DE VITORIA - VITÓRIA - ES - BRASIL;

Introduction: The Bland-White-Garland syndrome, also known as ALCAPA (Anomalous Left Coronary Artery from the Pulmonary Artery), is a rare congenital heart disease characterized by the anomalous origin of the left coronary artery from the pulmonary artery. Typically diagnosed in infancy, it carries high mortality when left untreated. Adult presentation is uncommon and depends on the progressive development of a well-developed collateral circulation between the right coronary artery and the left coronary system. We present a case of ALCAPA diagnosed in adulthood, highlighting its clinical and diagnostic features. Case Description: A 48-year-old female patient, without traditional cardiovascular risk factors, presented with exertional dyspnea, typical chest pain triggered by physical activity, and episodes of syncope. Echocardiography demonstrated dilation of the left chambers, with preserved systolic function and evidence of diastolic dysfunction of the left ventricle. Myocardial perfusion scintigraphy revealed anterior wall ischemia. Coronary angiography was performed, showing aneurysmal dilation and tortuosity of the right coronary artery (Figure 1A), in addition to an extensive network of fistulas with collateral circulation to the left coronary artery (Figure 1B). Absence of the origin of the left coronary artery from the sinus of Valsalva was observed, with retrograde filling from the right coronary collateral network and draining into the main pulmonary artery (Figure 1C), establishing the diagnosis of ALCAPA. Coronary computed tomography angiography confirmed the anomalous origin of the left coronary artery from the pulmonary artery. Given the ischemic burden and risk of adverse events, surgical correction was indicated and successfully performed. Conclusions: ALCAPA syndrome in adults is a rare and potentially severe condition. The combination of coronary angiography and coronary computed tomography angiography was crucial for diagnosis and appropriate anatomical characterization of the anomaly, reinforcing the role of multimodality imaging in the diagnostic refinement of coronary malformations. Figure 1: Coronary angiography. (A) Right coronary artery (RCA) with diffuse aneurysmal dilation. (B) Extensive network of fistulas with well-developed collateral circulation to the left coronary artery (LCA). (C) Flow through the anomalous LCA occurring via retrograde filling from the collateral network arising from the RCA and draining into the main pulmonary artery.

ASCENDING AORTA AND ARCH REPLACEMENT IN A 6-YEAR-OLD CHILD DUE TO PSEUDOANEURYSM: A CASE REPORT.

ANA LUISA DIAS NEVES[1]; ANA CAROLINA SOUZA SILVA[1]; LUANA DE PAIVA RODRIGUES GUIMARÃES[1]; RAYANE RODRIGUES ALVES[1]; THAÍSSA LORRANE FERREIRA DOS SANTOS[1]; ROBSON DE SOUZA ALMEIDA JUNIOR[2]; GUSTAVO KLUG PIMENTEL[2]; FÁBIO BINHARA NAVARRO[2]; GABRIELA ZAMUNARO LOPES RUIZ[3];

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) HOSPITAL PEQUENO PRÍNCIPE - CURITIBA - PR - BRASIL; (3) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introduction: Aortic pseudoaneurysm is a transmural disruption with dilation of the aortic wall. It is a rare complication of cardiac surgery, with an incidence of <0.5%. In pediatrics, it is even less common and usually secondary to aortic coarctation repair, valvular surgeries or ventricular septal defect (VSD) repair. Its pathogenesis is associated with surgical manipulation, due to cannulation and suture sites representing points of vulnerability. Because it is often asymptomatic, diagnosis depends on clinical suspicion and imaging studies. This abstract highlights a pediatric aortic pseudoaneurysm as a late complication of prior cardiovascular surgery. Case Description: The patient is a 6-year and 2-month-old female, weighing 20.5 kg. At birth, was diagnosed with aortic coarctation, VSD, atrial septal defect, bicuspid aortic valve and mitral regurgitation. A coarctation repair, a patent ductus arteriosus ligation, a pulmonary artery banding, and a definitive VSD repair were successfully performed in her first months of life, with satisfactory evolution, adequate development and clinical progress in weight and height. At 6 years, began experiencing pain and paresthesia in both lower limbs, exacerbated by ambulation. Initially interpreted as “growing pains,” the increasing symptoms led to hospitalization. Lower limb Doppler Ultrasound identified thromboembolism in the right and left superficial femoral arteries. Extensive research was initiated to define the origin of the event, and an angio-CT scan revealed a lobulated and irregular pseudoaneurysm in the proximal third of the aortic arch, measuring 6.9 cm in its transverse axis and 4.3 cm in the anteroposterior axis, with a mural thrombus causing stenosis of the brachiocephalic trunk. The aortic pseudoaneurysm was resected, followed by complete reconstruction of the vessels interposing a Dacron tube over the ascending aorta and arch, with reimplantation of the brachiocephalic trunk and left carotid artery. The procedure occured uneventfully, the patient had a favorable postoperative recovery and was discharged in good clinical conditions. Conclusions: Aortic pseudoaneurysm following cardiac surgery is a rare complication. Complete reconstruction of the ascending aorta and arch constitutes an effective surgical approach, yielding favorable outcomes. The asymptomatic nature underscores the longitudinal surveillance and extensive diagnostic investigation in clinically suspicious cases as essential tools for early diagnosis and successful treatment.

INTRACARDIAC RETENTION OF A LEAD PELLET FROM AN AIR GUN IN THE INTERVENTRICULAR SEPTUM: 16-YEAR FOLLOW-UP

PEDRO FORTES DE ANDRADE COSTA[1]; ISABELA BARROSO ASSUF[1]; FERNANDA TROCCOLI NORONHA MACEDO ACHÁ[1]; ALEXIA LORIATO SIMÕES[1]; CÍNTIA CHAVES MATOSO[1]; THAISSA SANTOS MONTEIRO[1]; MARIA CAROLINA TERRA COLA[1]; FABIO AKIO NISHIJUKA[1];

(1) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Cardiac injuries caused by projectiles are rare, especially in childhood. The intracardiac retention of metallic foreign bodies raises concerns regarding mechanical complications and the risk of lead intoxication. The management of such cases remains controversial. Case Description: A 19-year-old male with a history of penetrating thoracic trauma caused by an air gun lead pellet at the age of 3 years. Following the injury, he developed three episodes of cardiorespiratory arrest, was successfully resuscitated, and transferred via aeromedical transport. Upon admission, a tension hemothorax was identified, and urgent chest drainage was performed. Imaging studies revealed a projectile lodged in the basal interventricular septum, near the aortic valve, and a conservative management approach was adopted. The patient remains asymptomatic, without complications. Imaging exams confirm stability of the projectile, with no structural repercussions. There has been no elevation in serum lead levels at any point during follow-up, with a current value of 0.7 µg/dL (reference value: up to 10 µg/dL), and no clinical signs of lead intoxication. Conclusions: Retention of lead-containing projectiles may be associated with the risk of systemic intoxication, particularly in locations with greater exposure to body fluids. In theory, continuous exposure may lead to gradual absorption of the metal and development of lead poisoning. However, projectiles encapsulated within fibrous tissue, especially in stable intracardiac locations without direct contact with turbulent blood flow or significant tissue erosion, may present a low risk of systemic leaching. International recommendations suggest periodic monitoring of serum lead levels. Levels below 5 µg/dL are considered low risk, with no indication for intervention beyond surveillance.

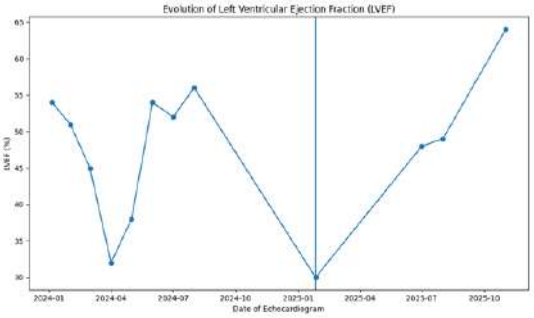
17371

RECOVERY OF VENTRICULAR FUNCTION AFTER OFF-LABEL USE OF SACUBITRIL/VALSARTAN IN A PRESCHOOL-AGED CHILD WITH SEVERE HEART FAILURE SECONDARY TO NON-COMPACTED MYOCARDIUM ASSOCIATED WITH TRPM4 AND TNNT2 GENES MUTATIONS.

ISABELLA MEDEIROS FELIX[1]; MARIA LUIZA AGUIAR BRASIL DE REZENDE[2]; RAFAELLA DHOM FERRARI MATOS[1]; CAMILA BLANCO CANGUSSU[1];

(1) UNIVERSIDADE FEDERAL DE OURO PRETO - OURO PRETO - MG - BRASIL; (2) PONTIFICIA UNIVERSIDADE CATOLICA DE MINAS GERAIS - CAMPUS BETIM - BETIM - MG - BRASIL;

Introduction: Sacubitril/valsartan is used in the management of patients with Heart Failure (HF). Unlike Europe and the United States, Brazil has regulatory approval only for adults due to the lack of large prospective randomized clinical trials in pediatric populations. We report the off-label use of sacubitril/valsartan in a patient with mutations in the TRPM4 and TNNT2 genes who did not respond satisfactorily to other therapeutic classes, supporting the potential use of this medication in the treatment of pediatric HF. Case Description: A 2-year-old male patient diagnosed with complete atrioventricular block during gestation and fetal bradycardia at birth. On the first day of life, he underwent implantation of an external pacemaker and, after 16 days, a unichamber epicardial pacemaker. During the etiological investigation, maternal lupus was ruled out; karyotype and CGH-array showed no abnormalities. Whole-exome sequencing identified mutations in TRPM4 and TNNT2. An echocardiogram suggested non-compacted left ventricle. The patient had been receiving Enalapril, Carvedilol, Hydrochlorothiazide, and Furosemide, and was under cardiological and arrhythmological follow-up due to significant biventricular systolic dysfunction, with a left ventricular ejection fraction (LVEF) of 25–30%. He experienced hospitalizations following vaccinations, including a severe episode after the MMRV vaccine, which progressed to cardiopulmonary arrest. Subsequently, his LVEF deteriorated to 10%, at which point sacubitril/valsartan in a compounded formulation was introduced to replace Enalapril and Hydrochlorothiazide. Serial echocardiograms demonstrated progressive recovery of ventricular function, with clinical improvement and an LVEF higher than the phase of treatment when conventional therapy was being used. Conclusions: In childhood, HF is potentially fatal, and proper treatment is essential. Several drug classes are used, but in some cases they are not sufficiently effective, requiring consideration of agents such as sacubitril/valsartan, which has shown efficacy in severe HF refractory to conventional therapy. However, in Brazil, its use in pediatrics remains off-label. The progressive improvement in LVEF and NT-proBNP levels, along with better clinical and hemodynamic status, highlights the drug's promising potential. Therefore, disseminating clinical evidence on its pediatric use is important to help reduce barriers to access.



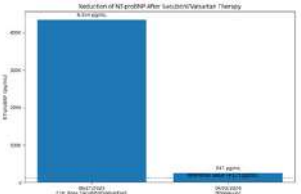


Figure 1. Evolution of left ventricular ejection fraction during follow-up, demonstrating improvement after initiation of sacubitril/valsartan. Source: author's own work.

RECURRENT PERICARDITIS AND CARDIOGENIC SHOCK AS MANIFESTATIONS OF FAMILIAL MEDITERRANEAN FEVER TRIGGERED BY CHIKUNGUNYA VIRUS: A PEDIATRIC CASE REPORT

PAULO EDUARDO GUARESQUI[1]; JULIA ACSA RODRIGUES DE ALMEIDA[1]; RAIZA BRITO CIPRIANO[1]; NICOLAS PIMENTA VALBAO[1]; MARCIO ANTONIO DE FARIA JUNIOR[1]; ALANA PAULO GARCIA[2]; RHAABY RODRIGUES MUZI[2]; VIVIANE DAMAS RIBEIRO DOS SANTOS SANTOS[2];

(1) ESCOLA SUPERIOR DE CIENCIAS DA SANTA CASA DE MISERICORDIA DE VITORIA - VITÓRIA - ES - BRASIL; (2) HOSPITAL ESTADUAL INFANTIL NOSSA SENHORA DA GLÓRIA - VITÓRIA - ES - BRASIL;

Introduction: Familial Mediterranean Fever (FMF) is a rare autoinflammatory disorder characterized by recurrent episodes of fever and serositis. While pericarditis occurs in less than 5% of patients, its progression to cardiogenic shock is an exceptional and life-threatening manifestation in the pediatric population. This report describes a severe cardiac presentation of FMF likely triggered by a preceding arbovirus infection. Case Description: A 11-year-old male native to Espírito Santo, Brazil, with a documented history of Chikungunya virus infection in August 2024 presented with recurrent abdominal pain, fever, and progressive dyspnea. In May 2025, he developed cardiogenic shock with a significantly reduced left ventricular ejection fraction (LVEF) of 32% and moderate pericardial effusion. Management required intensive care support, including inotropes (dobutamine and noradrenaline) and intravenous immunoglobulin. Based on the Tel Hashomer clinical criteria—recurrent fever, chest pain, abdominal pain, and serositis—a clinical diagnosis of FMF was established. The patient showed a dramatic response to a combined regimen of corticosteroids and colchicine, with LVEF recovering to 78.9% within days. However, several relapses of serositis (pericardial and pleural effusions) occurred in July and November 2025, and most recently in March 2026, whenever medication was tapered or the colchicine dose was reduced. These recurrences confirmed the autoinflammatory nature of the disease and the requirement for continuous therapy. Follow-up in March 2026 demonstrated clinical stabilization and a preserved LVEF of 61.4% under a maintained therapeutic dose of colchicine. Conclusions: This case highlights that FMF-related serositis can present as severe, life-threatening cardiogenic shock in children. It also suggests that arboviruses, such as Chikungunya, may act as potent inflammatory triggers for FMF in genetically predisposed individuals. The application of clinical criteria (Tel Hashomer) and the dramatic response to colchicine remain the gold standard for diagnosis when genetic testing is unavailable, emphasizing the need for high clinical suspicion in cases of recurrent pediatric serositis.

SCORPION STING: A DIAGNOSTIC AND THERAPEUTIC CHALLENGE THAT CAN BE FATA.

THAÍS CRISTINA VIEIRA ALVES[1]; MILENA DE LIMA MARTINS[1]; LOURDES DE FÁTIMA GONÇALVES GOMES[1]; BIANCA OLIVEIRA DE SIMONI[1]; JULIA MAYUMI SANTOS MITSUNAGA[1]; JOÃO VICTOR DE SOUSA[1]; GABRIELA MENDONÇA DE OLIVEIRA[1]; GIULIA SALGADO AZEVEDO[1]; AMANDA LOPES DE FREITAS[1]; RUFINO JURANDIR RIBEIRO NETO[1];

(1) UNIVERSIDADE FEDERAL DE UBERLÂNDIA - UBERLÂNDIA - MG - BRASIL;

Introduction: Scorpionism is a major public health problem in tropical regions. In Brazil, among the associated severe forms, the *Tityus* genus stands out, whose neurotoxins act on sodium, potassium, and calcium channels, promoting the release of catecholamines and acetylcholine, resulting in myocardial dysfunction and acute heart failure. This report presents a case of scorpionism in a child, illustrating that the greater the venom load per kilogram, the greater the severity. In the diagnostic approach, it is essential to rule out differential diagnoses, mainly diabetic ketoacidosis, cardiac arrhythmias, and cardiovascular dysfunctions of other causes. Case Description: A 4-year-old female patient, previously healthy, was admitted with sudden and intense pain in her right knee during school activity, vomiting, pallor, profuse sweating, and drowsiness. In the emergency room, she presented with sialorrhea and ocular deviation, being treated as a seizure with diazepam, without clinical improvement. Subsequently, capillary blood glucose ranged from 150 to 250 mg/dL and was treated as diabetic ketoacidosis. The patient developed tachypnea, thermal gradient, cold extremities, weak pulses, and hypertension. Laboratory tests revealed leukocytosis, hyperglycemia, metabolic acidosis, and elevated lactate. Due to the lack of clinical improvement and the epidemiological context, after six hours, specific antivenom for moderate scorpion envenomation was administered, along with fluid restriction. Due to acute heart failure and elevated cardiac enzymes (troponin: 6,098 ng/mL and CK-MB: 31.9 ng/mL), an echocardiogram was performed, which demonstrated significant left ventricular systolic dysfunction, an ejection fraction of 32%, and mitral and tricuspid regurgitation. After confirming the suspicion with the identification of the etiological agent at the school, a dose of antivenom for severe scorpion stings was administered, following a specific therapeutic protocol, and the child showed progressive overall improvement. Conclusions: This is a case of pediatric and cardiological emergency, in which the uncertain diagnosis delayed appropriate clinical treatment, increased morbidity, and potentiated the risk of death for the child. Fatality in these cases results mainly from early and severe cardiac compromise; therefore, immediate diagnosis and treatment are essential, even before investigating laboratory and imaging abnormalities, and it is always necessary to consider the possibility of a tropical disease.

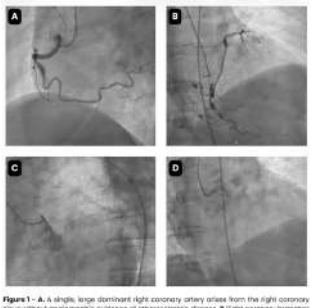
SINGLE RIGHT CORONARY ARTERY IN AN ELDERLY PATIENT WITH CHAGAS CARDIOMYOPATHY: A CASE REPORT

EMMANUEL OBERDA NOMINATO[1]; PAULO HENRIQUE SANTOS MANTOVANI[2]; ARTHUR ÁVILA REIS RONCARATI MIRANDA[1]; MARIA EDUARDA MARTINS FERNANDES[3]; CATHARINA CARVALHO E CASTRO[4]; CAIO LOUREIRO GIL[2]; MARIA EDUARDA GARAY DULTRA[1]; IURE KALININE FERRAZ DE SOUZA[1]; SÔNIA FRANCISCA DE SOUZA[2];

(1) UNIVERSIDADE FEDERAL DE OURO PRETO - OURO PRETO - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) FACULDADE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (4) PONTIFICIA UNIVERSIDADE CATOLICA DE MINAS GERAIS - CAMPUS BETIM - BETIM - MG - BRASIL;

Introduction: Coronary artery anomalies represent a heterogeneous group of congenital abnormalities with variable clinical implications. Single right coronary artery is an extremely rare variant in which the entire coronary circulation arises from a single right-sided artery and may, depending on its course, cause ischemic symptoms or sudden cardiac death. Chagas disease, endemic in Latin America, may progress to chronic cardiomyopathy with diffuse myocardial fibrosis, ventricular dysfunction, and substantial arrhythmic risk. The coexistence of these conditions has not been previously reported and represents a rare, highly complex clinical scenario. Case Description: A 65-year-old woman under long-term follow-up for chronic Chagas cardiomyopathy presented with new-onset fatigue, palpitations, dyspnea, and exertional chest pain. Comorbidities included hypothyroidism, obesity, systemic arterial hypertension, dyslipidemia, and type 2 diabetes mellitus. Prior cardiac evaluation showed right bundle branch block and left anterior fascicular block on electrocardiography, 1,943 premature ventricular contractions, three episodes of non-sustained ventricular tachycardia, and 13 pauses up to 2.2 seconds on Holter monitoring, and a left ventricular ejection fraction (LVEF) of 52%, apical aneurysm without thrombus, and mild systolic dysfunction on echocardiography. Given the new symptoms and prior findings, further investigation was performed. Myocardial perfusion scintigraphy revealed significant reversible ischemia in the apical and apical inferior segments (Summed Difference Score = 10; LVEF drop from 57% to 41% under stress). After multiple catheterization attempts, coronary angiography showed absence of the left coronary trunk and a dominant, large, non-atherosclerotic right coronary artery supplying the left coronary territory via the posterior ventricular branch, consistent with single right coronary artery. Conclusions: This case describes the coexistence of single right coronary artery and chronic Chagas cardiomyopathy in a patient surviving into the seventh decade, highlighting late survival despite adverse prognostic features. Ischemia was likely multifactorial, involving Chagas-related microvascular dysfunction, multiple cardiovascular risk factors, and a possible contribution from the coronary anomaly. This case reinforces the need for additional workup in patients with Chagas cardiomyopathy and ischemic symptoms, since these findings should not be automatically attributed to the underlying disease.



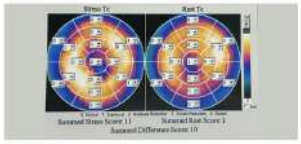


Figure 1 - A. A single, large dominant right coronary artery arises from the right coronary sinus without angiographic evidence of atherosclerotic disease. **B** Right coronary branches extended toward the anterior heart region. **C–D** Repeated attempts to identify or selectively catheterize the left coronary artery were unsuccessful.

Figure 2: Myocardial perfusion scintigraphy

Myocardial perfusion scintigraphy. Stress and rest polar maps showing reversible perfusion defects predominantly in the apical and apical-inferior segments. The summed stress score was 11, the summed rest score was 1, and the summed difference score was 10, consistent with reversible ischemia.

SUDDEN DEATH FROM BILATERAL ATRIAL MYXOMA IN A 15-YEAR-OLD PATIENT: A POST-MORTEM CASE REPORT.

JOÃO PEDRO TEIXEIRA BENTES MONTEIRO[1]; ARTUR DIÓGENES VASQUES FARIAS[1]; MARINA DE ANDRADE NORÕES BEZERRA[1]; ANTONIO ARAGÃO XEREZ JUNIOR[1]; SARAH MENDES CAVALCANTE[1]; VANESSA ARAUJO PINHEIRO[1]; DAVI PONTE PIERRE[1]; LUCAS MACÊDO AURÉLIO PAIVA[1]; NICOLE AIRES PERAZOLO[1]; TIAGO MOURA FAÇANHA[1]; LAYSE DIÓGENES BRAGA LIMA[1]; PEDRO MANSUETO MELO DE SOUZA[1];

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introduction: Atrial myxomas are the most common primary cardiac tumors, typically appearing as solitary masses in the left atrium. Bilateral involvement is exceedingly rare, occurring in less than 5% of cases, and is often associated with familial syndromes like Carney Complex. Due to their obstructive and embolic potential, they can cause syncope and sudden death, occasionally mimicking neurological disorders. Case Description: A 15-year-old female with a reported five-year history of epilepsy, treated with valproate, was admitted following an acute onset of intense headache followed by a seizure and syncope. She arrived at the hospital in cardiorespiratory arrest and did not respond to resuscitation maneuvers. Post-mortem examination revealed two large vegetating masses, one in each atrium, both measuring approximately 5.0 x 3.0 cm. Microscopy confirmed tumoral masses in both atria composed of spindle cells within a rich myxoid stroma and areas of hemorrhage. Emboli of myxoid material were identified in the pulmonary artery parenchyma. Additional findings included mild pulmonary and cerebral edema, as well as sinusoidal liver congestion. The cause of death was determined to be bilateral atrial myxoma. The mechanism of sudden death likely involved direct cardiac blood flow obstruction by the tumors or potential coronary embolization. Conclusions: This case underscores the lethal potential of bilateral atrial myxoma in pediatric populations. The reported history of epilepsy may have been a clinical manifestation of previous embolic events or transient low cardiac output rather than a primary neurological condition. High clinical suspicion and early echocardiographic screening are essential in young patients presenting with atypical syncope or seizures to prevent fatal outcomes.

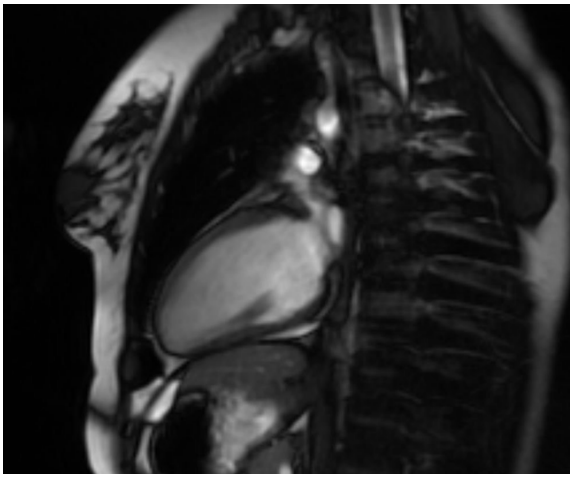
TOPSY-TURVY HEART WITH AORTOPULMONARY WINDOW: MANAGEMENT AND CLINICAL COURSE OF AIRWAY COMPRESSION IN THE POSTOPERATIVE PERIOD

MATHEUS PAGNANO DE SOUZA[1]; JOÃO VITOR FERREIRA DOMINGOS[1]; LARISSA MILKEM VIEIRA[2]; BIANCA TAFURI DANUNCIO[1]; LOURDES GONÇALVES GOMES[1]; CLÁUDIO RIBEIRO DA CUNHA[1]; JÉSSICA SILVA SILVÉRIO[1];

(1) UNIVERSIDADE FEDERAL DE UBERLÂNDIA - UBERLÂNDIA - MG - BRASIL; (2) FACULDADE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;



Introduction: Aortopulmonary window (APW) is a rare congenital heart defect, accounting for less than 0.2% of cardiac malformations. Its association with Topsy-Turvy Heart (TTH), a complex anomaly involving rotation of the cardiac axis and great vessels, is exceptionally uncommon and poses significant diagnostic and therapeutic challenges, especially regarding respiratory and hemodynamic complications related to the postoperative period. Case Description: A male infant was diagnosed with type I APW associated with atrial septal defect, patent ductus arteriosus, and TTH, characterized by a right aortic arch and dextroposition of the ascending aorta. At three months of age, the patient underwent successful surgical correction of intracardiac shunts using bovine pericardial patches. In the postoperative period, he developed persistent pulmonary hypertension (PH) and recurrent left-sided atelectasis. Further investigation with computed tomography angiography and bronchoscopy revealed extrinsic compression of the left main bronchus due to anomalous vascular anatomy, associated with tracheobronchomalacia. Concurrently, cardiac catheterization confirmed persistent PH (systolic pulmonary artery pressure of 58 mmHg). Management included optimization of pulmonary vasodilator therapy and intensive nutritional support. Over time, the patient showed progressive clinical improvement, with resolution of oxygen dependency, stabilization of respiratory function, and appropriate weight gain at 13 months of age. Conclusions: This case highlights the complex interaction between anomalous cardiovascular anatomy and airway mechanics in TTH. In complex positional congenital heart diseases, surgical correction represents only the initial step toward reducing morbidity and achieving clinical stabilization. Persistent ventilatory dependence should raise suspicion of extrinsic airway compression resulting from the abnormal relationship between the great vessels and the bronchial tree. This report demonstrates that favorable clinical outcomes, including independence from

TTN-ASSOCIATED DILATED CARDIOMYOPATHY: SUSTAINED FUNCTIONAL RECOVERY AND MYOCARDIAL FIBROSIS IN A PEDIATRIC PATIENT FOLLOWING FAMILIAL SUDDEN DEATH

ANA CRISTINA MESQUITA DE CAMPOS[1]; SARA DANTAS NASCIMENTO DUARTE[1]; RAIMUNDO FRANCISCO DE AMORIM JUNIOR[1]; ROBERTO MORENO MENDONÇA[1]; THALLYS YOHANIS BENICIO FERNANDES[1];

(1) UFRN - NATAL - RN - BRASIL;

Introduction: Dilated cardiomyopathy (DCM) is a leading cause of heart failure in children and adolescents. Loss-of-function variants in the TTN gene are among the most common genetic causes of familial DCM, with variable clinical expressivity. Etiological diagnosis is essential for clinical management and family screening, particularly given the risk of severe presentations. Case Description: A previously healthy 10-year-old female presented with progressive dyspnea, daily palpitations, and 10 kg (22.05 lb) weight loss over four months. During pre-operative cardiac evaluation for adenoidectomy, echocardiography revealed severe biventricular systolic dysfunction (left ventricular ejection fraction, LVEF, 22%), diffuse hypokinesia, significant mitral regurgitation, and chamber dilation. Acute myocarditis secondary to household COVID-19 exposure was initially suspected. She was admitted to the PICU and treated with dobutamine, diuretics, captopril, spironolactone, and hydralazine, achieving clinical stabilization; cardiac transplantation evaluation was initiated. Three years later, her 18-year-old brother died suddenly without prior cardiac investigation, prompting familial screening. Genetic sequencing identified a heterozygous splicing variant c.56648-1G>A in the TTN gene, classified as likely pathogenic. The patient demonstrated progressive ventricular recovery: LVEF 31% (2021), 48% (2022), 57% (2023), and 60% (2025). Cardiac MRI revealed non-ischemic midmyocardial fibrosis in the basal and mid-basal inferolateral wall of the left ventricle. Currently aged 15 years, she remains asymptomatic on carvedilol, enalapril, and spironolactone, with preserved systolic function. Conclusions: This case underscores the importance of genetic investigation in pediatric DCM of undetermined etiology. Sustained LVEF recovery over four years demonstrates the therapeutic potential of guideline-directed medical therapy in TTN-associated DCM. However, the presence of myocardial fibrosis and familial sudden death history raise critical concern regarding ventricular arrhythmia risk despite functional recovery.

BRIDGING STRATEGY IN CARDIAC DEVICE INFECTION IN A PACING-DEPENDENT PATIENT WITHOUT CONTRALATERAL ACCESS

BRUNO PORTELA DIAS[1]; VINICIUS GABRIEL NUNES DE FREITAS[1]; ALEX BRUNO FERREIRA REBELO[1]; PAULO ROBERTO CAMPBEL REBELO[1]; MARIA PAULA FERREIRA REBELO[1]; POLYANA COSTA BRANDÃO[1]; ENDERSON DOS SANTOS BARBOSA[1]; CAMILA ROBERTA FERREIRA REBELO[2]; IAGO VINICIOS MARAMALDE GIBSON[1]; ISABELA CALANDRINI SERRUYA[1]; ÁLAN BRENO FERREIRA REBELO[1];

(1) UNIVERSIDADE FEDERAL DO AMAPÁ - MACAPÁ - AP - BRASIL; (2) UNIVERSIDADE NILTON LINS - MANAUS - AM - BRASIL;

Introduction: Infection of cardiac implantable electronic devices (CIEDs) requires complete system extraction. In patients who are pacing-dependent and have limited venous access, management becomes particularly challenging, requiring safe and innovative alternative strategies. Case Description: A 60-year-old male patient with heart failure with reduced ejection fraction of ischemic etiology, worsened by pacemaker-induced dyssynchrony, was on optimized medical therapy at maximum doses and progressed to NYHA functional class IV. He had a history of complete atrioventricular block and was dependent on ventricular pacing, in addition to having chronic kidney disease on dialysis. He had previously undergone cardiac resynchronization therapy with an implantable cardioverter-defibrillator (CRT-D), with initial clinical improvement. Subsequently, he developed a device pocket infection, with persistent purulent drainage and failure of antibiotic therapy. Given the indication for complete system extraction and considering pacing dependence, an aggressive bridging strategy was chosen, consisting of implantation of a single-chamber pacemaker via the transvenous route, with an active-fixation lead and an externalized generator positioned in the cervical region, performed during the same surgical procedure as removal of the infected system. The patient evolved with hemodynamic stability, adequate ventricular capture, and no need for admission to the intensive care unit, showing progressive clinical improvement. After complete treatment of the infection, definitive device reimplantation was performed at the same previously infected site, with good wound healing. Contralateral reimplantation was not performed due to the presence of an arteriovenous fistula in the right upper limb, essential for hemodialysis. Conclusions: In patients with CIED infection, pacing dependence, and limited venous access, the use of a pacemaker with an active-fixation lead and an externalized generator represents an effective bridging strategy. Furthermore, reimplantation at a previously infected site, after complete infection control, may be a safe and feasible alternative in selected cases.

21764

CASE REPORT: INFLIXIMAB IN REFRACTORY TAKAYASU ARTERITIS WITH SEVERE NON-ISCHEMIC CARDIOMYOPATHY IN A PATIENT WITH SEVERE METABOLIC COMORBIDITIES

ANNE CAROLINE TAUFFER LANDIM[1]; FERNANDA LIMA MARTINS[1]; JOÃO VICTOR MARQUES NASCIMENTO[1]; UILIAM DE OLIVEIRA SANTOS[1]; GABRIELA MENDONÇA OLIVEIRA[1]; GISELE BARRETO DEUS[1]; FLÁVIA BITTAR ARANTES[1];

(1) UNIVERSIDADE FEDERAL DE UBERLÂNDIA - UBERLÂNDIA - MG - BRASIL;

Introduction: Takayasu Arteritis (TA) is a large-vessel vasculitis with an incidence of 1.11/1,000,000 person-years. Heart failure (HF) affects 20% of cases, with a five-year event-free survival rate of 54.7%. Although TA-associated cardiomyopathy is typically attributed to hemodynamic overload, histopathological evidence confirms inflammatory myocarditis as an independent and reversible mechanism. Disease activity shows poor clinical-laboratory correlation; vascular progression occurs in 61% of patients in apparent remission. We report the management of refractory TA with concomitant non-ischemic HFrEF. Informed consent was obtained. Case Description: A 40-year-old female patient with Takayasu Arteritis (TA) diagnosed in 2011 exhibited refractoriness to multiple regimens. In 2022, during the postpartum period, she presented with disease reactivation (aortic arch syndrome), aortic root thickening (10 mm), and pulmonary hypertension (38 mmHg). Pulse therapy and cyclophosphamide were initiated, with the latter discontinued in 2023 due to therapeutic failure. Aortic thickening regressed to 6 mm; luminal stability sustained the decision not to intensify immunosuppression (ACR 2021). In April 2025, cardiovascular evaluation revealed HFrEF (EF 29%). Coronary angiography ruled out obstructive disease; ventriculography confirmed diffuse hypokinesia. The absence of coronary artery disease and the responsiveness to corticosteroids suggest inflammatory myocarditis as the determinant of HF. In June 2025, a biopsy of lung nodules (<1 cm) confirmed rheumatoid nodules, evidencing extravascular manifestations. In December 2025, headache and cervicalgia prompted further pulse therapy, but CTA/MRA demonstrated anatomical stability, configuring clinico-radiological dissociation. Lipid decompensation and ventricular dysfunction restricted the use of tocilizumab (risk of LDL >160 mg/dL in 10% of cases). Despite the ATTACH trial associating infliximab (10 mg/kg) with HF mortality, prior failure of cyclophosphamide and leflunomide necessitated its maintenance under monitoring. Current management: infliximab, azathioprine (200 mg/day), prednisone (20 mg/day), and optimized HFrEF therapy (metoprolol, SGLT2 inhibitors, and ARNI). Comorbidities: epilepsy, fibromyalgia, and previous DVT. Conclusions: Management of TA with HFrEF requires strategies beyond inflammatory suppression. In restriction scenario, infliximab under cardiovascular surveillance was viable for inflammatory control and stabilization of ventricular dysfunction.

20609

CHRONIC ENDOMYOCARDIAL FIBROSIS ASSOCIATED WITH PERSISTENT AF AND TACHYCARDIOMYOPATHY: A THERAPEUTIC CHALLENGE

SARAH ALVES PEREIRA DOMINGOS[1]; GUSTAVO CAMPOS SABINO[1]; GABRIEL BRANT MOREIRA FERREIRA[1]; CHRISTIANO GONÇALVES DE ARAÚJO[2];

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introduction: Endomyocardial fibrosis (EMF) is a rare restrictive cardiomyopathy that progresses from an acute inflammatory phase to a chronic fibrotic phase. In the latter, the deposition of fibrous tissue in the ventricular endocardium leads to apical obliteration and severe diastolic dysfunction. More than 30% of EMF patients present with atrial fibrillation (AF), which is associated with embolic complications and tachycardiomyopathy. EMF is endemic to certain regions, carries a guarded prognosis and has a 2-year mortality rate of 75% with medical treatment alone. This study aims to report a therapeutic challenge involving chronic-stage EMF associated with AF. Case Description: A 72-year-old male with left ventricular endomyocardial fibrosis and heart failure with reduced ejection fraction (HFrEF) of mixed etiology (EMF/tachycardiomyopathy due to AF) was diagnosed in 2022 after presenting with severe ventricular dysfunction (LVEF 26%). His ejection fraction has been oscillating, improving to 56% in 2023 following cardioversion, but dropping again in 2026 during a hospitalization for decompensated HF. He was admitted with a “cold and wet” hemodynamic profile, NYHA class IV dyspnea, orthopnea, and exertional chest pain. He also exhibited wasting syndrome (13 kg weight loss in three months), however, screening for occult malignancy was negative. Echocardiography and Chest Computed Tomography revealed that the apical region was completely obliterated (25% of the cavity) by a hyperechoic and calcified structure, consistent with chronic-phase EMF and an LVEF of 38%. The ECG showed AF and left bundle branch block, while coronary angiography revealed no obstructive lesions. During hospitalization, due to arterial hypotension and signs of hypovolemia, losartan and furosemide were discontinued, and a cautious fluid challenge was performed, resulting in improved perfusion. The patient showed clinical improvement and was discharged for outpatient follow-up, with a planned ablation. Conclusions: Heart failure management in EMF patients is complex, as AF can drastically worsen systolic function. Identifying the fibrotic stage through imaging is essential to avoid unnecessary immunosuppression and focus on hemodynamic optimization. Although surgical endomyocardectomy is the definitive option for cavitary deobliteration, its use is limited by high operative risk and perioperative morbidity and mortality. Thus, strict rhythm control and outpatient follow-up remain the primary strategies for this patient profile.

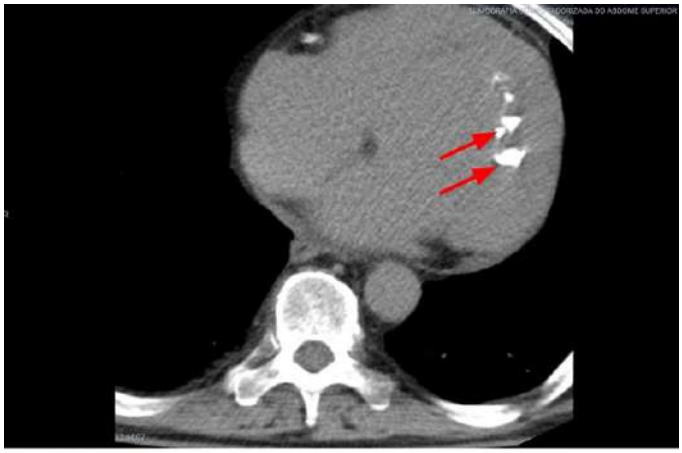

Figure 1: Computed tomography of the chest, mediastinal window, showing coarse endocardial calcifications.

18819

COCAINE-INDUCED CARDIOTOXICITY LEADING TO DILATED CARDIOMYOPATHY AND CARDIOEMBOLIC STROKE: A CASE REPORT

PEDRO NUNES HUMMES[1]; JAZIEL HENCKE LOPES[1]; VINICIUS FELIPE REOLON[1]; BERNARDO ROMAGNA BERTO[1]; GABRIELE PETRY PEREIRA DA SILVA[1]; NUR ABDALLA JUMA ABDEL HAMID[1]; GABRIELA FIGUEIREDO ANDRIOLA[1]; PAOLA SARAIVA MARINHO[1]; BETTINA SCHMITT[1]; AMANDA RIVA ROHERS[1]; EDUARDO STEFFEN COMASSETTO[1]; VITOR BONIATTI NEVES[1];

(1) PUCRS - PORTO ALEGRE - RS - BRASIL;

Introduction: Cardiotoxicity is defined as structural or functional damage to the myocardium caused by exogenous substances. This condition is frequently associated with the use of antineoplastic drugs; however, recreational drugs such as cocaine have increasingly been recognized as important contributors. Cocaine can induce cardiotoxicity through direct myocardial injury, coronary vasospasm and prothrombotic effects. The aim of this case report is to demonstrate how cocaine use contributes to cardiotoxicity, highlighting its role as a cause of Dilated Cardiomyopathy. Case Description: A 43-year-old female patient, with a past medical history of hypertension, smoking and cocaine use presented to the emergency department with a history of progressive dyspnea over 3 weeks, which had progressed to dyspnea at rest, associated with orthopnea and bilateral lower limb edema, bilateral diffuse rales on lung auscultation, O2 saturation of 92% and BNP 6.180 pg/mL. Chest CT revealed bilateral diffuse consolidations with ground-glass opacities and cardiomegaly. She was admitted for treatment of decompensated heart failure (HF) secondary to a respiratory tract infection. There was no family history of HF. Further evaluation included cardiac magnetic resonance imaging, which demonstrated eccentric hypertrophy and global systolic dysfunction in both ventricles, with a left ventricular ejection fraction (LVEF) of 20%. Two thrombi were identified in the apical region of the left ventricle, suggesting dilated cardiomyopathy. Coronary angiography revealed no evidence of atherosclerotic disease. During hospitalization, the patient initially showed clinical improvement but unexpectedly experienced two consecutive cardiac arrests, with return of spontaneous circulation after 8 and 12 minutes, respectively. During recovery in the intensive care unit, she developed focal motor neurological deficits, and brain MRI findings were consistent with an embolic stroke in the territory of the right middle cerebral artery. Despite these complications, the patient gradually improved and was discharged after 36 days of hospitalization. Conclusions: This report describes a severe case of dilated cardiomyopathy complicated by cardiac arrest, left ventricular thrombus formation, and progression to cardioembolic stroke, likely secondary to cocaine-induced cardiotoxicity. It also underscores the importance of investigating substance use in cases without a clearly defined etiology, given its significant impact on management and prognosis.

18409

DIFFERENTIAL DIAGNOSIS OF INFILTRATIVE CARDIOMYOPATHY IN A POST-RENAL TRANSPLANT PATIENT: A CASE REPORT

THAÍS CRISTINA VIEIRA ALVES[1]; BIANCA OLIVEIRA DE SIMONI[1]; JULIA MAYUMI SANTOS MITSUNAGA[1]; JOÃO VICTOR DE SOUSA[1]; GABRIELA MENDONÇA DE OLIVEIRA[1]; MILENA DE LIMA MARTINS[1]; THIAGO ARRUDA REZENDE[1]; LUIZ ROBERTO CRUVINEL HERCOS JÚNIOR[1]; GUSTAVO HENRIQUE DE LIMA E SILVA[1];

(1) UNIVERSIDADE FEDERAL DE UBERLÂNDIA - UBERLÂNDIA - MG - BRASIL;

Introduction: Infiltrative cardiomyopathies represent a diverse group of pathologies characterized by the deposition of substances in the interstitium or in myocytes. Although amyloidosis is the most frequent cause, differential diagnosis with phenocopies, such as Fabry disease and dialysis-related beta-2-microglobulin (B2M) amyloidosis, is fundamental, especially in patients with multiple systemic comorbidities. This report aims to describe the complexity involved in the differential diagnosis of hypertrophic cardiomyopathies. Case Description: A 56-year-old male patient with a history of hypertension and chronic kidney disease (CKD) underwent a kidney transplant in 2022 after 17 years of hemodialysis. He presented with chronic atrial fibrillation and bilateral hearing loss and was hospitalized due to recurrent falls preceded by objective vertigo and diplopia. Cardiologic evaluation revealed an echocardiogram demonstrating left ventricular hypertrophy, with an interventricular septum measuring 20 mm and a posterior wall of 22 mm, biatrial enlargement, and diffuse myocardial hyperreflectivity with a granular appearance, suggestive of infiltrative cardiomyopathy. The electrocardiogram showed high-amplitude QRS complexes, diverging from the low-voltage pattern typically associated with amyloidosis. However, electroneuromyography demonstrated involvement of the sensorimotor fibers of the median nerves in the wrist segment, of a demyelinating nature with secondary axonal loss, compatible with chronic bilateral carpal tunnel syndrome of at least moderate severity, more pronounced on the right side, a characteristic finding of amyloidosis. Myocardial pyrophosphate scintigraphy was negative for transthyretin amyloidosis, and serum immunofixation did not detect a monoclonal component, thus reducing the likelihood of AL amyloidosis. Given the combination of myocardial hypertrophy, early-onset CKD, and axonal neuropathy confirmed by electroneuromyography, hypotheses of Fabry disease and β2M amyloidosis secondary to prolonged hemodialysis were raised, and active investigations into these conditions are currently underway. Conclusions: In this case, the discrepancy between echocardiographic and electrocardiographic findings made it necessary to investigate rare etiologies. It is important to emphasize that, in kidney transplant recipients with a history of prolonged dialysis, the recognition of extracardiac warning signs is essential to avoid diagnostic errors and guide specific therapeutic management.

15726

DILATED CARDIOMYOPATHY ASSOCIATED WITH A TTN GENE MUTATION IN AN ADOLESCENT

CAIO NOGUEIRA AFFIUNE SILVA[1]; YASMIN BARROS CORREA[1]; FELIPE NOGUEIRA AFFIUNE SILVA[2];

(1) UNIFIMES - TRINDADE - GO - BRASIL; (2) INSTITUTO DE CARDIOLOGIA E TRANSPLANTE DO DISTRITO FEDERAL - DISTRITO FEDERAL - DF - BRASIL;

Introduction: Heart failure in young patients poses a diagnostic challenge, particularly in non- ischemic etiologies such as genetic cardiomyopathies. TTN truncating variants are among the most common causes of dilated cardiomyopathy, with presentations ranging from subclinical disease to acute heart failure. Multimodality imaging combined with genetic testing is essential for accurate etiological diagnosis and management. Case Description: A previously healthy 16-year-old adolescent presented with a 20-day history of nausea, vomiting, and progressive dyspnea, which progressed to orthopnea and lower extremity edema, with no evidence of current or previous infectious disease. Physical examination revealed a gallop rhythm with a grade II/VI systolic murmur in the mitral area, blood pressure of 80/60 mmHg, and a heart rate of 112 bpm, with signs of low cardiac output. The electrocardiogram showed ventricular bigeminy. Transthoracic echocardiography revealed biventricular and biatrial enlargement, diffuse systolic dysfunction with a left ventricular ejection fraction (LVEF) of 30%, severe mitral regurgitation, and moderate tricuspid regurgitation. The patient was hospitalized and treated with vasoactive and decongestive therapy with intravenous dobutamine and furosemide, showing progressive symptomatic improvement. Cardiac magnetic resonance imaging demonstrated enlargement of the atrial chambers and left ventricle (LVEDV 228 mL / LVEFV 126 mL), with severe systolic dysfunction due to diffuse hypokinesia (LVEF 20%) and absence of late gadolinium enhancement. Right heart catheterization (using milrinone at 0.3 mcg/kg/min) showed a cardiac output of 5.8 L/min, a cardiac index of 3.04 L/min/m², and post- capillary pulmonary hypertension characterized by a low transpulmonary gradient (PAPm of 31 mmHg and transpulmonary gradient of 4 mmHg). After stabilization of cardiogenic shock, guideline-guided drug therapy was initiated, including amiodarone 200 mg, carvedilol 3,125 mg, dapagliflozin 10 mg, valsartan 80 mg, and furosemide 40 mg. The patient was discharged after clinical improvement. Genetic testing identified a heterozygous pathogenic mutation in the TTN gene. After two months of outpatient follow-up, he remains clinically stable under therapeutic optimization. Conclusions: This case highlights an acute presentation of TTN gene-related dilated cardiomyopathy in an adolescent, mimicking myocarditis, highlighting the importance of early etiological investigation and immediate guideline-guided therapy.

EARLY HEART RETRANSPLANTATION AND IMMUNO-HEMATOLOGICAL CHALLENGE: THE ROLE OF MONOCLONAL GAMMOPATHY IN CARDIAC ALLOGRAFT VASCULOPATHY

GUSTAVO CAMPOS SABINO[1]; SARAH ALVES PEREIRA DOMINGOS[1]; JULIA KELLY CAMPOS[1]; ANA CAROLINA SOUZA SILVA[1]; RAYANE RODRIGUES ALVES[1]; THAÍSSA LORRANE FERREIRA DOS SANTOS[1]; PEDRO HENRIQUE MILAGRES[1]; BIANCA ITUASSU MAPA NOVATO VICENTE GALLO[1]; DANIEL NARDI[1]; MATHEUS FERBER[1]; GABRIELA ZAMUNARO LOPES RUIZ[1]; BEATRIZ COSTA HAIASHI[1];

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introduction: Cardiac Allograft Vasculopathy (CAV) is the leading cause of late heart transplant failure, affecting 30 to 50% of patients within 5 years. Retransplantation in these scenarios is exceptional, reserved for selected patients with severe systolic dysfunction. The coexistence of Monoclonal Gammopathy of Undetermined Significance (MGUS) adds extreme complexity to this management, as MGUS is an independent risk factor for cardiovascular events and chronic inflammatory dysregulation. Its association with an accelerated progression of CAV raises the strong hypothesis of an overlapping and significant pathophysiological mechanism, making this clinical scenario unique and underexplored in the literature. Case Description: We report the case of a 51-year-old male patient with ischemic cardiomyopathy, type 2 diabetes mellitus and MGUS, who underwent a primary heart transplant in 2022. He had an atypically rapid progression to severe CAV (ISHLT CAV 3) and biventricular dysfunction after 3 years. Catheterization in 2025 confirmed the distal occlusion of the left anterior descending (LAD) and posterior descending (PDA) coronary arteries. He was referred for retransplantation, with preoperative exams revealing global bone marrow hypoplasia on the myelogram. The procedure took place in June 2025, and the postoperative period required intensive management, marked by bradycardia, pneumonia, and secondary pancytopenia, evidencing profound hematological fragility to immunosuppression and infection. Despite the development of chronic kidney disease, the rigorous adjustment of the immunosuppressive therapy, using tacrolimus, mycophenolate, and prednisone, enabled an excellent recovery. 3 months after the surgery, the patient is asymptomatic, with preserved biventricular function (LVEF 72%) and endomyocardial biopsies negative for rejection. Conclusions: Graft failure due to severe CAV in just 3 years is an early outcome, and this case suggests a possible interaction between the chronic inflammatory state inherent to MGUS and the pathogenesis of the vasculopathy, configuring a manifestation of monoclonal gammopathy of cardiovascular significance. The therapeutic success in the face of severe bone marrow hypoplasia and infectious complications demonstrates the viability of high-risk retransplantation. This reinforces the need for intensive cardiovascular surveillance in transplant recipients with plasma cell dyscrasias and highlights the importance of individualization of the immunosuppressive protocol.

Introduction: Hypertrophic cardiomyopathy (HCM) is an autosomal dominant genetic disorder characterized by left ventricular hypertrophy. In symptomatic patients, left ventricular outflow tract (LVOT) obstruction—often exacerbated by systolic anterior motion (SAM) of the mitral valve—is the primary driver of clinical symptoms. Without relief of this mechanical obstruction, patients face an increased risk of progression to limiting heart failure, arrhythmias, and sudden cardiac death. Case Description: A 40-year-old male was diagnosed with severe obstructive asymmetric septal HCM. During follow-up, he exhibited high-risk criteria for sudden cardiac death: a positive family history, recurrent syncope, myocardial fibrosis on magnetic resonance imaging, and exertional hypotension. Despite maximally tolerated beta-blocker therapy, the patient remained highly symptomatic and functionally limited. Echocardiographic evaluation revealed a severe worsening of the resting LVOT gradient, increasing from 40 mmHg to 71 mmHg. Given the high arrhythmic and hemodynamic risk, a prophylactic implantable cardioverter-defibrillator (ICD) was considered, and targeted therapy with Mavacamten (5 mg/day) was initiated. Following treatment optimization, the patient experienced remarkable symptomatic improvement, accompanied by a drastic reduction in the LVOT gradient to 10 mmHg at rest and 19 mmHg during the Valsalva maneuver. Conclusions: Mavacamten, a first-in-class cardiac myosin inhibitor, directly targets the underlying pathophysiology of HCM by reducing dynamic LVOT obstruction. In this patient with refractory symptoms and high clinical risk, Mavacamten safely and effectively relieved the outflow gradient and improved functional capacity. This case underscores the transformative role of targeted myosin inhibition in the medical management of severe obstructive HCM, providing an effective pharmacological alternative to invasive septal reduction therapies.

ENDOMYOCARDIAL FIBROSIS AND BIVENTRICULAR THROMBOSIS: A DIAGNOSTIC CHALLENGE IN HYPEREOSINOPHILIC SYNDROME

SARAH ALVES PEREIRA DOMINGOS[1]; GUSTAVO CAMPOS SABINO[1]; GABRIEL BRANT MOREIRA FERREIRA[1]; CHRISTIANO GONÇALVES DE ARAÚJO[2];

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introduction: Hypereosinophilic Syndrome (HES), whether primary or secondary, is a rare disorder characterized by eosinophil overproduction, potentially causing severe multiorgan damage. Cardiac involvement is frequent, typically progressing from an acute inflammatory phase to a thrombotic stage, and ultimately to chronic endomyocardial fibrosis marked by intracavitary obliteration. This report highlights the importance of early diagnosis and clinical management during the acute phase to alter the disease's natural history. Case Description: A 49-year-old female with no previous comorbidities was admitted with lower limb edema, hepatomegaly, and jugular venous distention. Laboratory tests revealed anemia (hemoglobin 9.4 g/dL), thrombocytopenia (platelets 99,000/mm³), and eosinophilia (57% in the myelogram and 683 eosinophils/mm³ in peripheral blood). Echocardiography showed right ventricular (RV) hypertrophy and dilation, accompanied by diffuse hypokinesia and systolic dysfunction. After transfer to a reference center, Cardiac Magnetic Resonance (CMR) imaging confirmed endomyocardial fibrosis (Figure 1), revealing biventricular subendocardial late gadolinium enhancement, moderate pericardial effusion, and extensive images suggestive of intracavitary thrombi, findings characteristic of the inflammatory and thrombotic stages. Following safety protocols, management prioritized empirical antiparasitic therapy (essential in endemic areas) to treat concomitant subclinical parasitosis, major secondary causes of eosinophilia, and prevent Strongyloides hyperinfection syndrome. Subsequently, prednisone (1 mg/kg/day) and rivaroxaban were initiated, guided by the CMR findings. The patient showed clinical stabilization and resolution of congestion, being discharged for joint outpatient follow-up by cardiology and hematology. Conclusions: This case illustrates the severity of acute cardiac involvement in HES and reinforces that identifying the initial inflammatory stage through CMR is essential to guide immunosuppressive therapy. While the chronic phase offers few options beyond symptom management and high-risk surgeries, early intervention in the acute phase enables heart failure compensation and halts myocardial damage, drastically improving the patient's prognosis.

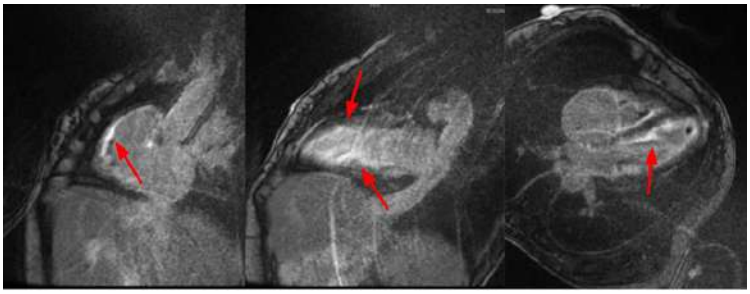

Figure 1: Cardiac magnetic resonance (CMR) findings demonstrating diffuse biventricular subendocardial late gadolinium enhancement (LGE) and a resting subendocardial perfusion deficit in the left ventricle (LV). Extensive hypointense masses, highly suggestive of intracavitary thrombi, are observed adhering to the endocardial surface of both ventricles

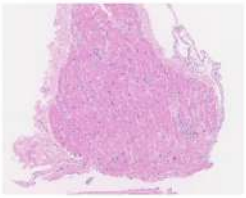
EOSINOPHILIC MYOCARDITIS AS A SEVERE CLINICAL PRESENTATION OF A CASE OF EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS

ANNA JÚLIA ANDRINO SCHNEIDER[1]; ISABELLE SANTOS TEIXEIRA DE ALENCAR[2]; LAURA LEITE DA ESCÓSSIA[2]; LARISSA MORAIS DE OLIVEIRA[3]; DIEGO BASTOS PORTO[1];

(1) UFC - FORTALEZA - CE - BRASIL; (2) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL; (3) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL;

Introduction: Eosinophilic myocarditis is a rare and potentially fatal condition, characterized by infiltration of eosinophils into the myocardium and associated with varying degrees of inflammatory damage, and may present as severe acute heart failure. One of the causes of this clinical entity is eosinophilic granulomatosis with polyangiitis, which is a small-vessel vasculitis with systemic involvement, marked by eosinophilia in the peripheral blood. We report a case with this diagnosis, highlighting the role of interdisciplinary integration in diagnostic investigation. Case Description: A 58-year-old female patient, with late-onset asthma and subacute peripheral sensory neuropathy, was admitted with a clinical picture of heart failure, presenting dyspnea on minimal exertion, orthopnea, paroxysmal nocturnal dyspnea and peripheral edema. Laboratory tests revealed significant and persistent eosinophilia (11,410/µL). Echocardiography showed severe systolic dysfunction of the left ventricle (LVEF 15%), extensive segmental akinesia and an apical thrombus (2.1 × 0.9 cm). Cardiac MRI demonstrated diffuse pericardial thickening and enhancement, with mesoepicardial non-ischemic fibrosis, consistent with inflammatory myopericarditis. Endomyocardial biopsy showed myocarditis in a resolving phase, with a lymphoplasmacytic infiltrate and rare eosinophils. The association of asthma, eosinophilia, and peripheral neuropathy allowed the diagnosis of eosinophilic granulomatosis with polyangiitis with cardiac involvement. After pulse therapy with corticosteroids and cyclophosphamide, there was clinical improvement, with partial recovery of ventricular function (LVEF 30%). Conclusions: This case highlights the diagnostic complexity of eosinophilic myocarditis in the context of eosinophilic granulomatosis with polyangiitis, especially in the setting of multisystem presentation. The absence of eosinophilia in endomyocardial biopsy does not exclude the diagnosis, emphasizing that integration of clinical, laboratory, and imaging data are essential for early diagnosis and timely initiation of immunosuppression, with potential reversal of cardiac involvement.

Image 1: Endomyocardial biopsy (hematoxylin–eosin staining) showing myocardial tissue with interstitial inflammatory infiltrate predominantly composed of lymphocytes, associated with focal myocyte injury. Rare eosinophils are identified, and findings are consistent with myocarditis in a resolving phase, possibly limited by sampling variability.



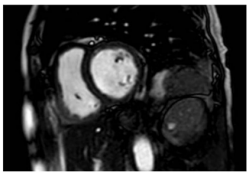


Image 2: Cardiac magnetic resonance imaging demonstrating late gadolinium enhancement with a mesoepicardial pattern involving the left ventricle.

HEART TRANSPLANTATION IN A CHILD WITH COMPLEX CONGENITAL HEART DISEASE: A CASE REPORT

GABRIEL ANDRE PEDRAL DINIZ LEITE[1]; GUSTAVO ANDRE PEDRAL DINIZ LEITE[1]; CARLOS HENRIQUE ROLEMBERG DA ROCHA[1]; ROBSON DE SOUZA ALMEIDA JUNIOR[2]; BRUNO HIDEO SAIKI SILVA[2]; FÁBIO BINHARA NAVARRO[2]; GUSTAVO KLUG PIMENTEL[2]; RAPHAEL PEREIRA QUINTANA[2]; GABRIELA ZAMUNARO LOPES RUIZ[1];

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (2) HOSPITAL INFANTIL PEQUENO PRINCIPE - CURITIBA - PR - BRASIL;

Introduction: Heart transplantation (HTx) is gold standard for end-stage heart failure and a viable strategy for patients with complex congenital disease (CHD), failure to thrive, severe arrhythmias, or restrictive cardiomyopathy. Decision-making weighs quality of life, alternative treatments, and life expectancy. This report details a pediatric patient, twice palliated, listed as a national priority for HTx. Case Description: 16-year-old female with heterotaxy (situs ambiguus, dextrocardia, unbalanced AVSD and double-outlet left ventricle) underwent neonatal aortic coarctation repair/PA banding and bilateral Glenn procedure at 8. Presented with worsening cyanosis and progressive functional decline. Hemodynamic evaluation revealed right pulmonary artery stenosis, continued with dyspnea, severe malnutrition and medical therapy intolerance due to hypotension persisted even after angioplasty. Onset of refractory supraventricular arrhythmias in January 2023 prompted a national priority listing for HTx. The procedure (CPB time 285'; cross-clamp 118'; total ischemia 325') required extensive anatomical reconstruction, including redirection of suprahepatic veins to the right atrium, innominate vein reconstruction with donor iliac vein graft, reversal of bilateral Glenn shunt and pulmonary trunk anastomosis. Immediate postoperative course was complicated by right-sided chamber dysfunction and acute rejection, requiring inotropic support, hemodialysis and successful treatment with corticosteroids and intravenous immunoglobulin. The patient was discharged26 days after the HTX; at 15-month follow-up, she remains clinically stable with preserved graft function and no evidence of rejection. Conclusions: While HTx in patients with complex CHD and univentricular physiology is well-established, it remains a scarcely discussed topic in literature due to extreme anatomical heterogeneity and high burden of prior palliative surgeries. These complexities often lead to exclusion from transplantation lists and there is a notable lack of high-level evidence regarding the exact indications and optimal timing for HTx in this population. This case demonstrates that the indication for HTx can be successfully driven by a severe decline in functional class, malnutrition and refractory arrhythmias rather than primary ventricular dysfunction alone. Despite the high risk of early mortality associated with complex CHD transplantation, survivors who overcome the critical perioperative period can achieve excellent long-term outcomes.

HEREDITARY TRANSTHYRETIN AMYLOIDOSIS PRESENTING MAINLY WITH CARDIOMYOPATHY IN A PATIENT WITH A PREDOMINANTLY NEUROLOGIC VARIANT (P.ILE127VAL): CASE REPORT

TIAGO ALVES DE MENDONÇA[1]; PEDRO CAMPOS DOS SANTOS PEÇANHA DE CARVALHO[1]; CARLOS VINICIUS DE SOUZA FELIPE[1]; MARIA LUIZA CORTÊS BONIFÁCIO PEREIRA[1]; TÚLIO PINHEIRO MACEDO DA SILVA[1]; DANIEL ELIAS MORAIS DO NASCIMENTO[1]; PEDRO ARTHUR NASCIMENTO DA SILVA[1]; CREUZA MACEDO GOES ROCHA[1]; YAGO ABRANTES CAVALCANTE[1]; FABIO MASTROCOLA[1];

(1) UFRN - NATAL - RN - BRASIL;

Introduction: Hereditary transthyretin amyloidosis (ATTRv) is a systemic, genetic, deposition disease that may present with cardiomyopathy. The p.Ile127Val variant is associated with a predominantly neurologic phenotype, with sensorimotor polyneuropathy and cranial nerve involvement, and a late cardiac phenotype, which may be underdiagnosed in clinical practice. This report describes the case of a patient with an atypical, primarily cardiac presentation of transthyretin amyloidosis due to the p.Ile127Val variant. Case Description: A 68-year-old White male patient from Rio Grande do Norte presents to cardiology due to incidental findings on imaging studies, without cardiac complaints or comorbidities and an unremarkable family history. No cardiovascular or neurologic abnormalities were found on physical examination. The electrocardiogram was also normal. A transthoracic echocardiogram revealed significant concentric left ventricular hypertrophy and right ventricular hypertrophy, with preserved function, and an interventricular septum measuring 13 mm. Subsequently, a cardiac magnetic resonance imaging study demonstrated predominantly septal myocardial hypertrophy; thickening of the interatrial septum; diffuse coarse foci of nonischemic-pattern myocardial fibrosis; and a marked increase in native T1 time and myocardial extracellular volume; findings that raised cardiac amyloidosis as the leading diagnostic hypothesis. Serum protein immunofixation showed no monoclonal protein, and the kappa/lambda ratio was of 1.31, within the normal range; thus ruling out light-chain amyloidosis. Myocardial scintigraphy with pyrophosphate showed grade 3 radiotracer uptake (Perugini scale), confirming transthyretin amyloidosis (ATTR). Genetic testing by next-generation sequencing of the TTR gene identified the pathogenic p.Ile127Val variant in heterozygosity, establishing the diagnosis of ATTRv cardiomyopathy. On neurologic evaluation, limb electroneuromyography showed no evidence of polyneuropathy, and a complaint of chronic watery diarrhea was interpreted as a probable dysautonomic symptom. The patient remains on treatment with tafamidis 20 mg/day, with favorable clinical course. Conclusions: This case combines a rare genetic disease, an uncommon mutation, and an atypical presentation, describing a patient with ATTRv due to the p.Ile127Val variant with an exclusively cardiac phenotype. Also, a discrepancy is noted between the high degree of abnormalities on imaging studies and the absence of cardiac symptoms.

LEFT VENTRICULAR MYOCARDIAL INVOLVEMENT IN SYSTEMIC SCLEROSIS–DERMATOMYOSITIS OVERLAP: BEYOND PULMONARY HYPERTENSION

MARIA LUIZA RODRIGUES TAMBORINI[1]; MARIANA PEZZUTE LOPES[1]; VITOR EMER EGYTO ROSA[1]; TALITA ROCHA MASCARENHAS[1]; EDUARDO CUKIERKORN[1]; FLAVIO TARASOUTCHI[1];

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction: Systemic sclerosis (SSc) is an autoimmune disease characterized by vasculopathy and progressive multisystem fibrosis. Cardiac involvement in SSc is described in a minority of cases and carries significant prognostic impact, with a 5-year survival rate close to 25% Case Description: A 69-year-old hypertensive female former smoker reported progressive dyspnea during follow-up for systemic sclerosis–dermatomyositis overlap syndrome, diagnosed by skin biopsy and electroneuromyography, while receiving methotrexate and prednisone. Initial echocardiography demonstrated a Pulmonary Artery Systolic Pressure of 54 mmHg and right chamber dilation. Right heart catheterization confirmed mixed pulmonary hypertension (mean pulmonary artery pressure 29 mmHg; pulmonary vascular resistance 2.4 WU; pulmonary capillary wedge pressure 18 mmHg after fluid challenge). Due to lack of clinical improvement, methotrexate was replaced with azathioprine. During follow-up, myocardial perfusion scintigraphy performed for dyspnea investigation showed transient anterolateral hypoperfusion, with no obstructive lesions on coronary angiography. Repeat echocardiography revealed left chamber dilation, severe tricuspid regurgitation, and moderate mitral regurgitation secondary to apical tethering of the posterior leaflet. Cardiac magnetic resonance imaging demonstrated biventricular dilation with severe dysfunction (RVEF 26%; LVEF 38%) and anterolateral subendocardial late gadolinium enhancement, consistent with SSc-related myocardial involvement. At the last clinical evaluation, the patient was no longer receiving immunosuppressive therapy due to stable cutaneous and esophageal disease, but remained symptomatic with NYHA functional class II dyspnea despite optimized heart failure therapy. Conclusions: Although cardiac involvement in SSc is most commonly associated with myocardial remodeling secondary to pulmonary hypertension, approximately 20% of patients may present primary myocardial involvement resulting from microvascular disease with recurrent ischemia-reperfusion injury, inflammation, and fibrosis. Given the poorer prognosis in these cases, regular follow-up with early identification of this presentation is essential for appropriate risk stratification and optimization of medical therapy.

PROGRESSION OF HYPERTROPHIC CARDIOMYOPATHY TO A DILATED PHASE ASSOCIATED WITH AN ALPK3 GENE MUTATION: A CASE REPORT

RICARDO ABBUD TORRES XAVIER[1]; SAMARA STAHLSCHMIDT DOZORSKI[2]; MARIA EDUARDA GIFFONI SILVEIRA[2]; MARCELY GIMENES BONATTO[2];

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (2) HOSPITAL SANTA CASA DE CURITIBA - CURITIBA - PR - BRASIL;

Introduction: Heart failure is a highly prevalent clinical syndrome, affecting more than 50 million people worldwide. Among its various etiologies, hypertrophic cardiomyopathy (HCM) stands out as a genetic disease characterized by ventricular hypertrophy, which classically progresses to heart failure with preserved ejection fraction. The genes most frequently involved genes include MYH7, MYBPC3, and TNNT2. More recently, mutations in the ALPK3 gene have been associated with both hypertrophic and dilated forms, often with a more aggressive clinical course. This study aims to report a case of hypertrophic cardiomyopathy progressing to a dilated phase, leading to advanced heart failure, associated with an ALPK3 gene mutation. Case Description: A 35-year-old male patient with previous diagnosis of congenital hypertrophic cardiomyopathy has been under follow-up since childhood. Approximately five years ago presented with clinical decompensation, progressing to heart failure with reduced ejection fraction (HFrEF). His symptoms have worsened two years ago following a dental infection. The last transthoracic echocardiography revealed left ventricular dilation (55/48 mm), severe systolic dysfunction (ejection fraction 25–30%) and septal hypertrophy. Additionally, biatrial enlargement, along with findings suggestive of noncompacted myocardium and grade III diastolic dysfunction (restrictive pattern), as well as mild mitral and tricuspid regurgitation. These findings indicated progression to a dilated phenotype, and a diagnosis of dilated cardiomyopathy of initially undefined etiology was established. Despite optimized medical therapy, the patient remains in New York Heart Association (NYHA) functional class III and was therefore referred for evaluation and listing for heart transplantation. To investigate the etiology of this atypical progression, further etiological assessment with exome sequencing was performed, revealing a mutation in the ALPK3 gene. Conclusions: This case highlights the importance of genomics in the investigation of heart failure, particularly when facing atypical disease progression. It emphasizes the relevance of identifying mutations associated with more aggressive phenotypes, such as those observed in this patient, which involved the ALPK3 gene, heading the progression from hypertrophic cardiomyopathy to a dilated phase. The integration of genetic, clinical, and imaging findings is essential for accurate diagnosis, prognostic stratification, and appropriate therapeutic management.

RIGHT-SIDED HEART FAILURE WITH AN OVERLAPPING PHENOTYPE BETWEEN CARCINOID HEART DISEASE AND COR PULMONALE: A DIAGNOSTIC CHALLENGE

ANTONIO ARAGÃO XEREZ JUNIOR[1]; IAN SANTOS ALENCAR OLIVEIRA[1]; NICOLE AIRES PERAZOLO[1]; JOÃO DA SILVA FERREIRA MARINHO[1]; JOÃO MACEDO COELHO NETO[1]; ISRAEL NASCIMENTO COUTINHO COSTA[1]; LAYSE DIÓGENES BRAGA LIMA[1]; EDUARDO CRUZ LOPES[1]; VANESSA ARAUJO PINHEIRO[1]; VIRNA TAVARES DE LIMA FERREIRA[2]; ISABELLE SANTOS TEIXEIRA DE ALENCAR[3]; JEFFERSON LUIS VIEIRA[3];

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL; (3) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introduction: Right heart failure (RHF) has multiple etiologies, including cor pulmonale and carcinoid heart disease. Cor pulmonale results from increased pulmonary vascular resistance, leading to right ventricular (RV) overload and tricuspid regurgitation due to annular dilation. In contrast, carcinoid heart disease is caused by vasoactive substances from neuroendocrine tumors, leading to fibrotic thickening and retraction of the valve leaflets, resulting in tricuspid regurgitation. Despite overlapping features, their distinct mechanisms require accurate differential diagnosis. Case Description: An 88-year-old male, heavy smoker, presented with significant weight loss, evolving with lower limb edema, dyspnea and chronic diarrhea. Physical examination revealed sarcopenia, systemic venous congestion and expiratory wheezing. Transthoracic echocardiography showed RV dilation with its dysfunction, associated with thickened tricuspid leaflets and severe coaptation failure, resulting in a single-chamber appearance. These findings, along with chronic diarrhea and a consumptive syndrome, raised suspicion for carcinoid heart disease. However investigation for neuroendocrine tumors with computed tomography (CT) and upper gastrointestinal endoscopy was negative, making the diagnosis less likely, although 5-hydroxyindoleacetic acid testing, the gold standard, was unavailable. Notably, although valvular abnormalities were suggestive, there was no unequivocal evidence of typical structural involvement, and these findings were interpreted with caution in the clinical context. Chest CT demonstrated centrilobular and paraseptal emphysema, consistent with chronic obstructive pulmonary disease (COPD), potentially explaining the right heart involvement. The patient showed significant clinical improvement after decongestion and bronchodilator therapy, being discharged for outpatient follow-up. Conclusions: In this case, echocardiographic findings and systemic symptoms suggested carcinoid heart disease, whereas pulmonary imaging, together with clinical improvement after COPD-targeted therapy, supported cor pulmonale as the most likely diagnosis. This overlap of clinical and imaging features highlights the complexity of RHF etiologies and reinforces the importance of integrating clinical, laboratory, and imaging data to guide appropriate management.

SEVERE CLINICAL PRESENTATION OF TAKOTSUBO SYNDROME WITHOUT AN APPARENT PRECIPITATING FACTOR: A CASE REPORT

EDUARDA TANIGUCHI RODRIGUES FIGUEIRA[1]; WASFI NASSER SHAHIN[1]; MARIA EDUARDA CASARINI DA COSTA[1]; JÚLIA PEDRISA AFARELLI[1]; ISABELA ROBERTO BARION[1]; JÚLIA LOPES RAVAGNANI[1]; JÚLIA BARBATI SPROESSER[1]; ISABELA FERRO[1]; GIULIO CHECCHINATO FACCHINI[1]; ALCIDES ROCHA DE FIGUEREDO JÚNIOR[1]; HÉLDER JORGE DE ANDRADE GOMES[1];

(1) FACULDADE DE MEDICINA DE JUNDIAI - JUNDIAÍ - SP - BRASIL;

Introduction: Takotsubo cardiomyopathy is characterized by acute left ventricular (LV) systolic dysfunction, typically involving dyskinesia of the mid-apical segments and hyperkinesia of the basal portions, of non-coronary origin. Non-significant findings on invasive coronary angiography, combined with the usual fast and complete recovery of LV function, may have created a false perception of benignity within the medical community. Therefore, we present a case report illustrating the potential severity of Takotsubo cardiomyopathy. Case Description: A 46-year-old female patient was admitted with sudden retrosternal chest pain starting 1 hour prior, described as pressure, intensity 10/10, radiating to the left upper limb, with no apparent triggering factor. She has a 40 pack-year smoking history and peripheral obstructive arterial disease (chronic total aorto-iliac occlusion), with intermittent claudication during moderate exertion, under medical treatment. In the emergency room, she suffered a cardiopulmonary arrest (CPA) with an initial rhythm of ventricular fibrillation, reversed with standard care. Vasoactive drugs were required due to progression to circulatory shock following resuscitation. The post-CPA ECG showed ST-segment elevation in multiple leads, without correlation to a particular coronary territory (Figure 1A). The first attempt at emergency coronary angiography failed due to access issues (aorto-iliac occlusion and radial puncture made impossible by the shock state). After 4 days of stabilization in the ICU, a second attempt revealed non-obstructive coronary artery disease (without involvement of the left anterior descending artery) and the typical appearance of Takotsubo syndrome on ventriculography (Figure 1B). From then on, the patient showed good clinical and neurological progress and was discharged to the hospital ward. As an outpatient (26 days after admission), the patient underwent cardiac magnetic resonance imaging, which showed normal LV systolic function and absence of late gadolinium enhancement (Figure 1C), accentuating the distinction between Takotsubo and STEMI as the patient's final diagnosis. Conclusions: Takotsubo syndrome is a clinical condition of increasing recognition, responsible for up to 6% of cases of women with acute coronary syndrome, and presents in-hospital mortality comparable to STEMI in current registries (~4%). Up to 28% of patients do not present an evident triggering event, as was the case with the patient in our report.

19564

SHOULD ALL CASES OF MYOCARDITIS BE CONSIDERED VIRAL IN ORIGIN? DIAGNOSTIC CHALLENGES OF LUPUS MYOPERICARDITIS IN A PATIENT WITH SYSTEMIC LUPUS ERYTHEMATOSUS—A CASE REPORT

RICARDO TANNURI CHUFFI SALVADEU[1]; GIULIA REZENDE GUARATTO[1]; THIAGO ARRUDA REZENDE[1];

(1) UNIVERSIDADE FEDERAL DE UBERLÂNDIA - UBERLÂNDIA - MG - BRASIL;

Introduction: Lupus myocarditis is a serious condition found in 1.6% to 5.7% of patients with systemic lupus erythematosus (SLE). Its pathophysiology involves immune-mediated and ischemic damage caused by the deposition of immune complexes, and it can progress to arrhythmias, cardiomyopathies, and heart failure. It is diagnosed based on a combination of signs and symptoms, elevated blood inflammatory markers, echocardiographic and electrophysiological studies, myocardial enhancement on contrast-enhanced magnetic resonance imaging (MRI), and biopsy showing immune complex deposition by immunofluorescence. Treatment is based on immunosuppression to control SLE. Case Description: A 35-year-old female patient, previously healthy, was referred to the emergency department in 2012 complaining of dyspnea, diffuse chest pain, and palpitations. On physical examination, no abnormalities were noted. Subsequently, cardiac troponin levels were measured in the blood (3.7 ng/mL), an electrocardiogram was performed (indicating right atrial overload and ST-segment depression), an echocardiogram (revealing grade I left ventricular diastolic dysfunction), and a chest computed tomography scan (showing pericardial effusion and pleural effusion), which raised suspicion of myopericarditis, confirmed by contrast-enhanced MRI, with no defined etiology. Subsequently, an etiological investigation of the myopericarditis was conducted, in which serology for HIV and Hepatitis B and C, as well as blood culture and VDRL, were negative; however, there was absolute and relative lymphocytosis on the complete blood count, a positive FAN tites of 1:1280, and positive anti-SSA, anti-SM, and p-ANCA antibodies, while the levels of other autoantibodies were negative. A myocardial biopsy was performed, revealing deposition of anti-nuclear immunoglobulins on immunofluorescence. She was then diagnosed with SLE associated with acute myopericarditis and pleuritis resulting from the first flare-up of the disease. Treatment with glucocorticoids and cyclophosphamide pulse therapy was indicated, leading to complete resolution of the condition. Today, at age 47, she undergoes regular treatment with 5 mg of prednisone once daily, with no disease recurrence. Conclusions: Acute SLE myocarditis is difficult to clinically suspect and diagnose; however, unlike viral myocarditis, it responds effectively to treatment. Therefore, it is essential to consider this differential diagnosis in young women with myocarditis and to seek more efficient diagnostic methods.

YAMAGUCHI SYNDROME IN A NON-ASIAN PATIENT PRESENTING WITH ATYPICAL CLINICAL MANIFESTATIONS: A CASE REPORT

VICTÓRIA ELISA CEOTTO[1]; ALINE BURATTI[1]; RAFAELA MORETTO MARCHIORO[1]; CAROLINE DUCATTI MEME[1]; IVANA ANNICHINO DIAS PACHECO[1];

(1) UNIVERSIDADE ANHEMBI MORUMBI - PIRACICABA - SP - BRASIL;

Introduction: Apical hypertrophic cardiomyopathy (AHCM), or Yamaguchi syndrome, is an uncommon morphological variant of hypertrophic cardiomyopathy characterized by predominant hypertrophy of the left ventricular (LV) apex. Although classically described in Asian populations, its occurrence in non-Asian individuals is increasingly recognized, often with atypical clinical presentation and potential misdiagnosis as acute coronary syndrome (ACS). Case Description: A 64-year-old Caucasian female with a history of systemic arterial hypertension presented with atypical chest pain and exertional dyspnea following emotional stress. Electrocardiography demonstrated diffuse anterior precordial T-wave inversion and criteria for LV hypertrophy. Serial high-sensitivity cardiac troponin assays showed mild elevation (38.5–54.1 ng/L), without dynamic ischemic pattern. Transthoracic echocardiography revealed preserved LV systolic function (ejection fraction 69%, Teichholz method), with marked apical hypertrophy and mild concentric hypertrophy of non-apical segments, raising suspicion for AHCM. Due to persistent symptoms despite optimization of antihypertensive therapy, invasive coronary angiography was performed, demonstrating non-obstructive coronary artery disease, including mild (30%) stenosis in the mid-left anterior descending artery associated with myocardial bridging, luminal irregularities in the circumflex artery, and ectasia of the right coronary artery. Given ongoing exertional dyspnea and suspected Yamaguchi phenotype, beta-adrenergic blockade (Bisoprolol 2.5 mg/day) was initiated, resulting in significant symptomatic improvement. Cardiac magnetic resonance imaging confirmed apical-predominant hypertrophic cardiomyopathy, with evidence of dynamic LV outflow tract obstruction at rest and late gadolinium enhancement consistent with non-ischemic myocardial fibrosis. Conclusions: AHCM is a distinct phenotypic variant requiring multimodality imaging for diagnosis, with cardiac magnetic resonance enabling precise assessment of apical hypertrophy and myocardial fibrosis. Late gadolinium enhancement and dynamic obstruction may be associated with increased arrhythmic risk. This case highlights the need to consider AHCM in non-Asian patients with atypical chest pain and elevated biomarkers. Multimodal imaging was essential for diagnosis, and beta-blocker therapy improved symptoms. Follow-up and family screening are recommended.

CARDIAC PARAGANGLIOMA AS A CAUSE OF SECONDARY HYPERTENSION: DIAGNOSTIC CHALLENGES IN A YOUNG PATIENT.

ISABELA CARVALHAL[1]; ANA LUÍSA CARVALHAL[1]; GIOVANA AJHORN MATTIELLO[1]; LAURA MANFROI[1]; MARCELO BOPP TESHEINER[1]; LAURA SMANIOTTO SARAIVA[1]; JAZIEL HENCKE LOPES[1]; PEDRO NUNES HUMMES[1]; MATHEUS CRIPPA PETRILLO[1]; VINICIUS FELIPE REOLON[1]; BETTINA SCHMITT[1]; MÁRIO WIEHE[1];

(1) PUCRS - PORTO ALEGRE - RS - BRASIL;

Introduction: Pheochromocytomas and paragangliomas are rare catecholamine-secreting tumors, accounting for approximately 0.1-0.6% of cases of secondary hypertension. Extra-adrenal tumors represent up to 15-20% of cases, whereas cardiac paragangliomas are exceptionally rare (<1%), posing significant diagnostic challenges due to their atypical location. Case Description: 20-year-old male with a family history of systemic arterial hypertension was presented with recurrent tachycardic palpitations and paroxysmal hypertension. Initial evaluation, including electrocardiogram, Holter monitoring and transthoracic echocardiography, showed no structural abnormalities; bisoprolol was initiated (5–10 mg/day). Biochemical assessment demonstrated markedly elevated urinary catecholamines (1424; reference 15-80) and plasma norepinephrine (2500 pg/mL; reference <460), confirming catecholamine hypersecretion. The patient underwent multidisciplinary evaluation; however, tumor localization remained inconclusive, with recurrent hypertensive crises requiring emergency care. Given persistent symptoms and exertional intolerance, further investigation was performed. Holter monitoring revealed rare supraventricular ectopy, a brief supraventricular tachycardia episode, and multiple sinus pauses >2.0 seconds (maximum 19.5 seconds), without ventricular arrhythmias. Transesophageal echocardiography identified a 5.4 × 5.4 × 3.7 cm sessile right atrial mass displacing the interatrial septum. Cardiac magnetic resonance imaging demonstrated a highly vascularized lesion adherent to the septum, and iodine-131 metaiodobenzylguanidine scintigraphy confirmed radiotracer uptake in the right atrial region. Preoperative management was performed with alpha-adrenergic blockade using doxazosin (6 mg/day) and beta-blockade with bisoprolol (15 mg/day), followed by surgical resection involving the right atrial wall and interatrial septum. The specimen measured 5.3 × 4.8 × 3.5 cm and weighed 48.6 g. Histopathological and immunohistochemical analyses confirmed cardiac paraganglioma as the cause of secondary hypertension. The postoperative course was uneventful. Conclusions: Cardiac paraganglioma is a rare cause of secondary hypertension, yet remains an important diagnostic consideration. Its atypical location poses diagnostic challenges, particularly when initial investigations are inconclusive, underscoring the importance of multimodal imaging and a multidisciplinary approach for accurate localization and definitive surgical management.

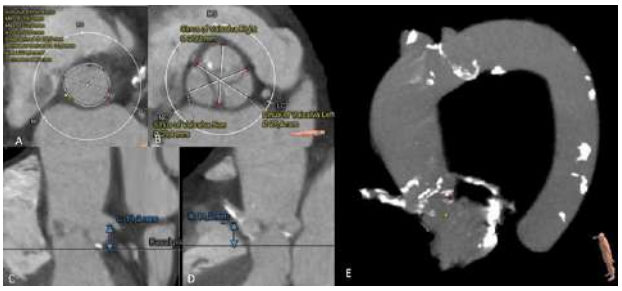
PULMONARY ARTERY ANEURYSM PRESENTING WITH NONSPECIFIC RESPIRATORY SYMPTOMS: CASE REPORT

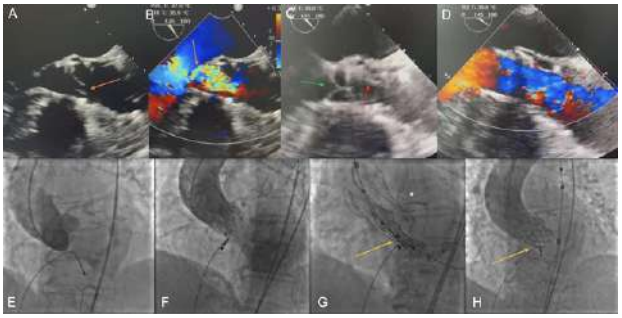
FERNANDO VIEIRA BRANDALISE[1]; JOÃO HENRIQUE STRAPASSON[1]; ARTUR KLIPPEL TONET[1]; IÁDINE ANDREIS DE OLIVEIRA[1]; MARINA VECINI TESSARI[1]; OTAVIO REIS BOF[1]; JOÃO BERNARDO FABRIS[1]; CAROLINA FILIPPIS FOCHESATO[2]; RONALD PAULO PINTO ZART[1]; JORGE JERRY BUSTAMANTE BUSTAMANTE[3];

(1) CENTRO UNIVERSITÁRIO DA SERRA GAÚCHA - CAXIAS DO SUL - RS - BRASIL; (2) UNIVERSIDADE DE CAXIAS DO SUL - CAXIAS DO SUL - RS - BRASIL; (3) POMPÉIA ECOSSISTEMA DE SAÚDE - CAXIAS DO SUL - RS - BRASIL;

Introduction: A 44-year-old male presented with bronchitis and respiratory symptoms, including recent expectoration and chronic bronchodilator use, associated with nonspecific symptoms such as excessive fatigue and intermittent dyspnea, without chest pain or syncope. Initial evaluation for primary pulmonary disease was unremarkable, prompting further cardiovascular investigation. Transthoracic echocardiography and CT angiography identified fusiform dilatation of the main pulmonary artery (40 mm) and right pulmonary artery (27 mm), while the left pulmonary artery remained normal (21 mm). Based on these findings, which were clinically significant given the risk of progression and potential for life-threatening events, the patient underwent pulmonary artery aneurysmorrhaphy. Case Description: Pulmonary artery aneurysm (PAA) is a rare and potentially life-threatening pathology of the pulmonary vasculature, most commonly associated with congenital heart disease or infections. PAA, it is frequently asymptomatic and incidentally diagnosed, as in the reported case. Therefore, the absence of pathognomonic symptoms makes diagnosis based solely on the patient's symptoms rare. However, symptoms of dyspnea, exertional fatigue, and the absence of chest pain or syncopal episodes, together with Transthoracic echocardiography and CT angiography enabled the diagnosis in this patient. Progressive dilatation of the pulmonary artery (≥70mm) may lead to catastrophic complications, including massive hemoptysis due to rupture, coronary artery compression resulting in acute coronary syndrome, bronchial or recurrent laryngeal nerve compression, and pulmonary artery dissection, which has, on average, a 50 to 100% chance of mortality (INOLAN, D. C et al. 2026). Nevertheless, the patient did not experience any of the possible complications due to early recognition and low dilation of the Pulmonary Artery. PAA is treated through a surgical procedure, which the patient underwent. Conclusions: Pulmonary artery aneurysm is a rare and diagnostically challenging condition due to its nonspecific presentation. This case emphasizes the importance of PAA, since its diagnostic difficulty stemming from the absence of pathognomonic symptoms, which could otherwise rule out differential diagnoses.



15282

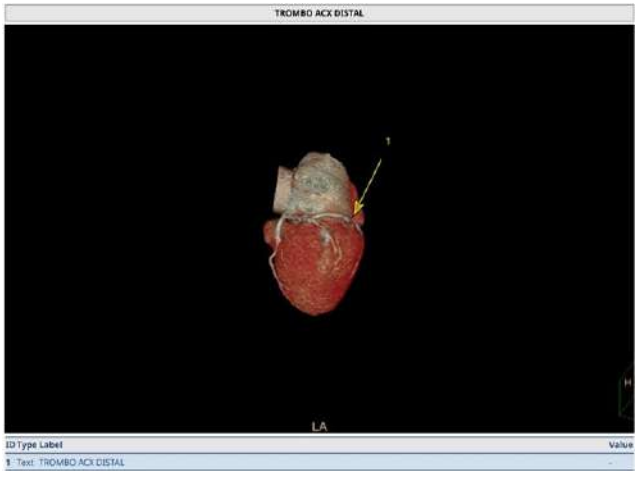


ACUTE LEAFLET INVERSION CAUSING CATASTROPHIC AORTIC REGURGITATION AFTER TAVI: SUCCESSFUL EMERGENCY TAV-IN-TAV BAILOUT IN A HIGH-RISK PATIENT

MARIA FERNANDA MIRANDA CARVALHO[1]; GUSTAVO CARVALHO[1];

(1) UNIVERISADE POSITIVO - CURTIBA - PR - BRASIL;

Introduction: Transcatheter aortic valve implantation (TAVI) is the standard of care for patients with severe aortic stenosis at high surgical risk. Despite its safety profile, acute structural valve dysfunction is rare and may result in rapid hemodynamic collapse, requiring immediate bailout strategies. Case Description: An octogenarian female with severe aortic stenosis, chronic kidney disease, and restrictive lung disease was considered at prohibitive surgical risk and referred for transfemoral TAVI. Pre-procedural imaging demonstrated favorable native valve anatomy for a self-expanding prosthesis, with moderate and symmetric calcification and a symmetric aortic annulus. A self-expanding Navitor valve (Abbott) was deployed via right femoral access. Immediately after implantation, acute valve failure occurred due to leaflet inversion, leading to torrential aortic regurgitation and profound hemodynamic instability. Rapid angiographic assessment confirmed severe prosthetic dysfunction. Given the life-threatening scenario, an emergent percutaneous bailout was performed. A balloon-expandable Myval 21.5 mm valve was implanted within the failed prosthesis (TAV-in-TAV strategy). The intervention resulted in immediate abolition of regurgitation, restoration of valve competence, and rapid hemodynamic recovery. The patient had an uneventful clinical course thereafter. Conclusions: Acute leaflet inversion is a rare but potentially catastrophic complication of TAVI that may lead to abrupt hemodynamic collapse. This case highlights that prompt recognition and immediate percutaneous intervention are crucial. TAV-in-TAV implantation represents a rapid, effective, and potentially life-saving bailout strategy, allowing restoration of valve function while avoiding emergent surgery in critically ill, high-risk patients.



20384

ACUTE MYOCARDIAL INFARCTION TRIGGERED BY DEFECATION STRAINING IN A PATIENT WITH PROSTHETIC VALVE THROMBOSIS POST-TAVR: A CASE REPORT.

OTÁVIO DA COSTA CARVALHO[1]; GIAN NATHANIEL ANAYA BISOGNIN[2]; ROMUALDO BOLZANI DOS SANTOS[2]; FERNANDO PASIN[2];

(1) UNIVERSIDADE FRANCISCANA - SANTA MARIA - RS - BRASIL; (2) HEMOCOR CARDIOLOGIA INTERVENCIONISTA - SANTA MARIA - RS - BRASIL;

Introduction: The transcatheter aortic valve replacement (TAVR) revolutionized the management of severe aortic stenosis by offering a less invasive alternative to surgical replacement in a large number of patients. Among potential complications, prosthetic valve thrombosis (PVT), though relatively uncommon, represents a significant challenge requiring careful monitoring and management strategies. This case report highlights a particularly intricate scenario involving PVT, further complicated by ST-elevation myocardial infarction (STEMI) in the context of a Valsalva-like maneuver. Case Description: A 75 year-old male with a history of alcoholism was admitted to the hospital with symptoms of community-acquired pneumonia. Three months prior, he had undergone a TAVR procedure in another institution. During his evaluation, an echocardiogram revealed a significant transvalvular gradient. Due to this, a computed tomography angiography (CTA) revealed intense thrombosis of the prosthetic valve. Anticoagulation was immediately initiated with enoxaparin. Approximately 48h after starting anticoagulation, he experienced severe chest pain and diaphoresis following prolonged straining during defecation. An electrocardiogram (ECG) showed findings consistent with STEMI. He was transferred to the intensive care unit and treatment was initiated with aspirin, clopidogrel, tirofiban, nitroglycerin and enoxaparin. His symptoms decreased and his condition stabilized within 36 hours. Coronary CTA demonstrated occlusion of the circumflex artery (CX) by a thrombus and a significant reduction in the thrombotic burden on the aortic valve. A new echocardiogram confirmed a reduction in the transvalvular gradient. After 10 days, coronary angiography showed no thrombus in the aortic valve and no significant coronary disease. Conclusions: The occurrence of a STEMI in a post-TAVR patient with prosthetic valve thrombosis presents an unique and complex case challenge. Low prosthesis implantation may have favored thrombus formation via turbulent flow in the left ventricular outflow tract. The excessive straining, which increased myocardial overload and systemic vascular resistance, likely contributed to the rupture of thrombus that subsequently embolized to the CX artery. This case highlights the importance of individualized risk stratification and management in post-TAVR patients with thrombotic complications, offering valuable insights into the potential management in selected cases of complex valve thrombosis.

16653

ASSOCIATION OF PARAVALVULAR LEAK AND MITRAL REGURGITATION POST TRANSCATHETER AORTIC VALVE IMPLANTATION: A CASE REPORT

KAYLANE ZUQUETO DA SILVA[1]; RICARDO MAURO GHETTI CABRAL[1];

(1) UNIVERSIDADE FEDERAL DE VIÇOSA (UFV) - VIÇOSA - MG - BRASIL;

Introduction: Transcatheter aortic valve implantation (TAVI) is a minimally invasive treatment for severe aortic stenosis. Moderate-to-severe paravalvular leak (PVL) occurs in approximately 3.4% of cases, while mitral regurgitation (MR) is present in 25–30% of patients undergoing TAVI. Both are associated with worse prognosis; however, their combined occurrence, particularly when mechanically related, represents a rare and highly challenging clinical scenario. Case Description: An 81-year-old woman with obesity, hypertension, and hyperlipidemia presented with a 2-month history of progressive dyspnea (NYHA functional class III). Transthoracic echocardiography (TTE) demonstrated concentric left ventricular hypertrophy with preserved systolic function (LVEF 62%), pulmonary hypertension (estimated pulmonary artery systolic pressure 50 mmHg), and severe aortic stenosis (aortic valve area 0.8 cm^2; mean gradient 43 mmHg). The patient underwent TAVI, which was technically challenging due to aortic tortuosity. Despite successful deployment, lack of annular calcification led to prosthesis instability with 14 mm ventricular migration and significant paravalvular leak. Three weeks later, the patient developed progressive heart failure symptoms, requiring recurrent hospital admissions. Follow-up TTE demonstrated ventricular displacement of the prosthesis associated with severe PVL and newly developed severe MR, attributed to mechanical interaction between the migrated prosthesis and the anterior mitral leaflet. Given the patient's high surgical risk, a simultaneous fully percutaneous strategy was pursued, consisting of a TAVI-in-TAVI procedure with complete PVL sealing combined with transcatheter edge-to-edge mitral valve repair. The procedure was successfully performed, and the patient showed symptomatic improvement to NYHA II. Final TTE demonstrated a well-positioned aortic bioprosthesis without residual PVL, a mean transvalvular gradient of 24 mmHg, and only mild residual mitral regurgitation. Estimated pulmonary artery systolic pressure decreased to 29 mmHg. Conclusions: This case highlights a rare complication of TAVI involving severe PVL associated with secondary severe MR due to prosthesis migration. Simultaneous treatment with a fully percutaneous TAVI-in-TAVI approach combined with transcatheter edge-to-edge mitral repair is exceptionally uncommon and technically demanding. In this high-risk patient, the strategy proved feasible and safe, resulting in substantial clinical and hemodynamic improvement.

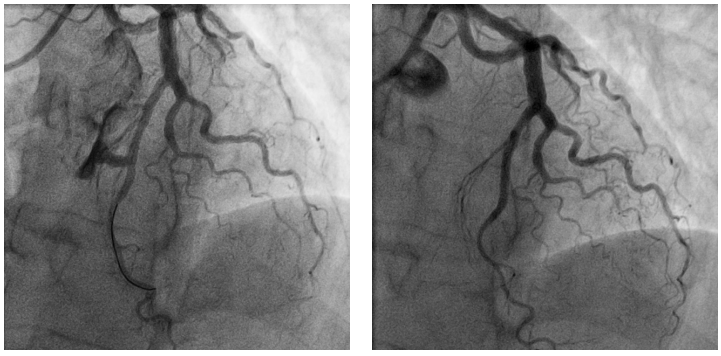
CARCINOID HEART DISEASE WITH SEVERE TRICUSPID REGURGITATION: PERCUTANEOUS MANAGEMENT WITH CAVAL VALVE IMPLANTATION (CAVI) USING THE TRICVALVE SYSTEM

ANA LUIZA DA SILVA BARBOSA[1]; MARIA EDUARDA REZENDE OLIVEIRA[1]; LIVIA LANZONI FREITAS[2]; ISADORA MARTINS FERREIRA BARRILARI[2]; DANILO SFORCINI TOMAZ AQUINO[3]; FABIANO RUBIAO LUCCHESI[3]; ANDERSON CAETANO SILVA[3];

(1) FACULDADE DE CIENCIAS DA SAUDE DE BARRETOS- DR PAULO PRATA - BARRETOS - SP - BRASIL; (2) FACULDADE DE CIENCIAS DA SAUDE DE BARRETOS - DR PAULO PRATA - BARRETOS - SP - BRASIL; (3) HOSPITAL NOSSA SENHORA, FUNDAÇÃO PIO XII - BARRETOS - SP - BRASIL;

Introduction: Tricuspid regurgitation (TR) is a prevalent valvular disease associated with significant morbidity and mortality. Traditionally underrecognized and often considered secondary to left-sided heart disease, its management has frequently been delayed until advanced stages, when surgical intervention carries higher risk, with in-hospital mortality rates around 9%, contributing to its undertreatment. In this context, percutaneous strategies have gained increasing attention, including edge-to-edge valve repair, annuloplasty, transcatheter valve replacement, and caval valve implantation. Among these approaches, bicaval valve implantation (Caval Valve Implantation – CAVI), represented by systems such as the TricValve, has emerged as a promising alternative for patients with severe TR and high surgical risk, leading to reduction of systemic venous reflux and clinical improvement. Thus, transcatheter therapies are redefining the management of TR, particularly in this high-risk population. Case Description: A 58-year-old female with hypertension, type 2 diabetes mellitus, dyslipidemia, hypothyroidism, and depression, on optimized medical therapy, presented with facial flushing and chronic diarrhea and was diagnosed with metastatic hepatic neuroendocrine tumor in the setting of carcinoid syndrome. She developed progressive cardiovascular symptoms, including exertional dyspnea (NYHA II), fatigue, palpitations, and lower limb edema. Cardiac evaluation revealed carcinoid heart disease with significant right-sided valvular involvement. Transthoracic echocardiography showed right chamber dilation and severe tricuspid regurgitation, along with mild-to-moderate mitral regurgitation and indirect signs of pulmonary hypertension, confirmed by cardiac magnetic resonance imaging. Given the severity of TR and high surgical risk, a percutaneous approach with caval valve implantation (TricValve system) was performed. Post-procedural echocardiography demonstrated well-positioned prostheses, with restoration of forward flow and resolution of systolic reflux in the hepatic veins, despite persistence of TR at the native valve level, as expected. Conclusions: This case highlights the role of transcatheter therapies in the management of severe TR in high-risk patients, particularly in carcinoid heart disease. Caval valve implantation proved effective in controlling congestive symptoms and improving clinical status, representing a valuable therapeutic option when conventional approaches are not feasible.



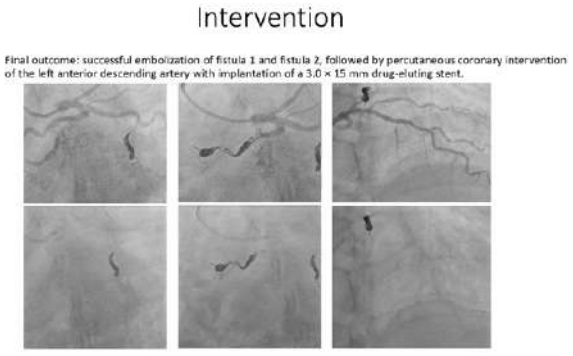
18529

LIFE-SAVING TREATMENT OF CORONARY PERFORATION USING A HANDMADE POLYURETHANE-COVERED STENT DURING ELECTIVE PCI

BEATRIZ ZILDA BALDI[1]; ANDRÉ CEDRO SOUZA[2]; MANOEL LUIZ CORREIA JUNIOR[1]; HUGO FERRAZ LACERDA[1];

(1) UNESULBAHIA - EUNÁPOLIS - BA - BRASIL; (2) GRUPO CDR - EUNAPOLIS - BA - BRASIL;

Introduction: Coronary artery perforation is a rare but catastrophic complication of percutaneous coronary intervention, particularly in severe forms associated with cardiac tamponade, emergency surgery, and substantial early mortality. Rapid sealing of the rupture while preserving distal coronary flow is essential. Although dedicated covered stents are the standard bailout strategy, they may be unavailable in time-sensitive scenarios. Case Description: A 64-year-old woman with hypertension, diabetes mellitus, and familial hypercholesterolemia underwent elective percutaneous coronary intervention of the left anterior descending artery for CCS class III stable angina. After implantation of a 2.25 × 30 mm drug-eluting stent, post-dilatation with a 2.5 × 20 mm non-compliant balloon resulted in an abrupt Ellis III coronary perforation with active contrast extravasation. Immediate prolonged low-pressure balloon inflation was performed to achieve temporary hemostatic control. As a dedicated covered stent was not readily available, a 2.25 × 15 mm drug-eluting stent was manually wrapped with sterile polyurethane material and deployed across the perforation site using a sandwich-type technique. This strategy achieved immediate angiographic sealing of the leak with preservation of TIMI 3 distal flow. Continuous intraprocedural echocardiographic monitoring demonstrated only minimal, non-progressive pericardial effusion, without hemodynamic compromise. No pericardiocentesis or emergency surgery was required. The patient remained stable throughout the procedure and had an uneventful in-hospital recovery. Follow-up echocardiography confirmed preserved biventricular systolic function and complete resolution of the pericardial effusion. Conclusions: This case highlights that implantation of a handmade polyurethane-covered stent may represent a feasible and life-saving bailout strategy for Ellis III coronary perforation when conventional covered stents are not immediately accessible. In carefully selected emergency situations, this rapidly deployable approach may provide prompt hemorrhage control, preserve coronary patency, and avoid escalation to surgical rescue.



15663

PERCUTANEOUS COIL EMBOLIZATION OF CORONARY FISTULAS IN A PATIENT WITH CONGENITAL ABSENCE OF THE LEFT PULMONARY ARTERY

GABRIELA DE SOUZA MARQUES[1]; MARCOS RAPHAEL DA SILVA[2]; GILVAN VILELLA PINTO FILHO[2]; CLARISSA CAMPOS DALL ORTO[2];

(1) EMESCAM - VITORIA - ES - BRASIL; (2) CATHE - TEIXEIRA DE FREITAS - BA - BRASIL;

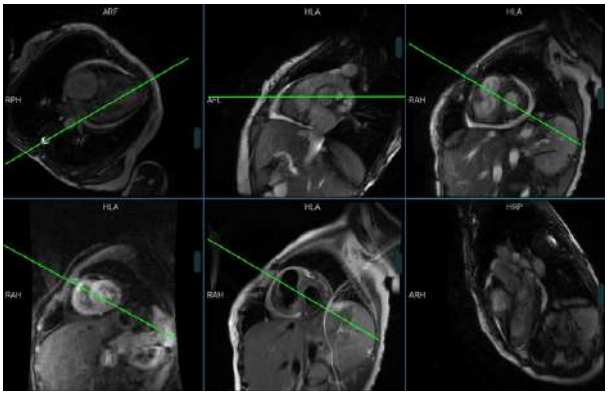
Introduction: Coronary fistulas are rare anomalies that may be asymptomatic or lead to myocardial ischemia, heart failure, and volume overload. Congenital absence of the pulmonary artery is an uncommon condition, often associated with extensive collateral circulation, increasing surgical complexity. In such cases, percutaneous embolization emerges as a less invasive alternative. Case Description: A patient with hypertension, dyslipidemia, and class I obesity presented with progressive exertional dyspnea (NYHA functional class III). The patient was on antiplatelet therapy, statin, beta-blocker, and diuretics. Physical examination was unremarkable. Coronary CT angiography showed moderate stenosis in the left anterior descending artery (LAD) and a calcium score of 63. Thoracoabdominal CT revealed congenital absence of the left pulmonary artery, with extensive mediastinal and left hilar collateral circulation, as well as left lung hypoplasia and mediastinal shift. Three-dimensional reconstruction identified two fistulas originating from the circumflex artery, draining into the mediastinum and left pulmonary hilum. Left ventricular enlargement and diffuse hypokinesia were also observed. Due to high surgical risk, a percutaneous approach was chosen. Embolization of the fistulas was performed via radial access using a microcatheter and detachable coils, achieving complete occlusion. Subsequently, LAD angioplasty with implantation of a drug-eluting stent (3.0 × 15 mm) was performed, with a satisfactory angiographic result. Conclusions: This case highlights the complexity of managing coronary fistulas associated with congenital absence of the pulmonary artery. Percutaneous embolization proved to be a safe and effective alternative in favorable anatomy, avoiding the high risks of surgery. Multimodal imaging planning and multidisciplinary decision-making are essential, as is follow-up to detect potential recanalization.

18634

A CASE REPORT OF A RARE CONDITION MIMICKING CORONARY ARTERY DISEASE SYMPTOMS

JULIANA MOYA DE PAIVA[1]; EDUARDO WILLIAM FARINHA CARVALHO[1]; LUIZA KANADANI CAMPOS DA SILVA[1]; ARTHUR MONTEIRO MARQUES MELLO[1]; DIEGO RABELO PEREIRA[1];

(1) UNIVERSIDADE FEDERAL DE UBERLÂNDIA - UBERLÂNDIA - MG - BRASIL;



Introduction: Takayasu arteritis (TA) is a chronic and idiopathic large vessel vasculitis. It predominantly affects females, who account for approximately 80% to 90% of cases. Despite its high mortality and morbidity, this rare disease may present with nonspecific symptoms, which can make diagnostic approach and management challenging. Case Description: Our patient is a 40-year-old woman with a 15-years history of Takayasu arteritis and who had experienced a recent disease flare after temporarily discontinuing her medications during pregnancy 4 years earlier. She sought medical care describing a history of five days of constricting chest pain, radiating to her back, worsened by physical exertion and associated with shortness of breath. Physical examination showed absence of ulnar and radial arterial pulses bilaterally. Following chest pain investigation, electrocardiography showed no signs of acute ischemia. A diagnostic coronary angiography ruled out coronary obstruction, and a transthoracic echocardiography identified segmental wall motion abnormality of the left ventricle, with dilated cardiomyopathy and LVEF of 29%. Some of the patient's previous exams included a CT angiography of the carotid and vertebral arteries, demonstrating regular and concentric parietal thickening of the aortic arch and supra-aortic vessels, along with minimal stenosis of the proximal brachiocephalic trunk, common carotid arteries and subclavian arteries, being those findings consistent with TA. After careful evaluation, the patient's current chest pain was considered related to TA and dual antiplatelet therapy was introduced, as well as standard therapy targeting heart failure with reduced ejection fraction (HFrEF). Immunosuppressive therapy was optimized so as to achieve clinical remission of the systemic inflammation. In order to address TA with poorly controlled clinical course and significant cardiovascular implications, the patient was referred for outpatient follow-up with the rheumatology team. Conclusions: This case demonstrates the difficulties of managing TA due to the scarcity of information about the condition and delayed diagnosis. Since the disease's early manifestations are often vague, such as fever and weight loss, most patients do not seek treatment before clinical deterioration. Therefore, it is important to raise awareness on TA, since it is associated with a poor prognosis if untreated.

19223

HYPEREOSINOPHILIC SYNDROME AND LÖFFLER ENDOMYOCARDITIS: A CASE REPORT

IGOR COGUI SANTON[1]; FELIPE GONÇALVES ROSA[1]; JOHAN ALMEIDA[1]; GIOVANNI HENRIQUE SOARES ARAÚJO[1]; ABNER FERNANDES SILVA[1]; THAÍS LANY DE OLIVEIRA LEÃO[1]; BEATRIZ TIEMI KITAMURA OKADA[1]; LILIAN SETSUKO NAMBU OLIVEIRA[1]; CHRISTIANO GONÇALVES ARAÚJO[1];

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introduction: Hypereosinophilic Syndrome (HES) is a rare hematologic disease characterized by persistent eosinophil overproduction. One of its most severe complications is Löffler endomyocarditis, in which granular toxicity damages cardiac tissues, progressing from an acute necrotic phase to thrombosis and obliterative fibrosis. Given its high risk of restrictive heart failure and thromboembolic events, prompt multidisciplinary care is vital. Case Description: A 49-year-old female patient, previously healthy, was transferred from a local facility to a tertiary referral center to expand diagnostic capabilities. She was admitted with acute right-sided heart failure, presenting with hepatomegaly 5cm below the costal margin, jugular venous distention, and lower limb edema. Initial laboratory workup revealed bicytopenia with anemia and a platelet count of 72000/mm³, alongside severe hypereosinophilia of 9450/mm³. An echocardiogram showed bilateral intramural thrombi and right ventricular wall motion abnormalities. Cardiac MRI confirmed the diagnosis by demonstrating significant obliteration of the right ventricle and left ventricular apex by thrombi, as well as T2-weighted hypersignal in the endomyocardial topography, consistent with severe fibrotic changes. After failure of empirical antiparasitic therapy (albendazole and ivermectin), focus shifted to primary hematologic causes. A myelogram confirmed this suspicion by documenting global marrow hyperplasia with 57% eosinophils. Corticosteroid therapy with prednisone was initiated, resulting in a rapid favorable response (within 48 hours, eosinophils dropped to 890/mm³ and and platelets normalized to 178000/mm³). During hospitalization, the patient suffered an transient paresis of the left upper limb. Brain MRI confirmed a minor ischemic stroke in the right precentral gyrus, ratifying the high cardioembolic risk despite early anticoagulation (rivaroxaban). Four months later, in outpatient follow-up, she remains asymptomatic (NYHA I), with complete eosinophilia remission (0.01%) and a 97% reduction in NT-proBNP levels, while continuing a gradual prednisone tapering. Conclusions: This case highlights Löffler endocarditis aggressiveness as a manifestation of HES and the importance of integrating laboratory and imaging findings in its management. Early immunosuppression reversed hematologic toxicity and prevented further cardiac deterioration. However, the ischemic complication emphasizes that rigorous thromboembolic surveillance is mandatory in this population.

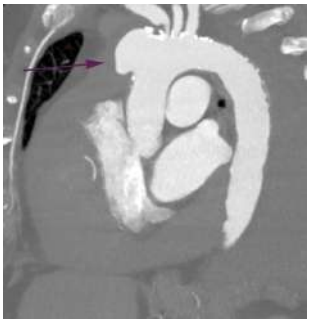
A CASE OF RIGHT VENTRICULAR OUTFLOW TRACT OBSTRUCTION CAUSED BY ISOLATED SINUS OF VALSALVA ANEURYSM

LIVIA LANZONI FREITAS[1]; ISADORA MARTINS FERREIRA BARRILARI[2]; ANNA LUIZA DA SILVA BARBOSA[2]; MARIA EDUARDA REZENDE OLIVEIRA[2]; DANILO SFORCINI TOMAZ AQUINO[3]; FABIANO RUBIÃO LUCCHESI[3]; ANDERSON CAETANO SILVA[4];

(1) FACULDADE DE CIENCIAS DA SAUDE DE BARRETOS DR PAULO PRATA - BARRETOS - SP - BRASIL; (2) FACULDADE DE CIENCIAS DA SAUDE DE BARRETOS - DR PAULO PRATA - BARRETOS - SP - BRASIL; (3) HOSPITAL NOSSA SENHORA, FUNDAÇÃO PIO XII - BARRETOS - SP - BRASIL; (4) HOSPITAL NOSSA SENHORA, FUNDAÇÃO PIO XX - BARRETOS - SP - BRASIL;

Introduction: Sinus of Valsalva aneurysm is a rare condition characterized by abnormal dilation of an aortic root sinus, either congenital or acquired, with an estimated prevalence of 0.09% in the general population and accounting for 0.1%–3.5% of congenital heart diseases, most commonly involving the right coronary sinus (65%–85%). Clinical presentation varies according to size and complications, ranging from asymptomatic cases to acute conditions due to rupture or compression of adjacent structures, often posing a diagnostic challenge and requiring multimodality imaging Case Description: A 73-year-old man with a medical history of hypertension presented to the emergency department with sudden-onset exertional dyspnea. Initial evaluation showed ST-segment depression in anterior leads and rising troponin, leading to ICU admission with suspected non-ST-elevation acute coronary syndrome. He was stable on nasal oxygen (HR 106 bpm, BP 129/92 mmHg, SpO□ 92%) with a 3/6 systolic murmur. During ICU stay, he developed progressive hypoxemia (SpO□ ~90%) requiring a non-rebreather mask at 15 L/min without respiratory distress. Arterial blood gas showed severe hypoxemia (PaO□ 67 mmHg; PaO□/FiO□ 67) with respiratory alkalosis (pH 7.44; PaCO□ 31 mmHg). Given the disproportionate hypoxemia and signs of right heart strain, further investigation was performed. Echocardiography demonstrated preserved left ventricular ejection fraction (57%), moderate right ventricular dilation and dysfunction, and a large sinus of Valsalva aneurysm (4.6 × 5.4 cm) from the right coronary sinus causing compression of the right ventricular outflow tract and pulmonary trunk, with significant obstruction and an estimated peak gradient of 57 mmHg. CT angiography confirmed impending rupture and extrinsic compression without pulmonary embolism, consistent with cor pulmonale. Surgical repair with ascending aorta replacement using a Dacron graft and right coronary reimplantation was performed .After surgery, the patient evolved with progressive right ventricular dysfunction, worsening hypoxemia, and hemodynamic deterioration, culminating in refractory shock and death. Conclusions: This case highlights an uncommon clinical presentation of unruptured sinus of Valsalva aneurysm mimicking acute coronary syndrome and causing severe hypoxemia due to right ventricular outflow tract obstruction, emphasizing the importance of early recognition and multimodality imaging in atypical cases.

18939

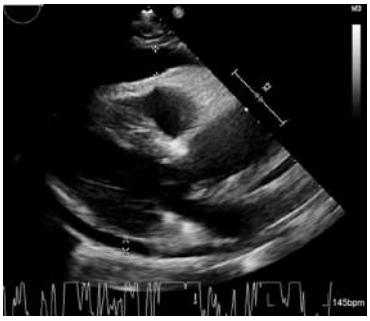


ATYPICAL PRESENTATION OF A PENETRATING AORTIC ULCER OF THE ASCENDING AORTA: A CASE REPORT

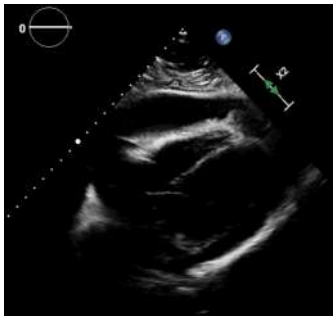
LUIZE BARDINI VITTO[1]; THAISSA DE OLIVEIRA[1]; ANNY CAROLINY CORRÊA BONFANTE[1]; RAFAEL DA RÉ DE SOUZA[1]; KARLA DOS SANTOS BARREIROS[1]; THAÍS VIEIRA DE MEDEIROS[1]; LEANDRO JÚNIOR NUNES DE ALMEIDA DE ALMEIDA[1]; AMADEU ANTONIO BERTUOL FILHO[1];

(1) UNIVERSIDADE DO EXTREMO SUL CATARINENSE (UNESC) - CRICIÚMA - SC - BRASIL;

Introduction: Penetrating aortic ulcer (PAU) is an uncommon cause of acute aortic syndrome (AAS), accounting for 2–7% of AAS cases. Only 7% of penetrating ulcers involve the ascending aorta. Its pathogenesis is related to atherosclerotic plaque formation that progresses to intimal disruption, penetrating through the aortic wall. This case report describes a patient with an ascending PAU with atypical presentation and fatal outcome. Case Description: A 75-year-old female patient was admitted with suspected abdominal sepsis after developing new-onset atrial fibrillation with rapid ventricular response. On the fifth hospital day, she presented with palpitations and dyspnea, with recurrent episodes of atrial fibrillation with rapid ventricular response. Transthoracic echocardiography (TTE) revealed a moderate pericardial effusion (20 mm), presumed to be reactive to the septic condition. On the fourteenth hospital day, the patient experienced acute deterioration with dyspnea and severe, tearing precordial pain radiating to the back. Given the clinical suspicion of AAS, an urgent computed tomography angiography (CTA) was requested. Following CTA, the patient developed hemodynamic instability. Bedside TTE demonstrated progression of the pericardial effusion (51–55 mm) with signs of cardiac tamponade. The cardiac surgery team was activated; however, before transfer she developed cardiac arrest. During resuscitation maneuvers, pericardiocentesis was performed, without clinical response, death was declared after 30 minutes of resuscitative efforts. The CTA report, released post-mortem, revealed a penetrating aortic ulcer measuring 2.5 × 2.0 cm at the transition between the ascending aorta and the aortic arch. The study confirmed direct continuity between the ulcer and the pericardial sac, suggesting a contained aortic rupture that progressed to massive hemopericardium. Conclusions: Although rare, penetrating aortic ulcer represents a highly lethal medical emergency and may present atypically, particularly in elderly patients. This case highlights how nonspecific manifestations and overlap with infectious conditions may delay diagnosis, leading to fatal outcomes. It underscores the importance of maintaining a high index of suspicion for acute aortic syndrome in the setting of unexplained clinical instability, enabling early diagnosis and timely intervention.



17852



BACTERIAL MYOPERICARDITIS DUE TO STAPHYLOCOCCUS AUREUS MIMICKING ST-ELEVATION MYOCARDIAL INFARCTION (STEMI): A CASE REPORT

LUIZA DE FREITAS RANGEL[1]; JOÃO VICTOR SOARES MARTINS[1]; ALCY SANSONE NETO[1]; REBECA FELIPE PEREIRA DE SOUZA[1]; MATHEUS MARQUES LOPES[1]; JOÃO LUCAS LUIZA O'CONNELL[1]; JOÃO VICTOR MANSOUR RESENDE[1];

(1) UNIVERSIDADE FEDERAL DE UBERLÂNDIA - UBERLÂNDIA - MG - BRASIL;

Introduction: Bacterial pericarditis accounts for less than 1% of acute pericarditis cases, carrying high mortality rates and risk of cardiac tamponade. Staphylococcus aureus is among the leading causative agents, typically through hematogenous dissemination. Myopericarditis presenting with ST-segment elevation may mimic ST-Elevation Myocardial Infarction (STEMI), often leading to immediate reperfusion therapy. This overlap complicates diagnosis, delays recognition of the infectious etiology, and should be considered in cases of atypical clinical courses. **Case Description:** A 66-year-old male patient with chronic kidney disease, chronic alcoholism, and recent peptic ulcer disease presented to the emergency department with continuous burning chest pain at rest. During evaluation, he developed atrial fibrillation, reverted with amiodarone, and ST-segment elevations in inferior and lateral leads. Presumed STEMI prompted left heart catheterization, which revealed 70% stenosis in the dominant right coronary artery, treated with angioplasty and stenting, and 95% stenosis in a small-caliber left circumflex artery, left unintervened. During in-hospital reassessment, chest pain exhibited a distinct pattern, characterized as pleuritic in nature, associated with a troponin plateau without the typical rise-and-fall pattern of myocardial necrosis. Transthoracic echocardiography demonstrated circumferential pericardial effusion with signs of diastolic filling restriction. The patient progressed to cardiac tamponade and underwent pericardiocentesis. Pericardial fluid culture isolated methicillin-sensitive Staphylococcus aureus (MSSA). Review of prior records identified positive MSSA blood cultures from a hospitalization one month earlier, associated with a labial skin lesion, regarded as the probable hematogenous source. Transesophageal echocardiography excluded endocarditis. Oxacillin was initiated for three weeks, with favorable clinical outcome. **Conclusions:** This case illustrates MSSA myopericarditis with cardiac tamponade mimicking STEMI, initially leading to management as ST-elevation myocardial infarction. Pleuritic chest pain, troponin plateau, and progressive pericardial effusion were pivotal findings that prompted diagnostic reassessment. Early identification of the infectious etiology enabled targeted antibiotic therapy and a favorable outcome, underscoring the value of continuous clinical reassessment in atypical presentations.

Introduction: Penetrating aortic ulcer (PAU) is part of the acute aortic syndrome spectrum and may progress to aneurysmal degeneration, contained rupture, or other signs of instability, often requiring urgent treatment. Lesions at the aortic isthmus or distal arch are particularly challenging because thoracic endovascular aortic repair (TEVAR) may require zone 2 deployment with intentional coverage of the left subclavian artery (LSA) to achieve an adequate proximal seal, which can lead to ischemic complications. **Case Description:** An 85-year-old man with hypertension, type 2 diabetes mellitus, coronary artery disease, and paroxysmal atrial fibrillation presented with a 2-week history of tearing chest pain radiating to the back, worsening over the previous 48 hours, with dyspnea, cough, and hemoptysis. CTA showed a PAU at the isthmus, immediately distal to the LSA, with enlargement on serial imaging from 25.9 mm to 6.5 x 3.7 cm, mural thickening, and adjacent soft-tissue infiltration, consistent with instability. He underwent TEVAR and intentional LSA coverage. Completion angiography showed successful exclusion without endoleak and preserved flow through the brachiocephalic trunk and left common carotid artery. On postoperative day 2, he developed acute left upper limb ischemia and underwent rescue left carotid-subclavian bypass. Because distal flow remained absent on intraoperative Doppler, the procedure was extended to brachial, radial and ulnar embolectomy, with retrieval of fresh thrombus from the brachial artery. Follow-up imaging confirmed exclusion of the lesion, proximal occlusion of the LSA, and patency of the bypass. Despite the successful treatment, the subsequent course was complicated by enterorrhagia due to newly diagnosed colon cancer, central nervous system bleeding, septic shock, and multiorgan dysfunction, culminating in death. **Conclusions:** This case highlights that acute upper limb ischemia may occur despite technically successful zone 2 TEVAR and that persistent ischemia after rescue carotid-subclavian bypass should prompt immediate reassessment for associated distal thromboembolism. Adjunctive distal embolectomy may be necessary when proximal revascularization alone is insufficient to restore limb perfusion.

Introduction: Transcatheter aortic valve implantation (TAVI) is a minimally invasive alternative to surgical replacement for patients at high surgical risk. Ventricular septal defect (VSD) is a rare complication after TAVI (~1.5% incidence), which may be associated with pressure from the bioprosthesis on the septum, device oversizing, extensive calcification of the valve annulus, or mechanical trauma. Management of these cases is not well established, ranging from a conservative approach to percutaneous or surgical closure, depending on the hemodynamic impact. Case Description: An 89-year-old male patient, independent for daily activities, with systemic arterial hypertension and symptomatic aortic valve disease. Transthoracic echocardiography (TTE) demonstrated an aortic valve area of 0.44 cm² (indexed 0.30 cm²/m²), a mean systolic gradient of 76 mmHg, a peak velocity of 5.6 m/s, and a DVI of 0.15, with moderate aortic regurgitation (PHT 445 ms) and preserved left ventricular systolic function (LVEF 57%). After a heart team discussion, due to symptoms, critical aortic stenosis, advanced age, and intermediate-to-high surgical risk (EuroSCORE II 7.27%), TAVI was selected. Percutaneous implantation of a size 26 aortic bioprosthesis (Sapien 3 ULTRA RESILIA) was performed via transfemoral access. Aortography confirmed good positioning of the bioprosthesis, absence of paravalvular leak, patent coronary arteries, and no complications. Transesophageal echocardiography (TEE) at the end of the procedure revealed an image suggestive of a ventricular septal defect (VSD) (Annex 1), possibly linked to septal rupture caused by prosthesis expansion in the setting of calcification. Given the hemodynamic stability, the patient was transferred to the Intensive Care Unit for monitoring. Post-procedural TTE showed a discontinuity in the interventricular septum (3.6 mm) adjacent to the endoprosthesis and the tricuspid valve, with flow into the right ventricle (RV), suggesting a perimembranous VSD. In the absence of RV overload, pulmonary hypertension, or hemodynamic impacts, conservative management was maintained with outpatient echocardiographic follow-up. Conclusions: With the expanding indications and increasing performance of TAVI in current clinical practice, rare complications such as ventricular septal defect may be more frequently encountered, often incidentally. In this setting, the assessment of symptoms and hemodynamic impact is essential to guide the decision between intervention and conservative management.

STAGED TREATMENT OF COMPLEX AORTIC DISSECTION

VINICIUS GARCIA COSTA E MELO[1]; BRUNA MAIA FURTADO DE FIGUEIREDO[1]; ANTONIO WILON EVELIN SOARES[2];

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (2) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introduction: Aortic dissection is an acute aortic emergency requiring early diagnosis to improve prognosis. This report describes a complex Stanford type A/DeBakey type I aortic dissection. Case Description: A 45-year-old male patient, weighing 73 kg, with hypertension, type 2 diabetes mellitus, gouty arthritis, and a history of smoking and alcohol use, presented 10 years ago with severe tearing precordial pain radiating to the back, associated with lipothymia. Diagnostic workup revealed Stanford type A/DeBakey type I aortic dissection with aneurysmal degeneration of the false lumen. He underwent surgical correction with aortic root reconstruction using a Dacron graft, with preservation of the native aortic valve through the David procedure. Six months after hospital discharge, he was readmitted with dyspnea on mild exertion, classified as New York Heart Association functional class II. Further evaluation showed severe aortic regurgitation with significant diastolic flow reinforcement, as well as persistent dissection involving the aortic arch and supra-aortic vessels, extending throughout the entire aorta to the iliac arteries. A new surgical approach was required, with mechanical aortic valve implantation and rerouting of branches to the brachiocephalic trunk and common carotid artery. Postoperatively, the dissection persisted, with dilation of the false lumen in the aortic arch and aorta, extending through the descending aorta to the iliac arteries. An attempt was then made to implant an endoprosthesis in zone 0 of the ascending aorta to correct the dissection. During the procedure, fracture of the prosthesis delivery system occurred, requiring removal of the introducer system together with a large portion of the dissection flap from the aortic arch and descending aorta via laparotomy, associated with embolectomy of the iliac and femoral arteries. The patient evolved without complaints, and definitive endovascular treatment was postponed. Follow-up imaging later showed only a residual dissection flap in the descending aorta, located 30 to 40 cm from the upper dental arch, with slow flow in the false lumen. After 9 years of follow-up, the patient remains clinically stable and asymptomatic. Conclusions: Aortic dissection is a complex condition that should be managed in specialized centers by a multidisciplinary team. This case required multiple surgical interventions by different teams to achieve a satisfactory outcome and improve life expectancy.

Introduction: Infective Endocarditis remains a condition with high morbidity and mortality, particularly when associated with structural cardiac complications. The coexistence of systemic infections and neglected tropical diseases may hinder diagnosis and delay appropriate treatment. Case Description: A previously healthy young adult male from a rural area was admitted with a three-week history of persistent fever associated with intense chills, night sweats, progressive fatigue, anorexia, 8-kg weight loss, and erythematous papules on the lower extremities consistent with Janeway lesions. Initially, he was treated at an emergency care unit with symptomatic medications and antiemetics, without clinical improvement. He was subsequently referred to a tertiary care center, where laboratory tests revealed leukocytosis, thrombocytopenia, and elevated inflammatory markers. Electrocardiography showed nonspecific abnormalities, and empirical broad-spectrum antibiotic therapy was initiated. Transthoracic echocardiography demonstrated mitral valve vegetation, while blood cultures were positive for Staphylococcus aureus. The diagnosis of infective endocarditis was established according to the modified Duke criteria, with two major and two minor criteria. Further investigation revealed a previous history of Visceral Leishmaniasis, considering the patient's epidemiological and occupational background. The patient progressed with severe valvular involvement requiring surgical mitral valve replacement. He remained hospitalized in a coronary intensive care unit receiving vancomycin, oxacillin, and gentamicin, with satisfactory clinical recovery after six weeks of treatment. Conclusions: This case highlights the importance of early investigation of infective endocarditis in patients presenting with prolonged fever and nonspecific systemic manifestations. In addition, it emphasizes the epidemiological relevance of visceral leishmaniasis as a possible predisposing factor for severe bacterial infections in vulnerable rural populations.

THE SOVEREIGN CLINIC: UNEXPECTED DIAGNOSIS OF GIANT ASCENDING AORTIC ANEURYSM IN AN ASYMPTOMATIC COMPANION — FROM CLINICAL SUSPICION TO SURGICAL TREATMENT

THALES CARVALHO TORTURELA[1]; FRANCISCO MAIA DA SILVA[1]; GABRIELA DAL CONTE[1]; LARA MARIA URBAN[1]; DIOGO PINA GAZZI[1];

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL;

Introduction: Giant ascending aortic aneurysms are associated with a high risk of potentially fatal complications, particularly type A aortic dissection. Although incidental findings may occur in asymptomatic individuals, diagnosis outside the usual clinical setting is uncommon. Case Description: A 60-year-old female patient with no previously known cardiovascular disease presented as a companion during an outpatient consultation, without specific complaints. She reported recent episodes of elevated blood pressure, with values reaching approximately 180/90 mmHg. Physical examination revealed visible pulsations in the sternal notch and left supraclavicular region, in addition to a blowing early diastolic decrescendo murmur at the aortic and accessory aortic areas, associated with an Austin Flint murmur at the mitral area. Based on these semiological findings, an urgent transthoracic echocardiogram was requested, revealing a giant ascending aortic aneurysm measuring 74 mm, associated with moderate aortic regurgitation and no signs of dissection. Due to the high risk of acute complications, the patient was urgently referred for surgical treatment and underwent ascending aortic aneurysm repair associated with aortic valve replacement using a biological prosthesis. During the postoperative period, the patient developed an acute neurological deficit compatible with cerebrovascular event, with partial motor impairment. She is currently under outpatient follow-up, showing functional improvement after rehabilitation. Conclusions: This case highlights the importance of clinical perception, demonstrating how initially nonspecific findings in an asymptomatic companion led to the diagnosis of a potentially fatal condition. Early recognition allowed surgical intervention before the occurrence of catastrophic complications, such as dissection, rupture, or sudden death.

TUBERCULOUS PLEUROPERICARDITIS WITH IMPENDING CARDIAC TAMPONADE: A CASE REPORT

MARLON DA SILVA PESSANHA SANTOS[1]; WELLYNGTON LUIZ DA SILVA FERNANDEZ[1]; RONALD DE CARVALHO NASCIMENTO[1]; GIOVANA DE SOUZA FERRO BARBOSA[1]; CARLOS EDUARDO DE SOUZA CARDOSO[2];

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) HOSPITAL ESCOLA ALVARO ALVIM - CAMPOS DOS GOYTACAZES - RJ - BRASIL;

Introduction: Tuberculosis (TB) remains a major global public health concern. According to the World Health Organization (WHO), extrapulmonary forms account for approximately 15–20% of TB cases, with pericardial involvement being a rare manifestation, corresponding to around 1–2% of these forms. This presentation may mimic autoimmune diseases, particularly in polyserositis. Although uncommon in developed countries, TB is the most frequent etiology of pericarditis in developing nations and is associated with a high risk of large pericardial effusion and progression to cardiac tamponade. Case Description: A 29-year-old female patient with a history of pulmonary TB confirmed by positive TRM-TB on bronchoalveolar lavage and early abandonment of RHZE treatment was admitted. She had prior emergency visits for respiratory complaints and had previously undergone therapeutic thoracentesis. Admitted with progressive dyspnea, cough, and fatigue, chest CT revealed tree-in-bud pattern, bilateral pleural effusion, and moderate pericardial effusion. She deteriorated hemodynamically and was transferred to the Intensive Care Unit. Echocardiography demonstrated a very large pericardial effusion (41mm) with swinging heart, right chamber collapse, significant respiratory flow variation, and septal bounce, indicating high risk of cardiac tamponade. She underwent pleurectomy with right pleuropericardial window, with subsequent clinical improvement. Although chest X-ray is not the primary imaging modality for diagnosing pericardial effusion, serial radiographs demonstrated significant reduction of the cardiac silhouette and pleural effusion, evidencing therapeutic success. Pericardial fluid was hemorrhagic/exudative; sputum smear microscopy was negative and PCR for Mycobacterium tuberculosis returned indeterminate, findings that do not exclude the diagnosis given the history of incomplete treatment. Conclusions: Pericardial tuberculosis, though rare worldwide, should be considered a differential diagnosis in pericardial effusion. Echocardiography is essential for early identification of hemodynamic compromise. Negative initial tests do not exclude the diagnosis; investigation of cavitary fluids and molecular methods is crucial. In cases of hemodynamic deterioration, surgical intervention may be decisive for clinical stabilization and improved prognosis.

TYPE B AORTIC DISSECTION AND MULTIVESSEL CORONARY ARTERY DISEASE: A HYBRID APPROACH COMPLICATED BY SPINAL CORD INJURY

THALYTA DE SOUZA ALVES[1]; LUAN AMARAL MAGALHÃES SOUSA[2]; LUCAS LOPES CAVALCANTI[2]; ANDRÉ JORGE NOGUES DE ALMEIDA[1]; AURIMARCIA DA SILVA TORRER[3]; CAROLINA REIS PERRUCI[3]; CARLOS FREDERICO COSTA LOPES[2]; TATIANA PATRÍCIA SIQUEIRA FIGUEIREDO TASSO[2];

(1) UFRN - NATAL - RN - BRASIL; (2) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL; (3) HOSPITAL DOS SERVIDORES - RECIFE - PE - BRASIL;

Introduction: Acute Stanford type B aortic dissection (TBAD) is a cardiovascular emergency characterized by involvement of the descending aorta distal to the left subclavian artery. Although medical therapy remains the main approach in uncomplicated cases, persistent pain, signs of malperfusion, or progression of the dissection may require endovascular or surgical intervention. The concomitant presence of multivessel coronary artery disease (CAD) increases therapeutic complexity and the risk of adverse outcomes, particularly neurological ischemic complications. Case Description: A 63-year-old male with a history of systemic arterial hypertension, previous myocardial infarction, and unilateral nephrectomy was admitted with TBAD and multivessel CAD, including 70% stenosis of the proximal left anterior descending artery. On admission, blood pressure was 190/90 mmHg, and the patient reported episodes of retrosternal burning pain over the previous two months, unrelated to exertion. Computed tomography angiography demonstrated TBAD involving the descending thoracic aorta, extending to the left iliac system and involving the celiac trunk, associated with aortic dilation and mural thrombus. Coronary angiography confirmed multivessel CAD, with severe lesions in the left anterior descending artery, first and second diagonal branches, and circumflex artery. The patient underwent off-pump coronary artery bypass grafting using a saphenous vein graft to the left anterior descending artery, combined with endovascular repair of the aortic dissection with stent graft implantation. Postoperatively, the patient developed spinal cord infarction due to anterior spinal artery compromise, possibly involving the artery of Adamkiewicz, resulting in lower limb motor deficit and neurogenic bladder. Subsequently, he underwent angioplasty for graft anastomotic stenosis and evolved with an episode of ventricular tachycardia. The patient achieved clinical stabilization and was discharged for multidisciplinary outpatient follow-up and rehabilitation. Conclusions: This case highlights the complexity of managing TBAD associated with multivessel CAD, emphasizing the importance of a multidisciplinary and individualized approach. Despite the technical success of the hybrid strategy employed, severe neurological complications such as spinal cord infarction remain rare but potentially disabling events following endovascular aortic repair, requiring early recognition, adequate clinical support, and specialized rehabilitation.

REVERSIBLE HIGH-GRADE ATRIOVENTRICULAR BLOCK IN AN ASYMPTOMATIC ENDURANCE ATHLETE: WHEN PHYSIOLOGY MIMICS PATHOLOGY

ISABELA CALANDRINI SERRUYA[1]; BRENDA LETÍCIA AMARAL DE SOUZA[1]; FERNANDA TÁVORA DOS SANTOS[2]; LETICIA LANI TEIXEIRA DAS CHAGAS[1]; BRUNO PORTELA DIAS[1]; VITÓRIA GOMES GURTYEV DE QUEIROZ[3]; JOSELI DA SILVA CALANDRINI SIDÔNIO SERRUYA[1];

(1) UNIVERSIDADE FEDERAL DO AMAPÁ - MACAPÁ - AP - BRASIL; (2) FACULDADE EVANGELICA MACKENZIE DO PARANA - CURITIBA - PR - BRASIL; (3) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL;

Introduction: Atrioventricular conduction disturbances are frequently observed in endurance athletes and are commonly attributed to increased vagal tone. While usually benign, the occurrence of prolonged pauses and higher-grade AV block—especially during wakefulness—may raise concern for underlying conduction system disease and create uncertainty regarding training safety. Case Description: A young female endurance athlete, actively engaged in long-distance running and marathon training, underwent cardiovascular evaluation as part of routine assessment to improve performance. She denied syncope, presyncope, or exercise limitation. Initial evaluation revealed first-degree AV block and sinus pauses up to 2.4 seconds, predominantly during sleep, consistent with heightened vagal tone. Over time, with progressive increase in training load, follow-up Holter monitoring demonstrated longer pauses. In 2025, pauses of up to 3.7 seconds were recorded during wakefulness, including daily activities, without associated symptoms. Concomitantly, second-degree AV block was documented, raising concern for possible pathological conduction disturbance. She was referred for further evaluation. Cardiac magnetic resonance imaging showed no evidence of structural heart disease, fibrosis, or infiltrative process, and echocardiography demonstrated normal cardiac structure and function. Given these findings, a period of detraining was recommended. Subsequent reassessment showed reduction of pauses and resolution of higher-grade AV block. The patient later resumed training progressively, without recurrence of significant conduction abnormalities on follow-up monitoring. Conclusions: This case highlights that marked conduction disturbances in endurance athletes, including pauses during wakefulness and apparent progression to higher-grade AV block, may still represent a reversible, physiologically mediated phenomenon. Recognition of this pattern is essential to avoid unnecessary interventions. Detraining can play a key role in distinguishing adaptive changes from true conduction system disease and may guide safe return to high-level physical activity.
