CORONARY FLOW RESERVE, NOT ISCHEMIA, PREDICTS LONG-TERM MORTALITY: A 10-YEAR RB-82 PET STUDY

NILSON TAVARES POPPI1; BEATRIZ MARTINS MODESTO1; MILENA DE SOUZA GOMES LUIZ1; BASILIO BENJAMIN DE CARVALHO JUNIOR1; JOSÉ SOARES JÚNIOR1; LUIZ ANTÔNIO MACHADO CÉSAR1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction/Background: Revascularization strategies guided by ischemic burden have not consistently translated into improved outcomes. Consequently, alternative markers may better predict prognosis and guide management in chronic coronary syndromes. Coronary flow reserve (CFR) assessed by positron emission tomography (PET) integrates the functional impact of both epicardial and microvascular disease. Although prior studies have demonstrated the prognostic value of CFR, long-term data beyond 10 years remain scarce. Objectives: To evaluate the long-term prognostic value of CFR compared with myocardial ischemia in symptomatic stable patients with suspected coronary artery disease (CAD) undergoing Rb-82 PET imaging. Methods: We prospectively analyzed 353 patients (53% men; mean age 63 years) referred for stress myocardial perfusion imaging with Rb-82 PET. The primary endpoint was all-cause mortality. CFR was quantified, and ischemia was assessed using the summed difference score (SDS). Median follow-up was 9.7 years (IQR 3.9-12.5). Cox regression analysis was used to identify independent predictors of mortality. Results and Conclusions: Results: During follow-up, 200 deaths occurred. Reduced CFR identified patients at higher risk of death, with early divergence and sustained separation of survival curves over a decade (log-rank p < 0.001) (Figure). In multivariable analysis, CFR emerged as the strongest independent predictor of mortality (HR 0.60, 95% CI 0.48–0.74; p < 0.001), along with age, diabetes, chronic kidney disease, and left ventricular ejection fraction (Table). In contrast, ischemic burden was not independently associated with outcomes. Conclusions: In symptomatic outpatients with suspected CAD undergoing Rb-82 PET imaging, CFR outperforms myocardial ischemia for long-term mortality prediction. These findings underscore the incremental and durable prognostic value of CFR over more than a decade of follow-up.

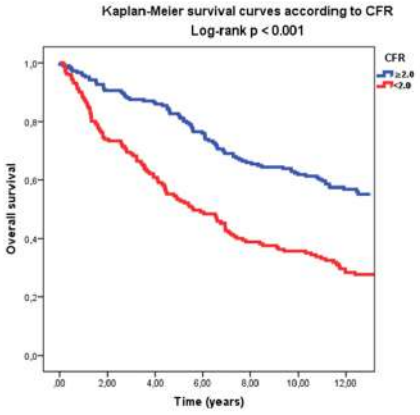

Table. Predictors of all-cause mortality

Variable	HR (95% CI)	p-value
CFR (per unit increase)	0.60 (0.48–0.74)	<0.001
Chronic kidney disease	2.46 (1.78–3.38)	<0.001
Age (per 10 years)	1.25 (1.10–1.42)	0.001
LVEF (per 5% increase)	0.93 (0.90–0.97)	0.001
Diabetes mellitus	1.42 (1.05–1.92)	0.021
SDS (ischemic burden)	0.99 (0.96–1.03)	0.663

CAD = coronary artery disease; CFR = coronary flow reserve; LVEF = left ventricular ejection fraction; SDS = summed difference score; HR = hazard ratio; CI = confidence interval.

EXERCISE TRAINING IMPROVES MYOCARDIAL PERFUSION, PHYSICAL CAPACITY, AND REDUCES PAIN IN INDIVIDUALS WITH MICROVASCULAR ANGINA: A RANDOMIZED CONTROLLED CLINICAL TRIAL

EDUARDO ELIAS VIEIRA CARVALHO1; DENISE MAYUMI TANAKA2; GIOVANI LUIZ DE SANTI1; LUCIANO FONSECA LEMOS OLIVEIRA1; JULIO CESAR CRESCENCIO3; LOURENÇO GALLO JUNIOR3; JOSE ANTONIO MARIN NETO3; MARCUS VINÍCIUS SIMÕES3;

(1) UNIVERSIDADE FEDERAL DO TRIANGULO MINEIRO - UBERABA - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) HOSPITAL DAS CLINICAS DA FACULDADE DE MEDICINA DE RIBEIRAO PRETO - USP - RIBEIRAO PRETO - SP - BRASIL;

Introduction/Background: Introduction: Microvascular angina (MVA) is a frequent syndrome, characterized by myocardial ischemia in the absence of coronary obstruction, with an impact on quality of life. Despite pharmacological treatment, many individuals remain symptomatic, highlighting the need for additional therapeutic approaches. Objectives: Objectives: To evaluate the effect of exercise training on myocardial ischemia, physical capacity, and quality of life, including pain, in individuals with MVA. Methods: Methods: Randomized controlled clinical trial, with 2:1 allocation to the exercise training group (G-TF=34; 57.1±8.9 years, 20 women) and control group (GC=18; 54.6±9.8 years, 12 women). The study was approved by a Research Ethics Committee (no. 13090/2011) and registered in the Brazilian Clinical Trials Registry (ReBEC; RBR-9p4kst). A total of 52 patients with MVA were investigated, characterized by typical chest pain, absence of obstructive coronary artery disease on catheterization, and presence of myocardial ischemia confirmed by myocardial perfusion scintigraphy. At baseline and after three months of follow-up, patients underwent myocardial perfusion scintigraphy with 99mTc-Sestamibi (stress/rest), cardiopulmonary exercise testing, and the SF-36 quality of life questionnaire. The G-TF performed moderate-intensity aerobic exercise training on a treadmill, 3 times/week, for 12 weeks. Statistical analysis was performed using mixed-effects models (group x time), with a significance level of 5%. Results and Conclusions: Results: The groups were similar regarding baseline clinical characteristics such as age, body mass index, and left ventricular ejection fraction (p>0.05). The G-TF showed a significant reduction in the summed difference score (7.9±6 vs 2.8±4.4; p=0.02) and summed stress score (9±6.3 vs 4±5.9; p=0.01), as well as a reduction in the number of ischemic segments (6.6±3.6 vs 2.4±3.6; p=0.02) and the percentage of the left ventricle affected (11.6±8.8% vs 4.2±6.5%; p=0.02). Additionally, an increase in VO□peak was observed (18.3±4.5 vs 20.7±5.2 mL/kg/min; p=0.002), along with a significant improvement in quality of life, with emphasis on the Pain domain (p<0.0001). No significant changes were observed in the control group. Conclusions: Exercise training reduces myocardial ischemia and improves physical capacity and quality of life, with emphasis on the control of anginal symptoms, in individuals with MVA, reinforcing its role as an effective non-pharmacological therapeutic strategy.

Heart Failure / Transplantation / Ventricular Assist Devices / Cardiomyopathies

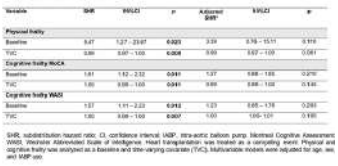
20173

COGNITIVE FRAILTY AND MORTALITY AMONG PATIENTS ON THE WAITING LIST FOR HEART TRANSPLANTATION: A PROSPECTIVE COHORT STUDY

FRANCE MATOS OLIVEIRA1; ERIKA TIEMI IKEDA1; JULIANA ARAUJO NASCIMENTO1; LUIS FERNANDO BERNAL DA COSTA SEGURO1; MONICA SAMUEL AVILA1; IASCARA WOZNIAK CAMPOS1; FABIO ANTONIO GAIOTTO1; MIGUEL MORITA FERNANDES-SILVA1; EDIMAR ALCIDES BOCCHI1; SANDRIGO MAGINI1; FERNANDO BACAL1; FABIANA GOULART MARCONDES-BRAGA1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;



Introduction/Background: Frailty is an important prognostic factor in patients with heart failure and in transplant candidates, while cognitive impairment remains an under-recognized component that may further worsen clinical outcomes. Objectives: This prospective study aimed to determine the prevalence of physical and cognitive frailty among heart transplant candidates and their association with mortality. Methods: Physical frailty was assessed using the Fried criteria; cognition was evaluated using the MoCA (cognitive screening) and WASI (general intellectual functioning); and depressive symptoms were measured using the BDI. Cognitive frailty was defined as the presence of ≥3 of 6 criteria in a modified Fried phenotype, which incorporated cognitive impairment as an additional domain. Results and Conclusions: A total of 150 patients listed for heart transplantation within the previous 30 days were included at a tertiary center in Brazil. The study population was predominantly male (70%), with Chagas disease etiology (35%), and a mean age of 49.8 ± 10.4 years. Physical frailty was present in 78.7% of patients, cognitive frailty in 88.7% (MoCA) and 86.7% (WASI), and depressive symptoms in 44%, which were significantly associated with physical frailty (p = 0.021). During 1-year follow-up, 41.3% of patients died and 67.3% underwent transplantation. Physical frailty was associated with an increased risk of early mortality after listing (initial SHR = 5.47; p = 0.023), with significant attenuation of this effect over time (TVC SHR = 0.99; p = 0.008). A similar pattern was observed for cognitive frailty, measured by both MoCA (initial SHR = 1.61; p = 0.011; TVC SHR = 1.00; p = 0.011) and WASI (initial SHR = 1.57; p = 0.012; TVC SHR = 1.00; p = 0.007), indicating a reduction in its impact on mortality risk over time. However, after multivariable adjustment, neither physical nor cognitive frailty remained independently associated with overall mortality. Physical and cognitive frailty were highly prevalent among heart transplant candidates and showed a time-dependent association with early mortality risk. After adjustment for disease severity markers, this association lost significance, suggesting that frailty may, at least in part, reflect the underlying clinical status at the time of listing rather than acting as an independent prognostic factor. These findings also raise questions regarding the adequacy of the Fried phenotype as a frailty assessment tool in this specific population.

Table 1 - Prevalence of physical frailty, cognitive frailty, and depressive symptoms

	Value (n=150)
Physical frailty score (0–5 points)	3.3 ± 1.1
Physical frailty components	
Unintentional weight loss	84 (56.0)
Exhaustion	70 (46.7)
Reduced handgrip strength	66 (44.0)
Slow gait speed	127 (84.7)
Low physical activity level	149 (99.3)
Physical frailty classification	
Non-frail (0 points)	0 (0.0)
Pre-frail (1–2 points)	32 (21.3)
Frail (≥ 3 points)	118 (78.7)
Cognitive frailty WASI (0–6 points)	4.2 ± 1.2
CogF classification – WASI	
Non-frail (< 3 points)	20 (13.3)
Frail (≥ 3 points)	130 (86.7)
Cognitive frailty MoCA (0–6 points)	4.2 ± 1.3
CogF classification – MoCA	
Non-frail (< 3 points)	17 (11.3)
Frail (≥ 3 points)	133 (88.7)
Beck Depression Inventory (BDI) total score	14.6 ± 9.0
BDI classification	
No depressive symptoms	84 (56.0)
Mild symptoms	38 (25.3)
Moderate symptoms	16 (10.7)
Severe symptoms	12 (8.0)

Categorical variables are expressed as absolute number and percentage [n (%)], and continuous variables as mean ± standard deviation. MoCA = Montreal Cognitive Assessment; WASI = Wechsler Abbreviated Scale of Intelligence; BDI= Beck Depression Inventory.

Table 2 - Physical and cognitive frailty in relation to all-cause mortality in a competing-risk analysis

SHR, subdistribution hazard ratio; CI, confidence interval; IABP, intra-aortic balloon pump; Montreal Cognitive Assessment; WASI, Wechsler Abbreviated Scale of Intelligence. Heart transplantation was treated as a competing event. Physical and cognitive frailty was analyzed as a baseline and time-varying covariate (TVC). Multivariable models were adjusted for age, sex, and IABP use.

IMPACT OF NURSE-LED MHEALTH ASSISTED COLLABORATIVE CARE ON ALL-CAUSE MORTALITY IN HFREF: THE TIME-HF CLUSTER RCT IN INDIA

PANNIYAMMAKAL JEEMON1; SIVADASANPILLAI HARIKRISHNAN1; SANJAY GANAPATHY1; NAVYA ANIKKADY1; SUNAIB ISMAIL1; GOVINDAN UNNI2; BAHULEYAN GOPALAN CHARANTHARALYIL3; MEERA PILLAI4; RACHEAL DANIEL5; RAJEEV EDAKKUTTY6; STIGI JOSEPH7; INDIA TIME-HF COLLABORATORS8;

(1) SREE CHITRA TIRUNAL INSTITUTE FOR MEDICAL SCIENCES AND TECHNOLOGY - INDIA; (2) JUBILEE MISSION HOSPITAL - INDIA; (3) ANANTHAPURI HOSPITAL - INDIA; (4) KIMS TRIVANDRUM - INDIA; (5) NIMS KOLLAM - INDIA; (6) COOPERATIVE HOSPITAL CALICUT - INDIA; (7) LITTLE FLOWER ANAGAMALI - INDIA; (8) TIME-HF COLLABORATORS - INDIA;

Introduction/Background: HFrEF drives high mortality and hospitalizations in India amid resource limits and fragmented care. The TIME-HF cluster RCT tested the effectiveness of a nurse-led, mHealth-facilitated collaborative care model to enhance treatment optimization and self-management on all-cause mortality. Objectives: To evaluate the effectiveness of a nurse-led, mHealth-facilitated collaborative care model to enhance treatment optimization and self-management on all-cause mortality in heart failure patients with reduced ejection fraction in India. Methods: We conducted a parallel-group, cluster-randomised controlled trial involving 1,507 adults with HFrEF across 22 centres in India. Clusters were assigned to the intervention or control arm in a 1:1 ratio using computer-generated random numbers. Participant enrolment occurred on a rolling basis over 6 to 12 months, and each patient was followed for at least 2 years after recruitment. The intervention comprised three sequential components: (1) screening and risk stratification; (2) support for lifestyle modification, including nutritional counselling, tobacco and alcohol cessation, physical activity planning, daily weight monitoring, evaluation for cognitive behavioural therapy, and recognition of warning symptoms, alongside pharmacologic optimisation; and (3) a nurse-facilitated, mHealth-supported disease management programme incorporating structured self-care education, active follow-up, and continuous monitoring of clinical status outside hospital settings. The main outcome for the present analysis was all-cause mortality. We performed survival analysis, including Cox proportional hazards models, to assess the intervention's effect, adjusting for the clustered study design. Results and Conclusions: Among the 1,507 participants (752 in the usual care group and 755 in the intervention group), 77.6% were men, with a mean age of 61.9 years (SD = 12.1). Over half (57.3%) resided in rural areas, and 70.1% had not completed ten years of schooling. Hypertension and diabetes were reported by 56.2% and 62% of participants, respectively, while 18.4% had chronic kidney disease. Ischemic heart disease was the underlying cause in 77.4% of cases. There were 216 mortality events (28.72%) in the usual care group, compared to 180 (23.84) in the intervention group. In the multivariable Cox proportional hazards model, the intervention group showed a 20% reduction in mortality compared with the control group (HR = 0.798, 95% CI: 0.652–0.977; p = 0.029, Figure 1).

THE SOCIOECONOMIC GRADIENT ECLIPSES CLINICAL SEVERITY IN DETERMINING LONG-TERM MORTALITY AFTER DECOMPENSATED HEART FAILURE

GIOVANNI POSSAMAI DUTRA1; BRUNO FERRAZ DE OLIVEIRA GOMES1; DAVI DE VASCONCELLOS DIAS2; FABIANA CARDOSO DE OLIVEIRA2; LUCAS DE SOUZA MARTINS PEREIRA1; LUAN CAVALCANTE VILAÇA LIMA2; JOÃO LUIZ FERNANDES PETRIZ1; PLINIO RESENDE DO CARMO JUNIOR1; EMILIA MATOS DO NASCIMENTO3; BASILIO DE BRAGANÇA PEREIRA2; GLAUCIA MARIA MORAES DE OLIVEIRA2;

(1) BARRA D`OR - RIO DE JANEIRO - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (3) UNIVERSIDADE ESTADUAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Conventional prognostic scores for decompensated heart failure (DHF) incorporate up to 13 clinical variables yet exclude social determinants of health (SDH). In highly unequal urban settings, the independent prognostic weight of SDH versus biological factors remains unquantified. Objectives: To compare the prognostic weight of SDH against conventional clinical variables for long-term mortality in DHF patients treated under standardized protocols at two tertiary centers in socioeconomically contrasting zones of Rio de Janeiro. Methods: Retrospective analysis of 1,023 consecutive DHF patients (2011–2021) at two private tertiary centers in the West Zone (Municipal HDI 0.959) and North Zone (HDI 0.814). All patients received standardized heart failure protocols. Primary outcome: all-cause mortality over median 6.9-year follow-up (IQR 4.4–9.9). Cox model with Elastic Net regularization selected from 26 predictors. Fine–Gray competing risk models estimated subdistribution hazards. Survival trees identified intersecting vulnerability phenotypes. Missing data addressed by multiple imputation. Results and Conclusions: Median age 78 years (IQR 68–85); 54.0% male; LVEF 45% (IQR 34–58%). Total mortality: 766 (74.9%); in-hospital: 110 (10.8%); post-discharge: 656 (64.1%). In the Cox–Elastic Net model, North Zone hospital admission was the strongest determinant (HR 2.43, 95%CI 2.06–2.86; P<0.001), exceeding all clinical and echocardiographic variables. Brown/Black ethnicity independently increased mortality (HR 1.44, 95%CI 1.12–1.86; P=0.005). Prior HF (HR 1.32; P=0.002) and diabetes (HR 1.18; P=0.036) were retained. Severe LV dysfunction exhibited a paradoxical apparent protective effect (HR 0.57), attributable to competing early in-hospital death (Fine–Gray SHR 2.25). Survival trees identified patients ≥79 years at the North Zone hospital with prior arrhythmias as the highest-risk phenotype. Female sex was protective post-discharge (HR 0.80; P=0.007). In DHF patients under standardized protocols, SDH—intra-urban hospital location and ethnicity—were the strongest independent determinants of long-term mortality, surpassing all clinical variables. The apparent protective effect of severe dysfunction reflects survivor bias from competing early mortality. These findings support integrating SDH into heart failure risk stratification.

VUTRISIRAN IN PATIENTS WITH TRANSTHYRETIN AMYLOIDOSIS WITH CARDIOMYOPATHY IN HELIOS-B WHO HAD PROGRESSED ON TAFAMIDIS

JOSÉ GONZALEZ-COSTELLO1; MICHEL KHOURI2; NITASHA SARSWAT3; JUAN PABLO COSTABEL4; CHONGSHU CHEN5; COLLEEN MOFFITT6; SATISH ERALY6; VINCENT ALGALARRONDO7;

(1) BELLVITGE UNIVERSITY HOSPITAL - SPAIN; (2) DUKE UNIVERSITY HEALTH SYSTEM - SP - UNITED STATES; (3) UNIVERSITY OF CHICAGO - SP - UNITED STATES; (4) 4CARDIOVASCULAR INSTITUTE OF BUENOS AIRES - SP - ARGENTINA; (5) ALNYLAM PHARMACEUTICAL - SP - UNITED STATES; (6) ALNYLAM PHARMACEUTICALS - SP - UNITED STATES; (7) BICHAT UNIVERSITY HOSPITAL - SP - FRANCE;

Introduction/Background: In the HELIOS-B study, vutrisiran met the primary endpoint, reducing the risk of all-cause mortality (ACM) and cardiovascular (CV) events versus placebo in patients with transthyretin amyloid cardiomyopathy (ATTR-CM). All secondary endpoints were met, with benefit observed in the overall and vutrisiran monotherapy populations. Although not powered, vutrisiran also showed a trend for improvement in patients receiving baseline tafamidis. Objectives: To evaluate, in post-hoc analyses, the impact of vutrisiran on CV events and ACM in patients identified as tafamidis progressors (patients in baseline tafamidis subgroup who enrolled in the study due to disease progression). Methods: HELIOS-B (NCT04153149) is a phase 3, international, double-blind, placebo-controlled study with an ongoing prespecified open-label extension. Tafamidis progression was defined by investigator assessment at baseline. The primary endpoint was a composite of ACM and recurrent CV events (CV hospitalization or urgent heart failure visit), analyzed during the double-blind period (up to 36 months) using a modified Anderson-Gill model. ACM was assessed through 42 months using a Cox proportional hazards model. Results and Conclusions: 654 patients were treated in HELIOS-B, including 259 patients receiving baseline tafamidis. Reasons for enrolling while on tafamidis were disease progression (n=61; 23.6%), potential clinical benefit without having progressed (n=164; 63.3%), and other/unknown (n=34; 13.1%). Cause of progression was cardiac disease for 60 patients and neuropathy for 14 patients (Table). In the subgroup identified as tafamidis progressors (n=61) vutrisiran showed favorable trends, with a 41% reduction in risk of the composite endpoint (HR 0.59; 95% CI 0.22–1.58; p=0.29, Figure) and a 56% reduction in ACM (HR 0.44; 95% CI 0.13–1.48; p=0.08) versus placebo, consistent with the overall population and the baseline tafamidis subgroup. All patients in the tafamidis progressors subgroup experienced at least one adverse event; with 4 (14.3%) deaths in the vutrisiran arm vs. 9 (27.3%) in placebo. Overall, there were a lack of adverse events in patients receiving dual therapy. CONCLUSIONS: In post-hoc analyses of HELIOS-B, patients with ATTR-CM progressing under tafamidis showed a favorable trend in reducing incidence of composite ACM and recurrent CV events with vutrisiran treatment. Originally presented at HFA 2025. Presenter: Ândrea V F Chaves, on behalf of the authors

Se: sensibility; Sp: specificity; OR: odd ratio; PPV: positive predictive value; NPV: negative predictive value; LR+: positive likelihood ratio; LR-: negative likelihood ratio; CI: confidence interval

Introduction/Background: Pathological Q-waves on the electrocardiogram (ECG) are traditionally considered markers of prior or silent myocardial infarction (MI). Their prognostic value in asymptomatic populations remains uncertain. Objectives: To evaluate the diagnostic performance of pathological Q-waves for detecting segmental wall motion abnormalities on the echocardiogram and their prognostic impact for predicting acute MI compared with other ECG abnormalities. Methods: We conducted a cross sectional and longitudinal analyses of data from a large multicentric Brazilian cohort. Diagnostic performance of pathological Q-waves for hypokinesia or akinesia in the echocardiogram was assessed and sensitivity, specificity, positive and negative predictive values and likelihood ratios (Sn, Sp, PPV, NPV, LR+, LR-) were calculated. Correlations were evaluated with Spearman's rank test. Cumulative MI incidence over a 5 year follow-up was compared between patients with pathological Q-waves and those with other ECG abnormalities using Kaplan Meier curves and adjusted for confounding variables with Cox proportional hazards models. Adjustment variables included sex, age, hypertension, diabetes, smoking and dyslipidemia. Statistical significance was set at p<0.05 and 95% confidence interval. Results and Conclusions: Among 3,267 echocardiograms, major Q-waves showed high Sp, but low Sn for segmental abnormalities (Sp 96.7%; Sn 28.3%; LR+ 8.7. LR-8.7; PPV 25.0%; NPV 97.2%) with weak correlation correlation (ρ = 0.18) (Table 1). Moderate correlations were observed between minor Q waves with ST-T abnormalities (ρ = 0.61) and isolated ST-T abnormalities (ρ = 0.76). In the multivariate model, 14,415 ECGs were evaluated and major Q-waves were not associated with incident MI after full adjustment (HR 1.9; CI 0.85-4.6; p = 0.11). Isolated major ST–T (HR 2.41; CI 1.018-4.8; p=0.015) and minor ST–T (HR 1.73; CI 1.01-2.9; p=0.045) remained independently associated with MI (Figure 1). Isolated Major Q-waves were not independent predictors of MI and its correlation to segmental wall abnormalities was poor when compared to other ECG findings, such as ST-T abnormalities. Our results emphasize the importance of adopting a probabilistic approach to ECG interpretation. In asymptomatic individuals, Q-waves should be interpreted cautiously and complementary evaluation with imaging studies may be helpful when the pre-test probability of previous MI is low or dubious.

REGIONAL INEQUALITIES IN CLIMATE VULNERABILITY TO CARDIOVASCULAR MORTALITY IN OLDER ADULTS IN THE STATE OF SÃO PAULO, BRAZIL

THAUÃ PEREIRA MENEZES1; SAMUEL DE MATTOS ALVES1; PAULO JOSE FORTES VILLAS BOAS1; CAROLINA LETÍCIA ZILLI VIEIRA2; JOÃO PAULO ASSIS GOBO3; ADRIANA POLACHINI VALLE1;

(1) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL; (2) HAVARD T. CHAN SCHOOL - UNITED STATES; (3) UNIVERSIDADE FEDERAL DEE RONDONIA - PORTO VELHO - RO - BRASIL;

Introduction/Background: Heat waves increase cardiovascular mortality in older adults, but this burden is unevenly distributed. Demographic, socioeconomic, and healthcare inequalities shape regional vulnerability to extreme heat, yet composite indices integrating epidemiological risk and adaptive capacity for heat-related cardiovascular mortality remain limited at subnational scales in Latin America. Objectives: To estimate the association between heat waves and cardiovascular mortality in older adults across the 17 DRS of São Paulo and to construct a composite climate vulnerability index. Methods: This ecological time-series study was conducted across the 17 Regional Health Departments (DRS) of the state of São Paulo and included individuals aged 60 years or older. Data from 2010–2019 and 2023 were analyzed; 2020–2022 were excluded to reduce distortions associated with the COVID-19 pandemic. Heat waves were defined as periods of at least three consecutive days with mean daily temperature ≥3 °C above the seasonal climatology, based on ERA5 reanalysis data. The association with cardiovascular mortality (ICD-10: I00–I99) was estimated using Distributed Lag Non-Linear Models (DLNM), with lags from 0 to 15 days. The composite vulnerability index combined seven indicators: heat wave-related relative risk, cardiovascular bed rate per 10,000 older adults, proportion of older adults, per capita health funding, primary care coverage, Human Development Index, and water supply coverage. Indicators were normalized using the Min–Max method, with protective variables inverted, and aggregated by arithmetic mean. Results and Conclusions: Heat waves were associated with increased cardiovascular mortality in older adults across all 17 DRS, with marked spatial heterogeneity. Heat-related excess mortality was most pronounced in adults aged 74–79 years. The composite index ranged from 0.181 to 0.844, identifying the highest vulnerability in inland regions — Registro, Presidente Prudente, Bauru, Marília, São João da Boa Vista, and Araçatuba — where elevated heat-related risk coincided with lower adaptive capacity. Greater São Paulo and surrounding areas showed the lowest vulnerability, reflecting stronger healthcare and socioeconomic infrastructure. These findings indicate that extreme heat impact depends on territorial inequalities in aging, healthcare, and socioeconomic conditions. The proposed index offers a framework to identify priority areas for climate adaptation, strengthen surveillance, and support equitable public health planning.

A NOVEL RISK SCORE TO PREDICT MORTALITY DURING THE VULNERABLE PERIOD AFTER ACUTE HEART FAILURE: THE BPC SCORE

ANA CAROLINA KRACHINSKI DE ANDRADE GAMA1; GUSTAVO SAROT PEREIRA DA CUNHA2; FABIO PAPA TANIGUCHI3; MIGUEL MORITA FERNANDES-SILVA1;

(1) UNIVERSIDADE FEDERAL DO PARANÁ - CURITIBA - PR - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (3) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL;

Introduction/Background: Acute heart failure (AHF) is a high-risk condition, with validated risk scores available to estimate in-hospital mortality. However, there are no specific tools for risk stratification during the vulnerable period—the post-discharge phase characterized by high mortality. Objectives: To develop and validate a risk score to predict mortality after hospitalization for AHF, named the BPC score, and compare its performance with the Acute Decompensated Heart Failure National Registry (ADHERE) and Get With The Guidelines–Heart Failure (GWTG-HF) scores, originally developed for in-hospital mortality prediction. Methods: This prospective cohort study included patients discharged after hospitalization for AHF from 20 public hospitals participating in the Brazilian Unified Health System (SUS) "Best Practices in Cardiology" program between 2016 and 2022. The outcome was all-cause mortality within 90 days after discharge. Patients were randomly divided into training (70%) and testing (30%) cohorts. Predictors were selected using multivariable Cox regression with forward stepwise selection, and weighted points proportional to β coefficients composed the BPC score. Discrimination was assessed using the area under the ROC curve (AUC) and calibration using the Hosmer–Lemeshow (H-L) test. Results and Conclusions: A total of 2,785 patients were included (age 60±15 years, 43% female, left ventricular ejection fraction 41±17%), of whom 176 died during the 90-day follow-up. Variables included in the new score were: age >75 years, Chagas etiology, discharge creatinine >2.5 mg/dL, reduced mobility during hospitalization, educational level , atrial fibrillation, discharge systolic blood pressure <90 mmHg, and prolonged hospitalization (Figure 1). Patients were stratified into risk categories according to BPC score tertiles: low risk (<4), intermediate risk (=4), and high risk (>4). Mortality risk doubled [hazard ratio (HR) 2.05; 95% CI 1.71–2.46; p<0.001] with each increase in BPC score risk category (Figure 1). In the testing cohort, the BPC score demonstrated superior discrimination (Figure 2) compared with ADHERE and GWTG-HF (AUC 0.73 vs 0.56 vs 0.64, respectively; p=0.01), with satisfactory calibration (H-L p>0.05) for all scores. In this national multicenter cohort of patients with AHF, the BPC score demonstrated good discrimination and satisfactory calibration for prediction of 90-day post-discharge mortality, outperforming traditional in-hospital risk scores during the vulnerable period.

BEYOND BLOOD PRESSURE: TIME TO PEAK REVEALS EARLY DAMAGE TO THE BRAIN AS A TARGET ORGAN IN HYPERTENSION

MIKAELLE COSTA CORREIA1; MATHEUS MARTINS DA COSTA1; SAYURI INUZUKA1; ANA LUIZA LIMA SOUSA1; GUSTAVO FRIGIERI2; WEIMAR KUNZ SEBBA BARROSO1;

(1) UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL; (2) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction/Background: Intracranial compliance has been proposed as an early marker of hypertension-mediated brain injury. However, the hemodynamic determinants of the time-to-peak (TTP) parameter remain unclear, particularly in the early stages of hypertension. Objectives: To investigate the hemodynamic determinants of TTP in individuals with untreated hypertension, evaluating the role of peripheral and central blood pressure, as well as parameters of pulsatility, arterial stiffness, and heart rate. Methods: This multicenter, cross-sectional study was conducted across six centers in Brazil and included 252 individuals with hypertension not receiving antihypertensive treatment. Measurements included office blood pressure, central blood pressure, and noninvasive intracranial pressure waveform analysis. TTP was analyzed in relation to peripheral and central hemodynamic variables, including systolic and diastolic blood pressure, pulse pressure (PP), augmentation index (AIx), pulse wave velocity (PWV), and heart rate (HR). Multivariable regression models were constructed, followed by discrimination analysis using receiver operating characteristic (ROC) curves and model comparison. Results and Conclusions: Central diastolic blood pressure (cDBP) showed an independent association with TTP ($p < 0.001$) and emerged as the main hemodynamic determinant. Age and sex also contributed significantly, with higher TTP values observed in females and a lower probability of elevated TTP in males. The inclusion of heart rate in the model significantly improved discriminative performance (AUC from 0.81 to 0.86; $p = 0.006$), whereas traditional peripheral and central blood pressure variables, as well as pulsatility and arterial stiffness parameters, did not enhance model performance. Collinearity analysis demonstrated low redundancy between cDBP and heart rate, indicating independent contributions of these variables. These findings suggest that TTP reflects a distinct hemodynamic domain, determined by the interplay between baseline pressure, cardiac cycle timing, and sex-related biological factors, capturing early cerebral alterations not detected by conventional hemodynamic measures and reinforcing its potential as a marker of target organ damage in hypertension.

HYPOXIC BURDEN AND RISK OF INCIDENT HEART FAILURE IN THE SLEEP HEART HEALTH STUDY

PALOMA RODRIGUES ROCHA1; PEDRO HENRIQUE GIANJOPPE DOS SANTOS2; DIEGO MUNDURUCA DOMINGUES2; SARA QUAGLIA DE CAMPOS GIAMPÁ2; GERALDO LORENZI-FILHO2;

(1) INCOR-INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction/Background: The apnea-hypopnea index (AHI) is the standard metric used to quantify obstructive sleep apnea severity, but it may not fully capture the physiological burden of intermittent hypoxemia. Hypoxic burden (HB) integrates frequency, depth and duration of oxygen desaturations, may better reflect cumulative nocturnal hypoxic exposure and improve cardiovascular risk stratification. Objectives: To evaluate the association between HB and incident heart failure (HF) in the Sleep Heart Health Study (SHHS), compare its performance with AHI, and explore whether this association varies across AHI-defined severity ranges. Methods: An observational cohort analysis was conducted using SHHS data, including participants without HF at baseline. HB was automatically derived from overnight oxygen saturation (SpO_2) signals from the SHHS database using a validated algorithm. The outcome was incident HF. Cox proportional hazards models were fitted to assess the association of HB and AHI with incident HF, using continuous log-transformed variables. Models were examined in unadjusted and clinically adjusted analyses. In a secondary analysis, participants were stratified according to conventional AHI ranges (0-5, 5-15, 15-30, and ≥30 events/h). Results and Conclusions: The cohort included 4,613 participants and 518 incident HF events. In the primary analysis, HB was associated with incident HF in the unadjusted continuous model (HR 1.92, 95% CI 1.29-2.87, p=0.001), whereas AHI was not (HR 1.28, 95% CI 0.86-1.89, p=0.219). In models including both HB and AHI, adjusted for age, sex, and race, HB remained significantly associated with incident HF (HR 1.70, 95% CI 1.13-2.57, p=0.011), whereas AHI did not (HR 0.87, 95% CI 0.60-1.27, p=0.467). In the secondary analysis, the association between HB and incident HF was strongest in lower AHI ranges: for AHI 0-5 events/h, HR 6.47 (95% CI 2.34-17.85, p<0.001) in the unadjusted model and HR 3.02 (95% CI 1.12-8.12, p=0.029) after adjustment; for AHI 5-15 events/h, HB was associated with incident HF in the unadjusted model (HR 2.53, 95% CI 1.37-4.67, p=0.003), with attenuation after adjustment (HR 1.86, 95% CI 0.97-3.56, p=0.061). No significant association was observed in AHI 15-30 or ≥30 events/h. HB showed a stronger association with incident HF than AHI in the primary analysis and may better identify cardiovascular risk within conventional AHI-defined severity categories, particularly among patients with low-to-moderate AHI, a group often considered at lower cardiovascular risk.

MINS NEARLY TRIPLES 30-DAY MORTALITY EVEN IN PATIENTS ALREADY AT HIGH RISK: AN AGE-STRATIFIED ANALYSIS OF 2,532 SURGICAL PATIENTS

LETÍCIA ZANGIROLAMI PERES1; THIAGO MOREIRA BASTOS DA SILVA2; BRUNO FERRAZ DE OLIVEIRA GOMES2; LUAN CAVALCANTE VILAÇA LIMA1; GIOVANNI POSSAMAI DUTRA2; NASSIM JOSÉ KEHDI2; HILSON AMORIM PARENTE2; DAVI DE VASCONCELLOS DIAS1; FABIANA CARDOSO DE OLIVEIRA1; LUCAS DE SOUZA MARTINS PEREIRA2; GLAUCIA MARIA MORAES DE OLIVEIRA1;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) BARRA D`OR - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: The impact of ageing on the incidence and prognosis of myocardial injury after non-cardiac surgery (MINS) in Brazil is unknown. Objectives: We aimed to characterise the incidence gradient, clinical severity, and short- and long-term outcomes of MINS across age groups in a Brazilian tertiary surgical intensive care unit (ICU). Methods: Historical cohort study of consecutive patients admitted to a surgical ICU following non-cardiac surgery (2011–2016), with a median follow-up of 6.7 years (maximum 10.2 years). MINS was defined as troponin elevation exceeding the 99th-percentile upper reference limit without a non-ischemic etiology. Patients were stratified into four age groups: <45, 45–64, 65–75, and >75 years. Primary outcome was long-term all-cause mortality. Secondary outcomes included 30-day and 1-year mortality. Odds ratios (ORs) with 95% confidence intervals (CIs) and Kruskal-Wallis tests were used as appropriate. Results and Conclusions: Results: Of 2,532 patients, MINS incidence followed a stepwise gradient: 3.7% (<45), 12.1% (45–64), 12.1% (65–75), and 18.3% (>75 years) (chi-square p<0.001). Patients >75 had 5.78-fold higher odds of MINS than those <45 (OR 5.78, 95%CI 3.28–10.20, p<0.001), and significantly higher incidence than the 65–75 group (OR 1.62, 95%CI 1.19–2.20, p=0.002). ICU severity increased progressively with age (SAPS3 median: 26, 33, 38, and 43 across groups; Kruskal-Wallis p<0.001). Despite lower mechanical ventilation rates in the >75 group (26.4% vs 52.0% in 45–64, p<0.001) — possibly reflecting ceiling-of-care decisions — outcomes were markedly worse: 30-day mortality 23.1%, 1-year mortality 43.3%, and long-term mortality 72.1%. Compared with the 45–64 group, patients >75 with MINS had 3-fold higher 30-day (OR 3.30, 95%CI 1.08–10.12, p=0.041) and 1-year mortality (OR 3.31, 95%CI 1.45–7.52, p=0.004), and nearly 5-fold higher long-term mortality (OR 4.72, 95%CI 2.27–9.79, p<0.001). Within the >75 group, MINS still conferred a 9.6-fold increase in 30-day mortality versus non-MINS peers (23.1% vs 3.0%, p<0.001). Conclusions: MINS incidence peaks at 18.3% in patients over 75, with long-term mortality exceeding 70%. Even in the context of high background mortality, MINS independently amplifies short-term risk nearly 10-fold in this group. These findings point toward systematic perioperative troponin surveillance as a priority in elderly surgical patients.

FACTOR XIA INHIBITORS FOR SECONDARY STROKE PREVENTION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

VINICIUS SILVA LARA1; EDSON LUIS DE BARROS SIQUEIRA1; LEONARDO GOUVÊA DE OLIVEIRA1; CARLOS EDUARDO SILVA CRUZ2; RENATO GARCIA LISBOA BORGES1; MARIA EDUARDA GRASSI3; VITÓRIA CAMPOS CORDEIRO1; LUANA KAORI SAKAGUCHI SAKAMOTO1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) UFMA - CAMPUS PINHEIRO - PINHEIRO - MA - BRASIL; (3) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL;

Introduction/Background: Secondary prevention after non-cardioembolic ischemic stroke or transient ischemic attack (TIA) remains challenging because reducing thrombotic risk is often accompanied by increased bleeding complications. Factor XIa (FXIa) inhibitors have emerged as a promising strategy to reduce thrombotic events while potentially preserving hemostasis. Objectives: To evaluate the efficacy and safety of FXIa inhibitors for secondary prevention in patients with non-cardioembolic ischemic stroke or high-risk TIA. Methods: A systematic review and meta-analysis of randomized controlled trials (RCTs) was conducted in accordance with PRISMA guidelines. The study included adults with non-cardioembolic ischemic stroke or high-risk TIA treated with FXIa inhibitors (asundexian and milvexian) compared with placebo or standard antiplatelet therapy. Primary outcomes were ischemic stroke and major bleeding according to the International Society on Thrombosis and Haemostasis definition. Secondary outcomes included any stroke, clinically relevant non-major (CRNM) bleeding, combined CRNM or major bleeding, intracranial hemorrhage, and all-cause mortality. Risk ratios with 95% confidence intervals were pooled using Mantel–Haenszel fixed effects model. Risk of bias was assessed using the Cochrane RoB 2 tool, and certainty of evidence was evaluated using the GRADE approach. Results and Conclusions: Three RCTs comprising over 16000 participants were included. FXIa inhibitors significantly reduced the risk of ischemic stroke (RR 0.76; 95% CI 0.68–0.86; I²=0%) and any stroke (RR 0.76; 95% CI 0.68–0.85; I²=0%) compared with placebo. No statistically significant differences were found for major bleeding (RR 1.15; 95% CI 0.90–1.46), intracranial hemorrhage (RR 1.12; 95% CI 0.73–1.70), or all-cause mortality (RR 1.00; 95% CI 0.85–1.18). Although numerically higher rates of CRNM bleeding (RR 1.50; 95% CI 0.90–2.48) and combined CRNM or major bleeding (RR 1.45; 95% CI 0.93–2.25) were observed with FXIa inhibitors, these differences did not reach statistical significance. Overall, FXIa inhibitors demonstrated significant reductions in recurrent ischemic stroke and any stroke without significantly increasing major bleeding, intracranial hemorrhage, or mortality. These findings suggest that FXIa inhibition may represent a promising therapeutic strategy for secondary stroke prevention, although further large-scale trials are needed to better define long-term efficacy and safety.

SEX-BASED COMPARISON IN QUALITY OF CARE AMONG PATIENTS WITH HEART FAILURE AND ACUTE CORONARY SYNDROME: A MULTICENTER STUDY IN BRAZIL

JULIA MOREIRA DINIZ1; LUIZ GUILHERME PASSAGLIA2; MAGDA CARVALHO PIRES1; FABIO PAPA TANIGUCHI3; ANTONIO LUIZ PINHO RIBEIRO2;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (3) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL;

Introduction/Background: Sex-related disparities in cardiovascular care have been widely reported, but it remains unclear whether these differences persist within structured quality improvement programs. Evaluating patterns of care in real-world settings may help contextualize previously described inequities. Objectives: To assess sex-based differences in the quality of care among patients hospitalized with heart failure (HF) or acute coronary syndrome (ACS) in a nationwide quality improvement registry. Methods: This multicenter prospective cohort study included patients hospitalized with HF or ACS across 18 hospitals participating in the Brazilian Best Practice in Cardiology Program between 2016 and 2022. Baseline characteristics, in-hospital mortality, and guideline-recommended performance measures were compared between women and men. Multivariable logistic regression models were used to evaluate the association between sex and in-hospital mortality, as well as selected performance measures, including adjustment for time since hospital enrollment in the program. Results and Conclusions: A total of 10,338 patients were included, of whom 3,812 had HF and 6,526 had ACS. Women presented with distinct clinical profiles in both cohorts and were less likely to undergo invasive strategies in ACS, including lower rates of eligibility for reperfusion (51.8% vs 62.5%, p<0.001), reperfusion performed (82.3% vs 86.3%, p=0.001), primary percutaneous coronary intervention (41.7% vs 49.8%, p<0.001), and coronary artery bypass grafting (10.5% vs 12.6%, p=0.019). Differences in adherence to performance measures were generally modest; however, women were less likely to receive selected evidence-based therapies at discharge, including beta-blockers (87.1% vs 90.4%, p=0.004) and spironolactone (54.4% vs 64.0%, p<0.001) in HF, and angiotensin-converting enzyme inhibitors/angiotensin receptor blockers (77.7% vs 80.3%, p=0.013) and beta-blockers (90.0% vs 91.6%, p=0.037) in ACS. In-hospital mortality did not differ between sexes in HF. In ACS, mortality was higher among women in unadjusted analyses, but sex was not independently associated with mortality after adjustment. Temporal improvements in selected performance measures were observed in both cohorts, without significant interaction between sex and time. Quality improvement initiatives may attenuate, but do not fully eliminate, sex-based imbalances in the use of evidence-based therapies, suggesting that additional targeted strategies are needed to advance equity in cardiovascular care.

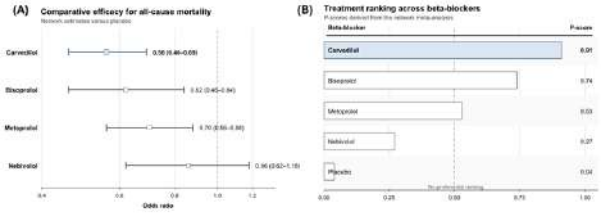
DO BETA-BLOCKERS REPRESENT A TRUE CLASS EFFECT IN HFREF? A NETWORK META-ANALYSIS OF RANDOMIZED TRIALS

MARIA FERNANDA BRETAS FRANZINI1; THALES DA FONSECA DORNELLES2; ALESSADRO MOTTA FRANZINI3;

(1) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - SP - BRASIL; (2) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL; (3) HOSPITAL SAO JOSE DO AVAI - ITAPERUNA - MG - BRASIL;



Introduction/Background: Beta-blockers are foundational in heart failure with reduced ejection fraction (HFrEF); however, whether their benefits reflect a true class effect or clinically meaningful differences between agents remains uncertain. Objectives: To assess whether beta-blockers exert a uniform class effect or display differential efficacy across clinically relevant outcomes in HFrEF. Methods: A systematic review of randomized controlled trials (RCTs) was conducted according to PRISMA, with a prospectively registered PROSPERO protocol. PubMed, Embase, and Cochrane Library were searched from inception to April 2026. RCTs comparing beta-blockers, including head-to-head and placebo-controlled trials in HFrEF, were included. Risk of bias was assessed using the RoB2 tool. The primary outcome was all-cause mortality (ACM); secondary outcomes were cardiovascular (CV) death and hospitalization for heart failure (HHF). A frequentist random-effects network meta-analysis was performed. Treatment effects were estimated as odds ratios (ORs) with 95% confidence intervals (CIs), and ranking probabilities were assessed using P-scores. Consistency was evaluated using node-splitting and transitivity based on key effect modifiers. Sensitivity analyses excluded metoprolol tartrate trials. Certainty of evidence was assessed using GRADE. Results and Conclusions: Sixteen RCTs (n = 16,892) were included. Compared with placebo, carvedilol (OR 0.56, 95% CI 0.46–0.69), bisoprolol (OR 0.62, 95% CI 0.46–0.84), and metoprolol (OR 0.70, 95% CI 0.56–0.88) reduced ACM, whereas nebivolol did not. Although most head-to-head comparisons were not statistically significant, a consistent directional pattern was observed, with carvedilol favoring lower ACM across the network, including a reduction versus nebivolol. Similar trends were observed for CV death. For HHF, only carvedilol showed benefit. Carvedilol ranked highest across outcomes according to P-scores. Low heterogeneity was observed across networks, with no evidence of inconsistency. These findings question the assumption of a uniform class effect among beta-blockers in HFrEF. Although most direct comparisons were not statistically significant, the consistency of effect estimates and ranking patterns across the network suggests that carvedilol may have a more favorable profile across key outcomes. Further head-to-head trials are needed to determine whether these differences reflect true pharmacologic superiority.

Figure 1. Network structure of randomized comparisons among beta-blockers and placebo across clinical outcomes: (A) all-cause mortality, (B) cardiovascular death, and (C) hospitalization for heart failure.[a]

[a]Node size is proportional to the number of participants, and edge thickness is proportional to the number of studies.

Figure 2. Comparative efficacy of beta-blockers in HFrEF.
(A) Network meta-analysis estimates for all-cause mortality versus placebo.
(B) Treatment ranking based on P-scores.
The consistent directional pattern across effect estimates and ranking supports potential differences between agents rather than a uniform class effect.

Introduction/Background: Rheumatic heart disease (RHD) is the leading acquired heart disease in young populations of developing countries. RHD has a marked female predominance that emerges early and intensifies in chronic stages. Thus, sex may influence disease progression and valvular remodeling, yet sex-specific phenotypes of RHD are underexplored. Objectives: To analyze sex-specific differences in phenotypic patterns, and long-term outcomes in chronic RHD, focusing on structural remodeling, valvular involvement, and clinical outcomes. Methods: A prospective cohort of chronic RHD patients was conducted from March 2011 to March 2026 at a tertiary center. Demographic, clinical, and echocardiographic data were collected at baseline, with follow-up every 6 months or based on symptoms. The outcome was a composite of atrial fibrillation (AF) onset, stroke, need for valve intervention (percutaneous or surgical), and cardiovascular mortality. The association between sex and outcomes was assessed using a Kaplan-Meier test and a Cox proportional hazards model adjusted for known prognostic factors, including symptoms and severity of valvular disease. Results and Conclusions: Overall, 903 patients were included, with a mean age of 48.4 ± 12.4 years, and 84% were women. At baseline, 329 patients were in NYHA class III/IV (36%) with mitral valve area of 1.2 ± 0.46 cm². Women more frequently had isolated mitral valve disease (55 vs 37%; p<0.001), while men had more multivalvular disease, particularly mitral and aortic (55 vs 39%; p<0.001). Moderate or severe mitral regurgitation associated with stenosis was more common in men (14 vs 9%; p=0.046). Over a median follow-up of 3.9 years (IQR 1.2–7.5), 462 patients (51%) experienced an adverse outcome, predominantly driven by valve interventions (116 percutaneous valvuloplasties and 233 valve replacements), along with 41 cardiovascular deaths. Women had higher rates of redo percutaneous intervention (13.6 vs 8.8%) and stroke (4 vs 2.7%), while men had higher rates of AF onset (5.4 vs 3%) and cardiovascular death (6.8 vs 4%). Mitral valve replacement rates were similar (26.4 vs 25.7%). In the Kaplan-Meier analysis, event-free survival rates were similar among sexes (p=0.113, Figure 1). Sex was not an independent predictor of outcomes in univariate and multivariate Cox models. Chronic RHD shows distinct sex-related phenotypic differences: men often have multivalvular disease, while women present isolated mitral valve involvement. Long-term outcomes and major interventions were similar between sexes.

MULTI-OMICS FOR THE BIOMOLECULAR CHARACTERIZATION OF BICUSPID AORTOPATHY AND DEVELOPMENT OF A POLYGENIC RISK SCORE IN A BRAZILIAN COHORT

MARIA MARIA SAMPAIO1; MAURO PAES LEME DE SÁ DE SÁ1; ADRIANA BASTOS CARVA2LHO1; BRUNO ANDRADE PARANHOS1; JOÃO HENRIQUE DINIZ BRANDÃO GERVÁSIO1;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Bicuspid aortic valve (BAV) represents the most prevalent congenital cardiac anomaly and serves as the primary risk factor for thoracic aortic aneurysms and dissections. The pathophysiology of BAV-associated aortopathy transcends simple hemodynamic alterations , suggesting a complex genetic architecture and proteomic profiles distinct from those of the tricuspid aortic valve (TAV). In highly admixed populations, such as in Brazil , significant genomic gaps limit effective risk stratification , which currently relies almost exclusively on aortic diameter measurements. Objectives: To investigate the biomolecular profile of aortopathy in Brazilian patients with Bicuspid Aortic Valve (BAV) using a multi-omics approach to extracellular matrix (ECM) genes, FBN1/TGF-B axis genes and smooth muscle cell (SMC) related genes, and to evaluate the efficacy of a novel functional genetic risk score and compare the phenotypes under the molecular and clinical perspective in our brazilian population for the first time. Methods: A prospective multicenter study was conducted involving patients undergoing proximal aortic surgery. The research integrated Whole Exome Sequencing (WES) and tissue proteomics (Liquid Chromatography-Mass Spectrometry) to compare Bicuspid Aortic Valve (BAV) and Tricuspid Aortic Valve (TAV) cohorts. We developed the Polygenic Functional Burden Score (PFBS) to quantify the cumulative impact of rare functional variants (Allele Frequency < 1%) within a panel of 49 candidate genes. These genes are specifically linked to extracellular matrix (ECM) homeostasis, cardiogenesis, and vascular function. Results and Conclusions: Proteomic analysis of aneurysmal ascending aortas identified 223 proteins exclusive to the BAV group. We observed a significant upregulation of fibrotic pathways in BAV tissue—a non-canonical finding in genetic aortopathies—characterized by the exclusive presence of TGFB1, LTBP3, and COMP. Genomic analysis revealed that the BAV group harbored a higher burden of rare variants in key genes, including NOTCH1, MYH11, TGFBR2, and SMAD3. The Polygenic Functional Burden Score (PFBS) was 3.6 times higher in the BAV group compared to controls (mean 34.8 vs. 9.5; p < 0.0001), with some patients exceeding 60 points. Bicuspid aortopathy possesses a distinct molecular signature defined by a chronic pro-fibrotic state and aberrant TGF-B signaling.

Introduction/Background: Left ventricle hypertrophy (LVH) is a structurally silent entity till echocardiography detects myocardial remodeling. This diagnostic latency may result in irreversible hypertrophic progression and diastolic dysfunction of the heart. Pre-structural metabolic fingerprints via serum metabolomic profiling may often enable early detection in this era of precision medicine. Objectives: To map the pre-structural metabolomic trajectory of LVH via ¹H-NMR and validate it against histopathology, echocardiography, and ELISA, identifying an early reversible intervention window. Methods: A total of 296 human subjects (ages male 52.6±14.1 yr, female 49.3±13.1 yr) were stratified into three groups: mitral stenosis as a disease control (DC, n=34); HTN with pressure overload and without hypertrophy (PO, n=141); and severe aortic stenosis with established LVH (n=121). All patients underwent echocardiography to assess cardiac parameters, including left ventricle mass (LVM), relative wall thickness (RWT), posterior wall thickness in diastole (LVPWd), IVSd, FS%, and EF%. Fasting serum samples were analyzed using 1D ¹H-NMR experiments at 800 MHz with TSP as a reference. Processed spectra were analyzed using MetaboAnalyst6.0. Histopathology and ELISA quantification were performed, including NT-proBNP, IL-6, TNF-α, hs-CRP, and TGF-β. Diagnostic performance was assessed using various statistical analyses with a receiver operating curve (ROC). Results and Conclusions: Chemometric analysis reveals that different combinations of betaine, 3-hydroxybutyric acid, phosphocholine, glycine, and creatinine metabolites with S-plots (VIP ≥ 1.5) are able to make clear class separation and play a significant role in distinguishing LVH cohorts from DC and PO (AUC = 0.945), LVH from DC (AUC = 0.92), PO from DC (AUC = 1.0), and LVH from PO (AUC = 0.989). Regression showed significant negative correlations between 3-hydroxybutyric acid and PW (p < 0.04) as well as LVM (p < 0.02). Phosphocholine demonstrated significant negative correlations with CO (p<0.017), IVS (p<0.002), PW (p<0.003), RWT (p<0.03), and LVM (p<0.005). Betaine showed significant negative correlations with IVS (p<0.008), PW, LVEF, RWT, and LV mass (all p<0.01). In contrast, creatinine showed significant positive correlations with CO (p < 0.016), IVS, PW, SV, RWT, and LVM (all p < 0.001). Glycine positively correlates with IVS, PW, and LVM (all p < 0.001) and RWT (p < 0.002).This study reveals that serum-based metabolic profiling offers a promising liquid biopsy-inspired early warning approach.

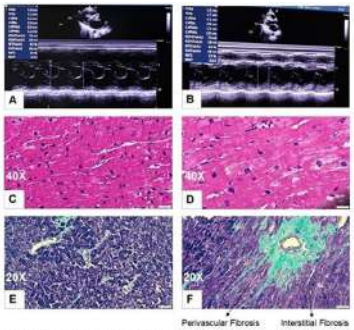

Figure 1: Echocardiographic and histopathological validation of DC vs concentric LVH. (A-B) shows M-mode echocardiographic of structural changes of LV DC vs. Concentric LVH. (C-D) H&E (40X) staining shows cardiomyocyte enlargement DC vs Concentric LVH and (E-F) represent masson trichrome staining (20x) shows increased fibrosis DC vs concentric LVH fibrosis.

MITOCHONDRIAL TRANSPLANTATION FROM BONE MARROW MESENCHYMAL STROMAL CELLS COMBINED WITH SILDENAFIL ATTENUATED VASCULAR REMODELING AND IMPROVED RIGHT VENTRICULAR DYSFUNCTION IN EXPERIMENTAL PULMONARY ARTERIAL HYPERTENSION

FELLIPE ANTUNES DOS SANTOS1; MARIA EDUARDA DE SÁ FERREIRA ONOFRE1; RENATA TRABACH SANTOS1; NAZARETH DE NOVAES ROCHA1; JOHNATAS DUTRA SILVA1; CARLA MEDEIROS DA SILVA1; CLARA ROCHA DE SOUZA PASTOR1; JULIA DALVI BATISTA1; ISADORA ANTUNES BOTELHO1; SABRINA SODRÉ DE SOUZA SERRA1; FERNANDA FERREIRA CRUZ1; PEDRO LEME SILVA1;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Pulmonary arterial hypertension (PAH) is characterized by progressive vascular remodeling and right ventricular (RV) dysfunction, processes that are increasingly associated with disturbances in cellular metabolism. Objectives: We investigated whether transplantation of exogenous mitochondria derived from bone marrow mesenchymal stromal cells, alone or combined with sildenafil, could improve mitochondrial homeostasis and attenuate cardiopulmonary remodeling in monocrotaline-induced PAH. Methods: Male Wistar rats were assigned to control (CTRL, n=8) or PAH (n=32) groups. Fourteen days after induction of PAH, animals were randomized to receive saline, sildenafil (20 mg/kg/day for 14 days), intravenous mitochondrial transplantation (100 µg, days 14 and 21), or combined therapy. On day 28, echocardiography, invasive measurement of RV systolic pressure (RVSP), pulmonary vascular histology, gene expression analyses (vimentin, VE-cadherin, and mitochondrial metabolism–related genes), and high-resolution respirometry were performed. Results and Conclusions: All treatments significantly reduced RVSP compared with untreated PAH. Mitochondrial therapy, alone or combined with sildenafil, decreased arteriolar α-smooth muscle actin content, whereas endothelial–mesenchymal transition was attenuated only with combined treatment. Mitochondrial transplantation and sildenafil increased Complex I–dependent respiration, whereas Complex IV activity improved exclusively with mitochondrial therapy. Combined treatment reduced plasma IL-6 and IL-1β levels compared with PAH. Thus, mitochondrial transplantation, particularly when combined with sildenafil, improved RV function, limited pulmonary vascular remodeling, reduced plasma inflammatory markers and changed key mitochondrial pathways in experimental PAH.

BIDIRECTIONAL ASSOCIATION BETWEEN BLOOD TRANSFUSION AND MINS IN NON-CARDIAC SURGERY: A FOUR-GROUP MORTALITY ANALYSIS

LETÍCIA ZANGIROLAMI PERES1; THIAGO MOREIRA BASTOS DA SILVA2; BRUNO FERRAZ DE OLIVEIRA GOMES2; GIOVANNI POSSAMAI DUTRA2; LUAN CAVALCANTE VILAÇA LIMA1; NASSIM JOSÉ KEHDI2; HILSON AMORIM PARENTE2; DAVI DE VASCONCELLOS DIAS1; FABIANA CARDOSO DE OLIVEIRA1; LUCAS DE SOUZA MARTINS PEREIRA2; GLAUCIA MARIA MORAES DE OLIVEIRA1;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) BARRA D`OR - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Blood transfusion and myocardial injury after non-cardiac surgery (MINS) may be bidirectionally related: anaemia and haemorrhage can reduce myocardial oxygen delivery and precipitate MINS, while MINS-related haemodynamic instability may necessitate transfusion. Objectives: We aimed to characterise this relationship and its prognostic impact in a Brazilian surgical intensive care unit (ICU). Methods: Historical cohort of patients admitted to a surgical ICU following non-cardiac surgery (2011–2016), with median follow-up of 6.7 years. MINS was defined as troponin elevation above the 99th-percentile upper reference limit without a non-ischemic etiology. Patients were stratified into four groups: neither MINS nor transfusion; transfusion only; MINS only; and MINS+transfusion. Bidirectionality was assessed by comparing MINS rates in transfused vs non-transfused patients (Direction 1), and transfusion rates in vasopressor-requiring vs haemodynamically stable MINS patients (Direction 2). Odds ratios (ORs) with 95% confidence intervals (CIs) were calculated. Results and Conclusions: Results: Of 2,532 patients, 525 (20.7%) received transfusion. MINS patients were transfused at more than twice the rate of non-MINS patients (38.2% vs 18.2%, OR 2.77, 95%CI 2.15–3.56, p<0.001), with elevated rates of FFP (12.6% vs 1.5%, OR 9.26), platelets (10.7% vs 1.4%, OR 8.20), and cryoprecipitate (3.2% vs 0.2%, OR 18.00) (all p<0.001). Supporting Direction 1, MINS rates were higher in transfused vs non-transfused patients (20.9% vs 7.9% elective; 29.0% vs 18.8% emergency surgery). Supporting Direction 2, transfusion was required in 58.7% of vasopressor-dependent MINS patients vs 31.8% of haemodynamically stable MINS patients (p<0.001). A stepwise mortality gradient was observed: 30-day mortality 1.1% (neither), 4.1% (transfusion only), 8.7% (MINS only), and 26.7% (MINS+transfusion). MINS+transfusion conferred OR 32.81 (95%CI 16.44–65.49) for 30-day and OR 12.65 (95%CI 7.67–20.87) for 1-year mortality vs neither (both p<0.001); transfusion further worsened prognosis among MINS patients alone (30-day OR 3.83, p=0.001). Conclusions: Transfusion and MINS are bidirectionally related: haemorrhage and anaemia appear to precipitate MINS, while MINS-related haemodynamic compromise amplifies transfusion requirements. Their co-occurrence identifies an extreme-risk phenotype with 30-day mortality exceeding 26%, pointing toward integrated haemostatic and cardiac monitoring in high-risk surgical patients.

EXTERNAL MULTICENTER VALIDATION AND REFINEMENT OF A MACHINE LEARNING–BASED SCORING MODEL FOR ICU OUTCOMES IN PATIENTS WITH ISCHEMIC HEART DISEASE: EICU-CRD AND MIMIC-IV CLIF COHORTS

LUCAS ALENCAR QUEIROZ1; RAFAEL DE SOUZA NATIVIDADE LOPES2; ISABELA MARTINS VIANA3; PAULA CORREA NOGUEIRA4;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) FUNDACAO HOSPITAL DE CLINICAS GASPAR VIANNA PA - BELÉM - PA - BRASIL; (3) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (4) HOSPITAL DA MULHER - SÃO PAULO - SP - BRASIL;

Introduction/Background: Ischemic heart disease (IHD) accounts for ~9 million deaths annually, with a substantial proportion requiring ICU care. Established scores (TIMI, GRACE, HEART) were not validated for the heterogeneous ICU-admitted IHD spectrum. Objectives: To derive and externally validate a multicenter machine learning–based scoring model for high-acuity ICU course and short-term mortality. Methods: Retrospective multicenter cohort. Derivation: eICU-CRD (~200 U.S. hospitals, 2014–2015). External validation: MIMIC-IV in CLIF format (2008–2019). Adults (≥18y) admitted to ICU with IHD (ICD-9 410–414, ICD-10 I20–I25) and ICU stay ≥4h were eligible. Twenty-nine variables from the first 24h fitted L2-regularized logistic regression (primary), random forest, and an AutoScore-style 10-feature score. Primary outcome: high-acuity composite (vasopressor >24h, ventilation ≥48h, dialysis, or in-hospital death). Performance: AUC (95% CI), calibration, decision curve analysis (DCA), leave-one-hospital-out cross-validation, intercept-slope recalibration. Results and Conclusions: Of 13,226 IHD patients (190 hospitals; median age 67y; 35.5% female), 4,344 (32.8%) experienced the primary outcome. Internal AUCs: 0.77 (0.75–0.80) for the composite, 0.86 (0.83–0.89) for 30-day mortality. External AUCs (MIMIC-IV CLIF, n=26,360): 0.72 (0.72–0.73) and 0.78 (0.77–0.79) (Figure 1). The 10-feature parsimonious score retained AUC within 0.02 of the full 29-variable model. External calibration showed overprediction, fully corrected by intercept-slope recalibration. Leave-one-hospital-out cross-validation: median AUC 0.83 (IQR 0.74–0.87; range 0.46–0.96). DCA showed positive net benefit between thresholds 10–40%. A multicenter-derived parsimonious ML model for ICU outcomes in IHD is transportable, outperforms a previously published single-center model for short-term mortality (AUC 0.86 vs 0.74), and is amenable to local recalibration. Substantial inter-hospital heterogeneity supports site-specific recalibration before deployment.

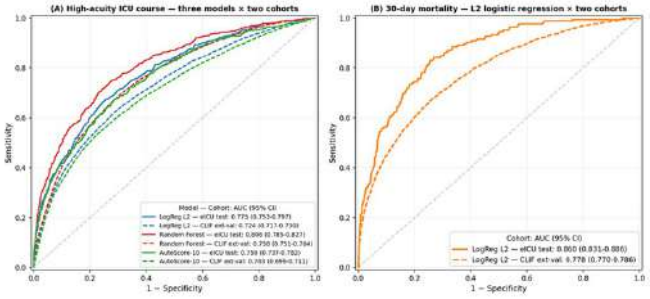

Figure 1. Receiver operating characteristic (ROC) curves. (A) High-acuity composite outcome — three models on the internal eICU-CRD test cohort and the external MIMIC-IV CLIF cohort. (B) 30-day mortality — L2 logistic regression on both cohorts. AUCs with 95% bootstrap confidence intervals.

STRESS-INDUCED HYPERGLYCEMIA AS A PREDICTOR OF IN-HOSPITAL MORTALITY IN ACUTE MYOCARDIAL INFARCTION

KAIO VINICIUS CAMPOS MARQUES1; MARIANA CRISTINA CORREIA1; BRENO VINICIUS DOS SANTOS PINTO1; JOÃO PEDRO BENEVIDES DE OLIVEIRA1; RODRIGO SILVA FORTES1; FRANCISCO A H FONSECA1; HENRIQUE T BIANCO1; BERNARDO F GARCIA1; PEDRO IVO MORAES1; MARIA CRISTINA DE OLIVEIRA IZAR1; ADRIANO CAIXETA1; ATTILIO GALHARDO1;

(1) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction/Background: Stress-induced hyperglycemia (SIH) is frequently observed during acute myocardial infarction (AMI) and is associated with transient elevations of catecholamines, cortisol, and pro-inflammatory cytokines. Defined as the ratio between admission plasma glucose and estimated average glucose (eAG), it may predict mortality and adverse cardiovascular outcomes. However, it is not incorporated into widely used risk stratification scores and has been poorly investigated in AMI patients undergoing a pharmacoinvasive strategy. Objectives: The objective of this study was to evaluate the association between SIH and in-hospital mortality in patients with ST elevation myocardial infarction (STEMI), with and without diabetes mellitus, undergoing a pharmacoinvasive strategy Methods: This retrospective cohort study included 1,613 patients with STEMI treated within a municipal healthcare network. The study was approved by the local Ethics Committee. Estimated average glucose (eAG) at admission was calculated from HbA1c values [eAG (mg/dL) = (28.7 × HbA1c) - 46.7] and SIH was estimated by the ratio between admission glucose and eAG. Demographic and laboratory data, risk factors, and angiographic parameters were collected using the Research Electronic Data Capture platform. Independent predictors of in-hospital mortality were identified through multivariate logistic regression analysis. Model discrimination and calibration were assessed using the area under the curve (AUC) and the Hosmer-Lemeshow test. Results and Conclusions: Patients who died during hospitalization had higher glucose levels at admission than survivors (median 173+/-150 vs. 122+/-59 mg/ dL; p < 0,001). SIH was strongly associated with in-hospital mortality, particularly among patients without a prior diagnosis of diabetes (p < 0.001). In multivariate analysis, SIH remained an independent predictor of mortality. The final model demonstrated excellent discrimination (AUC = 0.90), with a sensitivity of 88.0% and specificity of 79.8%. Predictors of in-hospital mortality (p < 0.05) were (OR, 95% CI): ischemic stroke (4.57, 1.4-14.98), hemorrhagic stroke (17.94, 4.5- 71.46), SIH (3.44, 1.79-6.6), no-reflow (3.08, 1.67-5.68), HbA1c (1.21, 1.07– 1.37), and age (1.05, 1.03-1.08). In conclusion, stress-induced hyperglycemia is an independent predictor of in- hospital mortality in STEMI patients undergoing a pharmacoinvasive strategy and may help identify high-risk individuals for more personalized therapeutic decisions.

CLINICAL ASSESSMENT OF THE ROLE OF CARINA ABLATION AFTER FIRST-PASS PULMONARY VEIN ISOLATION: FIRST RESULTS OF THE CARINA STUDY

GUILHERME MOREIRA PIZETTA1; HENRIQUE TEIXEIRA GIESTAS SERPA1; THAIS COUTINHO NICOLA1; EDUARDO SERPA1; LUISA CARVALHO BENEDITO1; CHRISTIANO LEMOS DA CUNHA1; CARLOS ALEXANDRE VOLPONI LOVATTO1; ALOYR SIMOES JR.1; FABRICIO SARMENTO VASSALLO1; LUIZ FERNANDO MACHADO BARBOSA2;

(1) HOSPITAL SANTA CASA DE MISERICORDIA DE VITORIA - VITÓRIA - ES - BRASIL; (2) ESCOLA SUPERIOR DE CIENCIAS DA SANTA CASA DE MISERICORDIA DE VITORIA - VITÓRIA - ES - BRASIL;

Introduction/Background: Background: Several predictors of recurrence after atrial fibrillation (AF) ablation have been described. Clinical and technical factors influence outcomes regardless of energy source or technique. Cryoablation and pulsed-field ablation show better long-term results, possibly due to closer contact with the carina region. Objectives: Objective: To evaluate whether, in patients achieving first-pass pulmonary vein isolation (FPI), additional carina ablation reduces recurrence. Methods: Methods: Prospective, randomized study from December 2023 to May 2025 with 63 patients undergoing first-time AF ablation in whom FPI was achieved. All patients perform antral pulmonary vein isolation and in patients randomized to carina ablation this approach was performed. Follow-up was for 10 ± 4.8 months. High-power short-duration protocol was performed using 50 W (TactiCath catheter) /6–12 s (30 ml/min flow) in 34 patients and 60W (Tactiflex catheter) for 6/9 s (20 ml/min flow) in 29 patients. Contact force was 10–20 g on the anterior wall and 5–10 g on the posterior wall of the left atrium. Intracardiac echocardiogram was used ant the descrition of the operator. Results and Conclusions: Results: Male were 49 (77,8%) with baseline characteristics similar between success and recurrence groups except for a higher CHA2DS2VA score (3.1 ± 1.6 vs 1.9 ± 1.7, p=0.008) in the carina group. The total recurrence rate was 31,7% (20 of 63). Recurrence occurred in 5/31 (16.1%) patients with carina ablation versus 15/32 (46.9%) without (p=0.014; OR 0.22, 95% CI 0.07–0.71). After multivariable adjustment for persistent AF, sex, BMI, CHA2DS2VA, left atrial diameter, and LVEF, carina ablation remained strongly protective (adjusted OR 0.07, 95% CI 0.01–0.41; p=0.003) with a NNT of 3.2. Follow-up period was 11.6±4.8 months. One pericardial effusion occurred 20 days post-ablation in the success group (with 60W). One patient died 13 months after ablation in complication of a stroke (recurrence group). Conclusion: In patients with FPI, additional carina ablation is associated with an 81% relative reduction in atrial tachyarrhythmia recurrence, supporting its use as a simple and effective adjunctive strategy during AF ablation.

GENOMIC LANDSCAPE AND CLINICAL OUTCOMES OF TUMORS INVOLVING THE HEART AND PERICARDIUM

VALBERT OLIVEIRA COSTA FILHO FILHO1; SILVESTE COELHO DOS SANTOS COSTA1; CARLOS CARLOS ALBERTO BARBOSA NETO1; FABRÍCIA CARDOSO MARQUES1; MARIANA LOPES1; MARIA EDUARDA MEDEIROS1; BÁRBARA CASTRO CARNEIRO1; MARIA EDUARDA CAVALCANTE1; REBECA OLIVEIRA1; MARIA EDUARDA AVELINO1; EDUARDA SEVERO1; MARKUS ANDRET CAVALCANTE GIFONI1;

(1) UFC - FORTALEZA - CE - Brasil;

Introduction/Background: Although tumors involving the heart and pericardium are clinically relevant because of their association with poor prognosis, their molecular features remain poorly defined. Objectives: To characterize the clinicogenomic landscape of tumors involving cardiac and pericardial sites, identify prognostic genomic alterations, and explore survival outcomes according to site of involvement. Methods: We conducted a retrospective analysis of a large U.S tumor sequencing cohort to identify tumors involving cardiac or pericardial sites. Survival was evaluated using Kaplan-Meier curves and hazard ratios (HR) were calculated using Cox proportional hazards models. Results and Conclusions: Of 54,331 tumors in our cohort, only 71 (0.13%) involved cardiac or pericardial sites. Patients were predominantly female (60%), with a median age of 51.5 years (IQR, 43.0-63.0). Cases comprised 17 primary cardiac soft tissue sarcomas, 13 cardiac metastases, 40 pericardial metastases, and one primary pericardial neuroblastoma. Lung adenocarcinoma was the dominant source of pericardial metastases (65%). Across the overall cohort, the most frequently altered genes were TP53 (39%), EGFR (24%), PIK3CA (15%), FAT1 (10%), RB1 (8%), and ATR (7%). All tumors were microsatellite stable. Site-specific analyses showed distinct molecular patterns. Among primary cardiac tumors, the most frequently altered genes were RPTOR (23%), ARID1B (15%), and ATR (15%), with a median OS of 16.3 months (IQR, 6.7-39.7). Among cardiac metastases, the most frequent alterations were TP53 (33%), followed by EGFR, NF1, and PIK3CA (22% each), with a median OS of 20.8 months (IQR, 8.4-29.3). Among pericardial metastases, the most frequently altered genes were TP53 (56%), EGFR (33%), and PIK3CA (19%), with a median OS of 23.7 months (IQR, 6.0-39.7). EGFR and RB1 alterations were associated with worse survival, with EGFR-mutant tumors showing an HR of 2.84 (95% CI, 1.28-6.31; p = 0.007) and RB1-mutant tumors showing an HR of 3.15 (95% CI, 1.08-9.20). Therefore, our findings show that tumors involving the heart and pericardium were rare and showed distinct site-specific genomic profiles. Recurrent alterations in potentially targetable genes, including EGFR, PIK3CA, and ATR, may reveal therapeutic vulnerabilities, while EGFR and RB1 alterations were associated with worse survival. These findings support genomic profiling as a tool for prognostic stratification and therapeutic hypothesis generation in this uncommon tumor population.

Introduction/Background: Patients with advanced clear cell renal cell carcinoma (ccRCC) treated with pazopanib, a vascular endothelial growth factor receptor tyrosine kinase inhibitor associated with improved survival, frequently develop arterial hypertension (AH). The mechanisms underlying these cardiotoxic effects remain unclear, although activation of the endothelin-1 (ET-1) system has been implicated. Objectives: We hypothesized that pazopanib induces endothelial dysfunction through activation of the endothelin-1/ETA receptor axis, contributing to develop of AH. Methods: To test this hypothesis, a translational study was conducted. Fourteen ccRCC patients (age:62±6 yrs and BMI:28±2 Kg/m2) undergoing treatment with pazopanib 800 mg/day and 7 ccRCC patients (age:60±6yrs and BMI:27±3 Kg/m2) in active surveillance were studied. Twenty four-hour systolic and diastolic arterial pressure (SAP and DAP), carotid intima-media thickness (IMTCA) and brachial artery flow-mediated dilation (FMDBA), reactive hyperemia index (RHI) and carotid-femoral pulse wave velocity (PWVcf) were evaluated at baseline and after 4 weeks of pazopanib and surveillance. Additionally, fifty-six male Wistar rats were treated for 21 days with sham, pazopanib, ETA antagonist ambrisentan, or both (n=14/group). SAP, DAP, baroreflex sensitivity, and mesenteric vascular reactivity were assessed Results and Conclusions: In patients, pazopanib increased the SAP, DAP, IMTC, and PWVcf, and decreased FMDBA and RHI, with no changes in active surveillance. In rats, pazopanib reproduced this phenotype, increasing SAP and DAP, an effect completely prevented by ambrisentan. Furthermore, ambrisentan attenuated the pazopanib-induced impairment of baroreflex sensitivity and the decrease in endothelium-dependent relaxation in mesenteric arteries. Our findings indicate that pazopanib induces systemic vascular dysfunction through ET-1/ETAR signaling. ETA receptor antagonism may be explored as a potential strategy to mitigate these effects.

Introduction/Background: Background: Functional stress testing identifies inducible ischemia but does not exclude underlying atherosclerosis or future risk. Coronary artery calcium (CAC) quantifies atherosclerotic burden and may provide incremental prognostic value. Its role in symptomatic patients with negative stress tests remains uncertain. We evaluated the prognostic value of CAC in this setting. Objectives: Objective: To evaluate the prognostic value of coronary artery calcium (CAC) in symptomatic adults with negative functional stress tests, and to determine its association with residual cardiovascular risk and adverse clinical outcomes. Methods: Methods: Systematic review and single-arm meta-analysis including adults (≥18 years) with negative stress tests (SPECT, stress echocardiography, PET, or CMR). Random-effects models were used to estimate pooled proportions with 95% confidence intervals (CIs). Heterogeneity was assessed using Cochran's Q and I². Results and Conclusions: Results: Six studies (N = 7,269; mean age 61.3 years; 43% male) were included. Despite negative stress tests, increasing CAC burden was consistently associated with worse cardiovascular outcomes. The prevalence of anatomically significant coronary artery disease (≥50% stenosis) increased from 0% (CAC=0) to 2.8% for CAC 1–399, 48.9% (~1 in 2) for CAC ≥400, and 71.4% (~3 in 4) for CAC ≥1000. Coronary revascularization increased from 0.04% for CAC=0 to 24.5% (~1 in 4) for CAC ≥400 and 38.0% (~1 in 3) for CAC ≥1000. Myocardial infarction increased from 0.77% for CAC=0 to 3.46% for CAC ≥400. All-cause mortality also increased with CAC burden, reaching 5.77% for CAC ≥400, Figure. Conclusion: In symptomatic patients with negative stress tests, CAC reveals a marked gradient of residual risk not captured by ischemia assessment. These findings support its complementary role in risk stratification and potential to guide further evaluation and preventive strategies.

THE PROGNOSTIC IMPACT OF CARDIOSELECTIVITY OF BETA-BLOCKERS PRESCRIBED DURING HOSPITALIZATION FOR DECOMPENSATED HEART FAILURE.

OTTO MAYER1; JOSEF JIRÁK2; JAN FILIPOVSKY1;

(1) 2ND DEPARTMENT OF INTERNAL MEDICINE, MEDICAL FACULTY OF CHARLES UNIVERSITY AND UNIVERSITY HOSPITAL, PILSEN - CZECH REPUBLIC; (2) DEPARTMENT OF INFORMATICS, UNIVERSITY HOSPITAL, PILSEN - CZECH REPUBLIC;

Introduction/Background: Beta-blockers show considerable variation in cardioselectivity (i.e., the relative affinity to the β1 receptor), even among those with evidence of benefit in the treatment of chronic heart failure (HF). Objectives: We aimed to evaluate whether the cardioselectivity of BBs prescribed during hospitalization for decompensated HF would affect the long-term prognosis of patients. Methods: In the prospective study, we followed 4053 patients hospitalized for decompensated HF. The entire cohort was divided into subgroups based on the cardioselectivity of the recommended beta-blocker (as stated in the discharge summary) Results and Conclusions: BBs with high cardioselectivity were associated with apparently better survival than moderately cardioselective or nonselective BBs (Figure 1). After complex adjustment, patients treated with a highly selective beta-blocker (bisoprolol) showed significantly lower five-year cardiovascular mortality than those with a lesser degree of cardioselectivity (mainly metoprolol) [HR 0.69 (95%CIs:0.52-0.92), p=0.011]. This difference remained in patients with HF with reduced ejection fraction (HFrEF) [HR 0.58 (95%CIs:0.37-0.89), p=0.013], but was not yet significant in HF with preserved ejection fraction [HR 0.66 (95%CIs:0.43-1.02), p=0.063]. In HFrEF patients only, highly cardioselective beta-blockers also showed a lower risk of cardiovascular mortality than BBs with vasodilatory properties (mainly carvedilol) [HR 0.55 (95%CIs:0.33-0.93, p=0.025]. In conclusion, the choice of a beta-blocker based on its degree of cardioselectivity may have prognostic implications in patients with chronic HF

DO GLP-1 RECEPTOR AGONISTS REDUCE ALCOHOL USE? A BAYESIAN META-ANALYSIS OF RANDOMIZED CLINICAL TRIALS

GIULIA CALDEIRA GAELZER1; PEDRO GOMES BATISTA2; MARCELA VASCONCELOS MONTENEGRO3; RAILLA RAQUEL ALBINO DOS SANTOS SILVA4; MUSHRIN MALIK5; CAROLINE FISCHER BACCA6; JULIANA GIORGI7; GUSTAVO LENCI MARQUES1;

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (2) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (3) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL; (4) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL; (5) BETH ISRAEL DEACONESS MEDICAL CENTER, UNITED STATES OF AMERICA - UNITED STATES; (6) CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL; (7) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introduction/Background: Background: Alcohol use disorder (AUD) remains associated with substantial morbidity and mortality, with limited pharmacologic options. Glucagon-like peptide-1 receptor agonists (GLP-1RAs), widely used in the treatment of metabolic disease, have shown potential neuromodulatory effects on reward pathways, suggesting a role in reducing alcohol consumption. Objectives: Objectives: To evaluate the effects of GLP-1RAs on alcohol-related outcomes using a Bayesian meta-analytic framework. Methods: Methods: A systematic review identified randomized controlled trials evaluating GLP-1RAs in adults with AUD. Bayesian random-effects models were applied using weakly informative priors. Outcomes included heavy drinking days, alcohol craving, and total alcohol consumption. Results were reported as mean differences (MD) with 95% credible intervals (CrIs) and 95% prediction intervals (PIs). Results and Conclusions: Results: Three randomized trials were included, encompassing heterogeneous populations (treatment-seeking and non–treatment-seeking individuals, varying BMI profiles). On heavy-drinking days, the pooled effect suggested a numerical reduction (MD = −2.19 days; 95% CrI = −10.99 to 6.67), with wide uncertainty and a broad prediction interval (−13.69 to 9.53). Craving showed a similarly imprecise estimate (MD = −0.82; 95% CrI = −3.90 to 2.24; PI = −6.74 to 5.09). Total alcohol consumption demonstrated a larger numerical reduction (MD −261.0 g; 95% CrI −548.13 to 46.91), though with substantial heterogeneity and uncertainty (PI −778.56 to 300.07). Across outcomes, posterior distributions were compatible with both a clinically meaningful benefit and no effect. Conclusions: GLP-1RAs demonstrate encouraging but highly uncertain signals for reducing alcohol consumption and related outcomes in AUD. The wide credible and prediction intervals reflect substantial between-study heterogeneity and limited sample size. These findings should be interpreted as hypothesis-generating, supporting the need for larger, adequately powered trials to define clinical efficacy and identify responsive phenotypes.

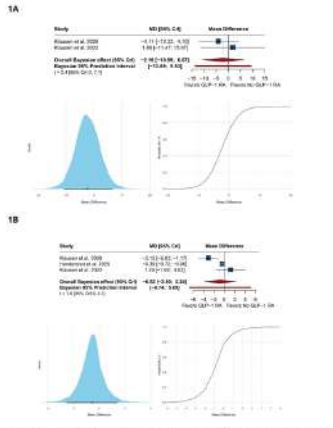

Figure 1. Bayesian forest plots illustrating the mean differences (MDs) between GLP-1 receptor agonists and no treatment, along with posterior density distributions for (A) heavy-drinking days and (B) craving.

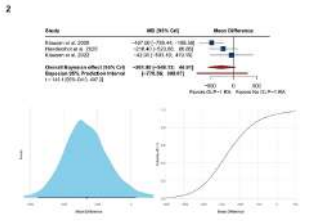

Figure 2. Bayesian forest plots illustrating the mean difference (MD) between GLP-1 receptor agonists and no treatment, along with posterior density distributions for alcohol consumption.

SACUBITRIL/VALSARTAN IN RESISTANT HYPERTENSION: A SYSTEMATIC REVIEW AND META-ANALYSIS

YASMIN DE SOUZA LIMA BITAR1; ANDRE RODRIGUES DURAES1; ENILSON CARMO BARBOSA DOS SANTOS1; MANSUETO GOMES NETO2; JORGE LUIS MOTTA DOS ANJOS1;

(1) UNIVERSIDADE FEDERAL DA BAHIA - PROGRAMA DE POS GRADUACAO EM MEDICINA E SAUDE - SALVADOR - BA - BRASIL; (2) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL;

Introduction/Background: Resistant hypertension (RH) affects approximately 10–15% of hypertensive patients and is associated with increased cardiovascular risk. Sacubitril/valsartan (Sac/Val), an angiotensin receptor–neprilysin inhibitor (ARNI), has demonstrated blood pressure–lowering effects; however, its role in RH requires systematic evaluation. Objectives: To evaluate the efficacy and safety of Sac/Val compared with conventional renin–angiotensin–aldosterone system (RAAS)-based therapies in patients with RH through a systematic review and meta-analysis of randomized controlled trials (RCT). Methods: We conducted a systematic review and meta-analysis of RCTs comparing sacubitril/valsartan with standard RAAS-based therapies in adult patients with RH. We searched multiple databases through January 2026 following Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 guidelines. Risk of bias was assessed using the revised Cochrane risk-of-bias tool for randomized trials (RoB 2), and certainty of evidence was evaluated using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) methodology. Primary outcomes included mean sitting systolic and diastolic blood pressure (msSBP/msDBP), change from baseline, and blood pressure control rate. Random-effects meta-analyses were performed using Review Manager version 5.4.1. PROSPERO Registration: CRD420251056456. Results and Conclusions: Three RCTs including 890 participants were analyzed. Sac/Val significantly reduced final msSBP (mean difference [MD] −9.10 mmHg, 95% confidence interval [CI] −13.77 to −4.44; I²=94%; low certainty) and increased the proportion of patients achieving BP control ≤140 mmHg (risk ratio [RR] 1.39, 95% CI 1.21–1.60; I²=0%; moderate certainty). No significant effect was observed for msDBP (MD −5.2 mmHg, 95% CI −12.03 to 1.7; very low certainty). There were no significant differences in adverse events, including symptomatic hypotension, hyperkalemia, or renal dysfunction (moderate certainty). Substantial heterogeneity was observed for BP outcomes. In conclusion, Sac/Val was associated with greater reductions in systolic blood pressure and improved BP control compared with conventional RAAS-based therapies in patients with RH, with a similar safety profile. However, the certainty of evidence ranges from low to moderate, and substantial heterogeneity limits the robustness of these findings, highlighting the need for larger, well-designed RCTs.

18042

GLP-1 RECEPTOR AGONISTS AND CARDIOVASCULAR OUTCOMES IN PATIENTS WITH TYPE 2 DIABETES ACROSS MYOCARDIAL INFARCTION-DEFINED POPULATIONS: A SYSTEMATIC REVIEW AND META-ANALYSIS

PEDRO GOMES BATISTA1; RAILLA RAQUEL ALBINO DOS SANTOS SILVA2; MARCELA VASCONCELOS MONTENEGRO3; MUSHRIN MALIK4; MRUNALINI DANDAMUDI5; JUAN PERES DE OLIVEIRA6; MARIA EDUARDA MOLINARI6; LARISSA LUCENA7; RAMON HUNTERMANN6; JULIANA GIORGI8; CAROLINE O. FISCHER BACCA6;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (2) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL; (3) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL; (4) BETH ISRAEL DEACONESS MEDICAL CENTER - UNITED STATES; (5) MONTEFIORE EINSTEIN MEDICAL CENTER - UNITED STATES; (6) CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL; (7) UNIVERSIDADE FEDERAL DO RIO GRANDE DO NORTE - NATAL - RN - BRASIL; (8) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introduction/Background: Patients with type 2 diabetes mellitus (T2DM) who survive myocardial infarction (MI) remain at high risk for recurrent cardiovascular events and heart failure (HF). Although glucagon-like peptide-1 receptor agonists (GLP-1 RAs) reduce cardiovascular events in stable atherosclerotic disease, their impact among patients with established MI has not been comprehensively synthesized. Objectives: To evaluate the association between GLP-1 RA therapy and cardiovascular outcomes in patients with T2DM across MI-defined cohorts. Methods: We searched MEDLINE, Embase, and Cochrane Central Register of Controlled Trials. Hazard ratios (HRs) with 95% confidence intervals (CIs) were pooled using random-effects models. Heterogeneity was evaluated using the I² statistic, and 95% prediction intervals (PIs) were calculated to estimate the expected range of true effects in future clinical settings. Outcomes included all-cause mortality, cardiovascular death, study-defined major adverse cardiovascular events (MACE), MI, stroke, and HF or hospitalization for HF. Statistical analysis was performed using R software version 4.5.0. Results and Conclusions: Seven studies, including 37,393 patients with T2DM and MI-defined populations (9556 receiving GLP-1 RAs), were analyzed. GLP-1 RA therapy was associated with lower all-cause mortality (HR, 0.67; 95% CI, 0.49-0.90; I² = 87.3%; PI, 0.27-1.63; P = 0.0085), reduced MACE (HR, 0.69; 95% CI, 0.56-0.84; I² = 55.6%; PI, 0.44-1.06; P = 0.0002), and fewer HF or HF hospitalizations (HR, 0.78; 95% CI, 0.62-0.98; I² = 77.6%; PI, 0.42-1.45; P = 0.0306). No significant associations were observed for cardiovascular death (HR, 0.85; 95% CI, 0.67-1.06; I² = 0%; PI, 0.42-1.69; P = 0.15), recurrent MI (HR, 0.82; 95% CI, 0.62-1.09; I² = 63%; PI, 0.41-1.63; P = 0.1753), or stroke (HR, 0.91; 95% CI, 0.68-1.22; I² = 61.2%; PI, 0.40-2.05; P = 0.5237). In patients with T2DM across MI-defined populations, GLP-1 RA therapy was associated with lower mortality, study-defined MACE, and HF-related events. Given the substantial heterogeneity, wide PIs for key outcomes, and predominance of observational data, these findings should be interpreted as hypothesis-generating and support the need for dedicated randomized trials.

CLINICAL AND RADIOLOGICAL PROFILE OF PATIENTS WITH TETRALOGY OF FALLOT AND PROLONGED QRS DURATION

MARIA FERNANDA ALENCAR VILLELA1; LUIZ GUILHERME GALLITO DEMARCO1; SARAH ESCRIVÃES CATARINO SAISSE1; PAULO GABRIEL CASTELANO DE ALMEIDA1; LAURA MIRANDA MORAIS FAVORITO1; FERNANDA CORREA DE OLIVEIRA RAMOS1; SOFIA TAYAH OMARI1; GIOVANA MARCONDES FREITAS1; PEDRO HENRIQUE MONTEIRO ARAUJO DA COSTA1; WALACE MAGALHÃES BARBOSA2; THAISSA SANTOS MONTEIRO2; FÁBIO AKIO NISHIJUKA1;

(1) FUNDACAO TECNICO EDUCACIONAL SOUZA MARQUES - RIO DE JANEIRO - RJ - BRASIL; (2) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Tetralogy of Fallot is the most common cyanotic congenital heart disease. Its prevalence has increased due to advances in clinical and surgical management. However, these patients often require multiple reinterventions, especially related to pulmonary valve replacement, placing them at higher risk for arrhythmogenic events. A QRS duration greater than 180 ms is known to be one of the factors associated with increased risk of ventricular arrhythmias and sudden cardiac death, making systematic follow-up essential. Objectives: To analyze the clinical and radiological profile of patients with Tetralogy of Fallot and prolonged QRS duration. Methods: This was a retrospective longitudinal cohort study based on electronic medical record review at a tertiary referral center for congenital heart disease. Patients with Tetralogy of Fallot were included, and QRS duration on electrocardiogram (ECG), fractional area change (FAC) on echocardiography, and right ventricular ejection fraction and volume on cardiac magnetic resonance imaging were analyzed. Results and Conclusions: Data from 185 patients were analyzed and divided into three groups: QRS <150 ms (n=111), QRS 150–180 ms (n=62), and QRS ≥180 ms (n=12). ECG analysis comparing patients with QRS ≥180 ms versus QRS <150 ms showed that the first group had lower right ventricular ejection fraction (43% vs. 55%) and higher right ventricular end-diastolic volume (196 mL/m² vs. 106 mL/m²). Worse FAC (39.6% vs. 42.3%) and a higher prevalence of right ventricular dysfunction (40% vs. 19%) were also observed. These findings suggest right ventricular remodeling and progressive functional deterioration associated with QRS prolongation. Therefore, ECG assessment at every outpatient visit in patients with Tetralogy of Fallot may contribute to clinical decision-making regarding complementary exams and earlier follow-up. The findings of this study demonstrate an association between QRS prolongation and structural and functional right ventricular abnormalities in patients with repaired Tetralogy of Fallot. This reinforces the importance of electrocardiographic and imaging follow-up in this population.

Clinical and radiological profile of patients with Tetralogy of Fallot based on QRS duration in milliseconds (ms) (n=185)

Clinical-radiological variables	QRS < 150 ms (n=111)	QRS 150–180 ms (n=62)	QRS > 180 ms (n=12)

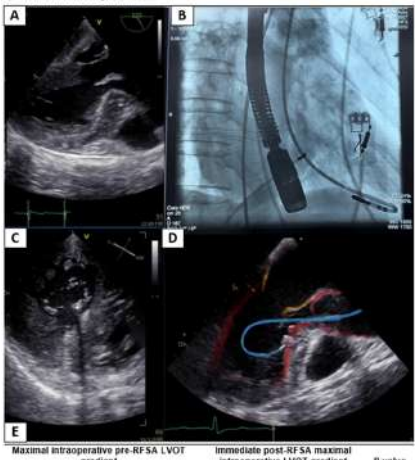
TRANSESOPHAGEAL ECHOCARDIOGRAPHY–GUIDED RADIOFREQUENCY SEPTAL ABLATION IN OBSTRUCTIVE HYPERTROPHIC CARDIOMYOPATHY: 1-YEAR FOLLOW-UP

BRUNO PEREIRA VALDIGEM1; ANDREA DE ANDRADE VILELA1; ANTONIO TITO PALADINO TITO PALADINO1; PLÍNIO JOSÉ WHITAKER WOLF1; LARISSA RIBEIRO BRUSCKY1; JORGE PLINIO ASSEF1; HUGO PLINIO BELLOTTI1; IBRAIM PLINIO PINTO1; LUCIANA ARMAGANIJAN1; EDILEIDE DE BARROS CORREIA1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;



Introduction/Background: The management of patients with symptomatic obstructive hypertrophic cardiomyopathy (HOCM) remains challenging. Radiofrequency septal ablation (RFSA) may represent a safe and effective strategy, with outcomes comparable to other septal reduction therapies, and may serve as a viable alternative for patients with refractory HOCM who are at high surgical risk for myectomy. Objectives: To evaluate the safety and efficacy of RFSA in patients with refractory HOCM who are at high surgical risk for septal myectomy. Methods: This was a single-center, retrospective, observational study including patients with HOCM and a LVOT gradient ≥50 mmHg (at rest/provoked), who were refractory to medical therapy and had contraindications to surgical myectomy, and who underwent RFSA between January 2018-October 2024 at a tertiary referral center (52-week follow-up). Comparisons were performed using parametric or nonparametric tests, according to data distribution, and associations between categorical variables were assessed using Fisher's exact test (p<0.05). Results and Conclusions: A total of 86 patients were included, with a mean age of 56.7±14.9 years; 77.9% were female, and 97.5% were in NYHA functional class III/IV. The mean maximal LVOT gradient (rest/provoked) was 97.5±37.1 mmHg. At 52 weeks following RFSA, resting LVOT gradients decreased from 78.6±39.9 mmHg to 29.9±29.4 mmHg (P<0.001), and maximal provoked gradients decreased from 97.5±37.1 mmHg to 41.7±35.8 mmHg, with 66% of patients achieving gradients ≤50 mmHg (P<0.001), with a significant reduction already observed intraoperatively (Figure 1). In addition, the prevalence of systolic anterior motion (SAM) of the mitral valve decreased from 80% to 40% (Table 1). These hemodynamic improvements translated into clinical benefit, with only 21% of patients remaining in NYHA class III/IV at 52 weeks (1.3% in class IV). RFSA was associated with a low complication rate, with no observed cases of stroke, ventricular septal defect, or pericardial effusion, and only one pacemaker implantation. There was one post-procedural myocardial infarction and one vascular complication, both successfully managed. Despite the high-risk profile of the cohort (contraindicated for myectomy), overall mortality remained low (2.3%), lower than that reported for septal myectomy in low- and intermediate-volume centers (5.6% and 2.9%, respectively). Overall, RFSA in refractory HOCM was feasible, effective, and safe, and may represent a viable alternative in experienced centers.

Table 1. Pre- and postprocedural clinical and echocardiographic characteristics of the study sample with statistical significance analysis

Characteristics	Pre-RFSA	Post-RFSA	P-value

IMPACT OF OBSTRUCTIVE SLEEP APNEA (OSA), INSOMNIA AND THE COMBINATION (COMISA) ON THE HYPERTENSION INCIDENCE: THE ELSA-BRASIL STUDY

HENRIQUE C. S. MUELA1; ERIQUE J. P. MIRANDA2; SORAYA GIATTI2; BARBARA K. PARISE2; NAIRA L FERREIRA2; JULIA A SOARES2; LUIZ A BORTOLOTTO1; PAULO A LOTUFO2; ISABELA M. BENSENOR2; LUCIANO F. DRAGER1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) CENTER FOR CLINICAL AND EPIDEMIOLOGICAL RESEARCH, UNIVERSITY HOSPITAL, UNIVERSITY OF SÃO PAULO, SÃO PAULO, BRAZIL. - SÃO PAULO - SP - BRASIL;

Introduction/Background: Sleep disorders are increasingly common in our society. Previous evidence suggests that both obstructive sleep apnea (OSA) and insomnia are associated with hypertension (HTN). Data on how the comorbid of OSA and insomnia (COMISA) is related to higher HTN risk (compared to either insomnia or OSA) are poorly explored. Objectives: To examine whether COMISA is associated with a higher incidence rate of HTN in the ELSA-Brasil cohort. Methods: The cohort included normotensive participants at the baseline, who underwent sleep study (type III) and sleep questionnaires. OSA was defined by an apnea-hypopnea index ≥15 events/h. Insomnia was defined using the CIS-R questionnaire. New cases of HTN were defined by blood pressure (BP) ≥140 and/or 90 mmHg during the follow-up period. The sample was divided into four groups: control (no OSA/no insomnia), insomnia, OSA and COMISA. ANOVA or Kruskal-Wallis test were used to compare variables. Poisson regression model was used to calculate the incidence risk rate (IRR). We adjusted the model considering the following confounders: age, sex, race, body mass index, baseline BP, diabetes and family history of HTN. The statistical significance was set at <0.05. Results and Conclusions: We evaluated 1,596 participants (61% women; mean age: 48 years; 64% white). There were 396 (24,8%) new cases of HTN (median follow-up of 8 years and 3,334 persons-year). The incidence of HTN was higher in participants with OSA and COMISA as compared to individuals with insomnia or the control group (no OSA/no insomnia). Difference in HTN incidence was significant only between the OSA group and the control or insomnia groups (p<0.001 and p=0.015), respectively. After adjustments, the presence of OSA and COMISA were associated with a higher IRR for new cases of HTN over the follow-up period. Both OSA and COMISA were associated with a higher incidence of HTN as compared to insomnia or control groups.

LEFT ATRIOVENTRICULAR AND LEFT ATRIAL VOLUMETRIC/MECHANICAL COUPLING INDEXES ARE INDEPENDENT PREDICTORS OF ALL-CAUSE MORTALITY IN PATIENTS WITH CHRONIC CHAGAS DISEASE

ROBERTO MAGALHÃES SARAIVA1; MAURO FELIPPE F MEDIANO1; HENRIQUE H VELOSO2; MARCELO TEIXEIRA HOLANDA1; ANDRÉA RODRIGUES DA COSTA1;

(1) INSTITUTO NACIONAL DE INFECTOLOGIA, FIOCRUZ - RIO DE JANEIRO - RJ - BRASIL; (2) INSTITUTO NACIONAL DE INFECTOLOGIA, FIOCRUZ, - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Chronic Chagas disease (CD) affects 8 million people worldwide and its cardiac form has a high mortality. Thus, new mortality predictors are still a matter of research. The predictive value of the new left atrioventricular (LACI) and left atrial (LA) volumetric/mechanical (LAVI/A') coupling indexes are yet to be determined in CD. Objectives: To investigate LACI and LAVI/A' all-cause mortality predictive value in chronic CD. Methods: Patients with chronic CD were included consecutively in this single-center longitudinal observational study. Patients with atrial fibrillation or suboptimal imaging were excluded. LACI was the ratio of LA over left ventricular (LV) end-diastolic volumes. LAVI/A' was the ratio of maximum LA volume over late diastolic mitral annulus velocity. LA volumes were obtained by 3D echocardiography. The endpoint was a composite of all-cause mortality or heart transplant. The associations with the endpoint independent from clinical, ECG, and 2D echocardiographic parameters (model I) or from model I adjusting variables plus LV and LA strain parameters (model II) were tested by multivariate Cox-proportional-hazards regression. Receiver operating characteristic curves were generated to define optimal cutoff values for endpoint prediction and their areas (AUC) were compared by pairwise comparison. Cumulative survival curves constructed using Kaplan–Meier method were compared by log–rank test. P values <.05 were considered significant. Results and Conclusions: A total of 382 patients (58.6% female; 53 ± 11 years) were followed for 6.6±2.7 years. Endpoint occurred in 82 patients (80 deaths/2 heart transplants; 32.5 events/1,000 person-years). The causes of death were heart failure (46%), sudden death (28%), stroke (4%), unrelated to CD (10%), and unknown (12%). LACI was associated with the endpoint in models I (HR 1.03, 95% CI 1.01-1.05, P=.01) and II (HR 1.03, 95% CI 1.01-1.05, P=.0008). LAVI/A' was also associated with the endpoint in models I (HR 1.08, 95% CI 1.05-1.12, P<.0001) and II (HR 1.09, 95% CI 1.05-1.12, P<.0001). Optimal cutoff for LACI was 21.2% (AUC 0.65, sensitivity 71.7%, specificity 53.7%, P<.0001) and for LAVI/A' was 3.3 mL×sec/cm−1per m2 (AUC 0.87, sensitivity 81.7%, specificity 83.7%, P<.0001). AUC for LAVI/A' was larger than the one for LACI (P<.0001). Those with LAVI/A'≥3.3 at baseline had a 19-fold higher risk for all-cause mortality. LAVI/A' is a new LA function index with promising all-cause mortality predictive value in CD.

GRAIN INTAKE PATTERNS AND METABOLIC SCORE FOR INSULIN RESISTANCE IN RELATION TO THE RISK AND SEVERITY OF PREMATURE CORONARY ARTERY DISEASE: THE MULTI ETHNIC STUDY IN LOW-MIDDLE INCOME COUNTRY

NOUSHIN MOHAMMADIFARD1;

(1) ISFAHAN CARDIOVASCULAR RESEARCH CENTER, CARDIOVASCULAR RESEARCH INSTITUTE, ISFAHAN UNIVERSITY OF MEDICAL SCIENCES, ISFAHAN, IRAN - IRAN;

Introduction/Background: Recent evaluations revealed that the age of CAD has gradually declined in middle-East countries. Both dietary habits and metabolic disturbances may contribute to its early onset. Due to global burden of disease data, low whole grain intake is the leading cause of coronary artery disease (CAD) burden. Moreover, the metabolic score for insulin resistance (METS IR) offers a practical, non insulin based surrogate for evaluating insulin resistance. Despite their conceptual connection, little is known about how these two factors, grain consumption pattern and metabolic status, relate to both the presence and severity of PCAD within a diverse ethnicities' population. Objectives: To assess the intake of whole and refined grain and METS IR relation to the risk and severity of PCAD. Methods: This was a multi-centric case-control study among Iranian eight ethnicities within the framework of the Iran premature coronary artery disease (IPAD) project. The data were collected from hospitals with catheterization laboratories. Cases were 2099 patients with a stenosis ≥75 % in at least one vessel or ≥50 % in the left main artery. Control group were 1168 individuals with normal angiography test. Grains intake was assessed using a validated semi-quantitative food frequency questionnaire. METS IR was calculated using fasting glucose, triglycerides, BMI, and HDL cholesterol. Multivariable logistic regression models estimated odds ratios (ORs) for the presence and severity of PCAD across intake categories and METS IR quartiles. Results and Conclusions: Participants with higher whole grain intake showed notably lower odds of both having PCAD (OR= 0.54, 95% CI: 0.40- 0.72; P<0.001) and also inverse association with its severity after full adjustment. However, a significant direct link was found between higher refined grains consumption and the risk of PCAD (OR= 1.43, 95% CI: 0.91-1.84; P= 0.013) but not its severity. METS IR demonstrated that individuals in the highest quartile had substantially higher odds of PCAD (OR= 3.15, 95% CI: 2.03–4.89; P< 0.001) and of severe PCAD (OR= 2.25; 95% CI: 1.37–3.68; P< 0.001). The magnitude of these associations differed across ethnic groups, with the clearest patterns observed in Fars, Gilak, and Kurd participants. Both dietary grain patterns and METS IR were independently associated with the risk and severity of PCAD in this large multi ethnic study. These findings highlight the importance of considering both nutritional quality and metabolic status when assessing susceptibility to premature coronary atherosclerosis in Middle Eastern populations.

17622

ACCURACY OF BODY ADIPOSITY INDEX (BAI) FOR THE ASSESSMENT OF BODY FAT PERCENTAGE COMPARED TO DUAL-ENERGY X-RAY ABSORPTIOMETRY (DXA) IN PATIENTS WITH HEART FAILURE.

TALITA RODRIGUES PARAIZO1; KELLI TRINDADE DE CARVALHO1; MARCELLA RODRIGUES GUEDES1; ANNA LUIZA CORREA DIAS1; JACQUELINE DA SILVA CABRAL1; ANA LUÍZA FERREIRA SALES1; MARCELO IMBROINISE BITTENCOURT1; FELIPE NEVES DE ALBUQUERQUE1; FABIO MAIA ABRAHAO1; MÁRCIA REGINA SIMAS TORRES KLEIN1; RICARDO MOURILHE-ROCHA1;

(1) UNIVERSIDADE ESTADUAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: The impact of obesity on clinical outcomes in individuals with heart failure (HF) has been widely investigated obtaining yielding controversial results, probably due to the use of parameters with low accuracy to assess body adiposity. Although largely used, the body mass index (BMI) has limitations, as it does not distinguish between body composition compartments. Conversely, dual-energy X-ray absorptiometry (DXA), considered the gold standard for assessing body fat percentage (%BF), has a higher cost and limited accessibility in clinical practice. In this context, it is essential to identify more accurate and cost-effective methods to estimate body adiposity. The body adiposity index (BAI) estimates %BF and is easily obtained; nevertheless, its accuracy in patients with HF has not yet been established. Objectives: To evaluate the accuracy of the BAI in estimating %BF compared to DXA in individuals with HF. Methods: A cross-sectional study including outpatients with HF, of both genders. Body fat percentage was estimated by BAI (%BF-BAI), calculated using the formula proposed by Bergman et al. (2011): hip circumference (cm) / height (m)^1.5 − 18, and by DXA (%BF-DXA), considered the reference method. The accuracy of BAI in estimating %BF was determined using Lin's concordance correlation coefficient (CCC) and Bland–Altman analysis. The strength of agreement (CCC) was classified according to the criteria proposed by Landis and Koch (1977). Results and Conclusions: A total of 157 patients were evaluated: 32% (n=50) women and 68% (n=107) men, with a mean age of 60.1±12.4 years, BMI of 29.2±6.0 kg/m², and waist circumference of 102.7±13.9 cm. The %BF estimated using BAI and DXA was, respectively, 28.5±4.5% and 32.6±7.6% in men, and 36.6±6.9% and 43.5±7.6% in women. According to the Pearson analysis, %BF-DXA showed a strong association with %BF-BAI (r=0.81; p<0.001). The CCC indicated moderate agreement between %BF-DXA and %BF-BAI (r_c=0.642; 95% CI=0.57–0.71; p<0.0001). Bland–Altman analysis revealed a bias (mean difference) of -5.0% for %BF-DXA compared with %BF-BAI, with 95% limits of agreement ranging from -15.56 to 5.51%. In individuals with HF, %BF-BAI demonstrates a strong association and moderate accuracy compared to %BF-DXA, slightly underestimating values. Considering the importance of assessing body adiposity in patients with HF, BAI may represent a practical and accessible tool for use in routine clinical practice.

CASE REPORT: CHALLENGES IN THE DIAGNOSIS AND MANAGEMENT OF MAST CELL ACTIVATION SYNDROME (MCAS) IN A PATIENT WITH HYPERMOBILITY SPECTRUM DISORDER, SEVERE DYSAUTONOMIA, AND SUSPECTED ASIA SYNDROME

JOSEANE BROSTEL FIGUEIREDO DAVID1; ADRIANA ABREU RESENDE1; ISABELLA CAROLINE DE FREITAS DOMINGOS1; ÁDHIRA GIOVANNA DE ANDRADE ALVES1; ISABELA CRISTINA BRAZ SANTOS1;

(1) ESCOLA SUPERIOR DE CIENCIAS DA SAUDE - BRASÍLIA - DF - BRASIL;

Introduction: Female, 35-year-old, previously active, living in a high-temperature region, developed progressive severe autonomic dysfunction beginning in January 2024, characterized by disabling fatigue, marked orthostatic intolerance, and major functional impairment requiring frequent supine positioning. Case Description: Her history included immune-triggering events, including COVID-19 (2021), followed by dengue and systemic inflammatory response syndrome in 2024, after which marked deterioration of autonomic stability occurred. She developed recurrent severe hypotension (70–80 mmHg) associated with presyncope, lipothymia, dyspnea on minimal exertion, and generalized weakness, requiring repeated hospitalizations for intravenous volume replacement. Orthostatic heart rate increased from approximately 80 bpm supine to 135 bpm standing, and tilt-table testing confirmed orthostatic intolerance. She also presented unintentional 12 kg weight loss over 1 year and significant gastrointestinal symptoms, including severe constipation (7–10 days without bowel movements), intermittent diarrhea, and prior erosive pangastritis. Physical examination demonstrated generalized joint hypermobility (Beighton score 8/9), temporomandibular instability, and connective tissue features consistent with Hypermobility Spectrum Disorder. Multisystem manifestations—including heat-induced pruritus, hypersensitivity to hymenoptera stings, chronic rhinorrhea, gastrointestinal involvement, and perimenstrual worsening—supported suspected MCAS. The presence of silicone breast implants (2016) raised suspicion for Autoimmune/Inflammatory Syndrome Induced by Adjuvants. The clinical course was refractory to fludrocortisone, desmopressin, and high-dose midodrine; pyridostigmine was discontinued due to alopecia. A multimodal strategy including vitamin C, venlafaxine, ivabradine, electrolyte supplementation, desmopressin as needed, glutamine, antihistamines, montelukast, ketotifen, famotidine, and a low-histamine diet resulted in blood pressure stabilization, improvement of gastrointestinal and respiratory symptoms, discontinuation of midodrine, and gradual functional recovery. Conclusions: This case highlights the complexity of overlapping dysautonomia, connective tissue disorders, and mast cell-related diseases, reinforcing the need for individualized multidisciplinary management and integrated autonomic and immune modulation for clinical stabilization.

CARDIAC INVOLVEMENT IN ROSAI-DORFMAN DISEASE: A CASE REPORT

JULIANA SAYURI MAIA HIROSE1; CAMILA HELENA RUFFO1; RAISSA MATIAS LEWINTER1; HUGO VINICIUS NEVES MORAIS1; GUILHERME LIMA FAVARO1; VICTORIA MARIA LIMA TOURINHO1; VITOR DIAS DE ALMEIDA1; EDUARDO DE BIASIO MILANO1; FABIO ANTONIO GAIOTTO1; RODRIGO RAMELLA MUNHOZ1; JOÃO BATISTA COSTA CARVALHO DE SERRO AZUL1;

(1) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introduction: Rosai-Dorfman disease (RDD) is a rare, benign condition that involves an overgrowth of histiocytes and rarely affects the heart. We describe below the case of a patient with this clinical condition. Case Description: A 56-year-old male, farmer, with no past medical history, recently developed hypertension, asymptomatic at the time of diagnose. Physical examination was normal. He underwent a transthoracic echocardiogram to evaluate target organ damage secondary to systemic arterial hypertension, which identified a lesion in the right atrium. Laboratory exams only revealed a slightly altered kidney function, with other tests normal. For further investigation, cardiac MRI was performed and showed a mass in the right atrium, extending through the inter-atrium septum to the left atrium, of rounded surface and regular edges of 40mm x 50mm. A Chest CT scan showed two elongated subpleural formations with attenuation of soft tissues, one located below the posterior segment of the 6th right costal arch, measuring approximately 40mm x 15mm. The second next to the anterior segment of the 1st left costal arch, measuring approximately 20 x 20mm. A FDG-PET/CT was then performed with an uptake in the interatrial lesion (SUV 5.7), and both thoracic lesions with a SUV of 5.1 and 5.6. Also, two new bone lesions were evidenced, one in the right humerus and the other in the sternal manubrium with SUVs of 6.1 and 6.9, respectively. To clear the diagnose, he was submitted to a biopsy of the right pleural lesion, which resulted in fibrosis with lymphoplasmacytic and histiocytic inflammatory infiltrate, without atypia. Due to the inconclusive result, an endomyocardial biopsy was done and was also inconclusive, showing only fragments of myocardium with signs of hypertrophy. The patient underwent surgical removal of the cardiac tumor. Due to the extensive involvement, including inaccessible structures, a cytoreductive strategy was performed, removing a large part of the mass and clearing the right ventricular inflow tract and right atrial chamber. The biopsy revealed Rosai-Dorfman disease, with HSL500 Panel showing KRAS A146P mutation. Conclusions: Rosai-Dorfman disease (RDD) usually presents with cervical lymphadenopathy, associated with fever and weight loss. Cardiac manifestation is considered rare, requiring differential diagnosis with lymphoma and sarcoma. Treatments include surgery, corticosteroids and targeted therapy.

CARDIAC MATURE MYOCYTE HAMARTOMA IN A PATIENT WITH METASTATIC SQUAMOUS CELL CARCINOMA: DIAGNOSTIC CHALLENGE OF A RIGHT VENTRICULAR MASS

THIAGO LEANDRO PEREIRA JACYNTHO1; JOÃO PEDRO SENFF1; SARA DE CAMARGO GUEIBER1; MARIANA MAINARDES SILVA1; SARAH FAGUNDES GROBE1; BRUNA OLANDOSKI ERBANO1; PEDRO FELIPE GOMES NICZ1; LARISSA DE OLIVEIRA RENGEL DOS SANTOS1; AMANDA DE NADAI COSTA1; LUCIA DE NORONHA1; GUSTAVO GAVAZZONI BLUME1; LIDIA ANA ZYTYNSKI MOURA1;

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL;

Introduction: Cardiac mature myocyte hamartomas (MMH) are extremely rare benign primary tumors, with approximately 34 cases reported up to 2023. They differ from rhabdomyomas and fibromas, which are more prevalent in children, by occurring predominantly in adults and being located in the ventricles. They are composed of disorganized mature myocytes and exhibit slow growth, with a variable clinical spectrum ranging from asymptomatic cases to arrhythmias and sudden death. Definitive diagnosis is histopathological, as imaging modalities such as echocardiography and cardiac magnetic resonance provide nonspecific findings and may mimic benign or malignant neoplasms. Case Description: A 40-year-old man with a history of tongue squamous cell carcinoma (SCC), treated with surgery, chemotherapy, and radiotherapy in 2024, was admitted in September 2025 after syncope. Initial evaluation revealed a left frontal expansive lesion, whose resection confirmed poorly differentiated SCC with meningeal involvement, consistent with metastasis. In the subsequent cardiological evaluation, transthoracic echocardiography (October 2025) revealed a heterogeneous mass in the right ventricle (2.95 × 2.50 cm), with cystic areas and mobile components, associated with segmental hypokinesia. Cardiac magnetic resonance imaging suggested a secondary neoplastic etiology, without excluding an infectious cause. A percutaneous endomyocardial biopsy via right heart catheterization was performed under echocardiographic guidance, identifying MMH in one of seven samples. Cowden syndrome was considered; however, the absence of clinical criteria and family history made this hypothesis unlikely. In the absence of significant ventricular dysfunction, cardiovascular symptoms, or pericardial effusion, and considering the unfavorable oncological prognosis, as well as the immunosuppressed state and recurrent infections, a conservative management strategy was adopted. During follow-up, a reduction in the mass was observed after chemotherapy, without cardiovascular events. Conclusions: We report a rare case of MMH diagnosed by biopsy in a patient with metastatic SCC. Despite its benign nature, the clinical course was atypical, with lesion reduction after chemotherapy, suggesting possible coexistence with metastatic disease. Cardiac metastases from tongue SCC are rare and associated with poor prognosis. This case highlights the diagnostic complexity of cardiac masses and the need for an individualized approach.

MALIGNANT OF THE PERIPHERAL NERVE SHEATH TUMOR (MPNST) WITH CARDIAC INVOLVEMENT: A RARE CASE REPORT OF PRIMARY SARCOMA OF THE HEART

ANA CAROLINA GARCIA PEDROSO DE OLIVEIRA SOUZA1; ANNE LOUREIRO XAVIER KISUKURI2; CAROLINA CAETANO DE SOUZA2; GABRIEL HENRIQUE EFFIO SOLIS2; ANDRÉ LUIZ POLO2; LARA GARCIA FERNANDES PEREIRA2; INGRID VICTORIA SANCHEZ MADRID2; ITALO CARNEIRO DE LIMA2; FERNANDO FOCACCIA PÓVOA2; RAMON MOTTA DA SILVA BRITTO2; JOÃO VICTOR SCARDINI MOREIRA2;

(1) IAMSPE - VITÓRIA - ES - BRASIL; (2) IAMSPE - SÃO PAULO - SP - BRASIL;

Introduction: Primary heart tumors are rare, representing less than 0.03% of autopsy findings. Among malignant tumors, sarcomas are the most common, with angiosarcoma being the most frequent. MPNST is an aggressive sarcoma that rarely affects the heart. It can occur sporadically or associated with neurofibromatosis type 1, and is characterized by rapid growth and a guarded prognosis. The clinical presentation is usually insidious and nonspecific, which delays diagnosis and complicates initial management. Brain MRI may be considered at the time of diagnosis due to the propensity for brain metastases. In selected cases, heart transplantation may be an option. Case Description: A 45-year-old woman with Hashimoto's thyroiditis, uterine fibroids, childhood glomerulonephritis. In 2024, she began experiencing a dry cough and dyspnea on exertion, which progressively worsened. She sought medical attention in 2025, when a chest CT angiography revealed pulmonary venous thrombosis, and full anticoagulation was initiated. Despite the therapy, she continued to experience dyspnea, cyanosis of the extremities, and functional impairment, prompting a new consultation. Chest CT scan revealed thrombosis in the right pulmonary vein and left atrium, as well as mediastinal lymphadenopathy. Echocardiography showed mitral valve thickening, an image adhered to its atrial surface, moderate mitral regurgitation, significant tricuspid regurgitation, and a pulmonary artery systolic pressure (PASP) of 79 mmHg. Hematological investigation was negative. With clinical worsening, signs of low cardiac output, and elevated PASP to 103 mmHg, cardiac surgery with mitral valve replacement was indicated. A tumor mass was identified in the right pulmonary vein and left atrium, without thrombi. The material was sent for histopathology, which revealed a high-grade spindle cell sarcoma, compatible with MPNST. After tumor excision, the patient experienced symptomatic improvement and a reduction in PASP. Conclusions: This report describes a rare case of cardiac MPNST with an atypical clinical presentation, initially mistaken for pulmonary thromboembolism. The refractory evolution to conventional treatment and the presence of significant pulmonary hypertension were essential for the diagnostic suspicion. The case highlights the relevance of considering malignant cardiac tumors in the differential diagnosis of intracardiac masses and progressive symptoms, especially when there is no response to the instituted treatment.

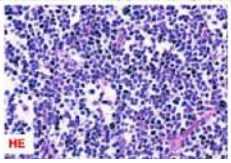
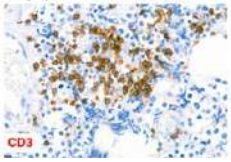
PRIMARY CARDIAC NULL PHENOTYPE CALLA-POSITIVE LYMPHOBLASTIC LYMPHOMA: A CASE REPORT OF FULMINANT PRESENTATION

MARCOS GABRIEL ALVES DA SILVA1; FAISAL VEIGA EL AOUAR1; BEATRIZ RIHS MATOS TAVARES1; AURELIO AUGUSTO GUEDES1;



(1) HOSPITAL SANTA ROSÁLIA - TEÓFILO OTONI - MG - BRASIL;



Introduction: Primary cardiac lymphomas are extremely rare neoplasms, accounting for a small proportion of cardiac tumors and extranodal lymphomas. They present with nonspecific clinical manifestations, frequently mimicking other cardiovascular diseases, which contributes to delayed diagnosis. Cases of primary cardiac lymphoblastic lymphoma with Null immunophenotype remain exceptionally rare in the literature and require extensive immunohistochemical characterization for accurate determination of cellular lineage. Case Description: An 85-year-old male patient initially presented with nonspecific symptoms characterized by hyporexia and unquantified weight loss, progressing to worsening dyspnea, precordial chest pain, and marked asthenia. Initial evaluation demonstrated mild lymphopenia, normocytic normochromic anemia, and a large pericardial effusion on echocardiography. After approximately 60 days and three hospital admissions for recurrent pericardiocentesis and bilateral pleural drainage, a repeat echocardiogram revealed an infiltrative intracardiac mass involving the right ventricle, measuring 60 × 26 mm, with extension into the right atrium and imaging features suggestive of neoplasia, as shown in the transthoracic echocardiography image. The patient underwent thoracotomy for pericardial drainage, pleural drainage, and biopsy of the lesion. He subsequently developed hemodynamic instability and died on the first postoperative day. Histopathological examination revealed diffuse high-grade neoplastic lymphoid proliferation infiltrating adipose tissue. Immunohistochemistry demonstrated an immature phenotype, with diffuse positivity for TdT, negativity for CD20 and CD3, positivity for CD10, MYC expression greater than 50%, and negativity for BCL-2 and EBV. These findings were consistent with CALLA-positive Null phenotype lymphoblastic lymphoma as evidenced em table 1. Conclusions: This case highlights the marked biological aggressiveness of immature phenotype lymphoblastic lymphomas with primary cardiac involvement, emphasizing the diagnostic challenge posed by nonspecific cardiovascular manifestations and rapid clinical deterioration. Although rare, these neoplasms should be considered in the differential diagnosis of infiltrative cardiac masses associated with recurrent pericardial effusion.

INTRACARDIAC SPINDLE-CELL SYNOVIAL SARCOMA CAUSING RIGHT VENTRICULAR OUTFLOW OBSTRUCTION: A MULTIMODALITY IMAGING AND CARDIO-ONCOLOGY CHALLENGE

JUSSARA GUIMARÃES DA ROCHA LIMA1; STEPHANIE CAROLINE DA COSTA FERREIRA2; VANESSA REIS DE ABREU CAVALCANTI3; LETÍCIA MARIA SANTIAGO SILVÉRIO2; ROBERTA RODRIGUES NOLASCO CARDOSO1; LUANA ALMEIDA DE ALENCAR LIMA1; JOANA SANTOS CESAR DE CARVALHO1; REINALDO DOS SANTOS MOURA1; CRISTIANE MONTEIRO DA CRUZ1; JOSÉ EDILSON DE FARIAS FILHO1; LARISSA LEITE DE SOUZA LEÃO1; ANTÔNIO EVERALDO VITORIANO DE ARAÚJO FILHO1;

Introduction: Primary cardiac sarcomas are rare and highly aggressive neoplasms, often presenting with nonspecific symptoms and delayed diagnosis. Within this spectrum, synovial sarcoma is exceptionally uncommon. This scenario underscores the growing role of cardio-oncology in integrating advanced imaging, hemodynamic assessment, and oncologic management. Case Description: A 34-year-old male presented with progressive dyspnea and chest pain. Electrocardiogram showed nonspecific abnormalities. Transthoracic echocardiography revealed a large intracavitary mass in the right ventricle (80.9 × 38.6 mm), causing dynamic right ventricular outflow tract obstruction, right chamber dilation, diastolic dysfunction, and moderate-to-severe tricuspid regurgitation. Chest computed tomography demonstrated an extensive filling defect extending from the right ventricle to the pulmonary trunk and its branches. Cardiac magnetic resonance imaging further characterized a heterogeneous mass attached to the tricuspid annulus and interventricular septum, extending through the right ventricular outflow tract into the pulmonary artery, associated with moderate right ventricular systolic dysfunction, strongly suggestive of primary malignant cardiac neoplasm. Partial surgical resection was performed. Histopathological and immunohistochemical analyses confirmed intracardiac spindle-cell synovial sarcoma. Despite intervention, the patient experienced rapid disease progression, with a decline in left ventricular ejection fraction (58% to 48%) and development of multiple pulmonary nodules consistent with metastatic dissemination. Palliative chemotherapy was initiated, requiring close cardiovascular monitoring in a specialized cardio-oncology setting due to the risk of further functional deterioration. Conclusions: This case highlights the diagnostic and therapeutic complexity of intracardiac synovial sarcoma, emphasizing the pivotal role of multimodality imaging and the need for integrated cardio-oncology care. Early recognition and continuous cardiovascular surveillance are essential, particularly in advanced disease, where therapeutic options are limited and prognosis remains poor.

LEFT ATRIAL INTIMAL SARCOMA MIMICKING MYXOMA: IMPORTANCE OF CARDIAC MAGNETIC RESONANCE IMAGING IN THE DIFFERENTIAL DIAGNOSIS OF INTRACAVITARY MASSES

CAMILLA FIDENCIO REIMBERG1; TIAGO SENRA GARCIA DOS SANTOS1; GUSTAVO REBEQUE MODOLO1; ANTONIO TITO PALADINO FILHO1; ARTHUR FELIPE GIAMBONA RENTE2; PEDRO CASAGRANDE2;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (2) REDE DOR - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Primary cardiac tumors are rare, and most are benign, with myxomas being the predominant type. Sarcomas represent the main primary malignant neoplasms of the heart and are associated with aggressive behavior and poor prognosis. Intimal sarcoma, although more common in large vessels, may involve cardiac chambers and often mimics benign lesions. Imaging differentiation is crucial for diagnosis and therapeutic planning. Case Description: A previously healthy 29-year-old woman presented with progressive dyspnea, orthopnea, and dry cough. Physical examination revealed signs of systemic congestion and a significant holosystolic mitral murmur. Echocardiography revealed a mass measuring approximately 40 mm in the left atrium, associated with severe mitral regurgitation and compression of the pulmonary veins. Cardiac magnetic resonance imaging demonstrated a heterogeneous lesion with marked late gadolinium enhancement and an infiltrative pattern involving the interventricular septum and mitral apparatus, suggesting malignant neoplasm. Due to clinical deterioration, the patient underwent emergency surgery due to obstruction of the left ventricular inflow tract. Partial resection of the mass was performed. Histopathological examination confirmed intimal sarcoma. The patient was referred for oncologic treatment. Differentiating benign from malignant cardiac masses remains a clinical challenge. Myxomas are generally pedunculated and attached to the interatrial septum, with more homogeneous characteristics. In contrast, malignant tumors tend to be infiltrative, heterogeneous, and associated with significant late enhancement. Cardiac magnetic resonance imaging stands out for its ability to provide tissue characterization, allowing identification of necrosis, vascularization, and local invasion. In the present case, these findings were fundamental in excluding benign hypotheses and guiding early surgical intervention. The prognosis of cardiac sarcomas remains poor, and early diagnosis is one of the main potentially modifiable prognostic factors. Conclusions: Left atrial masses with atypical characteristics should raise suspicion for malignancy. Cardiac magnetic resonance imaging plays a central role in diagnostic differentiation and therapeutic planning and may directly impact patient survival.

BEYOND IDIOPATHIC: STEROID-DEPENDENT RECURRENT PERICARDITIS REVEALING NOD2- ASSOCIATED AUTOINFLAMMATORY DISEASE

ISABELLA MOREIRA DE SOUZA1; FÁBIO HENRIQUE BEZERRA XIMENES1; PAULA CRISTINA MONTINA1; FABRÍCIO DA SILVA1;

(1) UNICEPLAC - BRASILIA - DF - Brasil;

Introduction: Refractory recurrent pericarditis remains a clinical challenge and is often labeled as idiopathic. However, autoinflammatory mechanisms are increasingly being recognized, with relevant therapeutic implications. Case Description: A 36-year-old woman, previously healthy, presented with severe low back pain and progressive weakness, which progressed to recurrent episodes of pericarditis. The episodes occurred monthly, often related to the menstrual period and painful ovulation. Initial treatment with colchicine and nonsteroidal anti-inflammatory drugs for six months, followed by azathioprine and prednisone (30 mg/day), did not prevent recurrences, which occurred during corticosteroid tapering and presented with chest pain and ventilation-dependent pain. The findings indicated a multisystemic nature, including peritonitis, appendicitis, bronchitis, pleural effusion, and parotid edema. PET-CT revealed hypermetabolic cervical and thoracic lymphadenopathy, as well as focal hypermetabolism at the antragastric/pancreatic interface. Cardiac magnetic resonance imaging (MRI) confirmed moderate pericardial effusion and mild pericardial late enhancement, with preserved systolic function. The patient developed neurological manifestations (severe headache, syncope, and epileptiform activity on electroencephalogram [EEG]), leading to a diagnosis of idiopathic intracranial hypertension with a cerebrospinal fluid opening pressure of 40 cmH□O and normal cerebrospinal fluid analysis. Investigations for infectious, neoplastic, and autoantibody causes were negative. Genetic testing (Exome NGS) identified a variant of uncertain significance (VUS) in homozygosity in the NOD2 gene, which is associated with Yao and Blau syndromes. Given the refractory nature of the condition, the clinical presentation, and the suspicion of an autoinflammatory syndrome, therapy with Anakinra [an interleukin-1 (IL-1) antagonist] was initiated at a daily dose of 100 mg. To date, the patient has shown clinical improvement and is being monitored with cardiac MRI, with remission of areas of late enhancement that indicated disease activity. Conclusions: Autoinflammatory diseases should be considered in cases of corticosteroid-dependent recurrent pericarditis. Recognition of this etiology allows for appropriate therapies targeted therapies, such as IL-1 blockade, with significant clinical impact. This case underscores the need to reevaluate the concept of “idiopathic” in refractory settings.

Introduction: Cardiac atrial septal lipoma is a rare cardiac benign neoplasm of mature adipocytes arising in the interatrial septum with an overall cardiac tumor incidence of 0.17–0.19% at autopsies. The surgical treatment of this condition generally involves the resection of the atrial septum with reconstruction of the septum with bovine pericardium. This approach may cause residual atrial septal defects, arrhythmias and conduction disturbances. We describe a new approach that involves complete removal of the tumor without resection of the atrial septum. Case Description: A 55-year-old woman presented with vertigo. Transesophageal echocardiogram showed a hyperechogenic mass with oval aspect involving the atrial septum near the atrial roof, measuring 21 x 48 mm, without pedicle and suggestive of a lipoma. Cardiac magnetic resonance demonstrated a mass in the right superior region of the atrial septum, adhered to the atrial roof, measuring 24 x 25 x 44 mm, compatible with a lipoma. The patient was submitted to surgery through median sternotomy with cardiopulmonary bypass and cardioplegia. The mass was completely dissected through Sondergaard's groove between the atria without opening the atria and the heart. The tumor, resembling an encapsulated lipoma, was totally excised. The aorta was released and the heart acquired sinus rhythm. An intraoperative transesophageal echocardiogram indicated the complete excision of the tumor and no residual atrial septal defect. Histopathological examination described a neoplasm of mature adipose tissue arranged in lobules without cytologic atypia, measuring 55 x 45 x 28 mm, compatible with a lipoma. Conclusions: The complete excision of an atrial septal lipoma without resection of the atrial septum was feasible and safe. This new technique may prevent complications related with the atrial septal resection.

Introduction: Dysferlinopathies (LGMD R2) are autosomal recessive muscular dystrophies caused by DYSF mutations, which impair calcium-dependent sarcolemmal repair. While primarily a skeletal muscle pathology, dysferlin is a critical component of the cardiac transverse tubule system, regulating vesicle trafficking and myocardial membrane integrity. In endemic regions, the clinical complexity is significantly amplified by the overlap with Chagas Disease, which possesses an aggressive tropism for the cardiac conduction system. This report aims to analyze a rare case of mixed-etiology cardiomyopathy involving a compound heterozygous patient, highlighting the synergistic burden of dystrophic fibrofatty replacement and chagasic inflammatory aggression on lethal arrhythmia risk. Case Description: An adult male patient with LGMD R2, confirmed via Next-Generation Sequencing (NGS) as a compound heterozygote, presented with progressive proximal weakness and total wheelchair dependence. Longitudinal follow-up (2023–2026) through serial 12-lead ECGs revealed a bifascicular block (Right Bundle Branch Block + Left Anterior Fascicular Block)—a hallmark of Chagasic damage—superimposed on an underlying dystrophic myocardial fragility. Complementary imaging suggested incipient diastolic dysfunction and reduced global longitudinal strain. Cardiac Magnetic Resonance (CMR) is planned to quantify the myocardial scar burden via late gadolinium enhancement (LGE), as the subendocardial and transmural fibrosis profiles are essential to distinguish degenerative from infectious damage. The clinical course was severely aggravated by a major depressive episode and a suicide attempt in 2025, resulting in a severe Traumatic Brain Injury (TBI) and permanent cognitive impairment. Current pharmacological management focuses on heart failure prevention using low-dose ACE inhibitors and beta-blockers, though titration remains limited by autonomic instability and the high risk of progression to total atrioventricular block. Conclusions: The synergy between genetic dystrophic fibrosis and Chagasic inflammatory damage imposes a severe arrhythmogenic burden, demonstrating that in advanced muscular dystrophies, invasive cardiological surveillance and rhythmic risk stratification are the primary determinants of survival.The cumulative myocardial fibrosis and electrical instability justify early consideration of an Implantable Cardioverter-Defibrillator for primary prevention of sudden cardiac death,even within complex neuro-palliative contexts.

NOVEL PTPN11 VARIANT IN NOONAN SYNDROME: NEONATAL PULMONARY STENOSIS AND MULTISYSTEMIC CHALLENGES

JOÃO VITOR FERREIRA DOMINGOS1; LARISSA MILKEM VIEIRA2; FABISA DA SILVA CALDAS CARVALHO1; MARCOS VINÍCIUS DE CASTRO1; RITA DE CÁSSIA RODRIGUES SILVA1; LOURDES GONÇALVES GOMES1;

(1) UNIVERSIDADE FEDERAL DE UBERLÂNDIA - UBERLÂNDIA - MG - BRASIL; (2) FACULDADE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introduction: Noonan Syndrome (NS) is a rare autosomal dominant RAS disorder that presents with cardiovascular involvement in up to 80% of cases, classically associated with pulmonary valve stenosis (PVS) and hypertrophic right ventricular (RV) cardiomyopathy. Severe neonatal forms are associated with lymphatic anomalies and myeloproliferative disorders that mimic Juvenile Monocytic Myeloid Leukemia. The objective of this report is to describe a case of NS caused by a undescribed pathogenic variant presenting with an extreme phenotype, focusing on the genotype-phenotype correlation and neonatal hemodynamic management. Case Description: A 38-year-old pregnant woman presented with increased nuchal translucency (5.3 mm), polyhydramnios, and fetal hydrops, suggesting a genetic syndrome. Fetal echocardiography (31 weeks and 3 days) revealed thickened atrioventricular valves with elongated leaflets, severe PVS (velocity 1.8 mm/s), and RV hypertrophy. A preterm male infant (2,195g; 42.5cm) was delivered via cesarean section at 32 weeks and 2 days. He required intubation in the delivery room, presenting signs of respiratory failure, cryptorchidism, and facial dysmorphisms (flat face, low-set ears). Neonatal echocardiography confirmed PVS (gradient 27 mmHg), right ventricular hypertrophy, patent foramen ovale, and patent ductus arteriosus. Treatment was initiated with oral beta-blocker and sildenafil. During follow-up was detected lymphatic dysplasia, evidenced by chylothorax (pleural triglycerides: 377 mg/dL), thrombocytopenia, and leukocytosis with peripheral blasts (1%), suggestive of a transient myeloproliferative disorder. The genetic panel confirmed the pathogenic variant in the PTPN11 gene [c.1505C>T:p.(Ser502Leu)]. The clinical course was aggravated by gastrointestinal dysmotility requiring exploratory laparotomy, multidrug-resistant pneumonia, and multiple organ failure, leading to death within 44 days. Conclusions: The extreme neonatal presentation of NS requires high clinical suspicion and a multidisciplinary approach. Management of right RV hypertrophy should be prioritized with beta-blockers to optimize diastole, and the use of positive inotropes is contraindicated as they exacerbate the obstruction. It is noteworthy that this report demonstrates a previously undescribed pathogenic variant in the PTPN11 gene, which resulted in severe phenotypic manifestations (right heart obstruction, lymphatic dysplasia, and hematological instability), limiting the patient's survival.

RESULTADO

Foi identificada uma variante patogênica, em heterozigose, no gene *PTPN11*.

MYOCARDIAL FRAGILITY IN GYG1-RELATED METABOLIC CARDIOMYOPATHY: A CASE WITH BRUGADA PHENOCOPY AND DELAYED DEVICE-RELATED RUPTURE

NURCAN ARAT1; ZÜMRÜT ARSLAN GÜLTEN2; UMRAN CETINCELIK3; SEVIL TOKDEMIR SISMAN4; KUDRET KESKIN1;

(1) HEALTH AND SCIENCE UNIVERSITY, SISLI HAMIDIYE ETFAL TRAINING AND RESEARCH HOSPITAL, DEPARTMENT OF CARDIOLOGY - TÜRKIYE; (2) SISLI HAMIDIYE ETFAL TRAINING AND RESEARCH HOSPITAL - TÜRKIYE; (3) SISLI HAMIDIYE ETFAL TRAINING AND RESEARCH HOSPITAL, DEPARTMENT OF MEDICAL GENETICS - TÜRKIYE; (4) SISLI HAMIDIYE ETFAL TRAINING AND RESEARCH HOSPITAL, DEPARTMENT OF RADIOLOGY - TÜRKIYE;

Introduction: Glycogen storage disease type XV (GSD-XV), caused by biallelic pathogenic variants in the GYG1 gene, is an ultra-rare metabolic disorder primarily associated with late-onset skeletal myopathy. Limited reports describe hypertrophic cardiac phenotypes and myocardial fibrosis, with variable manifestations including arrhythmias and heart failure. However, myocardial mechanical integrity in GYG1-related disease and its implications for device-related outcomes remain poorly defined. This case highlights a potential susceptibility to delayed, life-threatening mechanical complications following intracardiac device implantation. Case Description: A 31-year-old male presented with chest pain, fatigue, and exertional dyspnoea. Electrocardiography revealed a spontaneous type-1 Brugada pattern with complete right bundle branch block. Transthoracic echocardiography showed non-obstructive left ventricular hypertrophy with preserved ejection fraction, while speckle-tracking showed reduced global longitudinal strain with heterogeneous distribution and no apical sparing. Cardiac magnetic resonance imaging showed mid-to-apical hypertrophy and patchy non-ischaemic late gadolinium enhancement consistent with myocardial fibrosis. Metabolic and systemic evaluations were unremarkable, supporting a cardiac phenotype. Genetic testing identified a homozygous pathogenic GYG1 variant (p.Asp102His), with no variants in genes associated with primary Brugada syndrome, supporting a substrate-related Brugada phenocopy. An implantable cardioverter-defibrillator was implanted due to high-risk features. Early follow-up was unremarkable at 1 and 3 months. At 6 months, evaluation revealed pericardial effusion progressing to tamponade. Device extraction confirmed lead-related myocardial rupture requiring surgical repair. The delayed asymptomatic presentation without procedural complications, device-related issues, or trauma suggests progressive myocardial vulnerability rather than acute perforation. Conclusions: This case demonstrates a cardiac-dominant phenotype of GYG1-related disease. Delayed lead-related myocardial rupture, unlike typical early perforation, supports intrinsic myocardial fragility, despite the absence of conventional risk factors. This may reflect structural weakening due to abnormal glycogen metabolism and fibrotic remodeling. Recognition of this vulnerability has implications for device strategies and follow-up. Multimodality imaging and genetic evaluation are essential for diagnosis and risk stratification.

CARDIAC SARCOIDOSIS ASSOCIATED WITH EPSILON WAVE AND VENTRICULAR TACHYCARDIA: A CASE REPORT

YASMIM DE SOUZA CARVALHO1; ROBERTO MUNIZ FERREIRA2; JOÃO GABRIEL BATISTA LAGE1; JOÃO PEDRO VAZ DE LIMA1; ISADORA BEZERRA DE LUCENA1; LUCAS SCHMITBERGER GAVAZZONI1; VICTOR COELHO MATTOS1; JULIANO CARVALHO GOMES DE ALMEIDA3; ROSA ANGÉLICA OSORIO BURGOS1; PEDRO PAULO NOGUERES SAMPAIO1;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) INSTITUTO DO CORACAO EDSON SAAD/UFRJ - RIO DE JANEIRO - RJ - BRASIL; (3) HOSPITAL SAMARITANO - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Sarcoidosis is a systemic inflammatory disease characterized by non-caseating granulomas in multiple tissues. Cardiac involvement occurs in about 5% of cases, mainly affecting the ventricular myocardium, as well as the pericardium, conduction system, and valves. It may present with heart failure (HF), palpitations, syncope, and sudden death (SD), often associated with ventricular arrhythmias. Case Description: A 41-year-old man with a history of anabolic steroid use presented with exertional dyspnea and fatigue for 3 months, along with a syncopal episode. On admission, he showed signs of systemic and pulmonary congestion, consistent with HF. Electrocardiogram revealed sinus rhythm, first-degree AV block, right bundle branch block, T-wave inversion in V1–V4, and a terminal positive deflection in V1 and V2 suggestive of an epsilon wave (Fig. A). Echocardiography showed biventricular dysfunction with an ejection fraction of 21%, diffuse hypokinesia, septal trabeculations, and tricuspid regurgitation. During hospitalization, he developed unstable ventricular tachycardia treated with electrical cardioversion, and a cardioverter-defibrillator was subsequently implanted. Multigene panel testing was negative. Cardiac PET/CT revealed heterogeneous hypermetabolism in the left ventricle (Fig. B), as well as uptake in thoracic and abdominal lymph nodes. Cardiac MRI showed extensive multifocal biventricular mesoepicardial late gadolinium enhancement suggestive of cardiac sarcoidosis (Fig. C). Axillary lymph node biopsy confirmed the diagnosis, showing non-caseating granulomatous lymphadenitis with giant cells and asteroid bodies. Immunosuppressive therapy was initiated, with joint follow-up by rheumatology. Conclusions: Cardiac sarcoidosis is an important differential diagnosis of cardiomyopathies in young patients and may initially present with ventricular arrhythmias. Although the epsilon wave is classically associated with arrhythmogenic right ventricular dysplasia, it may also occur in sarcoidosis. Other genetic cardiomyopathies should be also considered, especially according to imaging findings. Histopathological confirmation should always be pursued. Treatment includes immunosuppression, HF management, and possibly secondary prevention of SD with an ICD.

RECURRENT INFLAMMATORY MYOCARDITIS IN A PATIENT WITH LIMB-GIRDLE MUSCULAR DYSTROPHY TYPE 2F: CORTICOSTEROID DEPENDENCE AND RESPONSE TO AZATHIOPRINE

THALLYS YOHANIS BENÍCIO FERNANDES1; DIANA ANDRADE SAFIEH1; JULIO CESAR VIEIRA DE SOUSA1; ROBERTO MORENO MENDONÇA1; VINICIUS TAVARES DE OLIVEIRA1; ANA CRISTINA MESQUITA DE CAMPOS1; SARA DANTAS NASCIMENTO DUARTE1; KAIO CÉSAR LIMA DOS SANTOS2;

(1) UNIVERSIDADE FEDERAL DO RIO GRANDE DO NORTE - NATAL - RN - BRASIL; (2) FACULDADE PITAGORAS DE MEDICINA - EUNAPOLIS - BA - BRASIL;

Introduction: Limb-girdle muscular dystrophies (LGMD) are hereditary diseases with progressive proximal muscle weakness. LGMD 2F (SGCD gene mutation) may involve cardiac manifestations, with dilated cardiomyopathy being the most frequent. Recurrent myocarditis in this context is rare and poorly described. Case Description: A 12-year-old male patient with LGMD 2F (mutation in exon 8 of the SGCD gene; peak CPK 7,700 U/L), presenting with loss of ambulation, upper limb weakness, neurogenic bladder, and gastroesophageal reflux disease. Annual cardiology follow-up had previously shown no abnormalities. The patient presented with multiple episodes of intense precordial pain radiating to the left upper limb, triggered by physical or emotional stress, accompanied by elevated troponin I (peak 7.93 ng/mL) and ST-segment elevation in V2–V5 on ECG, initially raising suspicion of anterolateral myocardial infarction and prompting two hospitalizations. Ischemic etiology and coronary anomalies were excluded by aortic and coronary computed tomography angiography. Subsequent ECGs revealed early repolarization disturbance. Cardiac magnetic resonance imaging (CMR) during the acute phase showed non-ischemic late gadolinium enhancement associated with hyperintensity on triple inversion recovery sequences, confirming acute myocarditis. Prednisone 2 mg/kg/day was initiated with immediate clinical response, normalization of troponin, and resolution of myocardial edema on follow-up CMR. However, the patient developed corticosteroid dependence, with symptomatic recurrences and rising biomarkers at every tapering attempt. Repeat CMR confirmed fibrosis in previously affected segments along with new foci of edema and hyperemia in previously unaffected segments. Methotrexate (titrated up to 17.5 mg/week) was introduced as a corticosteroid-sparing agent but was discontinued due to severe gastrointestinal intolerance. Azathioprine 50 mg/day was then started in combination with ondansetron, with good tolerability, allowing gradual reduction of prednisone to a physiological dose (5 mg/day), with no new myocarditis episodes since initiating this combination. Conclusions: This case highlights recurrent myocarditis as a rare cardiac manifestation of LGMD 2F and suggests that recurrent inflammatory episodes may potentially contribute to the development of dilated cardiomyopathy observed in these patients. Azathioprine proved effective as a corticosteroid-sparing immunosuppressant in the setting of corticosteroid dependence.

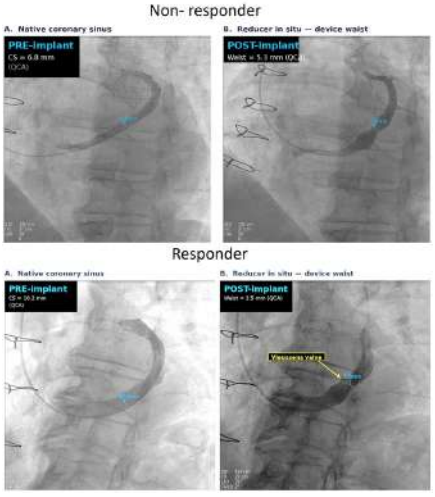
WAIST-TO–CORONARY SINUS DIAMETER RATIO AS A POTENTIAL PREDICTOR OF RESPONSE TO NOVEL CORONARY SINUS REDUCER THERAPY IN REFRACTORY ANGINA: A PILOT CASE SERIES



MICHAL PLEWKA1; TOMASZ GÓRNIK1;

(1) MEDICAL UNIVERSITY OF LODZ, POLAND, DEPARTMENT OF INVASIVE CARDIOLOGY AND CARDIAC ARRHYTHMIAS - POLAND;

Introduction: Coronary sinus reducer (CSR) implantation is a novel therapeutic option for patients with refractory angina not amenable to revascularisation. However, response to therapy is heterogeneous and predictors of clinical and perfusion improvement remain insufficiently defined. In this case series we hypothesised that anatomical and device-related parameters, including the waist-to–coronary sinus (CS) diameter ratio as a surrogate of effective constriction, may be associated with therapeutic response following CSR implantation. Case Description: Four patients (3 male/1 female; age 61–86 years) with refractory angina (CCS III–IV), LVEF 44–56%, and baseline ischaemic burden of 10–26% underwent CSR implantation on optimal medical therapy. CS diameter and device waist were assessed by quantitative coronary angiography (QCA) at implantation. Follow-up SPECT at 4 months was performed using an identical pharmacological stress protocol on the same gamma camera and interpreted by a single blinded reader. CS diameter ranged 5.5–10.2 mm (mean 7.45 mm), waist 3.3–5.3 mm, and waist-to–CS ratio 0.34–0.78. Three patients demonstrated improved perfusion with a reduction in ischaemic burden of 5–10 percentage points, associated with CCS class improvement (1–3 grades) and 6MWT increase (10–47%). The greatest benefit was observed in the patient with the largest CS diameter and lowest ratio (0.34), whereas the non-responder showed the highest ratio (0.78), suggesting inadequate narrowing and insufficient pressure gradient as a potential mechanism of failure. Conclusions: In this preliminary case series, a higher degree of relative coronary sinus constriction, expressed as a lower waist-to–coronary sinus diameter ratio, was associated with greater improvement in myocardial perfusion, symptoms, and functional capacity after CSR implantation. Conversely, limited device-induced narrowing may be linked to absent or attenuated response, suggesting a potential mechanistic role of pressure gradient generation in treatment efficacy. These findings are hypothesis-generating and warrant validation in larger prospective studies.

Table 1. Patient characteristics and outcomes.

Pt	Age/Sex	CCS pre	SPECT% pre	CS diam. (mm)	Waist (mm)	SPECT% post	ΔSPECT (pp)	CCS post	6MWT Δ (%)
1	70 / M	IV	28%	6.8	5.3	29%	+3	III (−1)	+13.5%

ANTI-INFLAMMATORY THERAPY IN CORONARY ARTERY DISEASE: A SYSTEMATIC REVIEW OF THE ROLE OF TIMING AND RESIDUAL INFLAMMATORY RISK

JENIFER DE MOURA PEIXOTO1; ISABELA CRISTINA SILVA DA SILVA1; DEBORAH VICTÓRIA DOS SANTOS GANZER1; JULIANE DA SILVA AZEVEDO1; RAFAEL DA SILVA AZEVEDO1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introduction/Background: Inflammation is a key driver of atherosclerosis, yet clinical trials of anti-inflammatory therapies in coronary artery disease (CAD) have yielded inconsistent results. Whether treatment efficacy is influenced by the timing of intervention and residual inflammatory risk remains uncertain. Objectives: To evaluate the impact of anti-inflammatory therapies on cardiovascular outcomes in CAD, with emphasis on disease phase (acute vs chronic) and inflammatory status. Methods: A systematic review was conducted following PRISMA 2020 guidelines. PubMed, Embase, and Cochrane CENTRAL were searched, identifying 648 records; 460 were screened after duplicate removal, and four randomized controlled trials (COLCOT, CANTOS, CIRT, and LoDoCo2) were included. Studies evaluated systemic anti-inflammatory therapies versus placebo in adult patients with CAD and were classified as acute (≤30 days post–myocardial infarction) or chronic disease. Risk of bias was assessed using the Cochrane RoB 2.0 tool. Resultados e Conclusions: Four trials (>25,000 patients) were analyzed. In the acute phase, COLCOT demonstrated that colchicine significantly reduced major adverse cardiovascular events (MACE) (HR 0.77; 95% CI 0.61–0.96). In chronic CAD, treatment effects were heterogeneous: in CANTOS, canakinumab reduced events in patients with elevated inflammatory markers (HR 0.85; 95% CI 0.74–0.98), whereas in CIRT, methotrexate showed no benefit (HR 0.96; 95% CI 0.79–1.16) and did not reduce inflammatory biomarkers. In LoDoCo2, colchicine demonstrated consistent benefit in stable disease (HR 0.69; 95% CI 0.57–0.83). Overall risk of bias was low, with minor concerns related to selective reporting and specific design features. Collectively, these findings indicate that anti-inflammatory therapy in CAD is not uniformly effective and is modulated by both timing of intervention and residual inflammatory risk. Early initiation after myocardial infarction and targeted use in patients with persistent inflammation appear to confer the greatest benefit, supporting a precision-based approach to inflammation modulation in atherosclerotic disease. Limitations include intertrial heterogeneity, differences in study populations and endpoints, and the absence of quantitative meta-analysis.

CORONARY ATHEROSCLEROSIS ON CCTA IN PATIENTS WITH ZERO CALCIUM SCORE: ASSOCIATION WITH MORTALITY OUTCOMES

MÁRCIA LIMA OLIVEIRA MUGNAINI1; PEDRO HENRIQUE BRAMBILA RODRIGUES BINOTTO1; FRANCO CAMARGO ZAPPAROLI1; LUCAS KAISER GOMES SILVA1; GUILHERME ALVES MARIATH COSTA1; MATHEUS FURTADO THÁ1; RODRIGO JULIO CERCI2; MARCELLO ZAPAROLI2; JOÃO VICENTE VITOLA2; TATIANA LORENA KAESTNER1; MARCIA OLANDOSKI1; JOSÉ ROCHA FARIA NETO1;

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (2) QUANTA DIAGNÓSTICO POR IMAGEM - CURITIBA - PR - BRASIL;

Introduction/Background: Coronary computed tomography angiography (CCTA) has become an important tool for assessing cardiovascular risk. While coronary artery calcium (CAC) scoring is widely employed as a risk stratification method, it does not capture all cardiovascular risks, especially in patients with a CAC score of zero. Notably, some individuals with a CAC score of zero exhibit signs of coronary atherosclerosis on CCTA, indicating a potential residual risk that is not fully understood. This raises important questions about the prognostic implications of coronary atherosclerosis in this specific population. Objectives: To evaluate the association between coronary atherosclerosis detected by CCTA and all-cause and cardiovascular mortality in patients with CAC score of zero. Methods: Observational study including patients who were submitted to CCTA and with a zero CAC. Exposure was presence of coronary atherosclerosis (negative vs. positive CCTA). Outcomes were all-cause and cardiovascular mortality. Participants were followed for approximately 6 years. Analyses included Kaplan–Meier curves with log-rank testing and Cox regression models (crude and adjusted for age, sex, and diabetes). Sensitivity analysis used Firth's penalized Cox regression. Proportional hazards assumptions were verified. Resultados e Conclusions: Results: Of 1,204 patients with CAC 0, 159 (13.2%) had any evidence of atherosclerosis (positive CCTA). These patients were older, more often male, and had more diabetes (all p<0.05) in comparison to those with a negative CCTA. During follow-up, 57 deaths (4.7%) occurred, with higher all-cause mortality in the positive group (8.8% vs. 4.1%). Survival was lower in the positive group (log-rank p=0.019). In unadjusted analysis, positive CCTA was associated with increased all-cause mortality (HR=2.03; 95% CI 1.11–3.72), but not after adjustment (HR=0.88; 95% CI 0.46–1.71). Age and male sex remained independent predictors. Similar findings were observed for cardiovascular mortality. Penalized models confirmed these results. Age was the main confounder. Conclusion: In patients with CAC score of zero, coronary atherosclerosis on CCTA was associated with higher mortality only in unadjusted analyses. After adjustment, no independent association was observed, suggesting that CCTA identifies higher baseline risk largely driven by age rather than independent prognostic value.

EARLY INITIATION OF SGLT2 INHIBITORS IN ACUTE CARDIOVASCULAR SETTINGS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF CLINICAL OUTCOMES

MARINA AZEVEDO AMARAL1; MARCILIO MARCÍLIO DE OLIVEIRA FILHO1; ANISIO UCHOA LEITE SANTANA2; MIGUEL CHAVES LENZI3; SUELEN QUEIROZ4; EDUARDO BELLO MARTINS5; ANTONIO ESCAMILLA GARCIA6;

(1) FACULDADE DE MEDICINA DE BARBACENA - BARBACENA - MG - BRASIL; (2) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (3) UNIVERSIDADE ESTADUAL DO RIO GRANDE DO NORTE - MOSSORÓ - RN - BRASIL; (4) UNIVERSIDADE ESTADUAL DE PONTA GROSSA - PONTA GROSSA - PR - BRASIL; (5) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (6) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL;

Introduction/Background: The optimal timing for initiating sodium–glucose cotransporter-2 inhibitors (SGLT2i) in acute cardiovascular conditions remains uncertain. While these agents have established benefits in chronic heart failure and cardiometabolic disease, their early use during acute myocardial infarction (AMI) or acute coronary syndrome (ACS) has not been fully elucidated. Objectives: To evaluate the impact of early in-hospital initiation of SGLT2 inhibitors in patients with acute cardiovascular events, assessing their effects on major adverse cardiovascular events (MACE) and mortality through a pooled analysis of randomized and observational studies. Methods: We conducted a systematic review and meta-analysis in accordance with PRISMA guidelines, including studies evaluating early in-hospital initiation of SGLT2i in patients with acute cardiovascular events. The primary outcome was major adverse cardiovascular events (MACE), and secondary outcomes included all-cause or cardiovascular mortality. Random-effects models (REML) were applied using inverse-variance weighting. Effect estimates were pooled as relative measures (hazard ratios and odds ratios). Leave-one-out sensitivity analyses were performed to assess robustness. Resultados e Conclusions: A total of 36,929 patients across 4 studies were included in this analysis . Early initiation of SGLT2 inhibitors in acute cardiovascular settings was not associated with a significant reduction in MACE (pooled effect 0.82, 95% CI 0.62–1.08; p=0.15; I²=16%). However, mortality was significantly reduced (pooled effect 0.65, 95% CI 0.53–0.78; p<0.001; I²=29.7%). Leave-one-out analyses supported the robustness of these findings, with no single study fully driving the mortality benefit, although the neutral MACE result appeared sensitive to exclusion of the largest study. The largest cohort, Wang 2025, showed significant reductions in cardiovascular composite outcomes and cardiovascular mortality with early SGLT2i initiation after acute myocardial infarction, whereas smaller studies mainly suggested benefit in heart failure-related outcomes or ventricular remodeling despite neutral composite endpoints . Overall, early in-hospital initiation of SGLT2 inhibitors appears to confer a survival benefit despite a neutral pooled effect on composite cardiovascular events, supporting their potential role in acute cardiovascular care and underscoring the need for further randomized evidence focused on hard clinical endpoints

ELEVATED APOLIPOPROTEIN(A) AS AN INDEPENDENT RISK FACTOR FOR ACUTE MYOCARDIAL INFARCTION IN YOUNG PATIENTS

MARCELO FLAVIO GOMES JARDIM FILHO1;

(1) HOSPITAL MUNICIPAL SALGADO FILHO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: The occurrence of acute myocardial infarction (AMI) in young patients has a major clinical, functional, and socioeconomic impact, in addition to a distinct etiopathogenic profile compared with that observed in older age groups. In this context, lipoprotein(a) [Lp(a)], a particle composed of low-density lipoprotein bound to apolipoprotein(a), has been recognized as a genetic marker of cardiovascular risk, with atherogenic, pro-inflammatory, and pro-thrombotic properties. Its role appears to be particularly relevant in premature coronary artery disease, especially in individuals without a substantial burden of traditional risk factors Objectives: To analyze the association between elevated Lp(a)/apolipoprotein(a) levels and the risk of AMI or acute coronary syndrome in young patients, with emphasis on its independence from conventional cardiovascular risk factors. Methods: Observational studies, a systematic review, and a meta-analysis investigating Lp(a) in patients with AMI, acute coronary syndrome, and premature coronary artery disease were analyzed, with attention to the magnitude of the association, early coronary outcomes, and adjustment for concomitant clinical variables Resultados e Conclusions: Elevated Lp(a) was consistently associated with a higher risk of premature coronary artery disease and acute myocardial infarction in young patients, independent of traditional cardiovascular risk factors. A systematic review showed an approximately threefold increase in risk in some subgroups, while a meta-analysis of 51 studies (100,540 participants) found significant associations with premature atherosclerotic cardiovascular disease (OR 2.15; 95% CI 1.53–3.02) and premature coronary artery disease (OR 2.44; 95% CI 2.06–2.90). Clinical studies further confirmed that elevated Lp(a) is frequent in young patients with acute coronary manifestations and remains an independent predictor even after adjustment for other variables. In patients under 50 years with AMI, Lp(a) ≥30 mg/dL was associated with a 3.22-fold higher risk of premature infarction. Overall, these findings suggest that Lp(a) contributes independently to coronary vulnerability in young individuals, even when conventional lipid parameters are not markedly abnormal. Elevated Lp(a)/apo(a) is an independent risk factor for premature MI and CAD in young patients, especially when traditional risk factors are absent or insufficient. Measuring Lp(a) may improve risk assessment in ACS, AMI, or a family history of early atherosclerosi

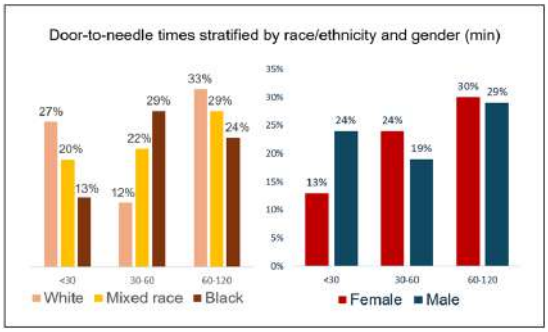
PREVENTION OF REPERFUSION INJURY IN MYOCARDIAL INFARCTION - PRIME, DOES PARACETAMOL REDUCE REPERFUSION INJURY IN PATIENTS PRESENTING WITH ST-ELEVATION MYOCARDIAL INFARCTION? A SINGLE SITE, HISTORICAL CONTROL, OPEN-LABEL, CLINICAL TRIAL

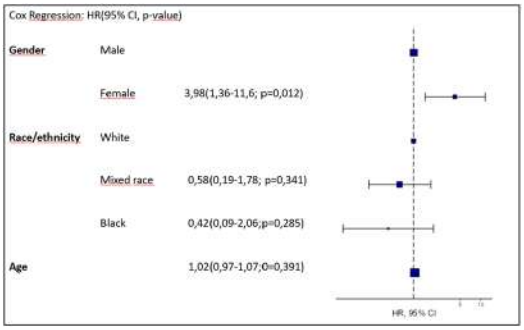
ADRIAN OWEN1;

(1) WAIKATO HOSPITAL - NEW ZEALAND;

Introduction/Background: ST-segment Elevation Myocardial Infarction (STEMI) remains a major cause of morbidity, mortality, and cost, including in New Zealand where outcomes are inequitable for Māori and Pacific peoples. Infarct size is a key determinant of prognosis. Although urgent reperfusion with percutaneous coronary intervention (PCI) or thrombolysis salvages threatened myocardium, reperfusion injury may substantially contribute to final infarct size. Pre-clinical data suggest paracetamol may reduce ischaemia–reperfusion injury via antioxidant effects and via its metabolite AM404, which may influence anandamide signaling associated with CB2 receptor activation. Given its low cost, even modest benefit could have meaningful clinical and financial impact. Objectives: To assess whether oral paracetamol given prior to PCI reduces biomarkers of infarct size in patients presenting with acute STEMI, and to evaluate feasibility and safety of this approach in routine acute care. Methods: Single-centre proof-of-concept study at Waikato Hospital. Patients with acute STEMI requiring primary or rescue PCI received oral paracetamol 1.5 g at recruitment alongside standard STEMI therapy, then 1 g four times daily for up to 4 days or until discharge. A historic control cohort was derived from the ANZACS-QI registry with chart review and matching by PCI type. Primary outcome: peak troponin 6–24 hours post-PCI (and delta troponin where available). Secondary outcomes: post-PCI ventricular arrhythmias, echocardiographic left ventricular ejection fraction (LVEF) within 4 days, and 30-day mortality. Recruitment occurred Aug 2024–Dec 2025. Resultados e Conclusions: Ninety-five patients were recruited; 13 were excluded and 7 lacked peak troponins, leaving 75 for the primary analysis (53 primary PCI; 22 rescue PCI). Compared with controls, mean peak troponin was lower by 2541 (34.5%) (4830 vs 7371; p=0.005); median peak troponin was 3456 vs 4250 (difference 1597; p=0.003). Delta troponin was also lower (2634 vs 4014; difference 2034; p=0.0002). Ventricular arrhythmias occurred in 11/82 (13.4%) trial patients vs 14/75 (18.7%) controls, LVEF impairment favoured paracetamol on AUC analysis, and 30-day mortality was 2/82 (2.4%) vs 4/75 (5.3%). Conclusions Paracetamol administration before PCI was feasible and safe in acute STEMI, including after cardiac arrest, with results consistent with reduced reperfusion injury and an estimated 20–25% reduction in infarct size. A randomised controlled trial is planned.



20283



RACIAL/ETHNIC AND GENDER INEQUITIES IN DOOR-TO-NEEDLE TIME AMONG PATIENTS WITH STEMI: RESULTS FROM THE EQUITY-MI COHORT.

ERIC COSTA ALMEIDA1; FELIPE NEVES ALBUQUERQUE1; ESMERALCI FERREIRA1; DENILSON CAMPOS DE ALBUQUERQUE1;

(1) HOSPITAL UNIVERSITARIO PEDRO ERNESTO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Limitations persist in the literature regarding disparities in the management of patients with ST-segment elevation myocardial infarction (STEMI), particularly when comparisons are made according to race/ethnicity and gender. Objectives: To compare clinical characteristics and to assess door-to-needle time (DNT) within 30 minutes and evaluate 180-day survival according to race/ethnicity (White, Brown [mixed race], and Black) and gender. Methods: EQUITY-MI is a single-centre, prospective cohort study of patients diagnosed with STEMI in the state of Rio de Janeiro, Brazil, who were referred to a single reperfusion centre.Continuous and categorical variables were analysed using Kruskal–Wallis and chi-squared tests. To estimate the effect of DNT within 30 minutes, logistic regression models were applied and odds ratios (ORs) were calculated. Survival analysis was performed using the Kaplan–Meier method with comparisons by the log-rank test. Cox proportional hazards models were used to estimate crude and adjusted hazard ratios (HRs) for 180-day mortality, adjusting for age, race/ethnicity, education level and household income. A significance level of 0.05 was adopted. Resultados e Conclusions: Among 504 patients, 27.2% were women and 67.8% self-identified as Black or Brown. DNT within 30 minutes occurred in 27.2% of White patients versus 12.5% of Black patients (p = 0.07). Black patients having 2.86-fold lower odds of achieving DNT within 30 minutes compared with White patients (OR = 0.349, p = 0.023), and women had lower odds than men (OR = 0.416; p = 0.015). In the interaction analysis, Black women had 5.49-fold lower odds of DNT within 30 minutes (OR = 0.182, p = 0.028).Kaplan–Meier analysis showed lower cumulative survival among women than men (log-rank p = 0.001), with no significant differences across racial/ethnic groups (p = 0.304). In Cox regression, female gender was independently associated with higher 180-day mortality in both unadjusted (HR 4.63; 95% CI 1.68–12.75; p = 0.003) and adjusted models (HR 3.98; 95% CI 1.36–11.66; p = 0.012). EQUITY-MI identified inequities in STEMI care and outcomes by gender and race/ethnicity. DNT often exceeded the recommended 30-minute target. Black patients and women had lower odds of timely thrombolysis, and female gender was independently associated with higher 180-day mortality. The interaction between race/ethnicity and gender revealed a pattern of intersectionality, with Black women experiencing the most unfavourable scenario compared with White men.

REDEFINING RISK BALANCE AFTER PCI: A SYSTEMATIC REVIEW AND META-ANALYSIS OF DE-ESCALATION AND PRECISION-GUIDED ANTIPLATELET STRATEGIES

MARINA AZEVEDO AMARAL1; MARCILIO MARCÍLIO DE OLIVEIRA FILHO1; SUELEN QUEIROZ2; ANISIO UCHOA LEITE SANTANA3; MIGUEL CHAVES LENZI4; MARIA EDUARDA SANTOS LUNA1; EDUARDO BELLO MARTINS5; ANTONIO ESCAMILLA GARCIA6;

(1) FACULDADE DE MEDICINA DE BARBACENA - BARBACENA - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE PONTA GROSSA - PONTA GROSSA - PR - BRASIL; (3) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (4) UNIVERSIDADE ESTADUAL DO RIO GRANDE DO NORTE - MOSSORÓ - RN - BRASIL; (5) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (6) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL;

Introduction/Background: The optimal antiplatelet strategy after percutaneous coronary intervention (PCI) remains a critical clinical challenge, particularly in balancing ischemic protection against bleeding risk. De-escalation strategies, including guided and unguided approaches, have emerged as potential alternatives to standard dual antiplatelet therapy (DAPT), yet their overall impact remains incompletely defined. Objectives: To evaluate the safety and efficacy of de-escalation and precision-guided antiplatelet strategies following percutaneous coronary intervention (PCI), with a focus on balancing ischemic and bleeding risks. Methods: A systematic review and meta-analysis of randomized controlled trials was conducted according to PRISMA guidelines. Trials comparing de-escalation or guided antiplatelet strategies versus standard therapy after PCI were included. The primary outcome was a composite clinical endpoint, with secondary outcomes including clinically relevant bleeding, myocardial infarction (MI), stent thrombosis, stroke, and all-cause mortality. Random-effects models (REML) were used to calculate pooled odds ratios (ORs) with 95% confidence intervals (CIs). Resultados e Conclusions: Across four randomized trials including 7,756 patients undergoing PCI, de-escalation and precision-guided antiplatelet strategies were associated with a significant reduction in the primary composite outcome (OR 0.60; 95% CI 0.44–0.82; P=0.0012; I²=58.9%). This benefit was primarily driven by a reduction in clinically relevant bleeding (OR 0.69; 95% CI 0.47–1.02; P=0.0608; I²=51.4%). Importantly, there were no significant differences in ischemic outcomes, including myocardial infarction (OR 0.72; 95% CI 0.50–1.06; P=0.0933; I²=3.2%), all-cause mortality (OR 0.80; 95% CI 0.49–1.32; P=0.38; I²=14.8%), or stroke (OR 0.58; 95% CI 0.31–1.10; P=0.0978; I²=0%) . Notably, de-escalation strategies were associated with a significant reduction in stent thrombosis (OR 0.42; 95% CI 0.19–0.94; P=0.035; I²=0%), reinforcing the absence of a safety trade-off. Overall, these findings demonstrate that de-escalation strategies effectively reduce bleeding risk while preserving ischemic protection, resulting in a favorable net clinical benefit. This supports a paradigm shift toward individualized, risk-based antiplatelet therapy following PCI.

APPLICABILITY OF SAPS 3 AND APACHE II SCORES IN A CARDIAC INTENSIVE CARE UNIT: A PROSPECTIVE STUDY

RAFAEL PETRI SANTOS PINHEIRO1; LEONARDO CASTRO LUNA2; VANESSA DOS REIS VON DOELLINGER2; MARCELO GOULART CORREIA2; BERNARDO RANGEL TURA2; LUCAS BONACOSSA SANT'ANNA2; STEPHAN LACHTERMACHER3;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL; (3) IDOMED/ESTACIO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Prognostic scores such as the Simplified Acute Physiology Score (SAPS) and the Acute Physiology and Chronic Health Evaluation (APACHE) are essential for assessing performance and predicting mortality in Intensive Care Units (ICUs). Objectives: To assess the performance of SAPS 3, including its Latin America (LA) and Brazil (BR) versions, and APACHE II in predicting in-hospital mortality in a cardiac intensive care unit (CICU). Methods: Prospective cohort of patients admitted between June 2022 and May 2024, followed until discharge or death. Data were extracted from electronic medical records. Calibration was assessed by comparing observed and predicted mortality using the Standardized Mortality Ratio (SMR), and discrimination was evaluated using the area under the receiver operating characteristic curve (AUC). Resultados e Conclusions: A total of 573 patients were included; 288 (50%) had three or more comorbidities, the median age was 63 years (IQR, 53-72), and 344 (60%) were male. Cardiovascular diseases accounted for 76% of admissions, the median SAPS 3 score was 55 points (49-63) and overall mortality was 15%. All models showed an SMR below 1, indicating that observed mortality was lower than predicted and suggesting good quality of care in the unit. Mean SMR values were 0.52 (95% CI, 0.32-0.72) for SAPS 3, 0.40 (95% CI, 0.26-0.54) for SAPS 3 LA, 0.79 (95% CI, 0.41-1.16) for SAPS 3 BR, and 0.86 (95% CI, 0.42-1.29) for APACHE II. Among the evaluated models, SAPS 3 BR showed the best calibration, with the SMR closest to 1, indicating better alignment with local clinical reality. Discrimination was also superior for SAPS 3 and its regional adaptations, with an AUC of 0.805, compared with 0.704 for APACHE II, a statistically significant difference (p = 0.00149). FIGURE 1 - SMR for different prognostic scores in the CICU FIGURE 2 - ROC curve for each prognostic score Overall, SAPS 3, particularly the Brazilian version, outperformed APACHE II and appears to be the most appropriate prognostic model for routine use in high-complexity cardiac ICUs in Brazil. Although overall mortality was higher than the national average, the lower-than-predicted mortality reinforces the adequacy of care delivered in this unit.

Introduction/Background: The ESC 0/1-hour algorithm is recommended for rapid rule-out of acute coronary syndromes in patients presenting with acute chest pain, demonstrating high safety in prior validation studies. However, these studies were predominantly conducted in populations with a low prevalence of coronary artery disease (CAD), potentially limiting generalisability to higher-risk settings. Objectives: To evaluate the real-world diagnostic performance and safety of the ESC 0/1-hour algorithm in a population with acute chest pain and high prevalence of CAD. Methods: Prospective cohort including consecutive patients presenting with suspected acute coronary syndrome at a tertiary cardiology centre between March and November 2024. High-sensitivity cardiac troponin I (hs-cTnI) was measured at presentation and after 1 hour. The ESC 0/1-hour algorithm was retrospectively applied for classification. The primary endpoint was myocardial infarction or all-cause death at 30 days. Diagnostic performance of hs-cTnI was assessed using receiver operating characteristic (ROC) curve analysis, with subgroup analyses according to prior CAD status. Resultados e Conclusions: A total of 681 patients were included (mean age 64.2 ± 11 years; 63% male), of whom 63.5% had known CAD. At 30 days, myocardial infarction occurred in 27% and mortality in 1.8%. Admission hs-cTnI demonstrated excellent discrimination for myocardial infarction or death (AUC 0.919; 95% CI 0.896–0.941), but performance was attenuated in patients with known CAD compared with those without CAD (AUC 0.906 vs. 0.942). The ESC 0/1-hour algorithm showed sensitivity of 85%, specificity of 91%, positive predictive value of 78%, and negative predictive value of 94%. However, rule-out safety was reduced in patients with known CAD, reflected by lower negative predictive values. Conclusion: In a population with a high prevalence of CAD the ESC 0/1-hour algorithm maintains good overall performance but reduced safety for rule-out in patients with known CAD, with negative predictive values below the 99% threshold recommended for safe discharge. These findings support a more individualized interpretation of accelerated diagnostic pathways incorporating coronary history.

Performance of the ESC 0/1-hour algorithm for 30-day death or myocardial infarction

30-day outcomes	Sensibility (CI 95%)	Specificity (CI 95%)	PPV (CI 95%)	NPV (CI 95%)
Death or MI	0.85(0.80-0.90)	0.91(0.88-0.93)	0.78(0.72-0.83)	0.94(0.92-0.96)
MACE	0.58(0.52-0.63)	0.94(0.91-0.96)	0.90(0.85-0.94)	0.71(0.67-0.75)

FACTORS ASSOCIATED WITH HOSPITAL READMISSION OF PATIENTS WITHIN ONE YEAR AFTER ACUTE MYOCARDIAL INFARCTION: THE ROLE OF A NURSE-LED MYOCARDIAL INFARCTION PROGRAM

FERNANDA FERNANDA LIMA1; LILIA DE SOUZA NOGUEIRA2; CAROLINE RUSSO FERREIRA1; BRUNA DANIELLA DE SOUSA DE LIMA2;

(1) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL; (2) ESCOLA DE ENFERMAGEM DA USP - SÃO PAULO - SP - BRASIL;

Introduction/Background: Cardiovascular diseases remain the principal cause of death worldwide. In this context, the Acute Myocardial Infarction (AMI) stands out due to its high morbidity, mortality, frequent hospital readmissions, and substantial healthcare costs. Despite advances in in-hospital care, post-discharge follow-up remains challenging. Nurse-led telephone monitoring may be an accessible strategy to improve continuity of care and prevent hospital readmissions. This study evaluated the contribution of a nurse-led telephone follow-up program for patients after AMI in a Brazilian setting. Objectives: To identify factors associated with hospital readmission within one year after AMI among patients enrolled in a nurse-led myocardial infarction follow-up program Methods: Retrospective cohort study conducted in a private hospital in São Paulo, Brazil. The sample included patients admitted with AMI and enrolled in the institution's Myocardial Infarction Program between 2017 and 2023. The dependent variable was cardiovascular hospital readmission within one year after discharge. Independent variables included age, sex, AMI type, lifestyle habits, medication adherence, reported symptoms, and successful nurse-led telephone contacts performed at six scheduled time points (7, 30, 90, 180, 240, and 365 days post-discharge). Generalized mixed-effects modeling was applied (5% significance level). Resultados e Conclusions: Among 683 patients analyzed (80.53% men; mean age 67.19 years; 66.62% non-ST-segment elevation AMI), successful telephone contact rates ranged from 96.34% at 7 days to 54.31% at 365 days post-discharge. A total of 74 cardiovascular readmissions were identified, most occurring within the first 30 days post-discharge (n=42). The number of successful nurse-led telephone contacts was the only independent predictor of the outcome. Each successful follow-up contact reduced the odds of hospital readmission by 25.3% within one year after AMI (OR 0.747; 95%CI 0.611–0.913; p=0.004). Conclusion: Structured nurse-led telephone follow-up after AMI was associated with a significant reduction in hospital readmissions of patients. These findings highlight the importance of nurse-led remote monitoring as a feasible strategy to ensure continuity of care, support long-term recovery, and improve cardiovascular outcomes after discharge.

22005

FACTORS INFLUENCING THE OUTCOMES OF PATIENTS TRANSFERRED FOR ANGIOPLASTY: ANALYSIS OF THE ACUTE MYOCARDIAL INFARCTION CARE NETWORK IN SALVADOR AND THE METROPOLITAN REGION, BAHIA

MATEUS XAVIER ANJOS1; BRENDA ALMEIDA DA SILVA1; MISAEL DE SOUSA DOS SANTOS1; EMERSON RAÍ ARAÚJO AZEVEDO1; CLARA MARIA SOUSA2; JEFFERSON HEBER MARQUES FONTES JUNIOR1; POLLIANNA DE SOUZA RORIZ1;

(1) SERVIÇO DE ATENDIMENTO MÓVEL DE URGÊNCIA (SAMU) - SALVADOR - BA - BRASIL; (2) UNEB - SALVADOR - BA - BRASIL;

Introduction/Background: Acute Myocardial Infarction (AMI) presents high morbidity and mortality, and percutaneous transluminal coronary angioplasty (PTCA) is essential for reducing complications and deaths, which are directly influenced by clinical and temporal factors. Objectives: This study aimed to analyze factors associated with the outcomes of patients transferred for PTCA within the public healthcare network of Salvador and its Metropolitan Region. Methods: Cross-sectional study using a regional STEMI care database (January 2017–April 2026). Patients with STEMI admitted to public healthcare units in Salvador, Bahia, and its metropolitan region transferred for PTCA were included. Suspected STEMI cases are reported to a multidisciplinary STEMI response team for ECG review, cardiology supervision, and reperfusion guidance. The variables analyzed included age, sex, GRACE score, affected myocardial wall, assistance times (door-to-ECG, door-to-needle, and door-to-balloon) in minutes, total ischemia time, mortality, total length of hospital stay in days, and complications. Categorical variables were described using absolute and relative frequencies, while numerical variables were expressed as median and interquartile range [IQR]. Pearson and point-biserial correlation tests were applied, expressed with p-values and 95% Confidence Intervals (95%CI), adopting a significance level of 5% (p<0.05). Resultados e Conclusions: A total of 1918 patients were included, predominantly male (1197;62.4%), with a median age of 62 years (IQR:15), most frequently classified as yellow risk category (762;52.67%), and with the inferior wall as the main electrocardiographic territory affected (878;48.03%). Primary PTCA was the main reperfusion strategy adopted (1245;64.91%). Regarding assistance times, the median total ischemia time was 330 minutes (IQR:307), door-to-ECG time was 19 minutes (IQR:33), and door-to-balloon time was 214 minutes (IQR 156). Significant correlations were identified between door-to-ECG time (0.04–0.13; p < 0.001), GRACE score (0.22–0.31;p<0.001), and length of hospital stay (0.002–0.09;p=0.041) with mortality. Furthermore, door-to-ECG time (0.03–0.12;p<0.001) and GRACE score (0.28–0.37;p<0.001) were correlated with the incidence of complications. Regarding length of hospital stay, significant correlations were identified with total ischemia time (0.03–0.14; p<0.001) and GRACE score (0.14–0.24;p<0.001). Longer delays and higher risk scores were linked to death, complications, and longer AMI hospitalization.

Table 1. Baseline characteristics, care-time intervals, and mortality-related correlations

Variable	Value / estimate	p-value
Total patients, n	1,918	—
Male sex, n (%)	1,197 (62.4)	—
Age, years, median (IQR)	62 (15)	—
Yellow risk category, n (%)	762 (52.67)	—
Inferior wall territory, n (%)	878 (48.03)	—
Primary PTCA, n (%)	1,245 (64.91)	—
Total ischemia time, min, median (IQR)	330 (307)	—
Door-to-ECG time, min, median (IQR)	19 (33)	—
Door-to-balloon time, min, median (IQR)	214 (156)	—
Door-to-ECG time correlation with mortality	0.04–0.13	<0.001
GRACE score correlation with mortality	0.22–0.31	<0.001
Length of hospital stay correlation with mortality	0.002–0.09	0.041

Note: Descriptive variables are reported as n (%) or median (IQR). ECG, electrocardiogram; GRACE, Global Registry of Acute Coronary Events; IQR, interquartile range; PTCA, percutaneous transluminal coronary angioplasty.

IMPACT OF LEVOSIMENDAN VERSUS DOBUTAMINE ON 30-DAY MORTALITY AND HOSPITAL STAY IN ACUTE DECOMPENSATED HEART FAILURE: A SYSTEMATIC REVIEW AND META-ANALYSIS

HILSON AMORIM PARENTE1;

(1) BARRA D`OR - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Acute decompensated heart failure (ADHF) with reduced ejection fraction frequently requires inotropic support. Dobutamine is widely used, but its impact on survival remains uncertain. Levosimendan, a calcium sensitiser with vasodilatory properties, may offer haemodynamic and clinical advantages over catecholaminergic inotropes. Objectives: To compare the effects of levosimendan versus dobutamine on short-term clinical outcomes in adults with ADHF and low cardiac output. Methods: We systematically searched MEDLINE, Embase and Cochrane Library from inception to 3 December 2024 for randomised controlled trials enrolling adults with ADHF or postoperative low cardiac output syndrome and left ventricular ejection fraction <40% requiring intravenous inotropes. Trials comparing levosimendan with dobutamine and reporting at least one outcome of interest were included. The primary outcome was 30-day all-cause mortality; secondary outcomes were length of hospital stay and renal function. Random-effects meta-analyses were performed, and risk of bias was assessed with RoB 2. Certainty of evidence was graded with GRADE. Resultados e Conclusions: Eight trials including 1973 patients (995 levosimendan, 978 dobutamine) met the criteria. Levosimendan significantly reduced 30-day mortality compared with dobutamine (OR 0.53, 95% CI 0.31–0.91; I²=27%). In four trials (n=325), levosimendan shortened hospital stay by a mean of 2.4 days (95% CI −3.33 to −1.47; I²=79%). Two studies reported renal outcomes, showing greater improvements in estimated glomerular filtration rate and reductions in serum creatinine with levosimendan. Certainty of evidence was moderate for mortality and very low for hospital stay. In adults with ADHF and low cardiac output, levosimendan was associated with lower short-term mortality and shorter hospital stay compared with dobutamine, with signals of renal benefit. Larger contemporary trials are needed to confirm these findings and to define the optimal use of levosimendan in this high-risk population.

LIDOCAINE IMPROVES RETURN OF SPONTANEOUS CIRCULATION COMPARED WITH AMIODARONE IN SHOCK-RESISTANT CARDIAC ARREST

MARCELO VIER GAMBETTA1; ARTUR MENEGHETTI COMPER1; FELIPE SOFKA MAZZI1; LARISSA SCHMITZ1; MARIA PAULA FONSECA RODRIGUES1; MATEUS YUSO TUTIDA1; SARAH VALENTE1; CAROLINE OLIVEIRA FISCHER-BACCA1;

(1) UNIDAVI - CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL;

Introduction/Background: Cardiac arrest (CA) remains a leading cause of morbidity and mortality worldwide. Approximately 20% of cases present with shockable rhythms (ventricular fibrillation or pulseless ventricular tachycardia), yet up to half of these patients fail to achieve sustained return of spontaneous circulation (ROSC), and only about 29% survive to hospital discharge. Current guidelines recommend the use of antiarrhythmic drugs, such as amiodarone or lidocaine, in cases of defibrillation-resistant CA. However, recent trials have shown inconsistent results, and the optimal choice between these agents remains uncertain. Objectives: To perform a systematic review and meta-analysis comparing the efficacy of lidocaine versus amiodarone in patients with CA. Methods: A systematic search of PubMed, Cochrane Library, and Embase databases was conducted to identify studies comparing lidocaine and amiodarone in CA. Pooled odds ratios (ORs) with 95% confidence intervals (CIs) were calculated using a random-effects model. Statistical heterogeneity was assessed using the I² statistic. A two-sided p-value <0.05 was considered statistically significant. Analyses were performed using RevMan software. Resultados e Conclusions: A total of 13 studies comprising 39,037 patients (71.5% male; mean age 64.5 ± 14.5 years) were included. Lidocaine was associated with a significantly higher likelihood of achieving ROSC compared with amiodarone (OR 0.87; 95% CI 0.74–0.94; p=0.0009 - Figure 1A). However, no significant differences were observed in survival to hospital discharge (OR 0.92; 95% CI 0.79–1.06; p=0.24 - Figure 1B) or unfavorable neurological outcomes (OR 1.12; 95% CI 0.88–1.44; p=0.36 - Figure 1C). Conclusions: In this meta-analysis, lidocaine was associated with a higher likelihood of achieving ROSC compared with amiodarone. However, this benefit did not translate into improved survival to hospital discharge or unfavorable neurological outcomes. These findings support a potential role for lidocaine in the early phase of CA, although further randomized evidence is needed to determine its impact on long-term outcomes.

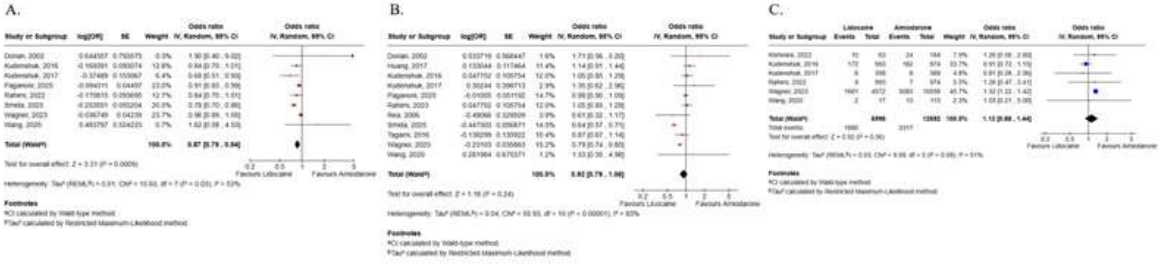

Figure 1. Forest plots comparing the effects of lidocaine and amiodarone between two groups. A. Return of spontaneous circulation. B. Survival to hospital discharge. C. Neurologic outcomes.

METHYLENE BLUE FOR PREVENTION OF VASOPLEGIC SYNDROME AFTER CARDIAC SURGERY WITH CARDIOPULMONARY BYPASS: A RANDOMIZED PILOT TRIAL IN A HIGH-RISK SETTING

RAFAEL MASSUTI1; MATHEUS RAMOS DA SILVA1; EDUARDA GOLIN PANISSON1; IULEK GORCZEVSKI1; LARA DE MATOS1; TASSIANE SCHNEIDER2; PIETRO SLIKA ROSSLER1; BIBIANA MAGGI1; GUILHERME WINTER1; RODRIGO VILLANOVA BRASIL1; FÁBIO EDUARDO CAMAZZOLA1; MARCELO SABEDOTTI1;

(1) UNIVERSIDADE DE CAXIAS DO SUL - CAXIAS DO SUL - RS - BRASIL; (2) UNIVERSIDADE FEDERAL DE CIENCIAS DA SAUDE DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Background: Vasoplegic syndrome (VS) is a relevant complication after cardiac surgery with cardiopulmonary bypass (CPB). It usually presents as persistent hypotension with low vascular resistance despite preserved cardiac output, often requiring high vasopressor doses and longer postoperative support. Although methylene blue (MB) is frequently considered in refractory cases, data on its prophylactic use are still scarce. Only a few small randomized trials tested different timing and dosing strategies. Objectives: Objective: To evaluate whether MB given immediately after CPB could reduce postoperative VS and related complications. Methods: Methods: We conducted a single-center randomized pilot trial including adult patients undergoing elective, urgent, or emergency cardiac surgery with CPB. Patients were assigned in a 1:1 ratio by an independent physician to receive MB or equivalent dosing of saline solution, only after separation from CPB. Because of the characteristic coloration, full blinding of the treating team was not feasible. MB was given at 2 mg/kg over 30 minutes, followed by 0.5 mg/kg/h for 6 hours. VS was defined by prespecified hemodynamic criteria within the first 48 postoperative hours. Secondary outcomes included vasopressor use, atrial fibrillation, acute kidney injury, transfusion, ICU and hospital length of stay, and 30-day mortality. Resultados e Conclusions: Results: Fifty-one patients were analyzed (26 in the control group and 25 in the MB group). Baseline and surgical characteristics were similar between groups, and most procedures were classified as urgent or emergency operations (88%). In this higher-risk setting with an incidence of VS slightly higher than reported in the literature, we found similar rates of VS in both groups (15% vs. 16%). After adjustments, MB was not associated with lower VS occurrence (OR 1.09; 95% CI 0.22–5.51; p>0.90). No relevant differences were observed in atrial fibrillation, acute kidney injury, transfusion, ICU stay, total hospital stay, or 30-day mortality. Conclusions: In this pilot randomized study, prophylactic MB started immediately after CPB did not reduce postoperative VS or improve clinical outcomes. Our findings do not support routine use of MB in unselected patients after cardiac surgery for prevention of VS and reinforce the need for larger studies evaluating better timing, dosing strategies, and more appropriate risk-based case selection.

19789

NOVEL TEMPORAL PREDICTORS OF IN-HOSPITAL MORTALITY FOLLOWING PRIMARY PPCI USING AI BASED MACHINE LEARNING : “3D RISK” STRATIFICATION IS THE WAY AHEAD!!

PRAYAAG KINI1;

(1) SRI SATHYA SAI INSTITUTE BENGALURU INDIA - INDIA;

Introduction/Background: In-Hospital mortality determiation for primary PCI patients is stilla moving target especially for third world countries where easily determinable bedside parameters may be moireuseful than costly ones Objectives: Background and Aim: Mortality prediction following primary PCI suffers from adynamicity mainly due to entry variables only being studied as Outcome predictors. Our study aimed to establish a dynamic 3D Risk nomogram “moving” with patient status to predict in-hospital mortality following primary PCI. Methods: Materials and methods: We studied the incremental role of Lactate: Albumin ratio and Systemic Inflammatory Response Index (SIRI) (latter calculated as Peripheral blood (N x M) / L) during hospital course as predictors. The Risk model generated by stepwise logistic regression and Machine Learning was then forward validated for real-world accuracy. Resultados e Conclusions: Results: Seven predictors generated by Regression and two ML models (KNN,SVM) were selected to build the weighted Risk score (using SHAPley analysis): ICU Serum Lactate/ Albumin > 2.2 anytime in hospital course (WF: 3.5), AW- STEMI with LBBB o rLVEF < 30%(WF: 3.0), Post PCI Myocardial blush grade < 2(WF: 3), In-hospital Vasotrope-Inotrope Index > 40(WF: 3.0), Insulin-requiring DM(WF: 2.5), SIRI> 1.5(WS: 2.5)and Admission MAPSE < 7 mm by ECHO (WF: 2.5). AUROC was 0.893 (95% CI: 0.61–0.96). On generating tertiles (T1 to T3) of the score of T1< 9.5,9.5-15 > 15 of total 20 points, Low, Intermediate and High risk cohorts yielded likelihood of mortality being linearly correlated at 4.5%, 19.5% and 33.7% respectively. In a forward Validation cohort of 249 patients from 2019, the score had an excellent predictive accuracy of 88% agreement (goodness-of-fit) and outperformed both the current best models-PAMI risk score and CADILLAC score- mainly due to its dynamic nature to reflect ongoing patient status.

Polypill and Mobile App for Stroke and Cardiovascular Primary Prevention

SHEILA CRISTINA OURIQUES MARTINS1; MICHAEL BRAININ1; CRAIG ANDERSON1; RENATO LOPES2; OTAVIO BERWANGER1; THAIS L SECCHI1; LUIZ A NASI1; VALERY FEIGIN1;

(1) HOSPITAL MOINHOS DE VENTO - PORTO ALEGRE - RS - Brasil; (2) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - Brasil;

Introduction/Background: Cardiovascular diseases (CVD) and stroke remain leading causes of death and disability worldwide, particularly in low- and middle-income countries, where implementation of effective primary prevention strategies remains suboptimal. Simplified pharmacological strategies combined with digital health interventions may improve cardiovascular risk control and promote healthier lifestyles at the population level. Objectives: To evaluate the safety and effectiveness of a fixed-dose polypill, with and without the Stroke Riskometer app (SRA), in adults with low-to-moderate cardiovascular risk. Methods: In this pragmatic, multicenter, 2-by-2 factorial, randomized, placebo-controlled trial, adults 50-75 years of age without established CVD and with systolic blood pressure (SBP) of 121-139 mmHg were assigned to receive a polypill (valsartan 80 mg, amlodipine 5 mg, and rosuvastatin 10 mg) or matching placebo, with or without use of the SRA. The two co–primary outcomes were the change from baseline to 9 months in SBP and cardiovascular health assessed by the Life's Simple 7 (LS7) score. Resultados e Conclusions: Results: A total of 371 participants underwent randomization; 94% completed 9-month follow-up. The mean estimated 10-year CVD-risk in the overall trial population was 6.5%, and the mean baseline SBP was 130 mmHg. At 9 months, SBP was lower in the polypill plus SRA group than in the placebo plus usual care group (mean [±SE], 117.5±0.9 vs. 128.1±1.7 mmHg; P=0.002). The LS7 score increased by 1.14 points in the polypill plus SRA group and by 0.64 points in the placebo plus usual care group (mean [±SE], 9.8±0.2 vs. 8.9±0.3; P=0.039). No serious adverse events were attributed to the polypill. Conclusions: The combination of a fixed-dose polypill and a mobile health application significantly improved blood pressure control and cardiovascular health metrics in individuals at increased cardiovascular risk, with a favorable safety profile. These findings support integrated pharmacological and digital health strategies as scalable approaches for stroke and cardiovascular primary prevention, particularly in resource-constrained settings.

POSTOPERATIVE MYOCARDIAL INJURY AND RENAL DYSFUNCTION DEFINE A HIGH-RISK CARDIORENAL PHENOTYPE AFTER NONCARDIAC SURGERY

BRUNO FERRAZ DE OLIVEIRA GOMES1; GIOVANNI POSSAMAI DUTRA2; THIAGO MOREIRA BASTOS DA SILVA2; HILSON AMORIM PARENTE2; LETICIA ZANGIROLAMI PERES3; LUAN CAVALVANTE VILAÇA LIMA3; DAVI DE VASCOCELLOS DIAS3; FABIANA CARDOSO DE OLIVEIRA3; LUCAS DE SOUZA MARTINS PEREIRA2; JOAO LUIZ FERNANDES PETRIZ2; GLAUCIA MARIA MORAES DE OLIVEIRA1;

(1) INSTITUTO DO CORACAO EDSON SAAD/UFRJ - RIO DE JANEIRO - RJ - BRASIL; (2) BARRA D`OR - RIO DE JANEIRO - RJ - BRASIL; (3) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Postoperative myocardial injury and renal dysfunction after noncardiac surgery may reflect cardiorenal vulnerability. Whether their coexistence identifies a phenotype with sustained mortality risk remains uncertain. Objectives: To evaluate whether postoperative myocardial injury combined with renal dysfunction defines a high-risk cardiorenal phenotype after noncardiac surgery. Methods: We performed a retrospective cohort study of adults admitted to a surgical ICU after noncardiac surgery with postoperative troponin surveillance. Myocardial injury after noncardiac surgery (MINS) was defined as troponin elevation above the assay upper reference limit. Estimated creatinine clearance was calculated by Cockcroft-Gault using age, sex, body weight, and creatinine on the day of peak troponin. Renal dysfunction was defined as creatinine clearance <60 mL/min and/or renal replacement therapy during ICU stay. Patients were classified as neither condition, renal dysfunction only, MINS only, or MINS plus renal dysfunction. Outcomes were 30-day, 1-year, and long-term all-cause mortality. Associations were estimated using SAPS 3-adjusted modified Poisson regression. Long-term survival was assessed using Kaplan-Meier curves and SAPS 3-adjusted Cox regression. Resultados e Conclusions: Among 2,392 patients, 1,796 had neither condition, 285 renal dysfunction only, 211 MINS only, and 100 MINS plus renal dysfunction. Mean age was 60.2±15.9, 76.8±10.9, 65.2±12.9, and 76.8±11.9 years, respectively. Median creatinine clearance was 125.1, 45.8, 116.0, and 42.6 mL/min, and renal replacement therapy was required in 0.0%, 15.8%, 0.0%, and 37.0%. Thirty-day mortality was 1.0%, 7.0%, 3.3%, and 25.0%; 1-year mortality was 5.1%, 22.1%, 10.0%, and 44.0%; and long-term mortality was 17.5%, 49.1%, 30.3%, and 69.0%. After SAPS 3 adjustment, MINS plus renal dysfunction was associated with higher 30-day mortality (aRR 8.93, 95% CI 3.93-20.26) and 1-year mortality (aRR 3.59, 95% CI 2.37-5.42). Kaplan-Meier curves showed long-term survival separation, and the combined phenotype remained associated with long-term mortality in Cox analysis (aHR 2.83, 95% CI 2.09-3.82). Conclusions: Postoperative myocardial injury and renal dysfunction define a high-risk cardiorenal phenotype after noncardiac surgery. Coexistence of MINS with reduced creatinine clearance and/or renal replacement therapy identified older patients with higher early, 1-year, and long-term mortality independent of global illness severity.

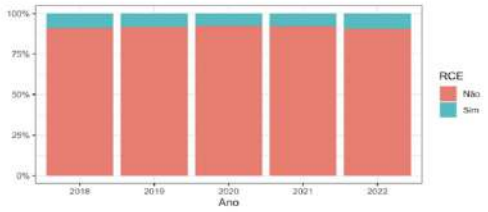
RETURN OF SPONTANEOUS CIRCULATION IN VICTIMS OF OUT-OF-HOSPITAL CARDIAC ARREST ATTENDED BY THE MOBILE EMERGENCY MEDICAL SERVICE OF SÃO PAULO (SAMU-SP)

BRUNA DANIELLA DE SOUSA DE LIMA1; THAINÁ MACÊDO DA SILVA1; FERNANDA RODRIGUES LIMA1; THATIANE FACHOLI POLASTRI1; MARISA APARECIDA AMARO MALVESTIO1; LILIA DE SOUZA NOGUEIRA1;



(1) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction/Background: Early recognition of out-of-hospital cardiac arrest (OHCA) and timely initiation of cardiopulmonary resuscitation (CPR) are associated with increased rates of return of spontaneous circulation (ROSC) and patient survival. However, evidence regarding care provided to these victims by the Mobile Emergency Medical Service of the city of São Paulo (SAMU-SP) remains limited. Objectives: To describe OHCA occurrences attended by SAMU-SP and to comparatively analyze victims with and without ROSC according to demographic characteristics and event-related variables. Methods: This was a retrospective study with a quantitative approach, analyzing occurrences attended by SAMU-SP. The study population consisted of OHCA victims assisted between 2018 and 2022, with records available in the Medical Priority Dispatch System™ (MPDS™). The variable of interest was ROSC, categorized as “yes” (respiratory rate >0 and/or Glasgow Coma Scale score >3) or “no” (respiratory rate =0 and Glasgow Coma Scale score =3) at scene or hospital admission. Demographic variables and event-related characteristics were analyzed. Descriptive statistics were performed, including absolute and relative frequencies, as well as median and quartiles. The study was approved by the Research Ethics Committees of the School of Nursing, University of São Paulo (CAAE No. 76111823.8.0000.5392) and the Municipal Health Department (CAAE No. 76111823.8.3001.0086). Resultados e Conclusions: A total of 34,863 OHCA occurrences attended by SAMU-SP were analyzed, of which 51% (17,864) were managed by Basic Life Support (BLS), 15.7% (5,428) by Intermediate Life Support (ILS), and 33.3% (11,571) by Advanced Life Support (ALS). Among these, 2,871 (8.24%) achieved ROSC, with a slight increase observed over the study period. ILS (9.86%) and ALS (8.01%) showed slightly higher proportions of ROSC compared to BLS (7.89%). Victims who achieved ROSC had a lower median age (53 versus 71 anos) and response time (23 versus 24 minites) than those without ROSC. The median scene (21 minutes), transport (10 minutes), and total (58 minutes) times were longer in the group with ROSC compared to the group without ROSC: 14, 6, and 30 minutes, respectively. OHCA victims who achieved ROSC were younger, had shorter response time, and were more frequently attended by ILS or ALS teams. In addition, these victims presented longer scene, transport, and total times compared to those who did not achieve ROSC.

STRUCTURAL ATRIAL CARDIOPATHY AND COGNITIVE DECLINE BEFORE STROKE: INSIGHTS FROM A COHORT STUDY AT A BRAZILIAN REFERRAL CENTER

GEANE VASCONCELLOS DE VASCONCELOS1; PEDRO VITOR DE BRITO FERREIRA1; NARA SAMARA SILVA FELIPE DOS SANTOS1; GABRIEL SOUZA MEDRADO NUNES1; MARIVALDO YSLAN SILVEIRA LEAL1; LUIZ PAULO OLIVEIRA MARTINS1; MARCOS PAULO RODRIGUES DE OLIVEIRA1; ANNA LARISSA CERQUEIRA MARTINS1; JOÃO VICTOR TEIXEIRA COSTA1; ANA CAROLINA COSTA FERREIRA DA SILVA1; VICTOR OGANDO SANTANA1; PEDRO ANTONIO PEREIRA DE JESUS1;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL;

Introduction/Background: Pre-stroke cognitive impairment is common in ischemic stroke patients and affects clinical outcomes. Atrial fibrillation (AF) is a known risk factor for stroke and dementia, but recent evidence suggests that structural changes in the left atrium may also contribute to thromboembolic events and cognitive decline, even without AF. The Informant Questionnaire on Cognitive Decline in the Elderly (IQCODE) is a validated tool to assess cognitive decline. Despite its importance, the relationship between structural atrial heart disease and pre-stroke cognitive decline is not well understood Objectives: To investigate the association between structural atrial cardiopathy and pre-stroke cognitive decline assessed by the IQCODE in ischemic stroke patients. Methods: This cohort included patients admitted to a referral hospital in Bahia, Brazil, with acute ischemic stroke between July 2023 and November 2026. Clinical and demographic data were collected via interviews, and echocardiographic measurements were obtained from records. Atrial heart disease was defined as left atrial diameter >38 mm in women and >40 mm in men. Pre-stroke cognitive decline was assessed using the IQCODE, administered to informants by trained researchers. Logistic regression, adjusting for age, sex, education, hypertension, diabetes, and AF, analyzed the association Resultados e Conclusions: A total of 496 patients were included. Of these, 86 (17.3%) had pre-stroke dementia according to the IQCODE. Atrial cardiopathy was identified in 157 patients (31.6%), while AF was present in 65 (13.1%). In crude analysis, atrial cardiopathy was not associated with pre-stroke cognitive decline (OR 0.98, 95% CI 0.86–1.11, p=0.76). Excluding AF patients, the association remained absent (OR=1.38, 95% CI=0.76–2.47, p=0.29). In multivariable regression, atrial cardiopathy was not associated with dementia (OR=0.95, 95% CI 0.56–1.59, p=0.78). Age (OR=1.03, p=0.015) and low education level (OR=1.78, p=0.040) were independently associated with dementia. In ischemic stroke patients, structural atrial heart disease was not associated with pre-stroke cognitive decline as assessed by the IQCODE. Advanced age and low education level were independent predictors of cognitive decline. These findings suggest that structural atrial heart disease alone may not be a significant factor in prior cognitive impairment. However, further studies are needed to explore its role in cognitive risk stratification.

SYSTEMATIC REVIEW OF COST-COMPARISON AND COST-EFFECTIVENESS STUDIES OF LEVOSIMENDAN VERSUS DOBUTAMINE IN ACUTE HEART FAILURE

HILSON AMORIM PARENTE1;

(1) BARRA D`OR - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Levosimendan and dobutamine are commonly used in acute heart failure (AHF), but economic evidence comparing these therapies remains limited. This study evaluated the economic outcomes of levosimendan versus dobutamine in adults with AHF. Objectives: To synthesise available evidence on the cost-effectiveness and cost analysis of levosimendan compared with dobutamine in adults with AHF or postoperative low-output states. Methods: A systematic search of MEDLINE, EMBASE, and the Cochrane Library was conducted through June 3, 2025, in accordance with PRISMA guidelines. An updated search was conducted in February 2026 in specialized economic evaluation databases, including EconLit, the NHS Economic Evaluation Database, and the Health Technology Assessment database. Studies comparing levosimendan and dobutamine in adults with AHF reporting cost-effectiveness outcomes or total hospital costs were included. Data extraction and quality assessment were performed using the CHEERS 2022 checklist. Resultados e Conclusions: Six studies (11,523 patients) were included. Three evaluated cost-effectiveness and three total costs. Levosimendan showed improved survival and shorter hospital stay with neutral or favorable incremental costs. ICERs ranged from €3,205 per life-year saved (Cleland) to overall cost savings of €4,787 per patient (Mardiguian). Total-cost analyses demonstrated cost neutrality (R$14,117 vs R$14,142 in Oliveira Jr.; €5,396 vs €5,275 in Lissovoy), whereas a Mexican budget impact analysis reported cost savings with levosimendan compared with dobutamine (MXN$108,673 vs MXN$117,782 per patient; approximately MXN$9,100 savings per patient). One-way sensitivity analyses confirmed result stability, while no probabilistic analyses were performed. Levosimendan was generally associated with cost neutrality or potential cost savings compared with dobutamine, mainly related to reduced hospitalization and resource utilization. Overall, the available evidence suggests a favorable economic profile, although further contemporary cost-effectiveness analyses are needed.

TERRITORIAL INEQUALITY IN THE SUPPLY OF EMERGENCY CORONARY ANGIOPLASTY IN THE SUS: A SPATIAL ANALYSIS OF RIO DE JANEIRO STATE

GUILHERME MACHADO OLIVEIRA VALLE1; JOÃO VICTOR DINIZ DE ANDRADE2; GABRIEL RANGEL COSTA DA SILVA CARDOSO2; AUGUSTO DE OLIVEIRA PERES2;

(1) UNIRIO - RIO DE JANEIRO - DF - BRASIL; (2) UNIRIO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Acute Myocardial Infarction (AMI) is a time-dependent condition that requires rapid intervention, with primary coronary angioplasty established as the gold-standard treatment for reperfusion. However, in Brazil, the supply of high-complexity services is unevenly distributed, reflecting severe structural asymmetries in the organization of the public health network. Objectives: To analyze the spatial distribution of AMI hospitalizations and the supply of emergency coronary angioplasty through the SUS across the 18 microregions of Rio de Janeiro state, aiming to identify territorial inequalities, care gaps, and hubs of technological concentration. Methods: An ecological and spatial study using data from SIH/DATASUS and IBGE for the period from January to December 2024. AMI hospitalizations by microregion of residence were cross-referenced with emergency Hospital Admission Authorizations (AIH) for primary angioplasty by location of procedure. To reduce billing bias, a three-month subsequent extraction margin was applied. AMI incidence rates, supply density, and the attraction index (angioplasties performed / local hospitalizations × 100) were calculated, analyzing the demand-supply relationship across the 18 microregions of the state. Resultados e Conclusions: Half of the state's microregions showed a total absence of angioplasty supply. Populous areas such as Campos dos Goytacazes, Baía da Ilha Grande, and Bacia de São João recorded 266, 259, and 248 AMI hospitalizations, respectively, without local procedure availability. The Vale do Paraíba Fluminense, the second most populous microregion (589 AMI cases), presented an attraction index of only 1.7% (10 procedures). In contrast, centralizing hubs absorbed significant external demand: Itaperuna recorded an index of 146.46% and Nova Friburgo 100.86%, while the Rio de Janeiro microregion concentrated the highest absolute volumes (28.96% attraction). These findings highlight severe territorial inequalities in the cardiovascular emergency network. While the Serrana and Northwest regions show higher installed capacity, Northern Rio de Janeiro and the Green Coast face critical care gaps. Excessive centralization and the persistence of underserved areas result in healthcare evasion and care fragmentation. In conclusion, there is an urgent need to review regionalization policies and high-complexity service contracting within the SUS to mitigate these disparities and ensure timely, equitable access to gold-standard reperfusion therapy across all regions of the state.

TROPONIN-TO-UPPER REFERENCE LIMIT RATIO AS A DOSE-RESPONSE PREDICTOR OF MORTALITY AFTER NONCARDIAC SURGERY

BRUNO FERRAZ DE OLIVERA GOMES1; GIOVANNI POSSAMAI DUTRA2; THIAGO MOREIRA BASTOS DA SILVA2; HILSON AMORIM PARENTE2; LUCAS DE SOUZA MARTINS PEREIRA2; LETICIA ZANGIROLAMI PERES1; LUAN CAVALCANTE VILAÇA LIMA1; DAVI DE VASCONCELLOS DIAS3; FABIANA CARDOSO DE OLIVEIRA3; JOÃO LUIZ FERNANDES PETRIZ2; GLAUCIA MARIA MORAES DE OLIVEIRA1;

(1) INSTITUTO DO CORACAO EDSON SAAD/UFRJ - RIO DE JANEIRO - RJ - BRASIL; (2) BARRA D`OR - RIO DE JANEIRO - RJ - BRASIL; (3) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Postoperative troponin elevation is associated with adverse outcomes after noncardiac surgery, but whether the magnitude of elevation relative to the assay upper reference limit identifies graded mortality risk remains uncertain. Objectives: To evaluate the troponin-to-upper reference limit ratio as a dose-response predictor of mortality after noncardiac surgery. Methods: We performed a retrospective cohort study of adult patients admitted to a surgical intensive care unit after noncardiac surgery with postoperative troponin surveillance. Peak postoperative troponin was divided by the assay-specific upper reference limit and categorized as ≤1x, >1–<5x, or ≥5x. Outcomes were 30-day and 1-year all-cause mortality. Associations were assessed using modified Poisson regression with robust variance, adjusted for age, sex, Revised Cardiac Risk Index, urgent surgery, high-risk surgery, and SAPS 3. Resultados e Conclusions: Among 2,228 patients, mean age was 63.9±16.2 years and 44.4% were male. Overall 30-day and 1-year mortality were 2.9% and 9.6%. Mortality increased stepwise across troponin-ratio categories: 30-day mortality was 1.7%, 8.0%, and 27.8% for ≤1x, >1–<5x, and ≥5x; corresponding 1-year mortality was 7.4%, 21.2%, and 48.6%. After adjustment, compared with ≤1x, >1–<5x was associated with higher 1-year mortality (adjusted risk ratio [aRR] 1.65, 95% CI 1.15–2.37), while ≥5x identified a markedly higher risk (aRR 2.69, 95% CI 1.82–3.97; p for trend <0.001). For 30-day mortality, adjusted risk increased from >1–<5x (aRR 2.56, 95% CI 1.27–5.14) to ≥5x (aRR 7.05, 95% CI 3.78–13.13; p for trend <0.001). As a continuous variable, each doubling of 1+troponin ratio was associated with higher 30-day (aRR 1.41, 95% CI 1.24–1.60) and 1-year mortality (aRR 1.22, 95% CI 1.12–1.33). Adding troponin-ratio categories to the clinical model improved 1-year mortality discrimination (C-statistic 0.792 to 0.811; likelihood-ratio p<0.001). Conclusions: The postoperative troponin-to-upper reference limit ratio showed a clear dose-response association with mortality after noncardiac surgery. Values ≥5x identified a particularly high-risk phenotype and may support early postoperative risk stratification beyond traditional clinical variables.

ASSOCIATION BETWEEN INTERATRIAL BLOCK AND CARDIOVASCULAR OUTCOMES IN AFRICAN AMERICANS: EVIDENCE FROM THE JACKSON HEART STUDY

JOÃO VITOR GARDELLI TRINDADE1; DANIEL TEIXEIRA DE CAMPOS E BARREIRO2; WLAMIR BATISTA RIBEIRO3; ERALDO RIBEIRO FERREIRA LEÃO DE MORAES4; JOSÉ NUNES DE ALENCAR3;

(1) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL; (2) FACULDADE DE MEDICINA DE MARILIA - MARÍLIA - SP - BRASIL; (3) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (4) INSTITUTO DE CARDIOLOGIA E RADIOLOGIA INTERVENCIONISTA DE RIO VERDE - RIO VERDE - GO - BRASIL;

Introduction/Background: Interatrial block (IAB), also recognized as Bayés Syndrome, is classified as partial (P-wave duration ≥ 120 ms with normal axis) or advanced (P-wave duration ≥ 120 ms with biphasic morphology in inferior leads). Both forms are associated with worse cardiovascular outcomes. However, African American populations remain significantly underrepresented in studies examining these associations. Objectives: To evaluate the prognostic value of partial and advanced IAB on cardiovascular and thromboembolic outcomes in an exclusively African American cohort using data from the Jackson Heart Study. Methods: We analyzed the prospectively collected data from the Jackson Heart Study, a community-based cohort of Black American adults aged 21–94 years. IAB was classified as partial (P-wave duration ≥120 ms; axis 0°–90°) or advanced (P-wave duration ≥120 ms; axis <0° with biphasic morphology in inferior leads). Participants with P-wave duration <120 ms served as the reference group (No IAB). Individuals with non-sinus rhythm, pacemaker use, unreadable or missing ECG data, or prevalent heart failure (HF) were excluded. Group comparisons used Kruskal–Wallis and chi-square tests. Kaplan–Meier and multivariable Cox models adjusted for major cardiovascular risk factors were used to evaluate coronary heart disease (CHD), HF, stroke, major adverse cardiovascular events (MACE), and all-cause mortality. Resultados e Conclusions: After exclusions, 3,646 participants were included: 1,974 (54.1%) without IAB, 1,639 (44.9%) with partial IAB, and 33 (0.9%) with advanced IAB. Baseline characteristics are summarized in Table 1. Over a median follow-up of approximately 11 years, advanced IAB was independently associated with MACE (HR 2.93; 95% CI 1.30–6.62). Partial IAB was independently associated with incident CHD (HR 1.46; 95% CI 1.03–2.07). No significant associations were observed between either IAB subtype and HF, stroke, or all-cause mortality. In this large African American cohort, advanced IAB was associated with increased risks of MACE, while partial IAB predicted incident CHD. These findings support the prognostic relevance of routine ECG identification of IAB in African American adults. However, the small number of advanced IAB cases resulted in wide confidence intervals, warranting cautious interpretation and confirmation in larger cohorts.

CLINICAL CHARACTERISTICS, HIGH-RISK CRITERIA, AND OUTCOMES OF ACCESSORY PATHWAY ABLATION IN CHILDREN: A COMBINED PROSPECTIVE-RETROSPECTIVE STUDY

SÔNIA MARIA CAVALCANTE DA ROCHA1; CAMYLLA SANTOS DE SOUZA1; MIRELLA ALBUQUERQUE MARTINS1; ANA LUIZA TORQUATO DE AQUINO1; RAYANE ALVES MARQUES1; NICHOLAS MILITÃO ALVES1; MATHEUS BARREIRA MONTE1; CECÍLIA GABRIELA DANTAS DE SOUZA2; RAFAELA RIOS SABINO2; ANDREA CONSUELO DE OLIVEIRA TELES1; CANDICE TORRES DE MELO BEZERRA CAVALCANTE1; KLEBIA MAGALHÃES PEREIRA CASTELLO BRANCO1;

(1) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introduction/Background: Ventricular pre-excitation is a primary cause of supraventricular tachycardia (SVT) in children. While many patients are asymptomatic, rapid anterograde conduction through the accessory pathway (AP) carries a risk of life-threatening arrhythmic events. Effective risk stratification remains a clinical priority, necessitating a multifaceted approach combining non-invasive and invasive evaluations to prevent sudden cardiac death. Objectives: To describe the clinical and electrocardiographic profile of pediatric patients with ventricular pre-excitation, evaluate acute and long-term transcatheter ablation outcomes, and identify specific factors associated with tachyarrhythmia recurrence. Methods: This longitudinal study included pediatric patients with ventricular pre-excitation and/or AP-mediated SVT evaluated between 2020 and 2025 at a tertiary pediatric cardiology center. Diagnostic workup involved clinical evaluation, 12-lead ECG, 24-hour Holter monitoring, and exercise stress testing. In patients referred for intervention, conventional electrophysiological study (EPS) was performed with multipolar intracavitary catheter placement and analysis of conduction intervals. High-risk EPS criteria were: shortest pre-excited R-R interval (SPERRI) during induced atrial fibrillation or rapid atrial pacing ≤250 ms, AP anterograde effective refractory period (APERP) ≤240 ms, multiple accessory pathways, or septal/parahissian location. 3D electroanatomical mapping was reserved for high anatomical complexity or re-ablation. Recurrence predictors were analyzed using logistic regression (OR; 95% CI). Resultados e Conclusions: We evaluated 78 patients (mean age 10.3 ± 3.6 years). Symptoms occurred in 67%, primarily palpitations, documented SVT, and syncope. High-risk EPS criteria were identified in 35 patients (45%). Ablation was indicated in 69 patients (88%), with an acute success rate of 92% (n=63; 95% CI: 83–96%). Over a mean follow-up of 24 months, recurrence occurred in 9 patients (12%; 95% CI: 6–21%). Multivariate analysis identified septal AP location (OR 3.1; 95% CI: 1.2–8.3; p=0.02) and the presence of multiple APs (OR 2.8; 95% CI: 1.1–7.2; p=0.03) as independent predictors of recurrence. No permanent major complications, including high-degree AV block, were observed. In septal/parahissian cases, the ablation strategy was individualized to prioritize the safety of the atrioventricular conduction system.

ELECTRICAL SYNCHRONY-GUIDED CARDIAC PACING FOR PREVENTION OF PACING-INDUCED CARDIOMYOPATHY

EMILIO ARIEL LOGARZO1; DANIEL FELIPE ORTEGA1; ANALIA GLADYS PAOLUCCI1; EVELYN GARCIA RODRIGUEZ1; TOMAS MARINACCI1;

(1) CLINICA SAN CAMILO - ARGENTINA;

Introduction/Background: The paradigm of cardiac pacing has shifted from traditional high ventricular apex (RVA) stimulation, which causes left bundle branch block (LBBB) and cardiomyopathy in 30% of cases, toward more physiological approaches. While His-bundle pacing faced technical hurdles, left bundle branch area pacing (LBBAP) has emerged as a preferred alternative. With 15 years of expertise, our group achieves high clinical success using conventional leads guided by electrical synchrony to prevent ventricular dysfunction and the subsequent need for CRT upgrades. Objectives: To evaluate the impact of electrical synchrony-guided physiological pacing on ventricular function, assessed via Doppler echocardiography, as a strategy to prevent myocardial dysfunction. Methods: This prospective multicenter study included patients 18 years of age or older with indications for permanent cardiac pacing. Implantation was performed using physiological pacing guided by electrical synchrony (Synchromax method). Clinical, electrical, and echocardiographic parameters were evaluated at baseline and during follow-up (minimum 2 months post-implant). Physiological pacing was defined by the achievement of a Synchromax Type 2 curve according to standardized charts. Resultados e Conclusions: Results: A total of 135 patients from centers in Argentina were enrolled (mean age 74 years; 68% male). Comorbidities included hypertension (82.4%), dyslipidemia (38%), and diabetes (14.6%). The primary indication was sick sinus syndrome (38%). During a mean follow-up of 9 months, the Type 2 pacing curve was achieved in 93% of patients and remained stable in all cases. Baseline Left Ventricular Ejection Fraction (LVEF) was 56.2%, significantly increasing to 59.4% during follow-up (p=0.018). In patients with baseline dyssynchrony (28% of the cohort; Curves #6 and #10), LVEF improved from a subnormal mean of 52.8% to 59.4% post-implantation (p=0.019). No significant changes were observed in lead thresholds, impedance, or sensing. The mean pacing burden was 76%. There were no reported complications, no CRT upgrades or heart failure-related hospitalizations. Conclusions: Electrical synchrony-guided physiological pacing significantly improves LVEF, particularly in patients with baseline ventricular impairment, and maintains stable electrical parameters over time. This technique represents a robust strategy to prevent pacing-induced ventricular dysfunction and reduce the long-term need for CRT upgrades.

FIVE-YEAR PERFORMANCE OF A STRUCTURED SYNCOPE UNIT IN BRAZIL: DIAGNOSTIC YIELD, READMISSIONS, AND SAFETY OUTCOMES IN 755 CONSECUTIVE PATIENTS

NÁGELA S V NUNES1; ALFREDO S BOMFIM1;

(1) COMPLEXO HOSPITALAR DE NITEROI - NITERÓI - RJ - BRASIL;

Introduction/Background: Background: Syncope Units structured according to the European Society of Cardiology (ESC) recommendations and the 2015 ESC Syncope Unit Position Paper aim to improve diagnostic accuracy, optimize resource utilization, and enhance patient safety through standardized care pathways and quality indicators. However, long-term real-world data from Latin America remain limited. Objectives: Objective: To evaluate the performance of a structured Syncope Unit in a Brazilian tertiary hospital over five consecutive years (2020–2025), using ESC Syncope Unit quality indicators. Methods: Methods: We conducted a prospective registry including all consecutive patients evaluated by the hospital Syncope Unit between January 2020 and December 2025. Clinical characteristics, ESC guideline-based risk stratification, diagnostic tests, final diagnosis, interventions, and quality indicators were systematically recorded. Service performance was assessed according to ESC Syncope Unit quality criteria described in the 2015 ESC Syncope Unit Position Paper. Primary outcomes included diagnostic yield, proportion of unexplained syncope, readmissions due to recurrent syncope, recurrence after pacemaker implantation (<1 year), and in-hospital mortality. Resultados e Conclusions: Results: A total of 755 patients were included (mean age 70±18 years; 52% female). According to ESC syncope risk criteria, 18% were low risk, 59% intermediate, and 23% high risk. An established diagnosis was achieved in 87.7% of patients; unexplained syncope accounted for 12.3%, which remained consistently below the ESC quality threshold of <20%. Readmissions due to recurrent syncope occurred in 2.2%, below the recommended <5%. Among patients with pacemakers, recurrence within 1 year was 6%, well under the recommended <20%. In-hospital mortality was 2.1%. These quality indicators remained stable and within ESC-recommended targets across all five years. Conclusion: This five-year real-world Brazilian cohort demonstrates that a structured Syncope Unit operating in accordance with ESC Syncope Unit quality criteria can achieve a high diagnostic yield, low rates of unexplained syncope, and excellent safety outcomes. These findings support the feasibility and effectiveness of implementing ESC Syncope Unit standards in Latin American tertiary hospitals.

MASKED BUNDLE BRANCH BLOCK VS. BIFASCICULAR BLOCK: A PROGNOSTIC ANALYSIS THROUGH ELECTROPHYSIOLOGICAL STUDY

AFONSO LUIZ TAVARES DE ALBUQUERQUE1; CAROLINE DE PAULA COUTINHO VAZ DE LIRA1; JOSE NILO DE CARVALHO NETO1; RODRIGO RUFINO PEREIRA SILVA1; IREMAR SALVIANO DE MACEDO NETO1; DARIO CELESTINO SOBRAL FILHO1;

(1) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL;

Introduction/Background: Masked bundle branch block (MBBB) is a form of standard bifascicular bundle branch block (BBB) that combines features of left bundle branch block (LBBB) and right bundle branch block (RBBB), and may indicate a worse prognosis and greater clinical severity. Objectives: To compare MBBB with standard BBB regarding clinical outcomes and functional or structural impairment. Methods: This was a comparative observational study with a cross-sectional baseline analysis and 24-month follow-up, approved by the local ethics committee under protocol number 1.378.059. Seventy adult patients were conveniently selected, of whom 45 underwent echocardiography, 24-hour Holter monitoring, electrophysiological study (EPS), laboratory testing, and serologic testing for Chagas disease or coronary angiography when indicated for etiologic assessment; 25 patients was not included for clinical reasons or refusal after inclusion. Patients with hemodynamic instability, age <18 years, and pregnancy were excluded. Participants were classified into two groups according to the electrocardiographic pattern, as assessed by two independent electrophysiologists: MBBB (G1, n=27) and standard BB (G2, n=18). A significance level of 5% (p<0.05) was adopted. Resultados e Conclusions: Mean age was 68.0 ± 11.7 years in G1 and 68.1 ± 11.3 years in G2. The most frequent etiology in both groups was chronic Chagas cardiomyopathy (66.7% vs. 54.5%), followed by coronary artery disease (16.7% vs. 22.7%). Palpitations were less frequent in G1 (15.9% vs. 50.0%; p=0.003). Patients with MBBB had larger left ventricular diameters (53.0 ± 11.6 mm vs. 43.0 ± 12.7 mm; p=0.002) and lower Teichholz ejection fraction (37.2% ± 13.9 vs. 51.0% ± 14.6; p<0.001). Persistent atrial fibrillation was more frequent in G1 (39.5% vs. 12.0%; p=0.018). Mean HV interval was longer in G1 (66.3 ± 18.3 ms vs. 52.9 ± 8.1 ms; p=0.006), with no significant difference in AH interval. During follow-up, 13 patients in G1 required pacemaker implantation, whereas no patient in G2 reached this endpoint (29.5% vs. 0%; p=0.001). There was also a trend toward higher mortality in G1 compared with G2 (25.0% vs. 7.4%; p=0.054). In this analysis, patients with MBBB showed greater structural and functional left ventricular impairment, higher prevalence of atrial fibrillation, and more pronounced infra-hissian conduction delay, with a higher frequency of progression to pacemaker implantation and/or death during follow-up, suggesting greater clinical severity compared with standard bifascicular block.

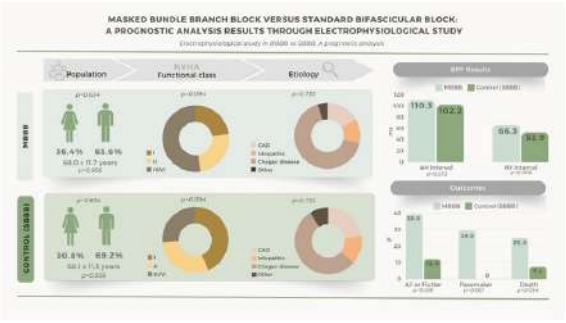

Table. Distribution of the composite outcome (death or need for pacemaker implantation) between the MBBB and Control groups.

	Group		
	MBBB	Control	P*
	N (%)	N (%)	
Composite outcome			**0.007**
Yes	28 (68.3)	9 (34.6)	
No	13 (31.7)	17 (65.4)

PAINFUL LEFT BUNDLE BRANCH BLOCK SYNDROME: A SYSTEMATIC REVIEW OF TREATMENT STRATEGIES IN CASE REPORTS

RODRIGO RUFINO PEREIRA SILVA1; CAROLINA JERONIMO MAGALHÃES1; CAIO CORREIA SILVA1; JOSE NUNES ALENCAR NETO2;

(1) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL; (2) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction/Background: The phenomenon of Painful Left Bundle Branch Block (PLBBB) was first brought into medical discourse by Vieweg in 1976, it presents a unique clinical challenge. Researchers reported a case of left bundle branch block (LBBB) and angina occurring during exercise without detectable coronary angiography abnormalities. This laid the foundation for the current understanding of “Painful LBBB Syndrome.” The underlying causes of this condition are yet to be understood. Sudden onset and resolution of pain in this syndrome do not typically align with coronary lesions or spasms causing myocardial ischemia. This systematic review aims to synthesize available case reports, focusing on treatment choices and patient outcomes, to better understand this rare but impactful cardiac phenomenon. Objectives: To enhance the clarity of PLBBB Syndrome management, deepening overall awareness of its clinical significance and therapeutic approaches. Methods: Databases including PubMed, Scopus, Web of Science, and Scielo were searched without restrictions on language or publication date. Following PRISMA guidelines, 128 articles were identified, with 31 meeting inclusion criteria. Data were extracted on patient demographics, clinical presentation, treatment regimens, and outcomes, using Microsoft Excel and assessed for bias with the Joanna Briggs Institute's tool. Resultados e Conclusions: The analysis included 45 patients with a mean age of 55.46 ± 12.23. Predominantly, LBBB episodes occurred during exercise (73.3%). Initial treatments comprised beta-blockers/calcium channel blockers (55.56%), pacemaker implantation (13.3%), antianginal medications (13.3%), and other modalities (17.7%). Refractoriness to initial treatment was observed in 66.7% of patients, with subsequent pacemaker implantation resolving symptoms in most cases. An overall satisfactory response was seen in 73.3% of patients post-treatment adjustments. The diverse approaches in treatment highlight the necessity for tailored therapeutic strategies. While pacemakers have demonstrated efficacy in controlling symptoms in several reported cases, it is essential to recognize the complex nature of this intervention. Pacemaker implantation, being a surgical procedure, carries long-lasting implications for patients. Hence, the continuation of pharmacological treatments might still be preferable until more definitive research is available. This review emphasizes the urgent need for further research to establish evidence-based guidelines to optimize outcomes for PLBBB.

Summarized Initial and Sequential Treatment Options

First Treatment (n)	Refractoriness	Second Treatment (n)
Beta blockers and Calcium Channel Blockers (25)	22	• Pacemaker (9) • Dual chamber (2) • His pacing (3) • BIV (3) • LBBAP (1) • Theophylline (1) • Increase in betablocker dose (2)
Antianginal (6)	5	• Pacemaker (2) • LBBAP (2) • Increase in Calcium Channel Blocker dose (1)
Pacemaker (6)	1	• Device programming adjustments (1)
Other (8)	3	• Pacemaker BIV (1) • Exercise prescription (1)

Abbreviations: BIV: Biventricular pacing (cardiac resynchronization therapy); LBBAP: Left bundle branch area pacing.

Introduction/Background: Pathogenic variants (PV) identified in whole exome sequencing (WES) of genetic testing have been reported in association with inherited cardiac diseases (channelopathies and arrhythmogenic cardiomyopathies) and sudden cardiac death (SCD). Objectives: To investigate the prevalence, sensitivity and specificity of PV in the diagnosis of patients with a SCD history in a cohort of a reference hospital. Methods: Prospective, cohort study, from 2022 to 2026, including 253 patients with a personal and/or family history of SCD and suspected inherited cardiac disease, referred for WES. PV were identified in 174/253 patients: 111/253 associated with SCD (channelopathies and arrhythmogenic cardiomyopathies) and 63/253 with other PV. Age: 3 months to 91 yo (mean= 43 yo), Sex: female in 138/253 patients. Variables analyzed: PV, history of SCD, phenotypic manifestation, electrocardiogram, echocardiogram and cardiac magnetic resonance imaging. PV results were expressed as prevalence and the remaining outcomes were expressed as incidence over the study period. Resultados e Conclusions: The prevalence of PV associated with SCD was 44% (111/253): TTR (cardiac amyloidosis) in 17% (42/253); SCN5A (Brugada and long QT syndrome) in 5% (12/253); KCNH2 (long QT syndrome) in 3% (7/253); FLNC (dilated cardiomyopathy) in 5% (12/253); LMNA (cardiomyopathy) in 1% (3/253); MYH7 (hypertrophic cardiomyopathy) in 4% (10/253); MYBPC3 (hypertrophic cardiomyopathy) in 4% (10/253); PKP2 (arrhythmogenic cardiomyopathy) in 1% (3/253); other cardiomyopathies TTN in 1% (2/253); ALPK3 in 1% (2/253); PRKAG2 in 1% (2/253); and TNNI3K in 0,4% (1/253). (Figure 1). The incidence of SCD death among patients with PV associated with channelopathies and/or arrhythmogenic cardiomyopathies was 59% (65/111): 56% (62/111) in family members and 7% (8/111) in probands. Sensitivity and specificity of PV for the diagnosis of SCD were 68% (65/96) and 51% (48/94), respectively. (Table I). Conclusions: In this cohort of a reference hospital, a high prevalence (44%) of PV associated with SCD was observed, as well as a high incidence of SCD in this group (59%). The sensitivity and specificity of the PV for the diagnosis of SCD were significant, 68% and 51%, respectively. The main PV associated with SCD were found in TTR (17%), SCN5A (5%), FLNC (5%), MYH7 (4%), and MYBPC3 (4%) genes. These findings highlight the importance of precision medicine in the evaluation of patients with suspected inherited cardiac diseases and SCD.

MIR-20A-5P AND MIR-210-3P AS PREDICTIVE BIOMARKERS OF TRASTUZUMAB-RELATED CARDIOTOXICITY IN ANTHRACYCLINE-FREE HER2-POSITIVE BREAST CANCER: A PROSPECTIVE PILOT STUDY

FERNANDO PIVATTO JÚNIOR1; MARCO AURÉLIO LUMERTZ SAFFI2; CAMILLE LACERDA CORREA2; EDUARDA FORESTI ENGLERT2; GÉRIS MAZZUTTI1; GUILHERME OLIVEIRA MAGALHÃES COSTA2; MARINA SIEBERT1; PEDRO EMANUEL RUBINI LIEDKE1; VINÍCIUS HENRIQUE FRITSCH2; ANDREIA BIOLO2;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL; (2) UNIVERSIDADE FEDERAL DO RIO GRANDE - RIO GRANDE - RS - BRASIL;

Introduction/Background: Cancer therapy-related cardiac dysfunction (CTRCD) is a clinically significant complication in HER2-positive breast cancer patients treated with trastuzumab (TTZ). Traditional biomarkers such as troponin and natriuretic peptides show limited predictive accuracy for early risk stratification. Circulating microRNAs (miRNAs) have emerged as promising non-invasive biomarkers; however, evidence in anthracycline-free, TTZ-treated populations remains scarce. Objectives: To evaluate the predictive capacity of six circulating serum miRNAs for CTRCD development in patients with early-stage HER2-positive breast cancer undergoing TTZ therapy without prior anthracycline exposure. Methods: Prospective cohort study of consecutive women aged ≥18 years with early-stage HER2-positive breast cancer treated at a breast oncology outpatient clinic (March 2019–March 2022), approved by the local ethics committee (protocol No. 2019-0010). Patients with prior anthracycline-based regimens were excluded. CTRCD was defined as LVEF reduction >10 percentage points to below 53%. Blood samples were collected before TTZ initiation. miRNA expression was quantified by RT-PCR. Participants were stratified into low- and high-expression groups for six prespecified miRNAs (let-7f-5p, miR-1-3p, miR-20a-5p, miR-126-3p, miR-130-3p, miR-210-3p) using optimal cut-offs by the Youden index. Time-to-event analyses used Kaplan-Meier curves and log-rank tests. Resultados e Conclusions: Twenty-five patients (mean age 55.7±12.4 years) were followed for a median of 12.4 months (IQR 10.7–16.6; 34.4 patient-years). CTRCD occurred in 3 patients (12.0%). High baseline expression of miR-20a-5p and miR-210-3p was significantly associated with lower CTRCD-free survival (log-rank p=0.007 and p=0.040, respectively; Figure 1A–B). Elevated baseline levels of miR-20a-5p and miR-210-3p demonstrated 100% sensitivity and specificities of 77.3% and 63.6%, respectively, for predicting CTRCD development. Conclusion. In this hypothesis-generating pilot study, elevated pre-treatment levels of miR-20a-5p and miR-210-3p predicted CTRCD development in early HER2-positive breast cancer patients receiving TTZ without prior anthracyclines. These findings warrant validation in larger prospective cohorts before clinical application.

PREHABILITATIVE EXERCISE IMPROVES CARDIORESPIRATORY FUNCTION IN ADULTS WITH LUNG CANCER ELECTED FOR SURGERY: A SYSTEMATIC REVIEW AND META-ANALYSIS

MARIA CRISTINA F. MAGALHÃES1; NATÁLIA CASAGRANDE2; FAVIL SINGH2; ANDERSON RECH2; RÉGIS RADAELLI2; BRUNA MARCON PANIZ2; GUILHERME TRICHES SILVESTRO2; GUILHERME NEVES EBERHARDT2; MARCONI GOMES DA SILVA2; VALENTINA VIRMOND MELLO SAAB1; PEDRO LOPEZ2;

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (2) UNIVERSIDADE DE CAXIAS DO SUL - CAXIAS DO SUL - RS - BRASIL;

Introduction/Background: Patients with cancer awaiting surgery often have reduced functional reserve, which can negatively affect perioperative outcomes. Exercise-based prehabilitation has gained attention as a way to improve cardiorespiratory fitness and better prepare patients for surgical stress. From a cardiovascular perspective, major surgery can be viewed as a stress test of physiologic reserve, making preoperative optimization particularly relevant. Objectives: To assess whether prehabilitative exercise improves cardiorespiratory function in adults with lung cancer elected for surgery. Additionally, we assessed whether this effect varies according to demographic, methodological and exercise modality characteristics. Methods: We searched seven databases from inception to June 2026 (CRD420251072796). Studies examining the effects of exercise-based prehabilitation in adults with lung cancer elected for surgery were included. A three-level mixed-effects meta-analysis was used, and results were expressed as standardized mean difference (SMD) with 95% confidence intervals. Subgroup and meta-regression analyses were performed based on demographic, methodological and exercise modality characteristics. Resultados e Conclusions: Ten studies were included. Patients with lung cancer (n= 805, 52.6% males) had a median age of 64 (IQR: 63.6, 66.9) years and BMI of 24.4 (IQR: 24.0, 24.7) kg.m-2. A total of 38.8% were elected for open surgery. Prehabilitative exercise modalities comprised aerobic (AE) or combined aerobic and resistance exercise (COMB). Prehabilitative exercise resulted in a significant improvement of 0.31 SMD (95% CI: 0.04–0.59; p=0.030; I2=28%) in overall cardiorespiratory function. In regard to subgroup analysis, benefits were evident in preoperative assessments, whereas cardiorespiratory function was preserved postoperatively. AE showed more consistent benefits than COMB. Cardiac and respiratory outcomes did not reach statistical significance when individually analysed. Benefits were irrespective of age or sex. Overall, our findings indicate that prehabilitative aerobic-based exercise programmes may improve preoperative cardiorespiratory function. Considering the limited available evidence, further investigation is warranted.

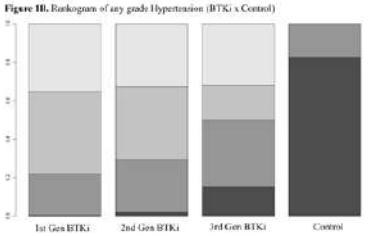
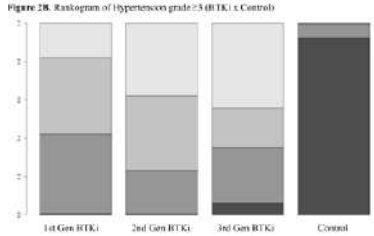
RISK OF HYPERTENSION IN PATIENTS TREATED WITH BRUTON'S TYROSINE KINASE INHIBITORS FOR ONCOHEMATOLOGICAL MALIGNANCIES: AN UPDATED BAYESIAN SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS OF RANDOMIZED CLINICAL TRIALS



FELIPE GILDO VILELA MIRANDA SANTOS1; CAUÃ ARAUJO DE CARVALHO1; PEDRO VITOR DE BRITO FERREIRA1; DAVI CHAVES ROCHA DE SOUZA1; JOÃO VITOR BENJAMIM PIRES1; JOÃO VICTOR TEIXEIRA COSTA1; EDVAN DE QUEIROZ CRUSOÉ1;

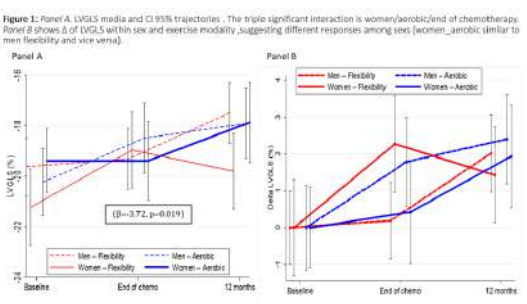


(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL;

Introduction/Background: Introduction: Bruton's tyrosine kinase inhibitors (BTKi) transformed the treatment of linked B-cell malignancies and chronic lymphocytic leukemia (CLL). However, this therapy has been associated with cardiovascular adverse effects – frequently hypertension (HTN) – and new generations of BTKi's were developed to reduce these risks. Nonetheless, it lacks an accurate comparison between each generation's HTN risk. Consequently, an exhaustive review of HTN incidence with each generation of BTKi is necessary to provide information on how to manage these patients. Objectives: Objective: To compare the risk of HTN between patients treated with different generations of BTKi for oncohematological malignancies. Methods: Methods: We strictly applied the PRISMA guidelines for network meta-analyses systematically searching PubMed, Cochrane and Embase on April 1st, 2026, for randomized clinical trials reporting HTN in patients with oncohematological malignancies enrolled for BTKi treatment. The primary outcome was any grade HTN and secondary outcome was HTN grade3. Data were extracted for statistical analysis using Excel and Rayyan software. Statistical bayesian network analysis was performed using RStudio (version 2024.12.1) and heterogeneity was assessed with I² statistics. Risk of bias was assessed with Cochrane RoB 2 tool and findings were summarized with GRADE assessment. Resultados e Conclusions: From 4,830 reports, 24 studies met the selection criteria and were analyzed, resulting in 11,013 patients. Primary outcome analysis (I²=0.8%) showed an increased risk of any grade HTN in 1st generation (ibrutinib) (RR 1.59; CrI 95% 1.09-2.39; SUCRA 0.29) and 2nd generation BTKi (acalabrutinib, zanubrutinib) (RR 1.66; CrI 95% 1.01-2.77; SUCRA 0.33), with inconclusive increase in 3rd generation BTKi (pirtobrutinib) (RR 1.48; CrI 95% 0.66-3.51; SUCRA 0.44), compared to control (SUCRA 0.93). Secondary outcome analysis (I²=2%) showed increased risk of grade 3 HTN in 1st generation (RR 1.81; CrI 95% 1.11-3.12; SUCRA 0.42), 2nd generation (RR 2.03; CrI 95% 1.16-3.77; SUCRA 0.29), with inconclusive increase in 3rd generation BTKi (RR 2.01; CrI 95% 0.78-5.21; SUCRA 0.32), compared to control (SUCRA 0.97). These findings indicate that early BTKi generations are associated to hypertension and the 1st generation appears to be less harmful in grade 3 hypertension. Therefore, patients being treated with 1st or 2nd BTKi generations potentially benefit from attentive control of treatment-developed hypertension.

20135

SEX-SPECIFIC LEFT VENTRICULAR SYSTOLIC FUNCTION RESPONSE TO AEROBIC EXERCISE DURING ANTHRACYCLINE CHEMOTHERAPY: AEROHEMONCO SECONDARY ANALYSIS



LUCIA FLORIO1; SANTIAGO RIVOIR1; SOLEDAD MURGUIA1; MATILDE BOADA1; VICTOR DAYAN1;

(1) HOSPITAL DE CLINICAS - URUGUAY;

Introduction/Background: Aerobic exercise is recommended to mitigate cancer therapy-related toxicity, and left ventricular global longitudinal strain (LVGLS) is sensitive to early systolic changes. The AEROHEMONCO randomized trial did not demonstrate an overall benefit of aerobic exercise in preventing systolic deterioration in lymphoma patients receiving anthracycline-based chemotherapy. Whether responses differ by sex remains uncertain. Objectives: To evaluate sex-by-intervention differences in systolic function at the end of anthracycline chemotherapy and at 12 months. Methods: AEROHEMONCO randomized patients with lymphoma to a supervised 12-week aerobic (active) or flexibility (control) exercise program during chemotherapy (19 subjects in each group). Echocardiography was performed at baseline, at the end of chemotherapy, and 12 months. LVGLS (primary outcome) and left ventricular ejection fraction (LVEF) were analyzed using mixed-effects models with random intercepts for participants and fixed effects for period, group, sex, and their interactions. A nonparametric sensitivity analysis compared within-subject LVGLS changes (Δ) using Mann–Whitney tests. Resultados e Conclusions: Basal characteristics by sex and group are shown in Table 1. In the LVGLS mixed model (n=102 measures, 38 participants), the Period×Group×Sex interaction was significant (p=0.032). The three-way interaction term (women_aerobic_the end of chemotherapy) was significant (β = −3.72, p=0.019), whereas the corresponding term at 12 months was not (p=0.946). Model-predicted LVGLS at the end of chemotherapy was -19.38% in women-aerobic vs -18.96% in women-flexibility, while men showed the opposite pattern (-18.48% aerobic vs -19.31% flexibility) (Figure 1). In the LVEF mixed model (n=103), LVEF declined over time (end of chemotherapy β=-2.84%, p=0.008; 12 months β=-4.66%, p<0.001) with no significant interactions. In the nonparametric sensitivity analysis, within the flexibility group, women showed greater LVGLS deterioration during chemotherapy than men (Δbaseline→end chemotherapy: median 2.20 vs -0.40; p=0.0001), while men worsened more from the end of chemotherapy to 12 months (Δend chemotherapy→12 months: median 1.80 vs -0.60; p=0.0006). In the aerobic group, men deteriorated during chemotherapy (median 1.80 vs -0.30; p=0.039). LVGLS trajectories were consistent with a sex-dependent intervention pattern at the end of chemotherapy (significant PeriodxGroupxSex interaction). These findings are hypothesis-generating and support confirmation in larger studies.

SYMPATHETIC-CARDIOVASCULAR REACTIVITY TO MENTAL STRESS IN BREAST CANCER PATIENTS TREATED WITH DOXORUBICIN-BASED CHEMOTHERAPY.

CAMILA SOUZA NUNES1; DAVID JUAN PASSOS PEREIRA2; PRISCILLA SECIOSO PENTAGNA1; CAROLINA LOPES MARTINS2; GABRIELLY MEL MEL SILVA2; THAIS DA SILVA RODRIGUES2; JOAO E IZAIAS2; BRUNA E ONO2; ARTHUR O SALES2; RENATA JUNQUEIRA MOLL BERNARDES2; ALLAN ROBSON SALES KLUSER2;

(1) INSTITUTO D`OR DE PESQUISA E ENSINO - RIO DE JANEIRO - RJ - BRASIL; (2) INSTITUTO D'OR DE PESQUISA E ENSINO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Data from our group indicates that breast cancer (BC) patients and disease survivors exhibit increased sympathetic neural activity and heart rate (HR) at rest. However, little is known about the sympathetic-cardiovascular responses during acute mental stress. Objectives: To test whether patients with BC, compared to controls, exhibit greater muscle sympathetic nerve activity (MSNA), lower brachial artery blood flow (BABF), and increased heart rate (HR) and blood pressure (BP) during a mental stress test. Methods: To test this hypothesis, we evaluated neurovascular and hemodynamic responses during acute mental stress in seven patients with BC (age: 47±9 years, BMI: 30±1 kg/m2) and ten control subjects (age: 48±8 years, BMI: 33±2 kg/m2). MSNA (Microneurography), brachial artery blood flow and vascular conductance (BABF and CV, Ultrasound), HR (Electrocardiogram), and systolic, diastolic, and mean arterial pressure (SAP, DAP, and MAP, Finometer) were assessed at rest and during a mental stress test. The mental stress protocol (Stroop Color Word) consisted of 3 minutes of rest, 3 minutes of mental stress, and 3 minutes of recovery. Resultados e Conclusions: At rest, patients with BC exhibit higher MSNA than control subjects ($p<0.05$) and a tendency to have higher HR ($p=0.06$). However, no difference was observed for SAP, DAP, MAP, BABF and CV ($p>0.05$ for all). During the mental stress challenge, a greater increase in MSNA and HR was observed in patients with BC compared to controls ($p=0.04$ for both) with no difference between the groups for SAP, DAP, MAP, BABF and CV ($p>0.05$ for all). Collectively, our data indicates that patients with BC exhibit greater sympathetic neural and HR reactivity during mental stress, indicating that these patients are at increased cardiovascular risk.

High PVC burden — no.(%) ‡	21 (52)

ACEI: Angiotensin-Converting Enzyme Inhibitors; MRA: Mineralocorticoid Receptor Antagonist; IRNA: Angiotensin Receptor-Neprilysin Inhibitor; CIED: Cardiac implantable Eletronic Device; iSGLT2: Sodium-Glucose Co-Transporter 2 Inhibitors; LGE: Late Gadolinium enhancement; AVB: Atrioventricular Block; NSVT: Non-sustained Ventricular Tachycardia. PVC: Premature Ventricular Beats
†Arrithmic symptoms were defined as palpitations, syncope, bradycardia or sudden death
‡ Defined as more than 500 PVC
* Plus-minus values are means ±SD

Introduction/Background: Cardiomyopathy due to laminopathy may present as overlapping phenotype spectrums including progressive heart failure, malignant arrhythmias, and early conduction system disease. A comprehensive understanding of LMNA variants presentation is therefore of critical importance. Objectives: To describe the clinical, epidemiological, and genetic characteristics of Brazilian patients with laminopathy followed at a quaternary cardiology center. Methods: A retrospective cohort study was conducted including patients harboring variants in the LMNA gene, followed from 2010 to 2026 at quaternary cardiology center. Demographic data, phenotypic characteristics, complementary test findings, and relevant clinical outcomes were collected. Additional analyses comparing missense versus non-missense variants were performed using the chi-square test or Fisher's exact test, as appropriate. For each outcome, odds ratios (OR) with 95% confidence intervals (95% CI) were estimated. To account for multiple comparisons across the evaluated outcomes, p-values were adjusted using the Benjamini–Hochberg false discovery rate (FDR) method. Statistical significance was defined as an adjusted p-value < 0.05. Resultados e Conclusions: A total of 40 patients were evaluated, 20 (50%) were female, median age was 49±11 years, with first symptoms presenting at 39±11 years old. Median follow-up was 45±5 months. The percentage for CIED and ventricular dysfunction were both 25 (62%). 25 were submitted to Cardiac Magnetic resonance evaluation with 20 (80%) presenting myocardial fibrosis. 23 (57%) patients had a nonmissense variants identified on genetic analyses, and 62% of variants were classified as pathogenic or likely pathogenic. Half of patients (50%) presented AVB, and 27 (67%) at least one episode of nonsustained ventricular tachycardia (NSVT) during follow-up (Tabela 1). When compared to missense variants, nonmissense mutations were marked by more need of pacemaker implantation (75% vs. 21%, FDR-adjusted p = 0.015). Higher PVC burden (83,3% vs 37.5%) and myocardial fibrosis (100% vs 54.6%) were also observed in the non-missense group, although these did not retain statistical significance. (Figura 1) This cohort reinforces the malignant cardiac phenotype of LMNA cardiomyopathy, with a high risk of conduction system abnormalities, and high burden of ventricular arrhythmias. Nonmissense variants had a worse prognosis confirming genotype–phenotype correlation.

DEVELOPMENT OF AN INTERACTIVE DATABASE OF LDLR, APOB, PCSK9, AND LDLRAP1 VARIANTS AND GENOTYPES OBSERVED IN HOMOZYGOUS FAMILIAL HYPERCHOLESTEROLEMIA (HOFH)

RAUL DOS SANTOS FILHO1; MAFALDA BOURBON2; LIAM BRUNHAM3; ROBERT HEGELE3; HANI SABBOUR4; HAYATO TADA5; JAIN WANG3; ROBYN HYLIND6; OMID KHAZAIE JAPALAGHI6; MICHAEL PARFENOV6; VANESSA RANGEL MILLER6;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) OUTRA - PORTUGAL; (3) OUTRA - CANADA; (4) OUTRA - UNITED ARAB EMIRATES; (5) OUTRA - JAPAN; (6) OUTRA - UNITED STATES;

Introduction/Background: Background: HoFH is characterized by extremely elevated LDL-C from birth leading to premature atherosclerotic cardiovascular disease and is caused by biallelic pathogenic variants in the LDLR, APOB, PCSK9 and LDLRAP1 genes. Genetic test interpretation is complicated by significant genetic heterogeneity, variants of uncertain significance (VUS), and complex inheritance patterns. Objectives: Objective: Provide a publicly available gene variant database for clinicians and scientists interpreting variants in LDLR, APOB, PCSK9 and LDLRAP1, and characterize HoFH genotypes. Methods: Methods: Variants were sourced from a comprehensive literature review (through 02/2025) and a sponsored testing program. Patients meeting biochemical (LDL-C ≥400 mg/dL) or genetic criteria (2 pathogenic [P] or likely pathogenic [LP] variants not in cis) for HoFH were included for further analysis. Data were assembled and stored in a MongoDB database and curated into a publicly available website (https://www.rarediseasegenes.com). Resultados e Conclusions: Results: The database reports 2,696 unique P/LP/VUS variants (LDLR: 2413 [~89%], APOB: 171 [6%], PCSK9: 104 [4%], and LDLRAP1: 44 [2%]) from 51,674 individuals, 5% of whom (n=2,564) met HoFH genetic (n=1,968) and/or biochemical (n=1,149) criteria. Most individuals meeting genetic criteria had biallelic variants in LDLR, PCSK9 or APOB (n=1,079 [55%]) whereas 107 [%5] had biallelic variants in LDLRAP1. Thirty-two percent of variants were classified as VUS (n=836), leading to 302 patients with biallelic variants with ≥1VUS. In these cases, 49/135 (36%) with LDL-C values reported met HoFH biochemical criteria. Biochemical presentation (mean LDL-C [mg/dL]) among individuals with biallelic P/LP variants ranged from 284-597 for individuals with PCSK9 or LDLR genotypes, respectively (Table). Notably, biochemical presentation among biallelic VUS-containing genotypes ranged from 192-544 for individuals with PCSK9 or LDLRAP1, respectively. Conclusions: Significant genetic and biochemical heterogeneity are observed among individuals who meet HoFH diagnostic criteria. Additionally, a high VUS rate contributes to challenges in diagnosis. Databases providing access to biochemical and molecular data may aid timely diagnosis and intervention.

Table. HoFH genotypes and LDL-C levels

Gene	HoFH positive genotype [a]	N (% of patients)	N (%) with LDL-C reported	Mean LDL-C (mg/dl) [b] ± SD (mg/dl)	Median LDL-C (mg/dl) [b] ± IQR (mg/dl)
LDLR	Biallelic identical variants	1063 (54%)	560 (53%)	597 ± 200	588 ± 231
	Biallelic different variants	664 (34%)	298 (45%)	566 ± 224	555 ± 282
APOB	Biallelic identical variants	10 (0.5 %)	7 (70%)	311 ± 55	306 ± 62
	Biallelic different variants	0	0	N/A	N/A
PCSK9	Biallelic identical variants	6 (0.3%)	6 (100%)	284 ± 48	283 ± 81
	Biallelic different variants	2 (0.1 %)	2 (100%)	234	234
LDLRAP1	Biallelic identical variants	107 (5%)	67 (63%)	519 ± 172	503 ± 184
	Biallelic different variants	17 (0.9%)	11 (65%)	533 ± 47	530 ± 75
All except *LDLRAP1*	Biallelic digenic	98 (5%)	63 (64%)	334 ± 162	308 ± 197
All	Biallelic identical variants	1186 (60%)	640 (54%)	583 ±201	573 ± 255
All	Biallelic different variants	684 (35%)	312 (46%)	561 ± 223	551 ± 265

FROM DIAGNOSIS TO GENETIC RECLASSIFICATION: THE ROLE OF WHOLE EXOME SEQUENCING IN CARDIOMYOPATHIES

BIANCA DOMIT WERNER LINNENKAMP1; LUCAS VIEIRA LACERDA PIRES1; BRUNO MOREIRA DOS SANTOS1; GIOVANNA NAPOLITANO PEREIRA1; BRUNO DE OLIVEIRA STEPHAN1; EDER ALENCAR MOURA1; ATMIS MEDEIROS HAIDAR1; MARJORIE MARJORIE HAYASHIDA MIZUTA1; MARIANA LOMBARDI PERES DE CARVALHO1; EMANUELLE LEONILIA MARQUES1; FÁBIO FERNANDES1; JOSE EDUARDO KRIEGER2;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) BENEFICENCIA PORTUGUESA - SAO PAULO - SP - BRASIL;

Introduction/Background: Cardiomyopathies are a heterogeneous group of myocardial disorders characterized by structural and/or functional abnormalities and may arise from both genetic and acquired etiologies. Genetic testing plays a critical role in diagnosis, risk stratification, and clinical management, while precision medicine approaches further enhance diagnostic accuracy and enable differentiation from genocopies. Objectives: To determine the prevalence of genocopies in patients with a presumed diagnosis of cardiomyopathies from the MAPA Genoma Brazil cohort of cardiac genetic diseases. Methods: We conducted a retrospective cohort study of 1,593 Brazilian individuals with clinically diagnosed cardiomyopathies to assess the diagnostic impact of whole exome sequencing. Genetic variants were classified according to ACMG criteria. Only individuals with pathogenic (P) or likely pathogenic (LP) variants in ClinGen-curated genes were included. Molecular results were compared with the initial clinical diagnoses. Resultados e Conclusions: Participants were classified as hypertrophic (46.6%), dilated (39.0%), left ventricular noncompaction (5.3%), arrhythmogenic (4.6%), restrictive (1.9%), amyloidosis (2.0%), and unspecified (0.6%). P/LP variants were detected in 34% (n=542) of individuals, with a yield of 45% in hypertrophic and 21% in dilated cardiomyopathies. Among P/LP carriers, 16% (n=87) showed discordance between molecular and initial clinical diagnoses. (Fig. 1) Genetic reclassification occurred in 25% (n=35) of dilated cases, including 9 in arrhythmogenic-related genes, 8 neuromuscular disorders, 7 storage diseases (PRKAG2, TTR), 4 in ALPK3, 2 RASopathies, 1 Marfan syndrome, and 4 other syndromes. 15% (n=50) of hypertrophic cardiomyopathies were also reclassified including 21 storage diseases (GLA, TTR, PRKAG2, KLHL24), 14 RASopathies, 4 dilated-related, 3 arrhythmogenic-related, and 8 other syndromes, such as McArdle, Carnitine Deficiency, and Char. (Fig. 2) 22 individuals harbored multiple P/LP variants and exhibited more severe or blended phenotypes. These findings underscore the critical role of genetic testing in refining cardiomyopathy diagnoses, as 16% of patients with a presumed diagnosis were reclassified as genocopies. Accurate genetic diagnosis enables personalized management, appropriate genetic counseling, and family screening, and may modify therapeutic strategies, ultimately reducing the risk of adverse outcomes such as sudden cardiac death in both probands and their relatives.

Introduction/Background: Endothelial nitric oxide synthase (eNOS) gene polymorphisms, particularly eNOS-786 T>C and eNOS G894T, are associated with impaired endothelial function through reduced nitric oxide bioavailability and may contribute to the development of coronary artery disease (CAD). Objectives: To investigate the association of eNOS-786 T>C and eNOS G894T polymorphisms with CAD and to evaluate the interaction between these genetic variants and cigarette smoking. Methods: This case–control study included 89 patients aged 18–50 years with angiographically confirmed CAD (acute coronary syndrome and angina pectoris) and 90 age-matched healthy controls. Genotyping for eNOS polymorphisms was performed using reverse hybridization, and statistical analysis was conducted using chi-square and logistic regression models. Resultados e Conclusions: Results: The homozygous eNOS-786 T>C variant was significantly more frequent in CAD patients compared to controls (p=0.0001), confirming its strong association with disease presence. For the eNOS G894T polymorphism, genotype distribution showed that the homozygous variant was detected exclusively in CAD patients (13%) and absent in controls, while the heterozygous variant demonstrated a borderline, non-significant association with CAD (p=0.059). Analysis of gene–environment interaction demonstrated that cigarette smoking significantly increased the risk of coronary artery disease among carriers of the homozygous eNOS-786 T>C genotype (OR=17.0; p=0.048) and the carriers of the heterozygous eNOS-G894T genotype (OR=17.2; p=0.0001). Conclusions: The homozygous eNOS-786 T>C polymorphism is significantly associated with CAD in young patients, while the homozygous eNOS G894T was present only in the patients with CAD. The homozygous eNOS-786 T>C genotype and heterozygous eNOS G894T variant may further contribute to disease susceptibility, especially in the presence of cigarette smoking. These findings highlight the importance of gene–environment interplay in CAD and support the potential role of eNOS polymorphisms as biomarkers for risk stratification.

GENOTYPE–PHENOTYPE CORRELATION IN HEREDITARY ATTR: REAL-WORLD DATA FROM A RARE DISEASE REGISTRY IN RECIFE, BRAZIL

ÂNDREA VIRGINIA FERREIRA CHAVES1; ANNA PAULA PARANHOS MIRANDA COVALESK1; VICTOR RODRIGUES PONTES2; MIRELA SILVEIRA ARENAS2; MARIA EDUARDA OLIVEIRA ALBUQUERQUE1; EVELINE BARROS CALADO3; BRIVALDO MARKMAN-FILHO1;

(1) HOSPITAL AGAMENON MAGALHAES - RECIFE - PE - BRASIL; (2) UNINASSAU BOA VIAGEM - RECIFE - PE - BRASIL; (3) HOSPITAL DAS CLINICAS - RECIFE - PE - BRASIL;

Introduction/Background: Transthyretin amyloidosis (ATTR) is a rare disorder caused by extracellular deposition of misfolded transthyretin, leading to progressive organ dysfunction. Hereditary ATTR (ATTRv) presents marked clinical heterogeneity, with different mutations associated with cardiac, neurological, or mixed phenotypes. Objectives: To evaluate the regional epidemiology of ATTRv and analyze genotype–phenotype correlations, focusing on cardiac involvement. Methods: Retrospective observational study based on a rare disease registry (RARUS), including 282 patients diagnosed with ATTRv through TTR gene sequencing. Descriptive and comparative analyses were performed to assess associations between variants and clinical presentation. Resultados e Conclusions: The most prevalent variants were Val142Ile (64.9%) and Val50Met (32.3%). Val50Met was not associated with isolated cardiac onset, presenting mainly with neurological or mixed manifestations. Val142Ile showed a heterogeneous profile, with 36.7% neurological onset and 15.5% cardiac onset. Asymptomatic individuals identified through family screening accounted for a relevant proportion (46.6% vs. 31.4%). Cardiac involvement was more frequent in Val142Ile, with higher prevalence of abnormalities on echocardiography and technetium-labeled pyrophosphate scintigraphy. TTR mutations are associated with distinct phenotypes in ATTRv. Val142Ile is more strongly associated with cardiac involvement, while Val50Met predominantly presents with neurological manifestations. These findings support genotype-based risk stratification and early screening strategies.

Introduction/Background: The progression of anabolic-androgenic steroid (AAS)-related cardiotoxicity remains incompletely characterized. We aimed to investigate whether increasing duration of AAS exposure is associated with a sequential pattern of structural, functional, and mechanical cardiac abnormalities assessed by advanced echocardiography. Objectives: To investigate the time-dependent progression of structural, functional, and mechanical cardiac abnormalities associated with anabolic-androgenic steroid exposure. Methods: This observational cross-sectional study included AAS users stratified according to exposure duration: 6 months–1 year (n=23), 1–2 years (n=22), and 2–5 years (n=13). Comprehensive transthoracic echocardiography with speckle tracking and myocardial work analysis was performed. Structural, systolic, diastolic, right ventricular, atrial, and myocardial work parameters were compared among groups using ANOVA with Bonferroni correction. Resultados e Conclusions: RESULTS Increasing AAS exposure was associated with progressive multilevel cardiac impairment. Early structural remodeling was characterized by progressive interventricular septal thickening. Functional abnormalities included reduction in left ventricular ejection fraction, worsening global longitudinal strain, impaired early diastolic strain rate, and reduction in right ventricular and atrial strain parameters. Mechanical abnormalities were identified by progressive reduction in global work index and global constructive work despite preserved myocardial work efficiency. These findings suggest a sequential pattern of cardiotoxicity progressing from structural remodeling to subclinical myocardial dysfunction and ultimately mechanical impairment. CONCLUSIONS Longer anabolic steroid exposure is associated with a time-dependent progression of cardiac abnormalities involving structural remodeling, subclinical dysfunction, diffuse multichamber involvement, and impaired myocardial work. This model may represent a comprehensive mechanistic framework for AAS-related cardiotoxicity detected by advanced echocardiography.[23]

DEEP LEARNING–ASSISTED ECHOCARDIOGRAPHIC DETECTION OF SUBCLINICAL LEFT VENTRICULAR DYSFUNCTION

AHMAD BASEER KAIHAN1; AHMAD NASEER KAIHAN2; FARID FARHIKHTA1; HASHMAT ULLAH FAIZI3; GUL AHMAD TANISH QAZIZADA1;

(1) BALKH UNIVERSITY FACULTY OF MEDICINE - AFGHANISTAN; (2) BAKH UNIVERSITY FACULTY OF MEDICINE - AFGHANISTAN; (3) NANGARHAR MEDICAL FACULTY - AFGHANISTAN;

Introduction/Background: Subclinical left ventricular (LV) dysfunction frequently precedes overt heart failure and is associated with adverse cardiovascular outcomes. Conventional echocardiographic assessment based on left ventricular ejection fraction (LVEF) lacks sensitivity for early myocardial impairment. Although global longitudinal strain (GLS) improves detection, its use remains limited in routine practice. Objectives: We aimed to develop and validate a deep learning–based model for automated detection of subclinical LV dysfunction from standard echocardiographic data. Methods: In this retrospective multicenter study, 15,248 transthoracic echocardiograms from three tertiary care centers were analyzed. Sample size was considered adequate to ensure stable model training and performance estimation, exceeding commonly recommended thresholds for deep learning applications in medical imaging. Subclinical LV dysfunction was defined as impaired GLS (>−18%) with preserved LVEF (≥50%). Data were randomly split into training (70%), validation (15%), and internal test (15%) cohorts. Model performance was evaluated using area under the receiver operating characteristic curve (AUC), sensitivity, and specificity, and compared with expert cardiologist visual assessment. An independent external validation cohort (n=2,134) from a separate institution was used to assess generalizability. Resultados e Conclusions: The deep learning model demonstrated excellent discrimination, achieving an AUC of 0.91 (95% CI 0.89–0.93) in the internal test set. At the optimal threshold, sensitivity and specificity were 90% and 87%, respectively. Compared with expert visual assessment (AUC 0.78, 95% CI 0.75–0.81), the model showed significantly improved performance (ΔAUC = 0.13, 95% CI 0.10–0.16; p<0.001), with higher sensitivity (90% vs 72%) and comparable specificity (87% vs 89%). Among patients with preserved LVEF, the model identified previously unrecognized subclinical dysfunction in 19% of cases. In the external validation cohort, model performance remained robust (AUC 0.89), supporting generalizability across different patient populations and imaging settings. Conclusion: Deep learning–assisted echocardiography enables accurate and scalable detection of subclinical LV dysfunction beyond conventional LVEF-based assessment. These findings support the integration of AI-driven tools into routine echocardiographic workflows to enhance early diagnosis and risk stratification in patients at risk for heart failure.

Title: Model Performance Compared with Standard Assessment

Metric	AI Model	Cardiologist Visual Assessment
AUC	0.91	0.78
Sensitivity	90%	72%
Specificity	87%	89%

DIFFUSE CARDIAC INVOLVEMENT IN ANABOLIC STEROID USERS: BIVENTRICULAR AND ATRIAL DYSFUNCTION BY ADVANCED ECHOCARDIOGRAPHY

RENATA RODRIGUES TEIXEIRA DE CASTRO1; JOÃO GIFFONI DA SILVEIRA NETO2; JOSÉ MARIA DEL CASTILHO2; CAIO GUEDES DE SOUSA2; ISSAM SHEHADEH2; MAICON ASSED3; DÉBORA CLAUDINO DOS SANTOS1; PAULO FELIPE GOMES SOUSA1; MARCELLO DE BRITO CAMPOS1;

(1) UNIG - NOVA IGUAÇU - RJ - BRASIL; (2) IPANEMA HEALTH CLUB - RIO DE JANEIRO - RJ - BRASIL; (3) UNIVERSIDADE UNIGRANRIO AFYA - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Anabolic-androgenic steroid (AAS) use may affect cardiac function beyond the left ventricle, but biventricular and atrial involvement remain underrecognized. We aimed to evaluate whether longer AAS exposure is associated with diffuse cardiac dysfunction assessed by advanced echocardiographic strain analysis. Objectives: To assess the impact of cumulative anabolic-androgenic steroid exposure on biventricular and atrial myocardial function using advanced echocardiographic analysis. Methods: This observational cross-sectional study included AAS users stratified by exposure duration: 6 months–1 year (n=23), 1–2 years (n=22), and 2–5 years (n=13). Comprehensive transthoracic echocardiography with speckle tracking analysis was performed. Left ventricular, right ventricular, and atrial strain parameters were compared among groups using ANOVA with Bonferroni correction. Resultados e Conclusions: RESULTS Baseline clinical characteristics were similar among groups. Longer AAS exposure was associated with progressive impairment of cardiac deformation across multiple chambers. Right ventricular global longitudinal strain decreased significantly across groups (20.86±2.75% vs 20.67±2.68% vs 18.48±1.99%; p=0.027), as did right ventricular free-wall strain (24.67±2.98% vs 24.24±3.69% vs 21.49±2.57%; p=0.0155). TAPSE also decreased with longer exposure (21.38±1.99 vs 19.37±2.41 vs 18.31±2.59 mm; p=0.001). Atrial function was similarly affected, with reductions in left atrial reservoir strain (37.65±6.40% vs 33.35±6.99% vs 29.69±5.95%; p=0.003), left atrial conduit strain (23.33±5.37% vs 20.11±5.44% vs 17.31±3.88%; p=0.0052), and right atrial strain (40.37±7.82% vs 35.83±8.20% vs 29.31±6.99%; p=0.0012). CONCLUSIONS Longer exposure to anabolic steroids is associated with diffuse cardiac involvement, including right ventricular dysfunction and impaired biatrial strain. These findings suggest that AAS-related cardiotoxicity is not limited to the left ventricle, but may represent a progressive multichamber myocardial disease.

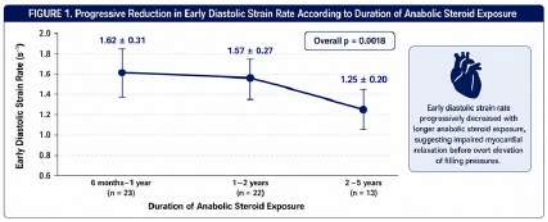
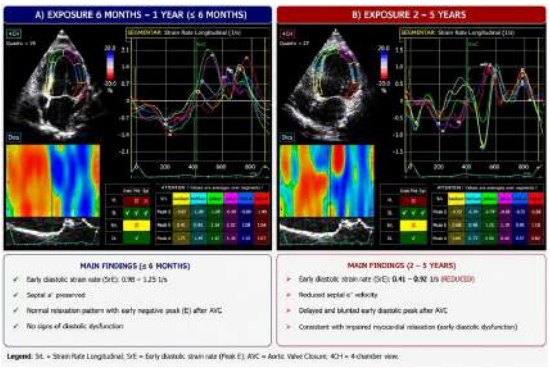
EARLY DIASTOLIC DYSFUNCTION IN ANABOLIC STEROID USERS DETECTED BY STRAIN RATE IMAGING

RENATA RODRIGUES TEIXEIRA DE CASTRO1; JOÃO GIFFONI DA SILVEIRA NETO2; JOSÉ MARIA DEL CASTILHO2; CAIO GUEDES DE SOUSA2; ISSAM SHEHADEH2; MAICON ASSED3; DÉBORA CLAUDINO DOS SANTOS1; PAULO FELIPE GOMES SOUSA1; MARCELLO DE BRITO CAMPOS1;



(1) UNIG - NOVA IGUAÇU - RJ - BRASIL; (2) IPANEMA HEALTH CLUB - RIO DE JANEIRO - RJ - BRASIL; (3) UNIVERSIDADE UNIGRANRIO AFYA - RIO DE JANEIRO - RJ - BRASIL;



Introduction/Background: Anabolic-androgenic steroid (AAS) use may induce early myocardial dysfunction before overt changes in conventional diastolic parameters. We aimed to evaluate whether diastolic strain rate imaging can detect early left ventricular relaxation impairment according to duration of AAS exposure. Objectives: To investigate the association between cumulative anabolic-androgenic steroid exposure and early diastolic dysfunction assessed by strain rate imaging. Methods: This observational cross-sectional study included AAS users stratified by exposure duration: 6 months–1 year (n=23), 1–2 years (n=22), and 2–5 years (n=13). Comprehensive transthoracic echocardiography with speckle tracking analysis was performed. Early diastolic strain rate, tissue Doppler indices, and conventional diastolic parameters were compared among groups using ANOVA with Bonferroni correction. Resultados e Conclusions: RESULTS Baseline clinical characteristics, including body size, heart rate, and resting blood pressure, were similar among groups. Early diastolic strain rate showed a significant progressive reduction with longer AAS exposure (1.62±0.31 vs 1.57±0.27 vs 1.25±0.20; p=0.0018). Post-hoc analysis confirmed significantly lower early diastolic strain rate in the 2–5-year group compared with both the 6-month–1-year group (p=0.003) and the 1–2-year group (p=0.008). Septal e' velocity was also reduced with longer exposure (9.7±1.6 vs 9.1±1.6 vs 8.15±1.28 cm/s; p=0.022), while E/e' remained unchanged, suggesting early relaxation impairment without increased filling pressures. CONCLUSIONS Longer duration of anabolic steroid exposure is associated with early diastolic dysfunction detected by strain rate imaging. The reduction in early diastolic strain rate despite preserved E/e' suggests subclinical impairment of myocardial relaxation before overt elevation of filling pressures.

TABLE 1. Diastolic Functional Parameters According to Duration of Anabolic Steroid Exposure

Parameter	6 months–1 year (n = 23)	1–2 years (n = 22)	2–5 years (n = 13)	p value
Early diastolic strain rate (s⁻¹)	1.62 ± 0.31	1.57 ± 0.27	1.25 ± 0.20	0.0018
Septal e' (cm/s)	9.7 ± 1.6	9.1 ± 1.6	8.15 ± 1.28	0.022
E/e' ratio	6.39 ± 1.31	6.14 ± 1.52	6.02 ± 1.83	0.766

Values are expressed as mean ± SD. ANOVA with Bonferroni post-hoc correction.

(1) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL; (2) SENAI CIMATEC - SALVADOR - BA - BRASIL; (3) FIOCRUZ - SALVADOR - BA - BRASIL;

Introduction/Background: Chronic Chagas cardiomyopathy (CCC) is an inflammatory and fibrotic disease in which cardiac magnetic resonance (CMR) enables noninvasive detection of myocardial fibrosis through late gadolinium enhancement (LGE). Global longitudinal strain (GLS) has been shown to detect subclinical myocardial dysfunction and predict adverse cardiovascular outcomes. Objectives: To evaluate the association between GLS and the presence of myocardial fibrosis in patients with stage B1 chronic Chagas cardiomyopathy. Methods: Cross-sectional study conducted at a tertiary referral center including 116 patients with stage B1 CCC. GLS was obtained by two-dimensional speckle-tracking echocardiography, according to American Society of Echocardiography recommendations. Myocardial fibrosis was assessed by LGE-CMR. The independent association between GLS and myocardial fibrosis was evaluated using multivariable logistic regression, adjusted for age, sex, left ventricular ejection fraction, and NT-proBNP, followed by backward stepwise selection. Resultados e Conclusions: Results: Baseline characteristics related to age and sex were similar between patients with and without fibrosis. Myocardial fibrosis was present in 56 patients (48.3%). Mean GLS was −18.5 ± 2.6%, with worse deformation in the fibrosis group (−17.9 ± 2.8% vs −19.0 ± 2.4%; p = 0.029). On multivariable analysis, GLS remained independently associated with the presence of myocardial fibrosis (OR 1.18; 95% CI 1.01–1.37; p = 0.033). In a sensitivity analysis restricted to patients with CMR-derived LVEF ≥ 60%, the magnitude of the association was maintained. Conclusion: In patients with stage B1 CCC, GLS was independently associated with myocardial fibrosis detected by CMR. These findings corroborate previous evidence and expand its applicability to this early disease stage, reinforcing the potential role of GLS as a complementary echocardiographic marker for identifying subclinical myocardial remodeling and for early risk stratification in this population.

Table 1. Baseline characteristics of patients with and without myocardial fibrosis.

Variable	Total (N=116)	Fibrosis (N=56)	No Fibrosis (N=60)	p Value
Age, y	59.5 ± 10.1	59.9 ± 9.2	59.0 ± 11.0	0.644
Female sex, n (%)	79 (68.1)	34 (60.7)	45 (75.0)	0.099
CMR-derived LVEF, %	65.5 ± 9.6	60.1 ± 10.4	70.6 ± 6.7	<0.001
GLS, %	−18.5 ± 2.6	−17.9 ± 2.8	−19.0 ± 2.4	0.029

Table legend: Baseline clinical, echocardiographic, and cardiac magnetic resonance characteristics of patients with chronic Chagas cardiomyopathy without ventricular dysfunction, stratified by the presence of myocardial fibrosis detected by late gadolinium enhancement. Data are presented as mean ± standard deviation or n (%). CMR = cardiac magnetic resonance; GLS = global longitudinal strain; LVEF = left ventricular ejection fraction.

LEFT VENTRICULAR MECHANICAL RESPONSE TO ISOMETRIC EXERCISE ASSESSED BY LONGITUDINAL STRAIN AND MYOCARDIAL WORK IN HEALTHY ADULTS

JULIANA LINS DA PAZ PORTELA1; MÁRCIO MENDES PEREIRA2; MARIA ESTEFÂNIA BOSCO OTTO3; AMANDA HENRIQUE SANTANA2;

(1) HOSPITAL ESPERANCA S/A(UDI HOSPITAL/REDE D'OR - SAO LUIS - MA - BRASIL; (2) HOSPITAL ESPERANCA S/A (UDI HOSPITAL/REDE D'OR) - SAO LUIS - MA - BRASIL; (3) HOSPITAL DF STAR - BRASILIA - DF - BRASIL;

Introduction/Background: Background Left ventricular (LV) ejection fraction is limited by load dependency and may fail to identify subtle mechanical adaptations. Global longitudinal strain (GLS) and myocardial work (MW) integrate deformation and afterload, providing a more comprehensive assessment of LV mechanics. Isometric handgrip exercise represents a simple and reproducible model of acute pressure overload. Objectives: Purpose To characterise LV mechanical responses to isometric handgrip exercise using GLS and myocardial work indices in healthy adults. Methods: Methods Thirty healthy individuals (mean age 29.3 ± 6.1 years; 50% male) underwent transthoracic echocardiography at rest and during sustained handgrip at 30–40% of maximal voluntary contraction. Blood pressure and heart rate were recorded. GLS, global myocardial work index (GWI), global constructive work (GCW), global wasted work (GWW) and global work efficiency (GWE) were derived from non-invasive pressure–strain loops. Paired comparisons and effect sizes were calculated. Resultados e Conclusions: Results Handgrip elicited a significant haemodynamic response, with systolic blood pressure increasing from 115 ± 16 to 133 ± 18 mmHg and heart rate from 72 ± 12 to 82 ± 10 bpm (both p<0.0001). LV ejection fraction remained unchanged (64.8% vs 64.4%; p=0.62). GLS showed a mild reduction (20.4 ± 2.6% vs 19.6 ± 2.5%; p=0.028; Cohen's d = 0.42), mainly in basal segments. In contrast, MW indices increased substantially: GWI rose from 1810 ± 322 to 2054 ± 403 mmHg% (p=0.0002; d = 0.77), GCW from 2172 ± 371 to 2486 ± 453 mmHg% (p<0.0001; d = 1.05), and GWW from 108 ± 44 to 160 ± 76 mmHg% (p=0.0008; d = 0.68). GWE showed a small reduction (94.8 ± 1.8% vs 93.6 ± 2.5%; p=0.022; d = 0.44), remaining within physiological limits. Segmental analysis demonstrated greater MW increases in basal and mid-ventricular segments, with no significant apical changes. Conclusion(s) In healthy adults, isometric handgrip induces preserved ejection fraction, mild load-related GLS reduction and marked increases in myocardial work. MW indices, particularly GWI and GCW, are more sensitive than GLS or ejection fraction for detecting acute LV contractile adaptation to pressure overload. Handgrip combined with myocardial work analysis is a robust approach for assessing LV mechanical reserve

MITRAL VALVE NAVIGATION: A FEASIBLE TECHNIQUE FOR ACCURATE ASSESSMENT OF MITRAL VALVE AREA

RODRIGO TOBIAS GIFFONI1; NAYANA FLAMINI ARANTES GOMES1; CAROLINA KUCHENBECKER SOARES1; HENRIQUE FAUSTINO VIEIRA DA SILVA1; WILLIAM SILVA BARBOSA1; EDUARDO ENRIQUE CARVALHO GRADE VALLEJO1; SARA REGINA SILVA CUPERTINO1; LUIZA HAIKAL DE PAULA1; MARIA DO CARMO PEREIRA NUNES1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Precise measurement of mitral valve area is central to define rheumatic mitral stenosis severity, but conventional echocardiographic methods have important anatomical and hemodynamic limitations. The Mitral Valve Navigation (MVN) method, derived from three dimensional transesophageal echocardiography, takes into account commissures and also the different depths between the tips of the cusps (more distal) and the commissural points (more proximal) in relation to the valve annulus. Furthermore, the irregularities of the leaflet edges are traced in different planes. The MVN method is, therefore, not based on geometric assumptions derived from direct two-dimensional (2D) and three-dimensional (3D) planimetry, but on the true valve anatomy. Objectives: To compare mitral valve area obtained by the MVN method with 2D planimetry, 3D planimetry and pressure half-time (PHT) in patients with rheumatic mitral stenosis. Methods: Observational study including 186 patients who underwent comprehensive echocardiographic assessment and off-line MVN analysis. Correlations were tested with Spearman coefficients, paired comparisons with Wilcoxon tests, agreement with Bland-Altman analysis, reclassification with McNemar tests, and intraobserver variability with the intraclass correlation coefficient. In addition to the cutoff of ≤1.5 cm2, the threshold of ≤1.0 cm2 was also evaluated. Resultados e Conclusions: MVN correlated significantly with all methods, with the strongest correlation observed for 3D planimetry (rho=0.529; p=0.001), followed by 2D planimetry (rho=0.465; p<0.001) and PHT (rho=0.367; p<0.001). MVN values were lower than those obtained by 2D planimetry (0.947±0.349 vs 1.013±0.275 cm2; p=0.004) and PHT (0.947±0.349 vs 1.032±0.263 cm2; p<0.001), with no significant difference in relation to 3D planimetry (p=0.420). There was no significant reclassification at either ≤1.5 cm2 or ≤1.0 cm2. The method showed excellent intraobserver reproducibility (ICC=0.834; p<0.001). MVN is feasible, reproducible, and more closely aligned with 3D planimetry, and may complement the quantification of rheumatic mitral stenosis severity, especially in discordant cases.

MVN vs 3D	rho=0,529; p=0,001
MVN vs 2D	rho=0,465; p<0,001 Wilcoxon p=0,004
MVN vs PHT	rho=0,367; p<0,001 Wilcoxon p<0,001
McNemar <=1,5	2D: 0,238 | PHT: 0,648 | 3D: 1,000
McNemar <=1,0	2D: 0,052 | PHT: 0,450 | 3D: 0,727
ICC intraobs.	0,834; p<0,001

MYOCARDIAL WORK INDICES IN NON-OBSTRUCTIVE HYPERTROPHIC CARDIOMYOPATHY, HYPERTENSIVE LEFT VENTRICULAR HYPERTROPHY, AND CONTROLS: COMPARISON AND DIAGNOSTIC ACCURACY

DANIEL RABISCHOFFSKY1; RAFAEL RABISCHOFFSKY2; BRUNO REZNIK WAJSBROT1; MARCELO IMBROINISE BITTENCOURT1; RICARDO ROCHA-MOURILHE1;

(1) UNIVERSIDADE ESTADUAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) HOSPITAL PRO CARDIACO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Hypertrophic cardiomyopathy (HCM) and hypertensive left ventricular hypertrophy (H-LVH) share morphological features but differ in pathophysiology, prognosis, and management. Conventional parameters such as EF and GLS have limited ability to distinguish these conditions. Myocardial work (MW), derived from pressure-strain loops, provides load-independent assessment of ventricular mechanics. Objectives: Primary: To compare MW indices (GWI, GCW, GWW, GWE) among patients with non-obstructive HCM, H-LVH, and controls. Secondary: To assess diagnostic accuracy of MW for differentiating HCM from H-LVH, evaluate correlations with structural/functional variables, and test incremental value of combined models. Methods: Cross-sectional study, 92 subjects: HCM (n=31, diagnosed per current guidelines, maximum wall thickness 15mm or greater not explained by pressure overload, non-obstructive gradient below 30 mmHg), H-LVH (n=31, SBP 140 mmHg or higher and/or antihypertensive therapy, elevated LVMI greater than 115/95 g/m2 or relative wall thickness greater than 0.42), controls (n=30). EF 50% or greater, sinus rhythm. EchoPAC software (GE Vivid E95). ANOVA or Kruskal-Wallis with Bonferroni correction. Spearman correlations. Multivariate linear regression with dummy coding. ROC curves with DeLong test, including MWT/PW ratio, MW indices, and combined logistic model. ICC and Bland-Altman for reproducibility (n=21). Resultados e Conclusions: GWI and GCW were significantly lower in HCM vs H-LVH and controls (p<0.001), with no difference between H-LVH and controls (p=0.142; p=0.763). GCW showed highest diagnostic accuracy (AUC=0.852; sensitivity 83.9%; specificity 82.0%; cut-off 1983 mmHg%). Combined model (MWT/PW + GCW) achieved 96.8% sensitivity and 100% specificity, correctly reclassifying 3 false positives from MWT/PW alone. HCM (beta=-0.615) and H-LVH (beta=-0.361) were independent negative predictors of GWI after adjusting for SBP (R2adj=0.427). GWE showed strongest correlation with LV mass (rho=-0.650). GCW reproducibility: ICC=0.931. MW indices characterize distinct mechanical phenotypes in HCM and H-LVH. GCW provides incremental diagnostic value over morphological assessment, achieving 100% specificity in borderline cases.

Introduction/Background: Anabolic-androgenic steroid (AAS) use has been associated with myocardial dysfunction and early cardiotoxicity, even in individuals without overt cardiovascular disease. We aimed to evaluate the impact of cumulative AAS exposure on subclinical left ventricular systolic function using speckle tracking echocardiography. Objectives: To evaluate the association between cumulative anabolic-androgenic steroid exposure and subclinical left ventricular systolic dysfunction using two-dimensional speckle tracking echocardiography. Methods: This observational cross-sectional study included AAS users stratified according to duration of exposure: 6 months–1 year (n=23), 1–2 years (n=22), and 2–5 years (n=13). Comprehensive transthoracic echocardiography with two-dimensional speckle tracking analysis was performed. Left ventricular global longitudinal strain (LV-GLS), regional strain, and conventional echocardiographic parameters were compared among groups using ANOVA with Bonferroni correction. Resultados e Conclusions: RESULTS Baseline clinical characteristics, including body size, heart rate, and resting blood pressure, were similar among groups. Progressive impairment in left ventricular systolic performance was observed with increasing duration of AAS exposure. LV-GLS demonstrated a significant stepwise reduction across exposure groups (19.1±2.4% vs 17.9±2.2% vs 15.0±2.1%; p<0.001). Post-hoc analysis confirmed significantly lower LV-GLS in individuals with 2–5 years of exposure compared with both shorter-duration groups. Regional strain analysis demonstrated predominant basal segment impairment, suggesting a nonphysiological remodeling pattern associated with chronic AAS exposure. Conventional systolic parameters also worsened with longer exposure, including increased left ventricular end-systolic volume and reduced ejection fraction. CONCLUSIONS Longer duration of anabolic steroid exposure is associated with progressive subclinical left ventricular dysfunction detected by speckle tracking echocardiography. Basal myocardial segments appear disproportionately affected, suggesting an early and regionally heterogeneous pattern of AAS-related cardiotoxicity.

(1) BOTKIN HOSPITAL - RUSSIA; (2) ROSTOV STATE MEDICAL UNIVERSITY - RUSSIA; (3) KUBAN STATE MEDICAL UNIVERSITY - RUSSIA;

Introduction/Background: A type of left ventricular remodeling in patients with coronary artery disease (CAD) is linked to the loss of contractility of the myocardium and leads to changes in function notwithstanding the preserved ejection fraction (Luisi G.A. et al., 2022, Lazar MA. et al., 2023). Nowadays, strain parameters, attained by speckle-tracking echocardiography (STE), especially by stress-echocardiography (SE) with vasodilators, are applied as additional predictors of remodeling along with ejection fraction (EF), end-systolic volume (ESV), and wall motion score index (WMSI) (Dell'Angela L. et al., 2024, El-Naggar H.M. et.al., 2023). Objectives: 71 patients underwent four-dimensional (4D) stress – echocardiography (SE) with Adenosine Triphosphate (ATP) at ultrasound department of Rostov State Medical University during 2018-2024. 1 group: 48 patients hospitalized with diagnosis of CAD, the mean age is 58 y. (95%CI: 55,27-60,72); and 2 group: 23 healthy adults, the mean age is 40,2 y. (95%CI: 26,53-55,12). 2 groups were similar by EF: 61,7 % ((95%CI: 59,63 – 63,04) vs 64,7 % (95%CI: 61,52 – 67,38) and by ESV: 46,52 ml (95%CI: 36,92 – 56,11) vs 42,87 ml (95%CI: 36,74 – 49,00). Methods: Global longitudinal strain (GLS), radial (GRS), circumferential (GCS), area (GAS), rotation (GRot) and twisting (GTwist) were reported by US scanner Vivid E95 GE with 4VC transducer at rest and at the peak of vasodilation during SE with ATP. According to our protocol (the patent for the invention of the RF № 2688441 (21.05.2019 y.)). ATP administered intravenously at a rate of 140 to 175 and 210 μg/kg/min. Resultados e Conclusions: Spearman's rank correlation coefficient showed strong correlation between GLS (r=0,74 (p=0,01)), and moderate correlation between GAS (r=0,6 (p=0,01)), apical Rotation (r=0,42 (p=0,00) and increasing of ESV during the SE. Multiple regression analyses detected the group influence of strain indicators the increase in ESV (marker of remodeling), F =12,58 (p=0,00). Formula for the calculation of remodeling criteria which consisted of 10 dynamic strain parameters at the peak of vasodilation with the cut off the point of 2,1 showed the high level of prediction in the class of heart failure: AUC 0,98 (se. 82,8%, sp. 95,2%, ac. 90,1%) (the patent for the invention of the RF № 2828733C1 (17.10.2024 y.)).

CLINICAL INDICATIONS, MAIN FINDINGS AND SAFETY OF CARDIAC MAGNET-IC RESONANCE FROM A PRIVATY OUTPATIENT FACILITY IN BRAZIL

LEONARDO SARA1; ÚDYSON ÁVILA BORGES2; LÍVIA MARQUES DE CASTRO3; CIBELE GONTIJO LOPES4; RENATA CAMPOS DE PIERI5;

(1) UNICAMP - CAMPINAS - MT - BRASIL; (2) UNIVERSIDADE FEDERAL DE MATO GROSSO DO SUL - CAMPO GRANDE - MS - BRASIL; (3) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (4) UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL; (5) FACULDADE DE MEDICINA DA UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL;

Introduction/Background: In recent years, cardiovascular magnetic resonance (CMR) is gaining prominence among diagnostic imaging modalities due to its versatility in the evaluation of a wide range of congenital and acquired diseases. Despite its solid clinical indications present in the main clinical guidelines worldwide, CMR is still un-derused. However, in Brazil, CMR has compulsory reimbursement from private health insurance companies and has increasing availability all over the country. Objectives: We aim to evaluate the main clinical indications, the demographic profile, the most frequent exam findings and adverse reactions in a real world setting. Methods: Consecutive patients submitted to routine CMR exam in a private diagnostic center in Goiania-Brazil were included. They were categorized by their clinical indication and the acquisition protocol used. We analyzed the main findings and classified them as major [moderate to severe ventricular dilation, hypertrophy, pericardial effusion, valve dysfunction and any grade of myocardial ischemia or late gadolinium enhancement (LGE), masses or congenital heart disease] or minor findings (mild alterations) and classified the adverse reactions as mild or moderate/severe. All patients underwent to cardiac exam in a 1.5 T scanner (GE Medical Systems, Milwaukee, WI, EUA) and all the exams were analyzed by trained cardiologists. Resultados e Conclusions: A total of 108 patients were enrolled from September 1st to September 30th 2025 (mean age of 58.2 ± 16 years; 39.8% female). The most common indication of CMR was related to ischemic heart disease (IHD), with (69.4%; n=75) or without suspicion of non-ischemic cardiomyopathy (65.7%; n=71). The other indications were cardiomyopathies (24.1%; n=26), myocarditis (4.6%; n=5), cardiac masses (3.7%; n=4), hemochromatosis (1.8%; n=2) and valve disease (n=1). Stress perfusion imaging were done in 70.4% of the cases. A normal CMR result was obtained in 35.2% of cases (n=38), minor findings in 13% (n=14) and major findings in 51.8% (n=56). The exam was extremely safe, with only 3 moderate and no severe adverse reactions. CONCLUSION: In a high-volume imaging center, investigation of IHD is the most frequent indication of CMR, followed by cardiomyopathies, with no severe adverse reactions observed. In most of the cases, major cardiovascular findings were detected, suggesting that CMR is most commonly used to evaluate more complex patients and also that the exam has a high diagnostic capability to detect a wide variety of alterations.

CLINICAL PREDICTORS OF HIGH CORONARY ATHEROSCLEROTIC BURDEN IN PATIENTS WITH ACUTE CHEST PAIN UNDERGOING CORONARY CTA

VICTOR COSTA RIBEIRO1; PEDRO HENRIQUE P ROHDE2; PAULO ROBERTO SCHVARTZMAN1; LEONARDO ALVES3; CARISI ANNE POLANCZYK1;

(1) HOSPITAL MOINHOS DE VENTO - PORTO ALEGRE - RS - BRASIL; (2) PUCRS - PORTO ALEGRE - RS - BRASIL; (3) UNIVERSIDADE FEDERAL DO RIO GRANDE - RIO GRANDE - RS - BRASIL;

Introduction/Background: Coronary computed tomography angiography (CTA) allows not only the detection of coronary stenosis but also the quantification of the extent of coronary atherosclerosis. The Segment Involvement Score (SIS) reflects the anatomic burden of disease and may provide incremental information for risk stratification in patients with chest pain. Characterizing the clinical profile and atherosclerotic burden of patients presenting to the emergency department with acute chest pain may improve our understanding of the role of this method in this clinical setting. Objectives: To evaluate the association between clinical characteristics and high coronary atherosclerotic burden, defined as a SIS ≥5, in patients presenting with acute chest pain who underwent coronary CTA. Methods: This observational study included 562 patients presenting to the emergency department with chest pain who underwent coronary CTA after exclusion of individuals with prior coronary artery disease. Demographic data, cardiovascular risk factors, coronary lesion characteristics, and calcium scores were assessed. Associations with a high atherosclerotic burden were estimated using prevalence ratios in crude and adjusted analyses. Resultados e Conclusions: The median age was 49 years (IQR, 42–60), and 47.7% of the patients were women. On coronary CTA, 61.8% of patients had no coronary lesions; among the remainder, 710 lesions were identified, predominantly minimal or mild lesions (83.5%). The prevalence of a high atherosclerotic burden increased with age, including in patients aged 50–69 years (PR, 2.10; 95% CI, 1.16–3.80) and those older than 70 years (PR, 3.11; 95% CI, 1.47–6.59), and was higher in men (PR, 3.14; 95% CI, 1.75–5.62). Among the cardiovascular risk factors, hypertension (PR, 2.37; 95% CI, 1.34–4.20) and diabetes (PR, 1.75; 95% CI, 1.04–2.93) were independently associated with SIS ≥5. Among patients presenting with chest pain who underwent coronary CTA, older age, male sex, hypertension, and diabetes were independently associated with a high atherosclerotic burden. These findings reinforce the consistent association between routinely obtained clinical variables and a greater anatomic coronary disease burden in this clinical setting. These results support the use of coronary CTA as a complementary tool for characterizing the atherosclerotic burden in this population.

CLINICAL PROFILE, CORONARY CTA FINDINGS, AND IN-HOSPITAL OUTCOMES OF PATIENTS PRESENTING WITH ACUTE CHEST PAIN IN A PRIVATE HEALTHCARE HOSPITAL

VICTOR COSTA RIBEIRO1; PEDRO HENRIQUE P ROHDE2; PAULO ROBERTO SCHVARTZMAN1; LEONARDO ALVES3; CARISI ANNE POLANCZYK1;

(1) HOSPITAL MOINHOS DE VENTO - PORTO ALEGRE - RS - BRASIL; (2) PUCRS - PORTO ALEGRE - RS - BRASIL; (3) UNIVERSIDADE FEDERAL DO RIO GRANDE - RIO GRANDE - RS - BRASIL;

Introduction/Background: Chest pain is one of the most common reasons for emergency department visits. In patients with a low probability of acute coronary syndrome, coronary computed tomography angiography (CTA) is the imaging test of choice for excluding obstructive coronary artery disease. In addition to its diagnostic role, real-world characterization of the clinical profile, anatomic findings, and outcomes of these patients may help define the value of this strategy in optimizing care pathways and hospital resource utilization in the private healthcare setting. Objectives: To describe the clinical characteristics, coronary CTA findings, and in-hospital outcomes of patients presenting with chest pain to a tertiary private healthcare hospital. Methods: This descriptive observational study included patients who underwent coronary CTA for the evaluation of acute chest pain. Demographic characteristics, cardiovascular risk factors, coronary artery calcium scores, and the presence, distribution, and severity of coronary stenosis were assessed, along with short-term in-hospital outcomes. Resultados e Conclusions: A total of 579 patients presenting with acute chest pain who underwent coronary CTA were included in the study. The mean age was 51.5 years, and 47.5% were women. The prevalence of hypertension, diabetes, smoking, and prior coronary artery disease was 41.5 %, 11.3%, 12.1%, and 2.8 %, respectively. A calcium score of 0 was observed in 64.7% of the patients. On coronary CTA, 60.3% of patients had no coronary stenosis, whereas 39.7% had at least one lesion. Among the 789 identified lesions, 82.1% were minimal or mild, 9.4% were moderate, and 8.5% were severe or occlusive, with a predominance in the left anterior descending artery territory (46.9%). Hospital admissions occurred in 19.7% of cases. Invasive coronary angiography was performed in 53 patients, and 40 underwent coronary revascularization, including 38 percutaneous coronary interventions and two coronary artery bypass grafting procedures. The use of coronary CTA in low-risk patients presenting with acute chest pain was associated with a high diagnostic yield and low rate of invasive coronary procedures. This strategy should be reinforced to support the more efficient use of hospital resources. These findings are consistent with those of prior randomized trials showing the safety of early CCTA-based evaluation in the emergency setting.

Table 1: Demographic characteristics, medical history, and clinical presentation of patients presenting to the emergency department with chest pain who underwent coronary CTA (n = 579).

Demographic Characteristics	
Age (years), mean (standard deviation)	51,5 (12,6)
Age groups (years), n (%)

DIFFERENT STROKES FOR DIFFERENT FOLKS: CARDIOVASCULAR COMPUTED TOMOGRAPHY FEATURES DISTINGUISHING CHAGASIC AND ISCHEMIC LEFT VENTRICULAR APICAL ANEURYSMS

BERNARDO KREMER DINIZ GONCALVES1; MARCELLO AUGUSTUS SENA2; WALLACE ANDRE SILVA3; CRISTIANO REMOR4; HENRIQUE FERREIRA5;

(1) UNIVERSIDADE FEDERAL DO TOCANTINS - PALMAS - RJ - BRASIL; (2) AKC DIAGNOSTICO - PALMAS - TO - BRASIL; (3) PALMAS MEDICAL CENTER - PALMAS - TO - BRASIL; (4) INTRACOR SANTA MONICA - REDENCAO - PA - BRASIL; (5) SANTA MONICA INTRACOR - REDENCAO - PA - BRASIL;

Introduction/Background: Background Apical aneurysm is a hallmark of chronic Chagas cardiomyopathy and reflects regional myocardial injury distinct from post– myocardial infarction ischemic aneurysms. While echocardiography has historically described these differences, a direct morphological comparison using cardiovascular computed tomography (CCT) has not been previously reported. Objectives: To provide the first CCT-based morphological comparison between ischemic and Chagasic left ventricular apical aneurysms, highlighting imaging features that may assist in etiological differentiation Methods: We retrospectively analyzed cardiovascular computed tomography studies performed at a single center between January and December 2025. Among 1,256 examinations, 4 cases of left ventricular apical aneurysm were identified: two associated with chronic Chagas disease and two with post–myocardial infarction ischemic cardiomyopathy. Coronary anatomy and aneurysm morphology were systematically evaluated. Resultados e Conclusions: Results Chagasic aneurysms demonstrated a characteristic small, focal, mammillary morphology with a narrow neck, confined to the apical segment and without associated coronary artery disease. In contrast, the ischemic aneurysm was larger, broad-based, and accompanied by severe obstructive disease of the left anterior descending coronary artery. These distinct CCT features allowed clear differentiation between etiologies. Conclusion This study provides the first CCT-based morphological characterization distinguishing Chagasic from ischemic left ventricular apical aneurysms. Cardiovascular computed tomography enables simultaneous assessment of ventricular morphology and coronary anatomy, offering a valuable non-invasive tool for etiological diagnosis in patients with apical aneurysms.

Introduction/Background: Scintigraphy with bone seeking tracers has revolutionized the non-invasive diagnosis of transthyretin amyloid cardiomyopathy (ATTR-CM). Recent evidence from large multicenter cohorts has identified right ventricular (RV) uptake as an emerging prognostic marker. However, the specific impact of the extent of RV tracer uptake on clinical outcomes requires further characterization, particularly in cohorts enriched for hereditary ATTR. Objectives: This study aimed to evaluate the prevalence and extent of RV uptake evidenced on 99mTc-pyrophosphate scintigraphy in patients with non-invasive diagnosis of ATTR-CM and its relationship with clinical outcomes. Methods: Patients with clinical suspicion based on symptoms of heart failure (HF) and characteristic findings on echocardiography or cardiac magnetic resonance were prospectively enrolled. Non-invasive diagnosis was established by visual myocardial uptake grade 2 or 3 on SPECT/CT and absence of monoclonal gammopathy . Genetic test was further performed. Extensive RV uptake on SPECT/CT was defined as tracer uptake encompassing the apical, mid-ventricular and basal segments while partial uptake was defined as involvement of basal or mid-ventricular segments, only. The primary composite endpoint included cardiovascular death, hospitalization for HF, and clinically significant arrhythmias. Resultados e Conclusions: Results: Thirty-eight patients were enrolled (mean age 76.1 ± 7.3, 78.9% male, 55.3 % African descent). A total of 54.5% were in NAC ATTR stage II or III, and 86.9% were in NYHA functional class II or III. Hereditary ATTR was present in 70.3% of patients, with Val122Ile as the most prevalent mutation (88.5%). Visual score of 3 for left ventricular uptake was observed in all SPECT/CT, with a predominantly homogeneous uptake pattern (94.7%). RV uptake was identified in 81.6% of scans. Extensive RV uptake was present in 60.5% of the studies, while partial RV uptake in only 21,1%. The occurrence of composite endpoint events was significantly higher in the group with extensive versus partial or absent RV uptake (52.12% vs. 20.0%, p=0.047). The group with extensive RV uptake had significantly shorter event-free survival (log-rank p=0.048) and extensive RV uptake was an independent predictor of outcomes in multivariate analysis (HR 3,69, p=0.047). Conclusion: In this cohort,the prevalence of RV involvement on scintigraphy was high and extensive RV uptake was most prevalent. Extensive RV uptake was independently associated with a greater risk of adverse outcomes.

19115

QUANTIFICATION OF RIGHT VENTRICULAR AMYLOID BURDEN WITH 18F-FLORBETABEN PET/CT AND ITS CORRELATION WITH 99MTC-PYROPHOSPHATE SCINTIGRAPHY, ECHOCARDIOGRAPHY AND CARDIAC MAGNETIC RESONANCE IN TRANSTHYRETIN CARDIAC AMYLOIDOSIS: A PILOT STUDY

ADRIANA PEREIRA GLAVAM1; MARCELO IMBROINISE BITTENCOURT2; PAULO HENRIQUE ROSADO DE CASTRO1; FRANCISCO DE ASSIS ROMEIRO FIGUEIROA BENICIO DE ASSIS3; ADRIANA SOARES XAVIER DE BRITO3; ISABELLA CATERINA PALAZZO3; ANA PAULA DOS REIS VELLOSO SICILIANO3; ALEX DOS SANTOS FELLIX3; GABRIEL CORDEIRO CAMARGO3; FILIPE MEDEIROS SOUZA DE OLIVEIRA3; SERGIO ALTINO DE ALMEIDA3; DENILSON CAMPOS DE ALBUQUERQUE1;

(1) INSTITUTO D'OR DE PESQUISA E ENSINO - RIO DE JANEIRO - RJ - BRASIL; (2) HOSPITAL UNIVERSITARIO PEDRO ERNESTO - RIO DE JANEIRO - RJ - BRASIL; (3) REDE DOR - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Right ventricular (RV) uptake on bone seeking tracer scintigraphy has emerged as a prognostic marker in transthyretin cardiac amyloidosis (ATTR-CA). However, how to estimate right ventricular (RV) amyloid burden using 18F-Florbetaben PET/CT in ATTR-CA remains understudied. Objectives: This pilot study aimed to quantify RV amyloid burden on 18F-Florbetaben PET/CT and assess its correlation with 99mTc-phyrophosphate scintigraphy, echocardiographic, cardiac magnetic resonance (CMR) imaging parameters, and biomarkers. Methods: Non-invasive diagnosis was established by visual myocardial uptake grade 2 or 3 on SPECT/CT in the absence of monoclonal gammopathy. Extensive RV uptake on SPECT/CT was defined as tracer uptake encompassing the apical, mid-ventricular and basal segments while partial uptake was defined as involvement of basal or mid-ventricular segments. ATTR-CA patients and 9 healthy volunteers further underwent a dynamic cardiac 18F-Florbetaben PET/CT scan performed for up to 40 minutes. Whole-heart static images were retrospectively reconstructed from the dynamic list-mode acquisition between 6 -11 min (Static 1), 15 -20 min (Static 2) and 25-30 min (Static 3). PMOD software was used to calculate left ventricle (LV) and right ventricle (RV) SUV averaged, SUV SD and blood pool in each of these intervals. VOIs were manually drawn contouring LV and RV walls, and blood pool activity (10 mm radius sphere in the left atrium). A cardiac time-activity curve (TAC) for LV, RV and blood pool was also acquired. Resultados e Conclusions: Fifteen patients were enrolled (mean age 77.9 ± 5.4, 86.7% male, 55.3 % African descent). Hereditary ATTR was most prevalent (Val122Ile 60.0%). A visual score of 3 for LV uptake was observed in all SPECT/CT.RV uptake was identified in 80.0% of scans. Extensive and partial RV uptake was present in 66.7% and 13.4%, respectively. RV uptake was detected in all PET/CT scans. Importantly, amyloid burden in those with partial or no RV uptake on scintigraphy was similar to those with extensive RV uptake on PET/CT. RV amyloid burden on PET/CT strongly correlated with NT-pro-BNP, LV and RV strain, RV and LV EF, TAPSE and ECV (each p< 0.05). PET/CT values of the nine controls were statistically significantly lower than ATTR-CA patients validating the methodology used to define RV amyloid burden. Conclusion: RV amyloid burden on PET/CT could be a novel marker of poor prognosis in ATTR-CA. Larger studies with longitudinal outcome data are needed to establish its independent prognostic value.

ANTIRETROVIRAL THERAPIES AND CARDIOVASCULAR RISK FACTORS IN PEOPLE LIVING WITH HIV AGED 50 OR OLDER: FINDINGS FROM STUDIES IN BRAZIL AND THE USA

FELIPE COSTA DE SOUZA1; CARRIE DOWN JOHNSTON2; MARSHALL J GLESBY2; CHRISTIANNE BRETAS VIEIRA SCARAMELLO1;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL; (2) WEILL CORNELL MEDICAL COLLEGE - UNITED STATES;

Introduction/Background: Progress in antiretroviral therapy has allowed an increase in the life expectancy of people living with HIV (PLWH). However, this population remains at increased risk of non-AIDS-related comorbidities, including cardiovascular diseases (CVD). Furthermore, some antiretroviral therapy (ART) drugs have adverse effects associated with increased cardiovascular risk. Objectives: This study evaluated the relationship between different ART regimens and cardiovascular risk factors in PLWH aged ≥50 years, using data from studies conducted in the USA and Brazil. Methods: Data were derived from two sources: a cross-sectional study including 163 PLWH from a tertiary hospital in the USA (2016–2019) and a cohort study including 107 PLWH from a tertiary hospital in Brazil (2023). ART regimens included integrase inhibitors (I group: USA=79; Brazil=41), protease inhibitors (P group: USA=27; Brazil=31), combined integrase and protease inhibitors (IP group: USA=21; Brazil=35), and nucleoside/non-nucleoside reverse transcriptase inhibitor combinations (O group: USA=36; Brazil=0). Interferon gamma (IFN), interleukin-6 (IL-6), tumor necrosis factor (TNF), and cell-free mitochondrial DNA (cf-mtDNA) were available only in the US study. Quantile regression (τ=0.5) was used to compare clinical, biochemical, and immunological variables across groups, adjusting for age, sex, race, duration of HIV infection, BMI, smoking, diabetes, antihypertensive therapy, and statin use. Analyses were performed in R. Resultados e Conclusions: The results are summarized in Table 1. The Brazilian IP group exhibited higher total cholesterol (TC) and creatinine levels (Cr), corresponding to a lower estimated glomerular filtration rate (eGFR). Notably, the American IP group showed elevated levels of inflammatory markers (IFN, IL-6, TNF) and cf-mtDNA, whereas the respective P group had lower CD4 counts and reduced CD4/CD8 ratios. No differences were observed in BMI, waist circumference (WC), systolic blood pressure (SBP), diastolic blood pressure (DBP), HDL, LDL, fasting glucose (Glu), high-sensitivity C-reactive protein (CRP), and viral load. Taken together, this data suggests that combined integrase and protease inhibitor regimens may be associated with less favorable profiles of several cardiovascular risk factors, including dyslipidemia, impaired renal function, and elevated inflammatory markers. Longitudinal studies are needed to corroborate these findings.

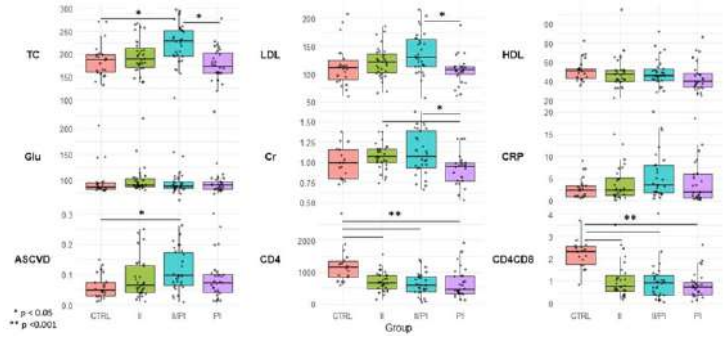
ASSESSMENT OF MEDICAL PRESCRIBING ADHERENCE TO DAPAGLIFLOZIN AND EMPAGLIFLOZIN IN HOSPITALIZED PATIENTS WITH HEART FAILURE WITH PRESERVED EJECTION FRACTION (HFPEF)

MISAEL SANTANA DE LIMA1;

(1) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL;

Introduction/Background: Heart failure with preserved ejection fraction (HFpEF) is a frequent, heterogeneous syndrome associated with multiple comorbidities, high healthcare burden, and recurrent hospitalizations. In this context, SGLT2 inhibitors (SGLT2i) play an important therapeutic role, although their incorporation into hospital practice remains variable. Objectives: To evaluate adherence to the medical prescription of dapagliflozin and empagliflozin in hospitalized patients with HFpEF, identify factors associated with their use, and describe clinical outcomes during the study period. Methods: This was a retrospective observational study based on an institutional 2024 database linking echocardiography and NT-proBNP. Hospitalized patients with left ventricular ejection fraction ≥50% and a diagnosis consistent with HFpEF were included, totaling 141 patients. Resultados e Conclusions: The sample was predominantly female (60.3%), with a median age of 86 years, and 51.8% of admissions were classified as cardiovascular. SGLT2i were prescribed in 31.2% of patients, with dapagliflozin in 22.7% and empagliflozin in 8.5%. Their use was more frequent in cardiovascular admissions (42.5% versus 19.1%). Patients receiving SGLT2i were younger and had lower NT-proBNP levels. In the multivariable analysis, cardiovascular admission was associated with a higher likelihood of prescription (OR 3.25), whereas NT-proBNP was associated with a lower likelihood of use (OR 0.54). All-cause mortality was 27.7%, with a predominance of non-cardiovascular deaths (24.1%) over cardiovascular deaths (3.5%). NT-proBNP and recurrent urinary tract infection were associated with mortality, whereas SGLT2i use did not remain significant after adjustment. Adherence to SGLT2i prescription in hospitalized patients with HFpEF was partial and influenced by clinical characteristics and the context of hospitalization, highlighting the need for institutional strategies to optimize therapy and expand the incorporation of evidence into clinical practice.



17836

CARDIOVASCULAR RISK IN PEOPLE LIVING WITH HIV AGED 50 OR OLDER USING DIFFERENT ANTIRETROVIRAL THERAPIES

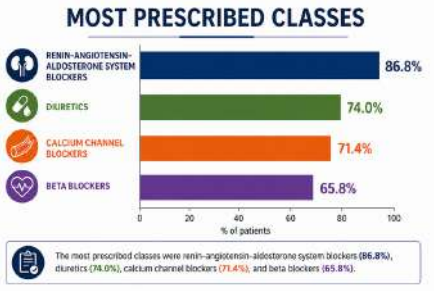
FELIPE COSTA DE SOUZA1; NATHAN CORRÊA ASSIS1; CHRISTIANNE BRETAS VIEIRA SCARAMELLO1;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL;

Introduction/Background: Advances in antiretroviral therapy (ART) have significantly increased the life expectancy of people living with HIV (PLWH). Nevertheless, this population remains at higher risk for non-AIDS-related comorbidities, particularly cardiovascular diseases (CVD). In addition, certain ART regimens may contribute to metabolic and cardiovascular risk. Objectives: This study aimed to evaluate cardiovascular risk in PLWH aged 50 or older according to the ART regimen. Methods: This cross-sectional study, approved by the institutional ethics committee, was conducted at a tertiary care hospital. A total of 111 participants were included, of whom 22 were HIV-negative, comprising the control group. PLWH (n=89) were divided into three groups according to ART (Integrase Inhibitors – II, n=31; Protease Inhibitors - PI, n=28; combined Integrase Inhibitors/Protease Inhibitors – II/PI, n=30). Groups were matched by age, sex, race, and years living with HIV. Individuals with prior CVD were excluded. Data collection occurred between July and December 2023 during outpatient visits that included clinical evaluation, anthropometric measurements, and blood sampling for laboratory analysis. ASCVD risk score was calculated. Normality was assessed using the Shapiro-Wilk test. Data are presented as median (IQR). Comparisons were performed using the Kruskal-Wallis test with Dunn's post hoc test and Bonferroni correction. Analyses were conducted in RStudio; p<0.05 was considered significant. Resultados e Conclusions: The results are summarized in Figure 1. The II/PI group presented a worse metabolic profile, with greater total cholesterol (TC) than the control and PI groups. In addition, higher LDL and creatinine (Cr) levels were observed in the II/PI group than in the PI group, and the ASCVD score was higher than in the control group. These data together suggest an elevated overall cardiovascular risk in the II/PI group. All three ART groups demonstrated a less favorable immunological profile than the control group, as evidenced by lower CD4 counts and reduced CD4/CD8 ratios. However, no differences were observed in HDL cholesterol, fasting glucose (Glu), or high-sensitivity C-reactive protein (CRP) compared to HIV-negative individuals. These findings indicate that ART regimens, especially if combined, may negatively impact cardiometabolic risk, highlighting the importance of individualized cardiovascular assessment and careful therapeutic selection in older PLWH.

17994

CLINICAL, BLOOD PRESSURE, AND PHARMACOTHERAPEUTIC CHARACTERIZATION OF A COHORT OF HYPERTENSIVE PATIENTS IN A TERTIARY CARDIOLOGY CENTER



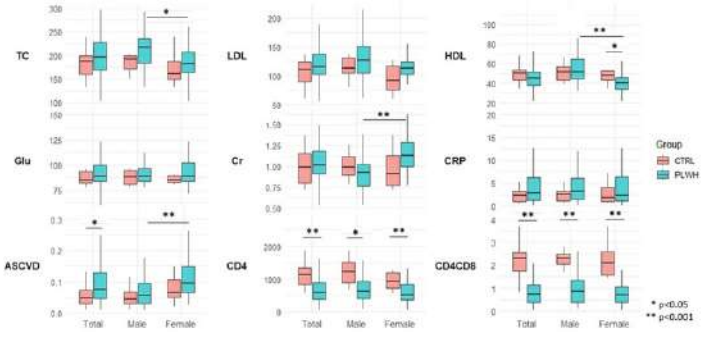
ROSANA LIMA GARCIA1; LUIZ APARECIDO BORTOLOTTO1; LUCIANO FERREIRA DRAGER1; HENO FERREIRA LOPES1; JOÃO VICENTE DA SILVEIRA1; FERNANDA CONSOLIM COLOMBO1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction/Background: Hypertension in tertiary care settings presents clinical complexity often associated with multimorbidity, polypharmacy, and difficult blood pressure control. Given its high prevalence in the public healthcare system, it is essential to characterize not only the epidemiological profile but also blood pressure control records and pharmacotherapeutic patterns, in order to support healthcare planning based on frequently updated data. Objectives: To describe the clinical, blood pressure, and pharmacotherapeutic profile of hypertensive patients treated in the Brazilian Public Health System (SUS) and followed at a tertiary cardiology center in the city of São Paulo. Methods: This is an observational, retrospective study including patients registered between January 2024 and December 2026, identified through the Medical and Hospital Information Unit database. Demographic, laboratory, and clinical variables were analyzed, including office blood pressure measurements and ambulatory blood pressure monitoring (ABPM), as well as prescription profiles and number of medications. Among patients with ABPM, the number of antihypertensive drug classes was evaluated according to blood pressure control, defined as systolic blood pressure ≤135 mmHg and diastolic blood pressure ≤85 mmHg during wakefulness. Resultados e Conclusions: In the hypertension outpatient clinic of a tertiary hospital, 3,745 patients were analyzed, with a predominance of females (61.1%) and individuals aged ≥60 years (69.0%). A high burden of comorbidities was observed, with 45.0% presenting an estimated glomerular filtration rate ≤60 mL/min/1.73 m². Mean office blood pressure was 139.9±24.7/83.8±11.7 mmHg, and 24-hour ABPM was 134.4±19.1/77.2±13.5 mmHg. Regarding pharmacotherapy, the mean number of tablets was 10.4±4.0, highlighting the relevance of polypharmacy. The most prescribed drug classes were renin–angiotensin–aldosterone system blockers (86.8%), diuretics (74.0%), calcium channel blockers (71.4%), and beta-blockers (65.8%). Among patients with ABPM (n=1,455), 50.8% achieved blood pressure control. A higher frequency of ≥5 antihypertensive classes was observed among uncontrolled patients (58.4% vs. 33.7%), suggesting greater therapeutic complexity associated with treatment resistance. These findings characterize a high-risk population with substantial polypharmacy and suboptimal blood pressure control. They highlight the need for structured management and better clinical data to support decisions and health policy in tertiary cardiology care.

Distribution of the number of tablets per patient among hypertensive patients treated in the SUS at a tertiary cardiology center

Variable	Result
Number of patients (n)	3745
Mean ± standard deviation	10.4 ± 4.0
Median	10
Minimum - maximum	3 - 35



17717

EVALUATION OF SEX-RELATED CARDIOVASCULAR RISK IN PEOPLE LIVING WITH HIV AGED 50 OR OLDER

FELIPE COSTA DE SOUZA1; NATHAN CORRÊA ASSIS1; CHRISTIANNE BRETAS VIEIRA SCARAMELLO1;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL;

Introduction/Background: People living with HIV (PLWH) are at higher risk for cardiovascular disease (CVD) than HIV-negative individuals. Although sex differences in cardiovascular risk are well-established in the general population, their influence in PLWH remains poorly understood. Elucidating these differences is crucial for guiding sex-specific clinical monitoring and preventive strategies. Objectives: This study aimed to evaluate sex-specific cardiovascular risk in PLWH aged 50 or older using antiretroviral therapy. Methods: This cross-sectional study, approved by the institutional ethics committee, was conducted at a tertiary care hospital. A total of 136 participants, 49% women and 51% men, aged 50 or older and without prior CVD, were included, being 107 PLWH and 29 controls (CTRL). Data were collected from July to December 2023 during clinic visits, followed by blood sampling. Anthropometric and laboratory parameters were assessed. ASCVD cardiovascular risk score was calculated. Normality was assessed using the Shapiro–Wilk test. Data are presented as median (IQR), and group comparisons were performed using the Wilcoxon test in R Studio. Resultados e Conclusions: The results are summarized in Figure 1. Compared with controls, women living with HIV had lower HDL cholesterol levels (40.4 [12.2] vs 47.7 [9.1]; p = 0.03). Overall, individuals living with HIV exhibited a higher ASCVD risk than controls (0.075 [0.082] vs 0.049 [0.044]; p = 0.03). Within the PLWH group, men had higher total cholesterol (TC) (217.0 [53.0] vs 182.0 [70.0]; p = 0.01) and HDL cholesterol (51.3 [20.2] vs 40.4 [12.2] ; p < 0.001) than women. In contrast, women showed higher creatinine levels (Cr) and ASCVD score than men (1.13 [0.29] vs 0.92 [0.26]; p < 0.001; and 0.096 [0.082] vs 0.055 [0.066]; p < 0.001, respectively). These findings indicate sex-dependent outcomes, with a potentially greater burden of renal impairment and overall cardiovascular risk among women living with HIV. Additionally, PLWH had lower CD4 counts (598 [500] vs 1140 [506] ; p < 0.001) and reduced CD4/CD8 ratios (0.74 [0.75] vs 2.30 [0.79]; p < 0.001), suggesting that increased cardiovascular risk may be partly related to persistent immune dysfunction. No differences were observed in LDL cholesterol, fasting glucose (Glu), or high-sensitivity C-reactive protein (CRP). More studies are needed to better understand sex differences in PLWH and to set strategies to improve their immune, metabolic, and cardiovascular health.

WORKSHOPS ON THROMBOLYTIC MANAGEMENT IN THE ACUTE MYOCARDIAL INFARCTION CARE PATHWAY: INTEGRATION OF CLINICAL PHARMACY AND OPTIMIZATION OF CARE PROCESSES IN THE PUBLIC HEALTH NETWORK

ROSANA LIMA GARCIA1; FLÁVIA MARIA PORTO TERZIAN2; ELAINE BUCH AMARAL3;

(1) SECRETARIA MUNCIPAL DE SAÚDE DE SÃO PAULO - SAO PAULO - SP - BRASIL; (2) SECRETARIA MUNICIPAL DA SAÚDE DE SÃO PAULO - SAO PAULO - SP - BRASIL; (3) HOSPITAL MUNICIPAL DR. MOYSES DEUTSCH - SÃO PAULO - SP - BRASIL;

Introduction/Background: ST-segment elevation myocardial infarction (STEMI) is a leading cause of cardiovascular mortality in Brazil. As a time-dependent condition, reducing door-to-ECG and door-to-needle times is critical to improving outcomes. Public healthcare systems face persistent challenges in implementing STEMI care pathways, particularly in settings where tenecteplase is used without immediate access to percutaneous coronary intervention. Logistical factors, including drug storage and dispensing, as well as the integration of clinical pharmacy services, may significantly impact door-to-needle times. Educational workshops were developed to address these gaps. Objectives: To report the implementation of workshops on thrombolytic management in STEMI, focusing on clinical pharmacy integration and standardization of care processes. Methods: Institutional descriptive experience report conducted in accordance with CNS Resolution No. 510/2016. Seven in-person workshops (November 2024–October 2025), each lasting four hours, were delivered to multidisciplinary professionals from emergency care networks. Participating units designated representatives from medicine, nursing, management, and pharmacy. Activities included interactive lectures, case-based discussions, performance indicator analysis, sharing of best practices, and identification of critical issues in thrombolytic storage and dispensing processes. The final session incorporated simulation-based training of the care pathway. Resultados e Conclusions: Approximately 500 professionals from 72 thrombolysis-capable units participated. Heterogeneity in storage and dispensing processes and gaps in integration between care teams and pharmacy services were identified, potentially impacting door-to-needle times. Key outcomes included standardization of STEMI kits, establishment of structured communication workflows, and increased involvement of clinical pharmacy in real-time assessment of thrombolysis indications and contraindications. The workshops proved to be an effective continuing education strategy, contributing to process standardization, strengthening clinical pharmacy practice, and potentially reducing treatment delays.

COMPETING PRIORITIES IN ACUTE ISCHEMIA: IMPACT OF CONCOMITANT CARDIAC DYSFUNCTION ON OUTCOMES AFTER MECHANICAL THROMBECTOMY

ENRICO PORTES VIEIRA LEITE URBAN1; GIOVANA DOMICIANO VARNIER1; FELIPE MESQUITA MOREIRA MOTA RODRIGUES1; DIEGO FARIA COLA1;

(1) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL;

Introduction/Background: Acute ischemic stroke (AIS) is a leading cause of global disability. While mechanical thrombectomy (MT) is the gold standard for large vessel occlusion, its success depends on rigorous perioperative hemodynamic management. Patients with cardiac dysfunction, such as atrial fibrillation and heart failure, face unique challenges where high blood pressure (BP) may cause reperfusion injury and low BP can exacerbate ischemia. Current guidelines lack specific targets for this group, creating a scenario of competing priorities between cerebral perfusion and myocardial stress. Objectives: To evaluate the association between perioperative BP parameters and clinical outcomes in patients with cardiac dysfunction undergoing MT. Methods: Following PRISMA 2020 guidelines, this systematic review and meta-analysis (PROSPERO CRD420261360557) searched PubMed, Embase, and Scopus for studies published between 2015 and 2025. It included adults with AIS and cardiac dysfunction treated with MT. A random-effects model was used to estimate the pooled rate of favorable functional outcomes (mRS 0–2 at 90 days). Resultados e Conclusions: RESULTS: Nineteen studies were analyzed. The pooled rate of favorable outcome was 48% (95% CI: 39%–57%), with high heterogeneity (I^2=99.5%). Atrial fibrillation, heart failure, and reduced ejection fraction were consistently linked to poorer recovery and higher mortality. High BP variability and nocturnal systolic BP were significant predictors of neurological deterioration and “futile recanalization,” where technical success fails to yield clinical benefit. CONCLUSION: Cardiac dysfunction and hemodynamic instability are critical independent prognostic determinants. Clinical success is heavily modulated by cardiovascular reserve; technical recanalization alone does not ensure recovery. These findings support a shift toward personalized, physiology-guided targets. Multidisciplinary integration is essential, and randomized trials are needed to define specific protocols for this vulnerable subgroup.

DURABILITY OF PROSTHETIC VALVES IN TRANSCATHETER AORTIC VALVE IMPLANTATION (TAVI) VERSUS SURGICAL AORTIC VALVE REPLACEMENT (SAVR) IN PATIENTS UNDER 75 YEARS: A SYSTEMATIC REVIEW

GABRIEL RIBEIRO GONÇALVES ACCIOLY SOUZA1; YURI FELIX BRANDÃO1; ISADORA EGYPTO MACHADO1; GIOVANA PEREIRA GURGEL1; JAMES NOBRE DE SENA1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introduction/Background: Aortic stenosis is one of the most prevalent valvular heart diseases and is associated with high morbidity and mortality when untreated. Surgical aortic valve replacement (SAVR) has long been the standard treatment, with well-established long-term outcomes. Transcatheter aortic valve implantation (TAVI), initially indicated for high-risk patients, has progressively expanded to lower-risk and younger populations. However, concerns remain regarding the long-term durability of transcatheter prostheses. Objectives: To evaluate prosthetic valve durability in patients under 75 years with aortic stenosis, comparing outcomes between TAVI and SAVR. Methods: We conducted a systematic review in accordance with PRISMA guidelines and registered it in PROSPERO (CRD420261363624). A literature search was performed in PubMed, Web of Science, and Embase databases, without time restriction and limited to English-language studies. The research question was structured according to the PICO framework, including patients under 75 years with aortic stenosis (P), undergoing TAVI (I), compared with SAVR (C), and assessing durability outcomes such as structural valve deterioration, bioprosthetic valve failure, reintervention, and hemodynamic performance (O). Eligible studies directly compared TAVI and SAVR in this population. Studies without a comparator group, without durability outcomes, involving patients ≥75 years without subgroup analysis, or non-original designs were excluded. Resultados e Conclusions: A total of 898 records were identified, with 227 duplicates removed. After screening 671 titles and abstracts, 33 studies were assessed for full-text eligibility, and 9 were included. The studies showed similar outcomes between TAVI and SAVR in the short and mid-term, with low rates of structural valve deterioration and reintervention. TAVI demonstrated superior hemodynamic performance, with lower transvalvular gradients. No significant differences were observed in mortality or neurological events up to 5 years. However, long-term data, particularly in younger populations, suggest higher mortality associated with TAVI. Additionally, TAVI was associated with higher rates of permanent pacemaker implantation and paravalvular regurgitation. Therefore, although TAVI represents an effective and less invasive alternative, its use in patients with longer life expectancy should be carefully considered, and further long-term studies are needed.

PERICARDIOCENTESIS IN THE BRAZILIAN PUBLIC HEALTH SYSTEM: A DECADE OF HOSPITALIZATIONS AND MORTALITY TRENDS IN THE SOUTHEAST REGION (2015-2024)

LUIZA MORAIS DINIZ1; LÍVIA LARA MARQUES2; LÍVIA KOBARG AKERMAN3; SELENA MENDES BRANDÃO4; LOUISE MOTA DA ROCHA SADY5; LUCAS FERNANDES ANANIAS6; TUANY CAROLINE BERNARDI6;

(1) UFSJ - UNIVERSIDADE FEDERAL DE SÃO JOÃO DEL-REI - SÃO JOÃO DEL-REI - MG - BRASIL; (2) PONTIFÍCIA UNIVERSIDADE CATÓLICA DE MINAS GERAIS, CAMPUS CONTAGEM - CONTAGEM - MG - BRASIL; (3) UNIARP - UNIVERSIDADE DO ALTO VALE DO RIO DO PEIXE - CAÇADOR - SC - BRASIL; (4) UNIVERSIDADE DE UBERABA - UBERABA - MG - BRASIL; (5) CENTRO UNIVERSITÁRIO FACID WYDEN - TERESINA - PI - BRASIL; (6) CENTRO EDUCACIONAL DINIZ - CAMPINA GRANDE - PB - BRASIL;

Introduction/Background: Pericardial effusion can cause hemodynamic instability and cardiac tamponade, making pericardiocentesis an essential diagnostic and therapeutic procedure. Despite its clinical relevance, Brazilian population data on hospitalizations and mortality related to this procedure in the SUS remain scarce, as most evidence derives from single-center studies. Objectives: To analyze temporal trends of hospitalizations and hospital mortality due to pericardiocentesis in the SUS, Southeast Region of Brazil, from 2015 to 2024. Methods: This observational, ecological, and retrospective study used secondary data from the SUS Hospital Information System (SIH/SUS) via DATASUS. Hospitalizations with procedure code 0406010773 in the Southeast region (SP, MG, RJ, ES) were analyzed. Variables included hospitalizations, deaths, year, and federative unit. Data were tabulated and exported for descriptive analysis of temporal trends, mortality rates, and annual percentage variation. Using public anonymized data, the study is exempt from Ethics Committee review (Resolution 510/2016). Resultados e Conclusions: Between 2015 and 2024, 2,992 hospitalizations for pericardiocentesis were recorded in the SUS Southeast Region, with 498 deaths and an average hospital lethality of 16.8%. A trend of progressive increase in hospitalizations was observed, rising from 213 cases in 2015 to 454 in 2024, indicating a possible growth in demand or access to this procedure, but also an increase in the incidence or severity of underlying conditions. São Paulo concentrated the largest share [1,531 hospitalizations (51.16%) and 237 deaths (54.81%)]; in contrast, Espírito Santo presented the lowest absolute volume [111 hospitalizations (3.70%) and 13 deaths (2.61%)]. This pattern highlights a strong concentration of the procedure in states with higher population density and greater installed capacity. Hospital lethality varied from 22.06% in 2015 to 12.33% in 2018, remaining high despite the increase in the number of procedures, indicating that it remains a marker for critically ill patients, in an emergency context. From the pandemic period onwards, a growth in hospitalizations was observed without a reduction in mortality, suggesting greater severity of cases, possible delays in seeking care, or systemic complications. Therefore, the increase in hospitalizations for pericardiocentesis in the analyzed period is consistent with the maintenance of high lethality and evidences that the procedure remains linked to severe and high-complexity conditions.

PREOPERATIVE ANATOMIC AND IMAGING PREDICTORS OF DURABLE PULMONARY VALVE–SPARING REPAIR IN TETRALOGY OF FALLOT

ANTONIO JHONATA ALVES LIMA1; JAMES NOBRE DE SENA2; MARIA CLARA AGUIAR TOMAZ3; YURI FELIX BRANDÃO4; NEWTON DIÓGENES PINHEIRO NETO4; AILTON CÉSAR DE ARAÚJO FILHO5; ROBERTO VICTOR PAIVA CAMURÇA6; EMILY BITTENCOURT DE SOUZA MARTINS6; ANNA LETÍCIA ALVES BOMFIM6; BENJAMIM ANTÔNIO PINHEIRO VIEIRA6;

(1) UNIVERSIDADE ESTADUAL DO CEARÁ - QUIXERAMOBIM - CE - BRASIL; (2) UNIVERSIDADE ESTADUAL DO CEARÁ - FORTALEZA - CE - BRASIL; (3) UNICHRISTUS - FORTALEZA - CE - BRASIL; (4) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (5) UECE - QUIXERAMOBIM - CE - BRASIL; (6) UECE - FORTALEZA - CE - BRASIL;

Introduction/Background: In Tetralogy of Fallot (TOF), the operative challenge is identifying which anatomy supports valve-sparing repair (VSR) without causing residual right ventricular outflow tract (RVOT) obstruction. While transannular patch (TAP) relieves obstruction, it leads to chronic pulmonary insufficiency and right ventricular volume overload. VSR offers a physiologic repair, but its feasibility and long-term durability require clearer definition. Objectives: To evaluate preoperative anatomic and imaging predictors for VSR in TOF, focusing on factors influencing the selection between VSR and TAP, the association between pulmonary annulus z-scores and surgical decision-making, and pooled reintervention rates. Methods: Systematic review and meta-analysis of predictors for VSR selection and durability. Outcomes included procedural selection, moderate/severe pulmonary regurgitation, residual RVOT gradient, reintervention, pulmonary valve replacement, and mortality. Risk of bias was assessed via QUIPS. Quantitative synthesis used pooled mean difference (MD) in preoperative z-scores and pooled reintervention rates. Resultados e Conclusions: Thirty cohorts were identified (21 for selection; 19 for durability). In the primary selection analysis (7 studies; 1,044 patients), VSR patients had significantly larger preoperative pulmonary annulus z-scores than TAP/non-VSR (MD 1.79; 95% CI, 1.38–2.20; I^2=83.0%), confirming annular size as a primary discriminator. However, high heterogeneity suggests no universal z-score cutoff. Qualitative synthesis associated successful VSR with favorable valve morphology, less main pulmonary artery hypoplasia, and lower residual gradients. For durability (6 studies; 569 patients), the pooled reintervention rate after VSR was 6.38% (95% CI, 2.66%–14.54%; I^2=75.3%). An expanded analysis (629 patients) showed a 7.32% rate (95% CI, 3.53%–14.57%). Findings indicate VSR has acceptable mid-term durability in selected patients. Late failure was driven by the interaction of annular dimensions, leaflet quality, RVOT geometry, and the adequacy of the index relief.Preoperative pulmonary annular z-score is a strong but incomplete predictor of VSR. Durable preservation depends on a broad anatomic profile beyond annular size. Data support patient-specific strategies to maximize preservation while minimizing late insufficiency and reintervention.

ANOMALOUS LEFT CORONARY ARTERY ORIGIN (ALCAPA): A DESCRIPTIVE STUDY OF CASES MANAGED OVER THE LAST 15 YEARS AT A QUATERNARY CARE CENTER

VÍTOR DORIA RICARDO1; JÉSSICA FONSECA CAMPOS DE OLIVEIRA1; MAGNO FELIPE1; FELIPE YU MATSUSHITA1; DEBORA DE OLIVEIRA ANTUNES ROCHA1; ISABELA ATTEN COLARES1; PAULA VIEIRA DE VICENZI GAIOLLA1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction/Background: Anomalous Left Coronary Artery from the Pulmonary Artery (ALCAPA) is a rare congenital heart disease (1:300,000 live births) characterized by the anomalous connection of the left coronary artery (LCA) to the pulmonary artery, leading to severe myocardial ischemia and high mortality if not treated early. Clinical presentation ranges from heart failure in infancy to asymptomatic cases in adulthood when sufficient collateral circulation is present. Diagnosis is established through echocardiography and cardiac computed tomography angiography. Surgical correction, involving reimplantation of the LCA into the aorta, is essential to reduce complications such as mitral regurgitation, ventricular dysfunction, arrhythmias, and sudden cardiac death. Postoperative mortality in some centers is reported to be 14%, with risk factors including left ventricular dysfunction and older age at the time of surgery. In the long term, survival rates exceed 98% at 20 years. Objectives: To evaluate the clinical outcomes of patients diagnosed with ALCAPA over the last 15 years at a quaternary referral center. Methods: This is a descriptive study based on epidemiological data and clinical outcomes (ventricular dysfunction, heart transplantation, and death), collected from medical records in the database of a quaternary hospital, including patients diagnosed with ALCAPA between 2010 and 2024. Resultados e Conclusions: The initial sample included 489 patients. After excluding incomplete records, duplicates, and cases with incorrect ICD coding, 71 cases remained. Of these, 56.3% were female, and most had no associated comorbidities. Two patients did not undergo surgery; among those operated on, 36.2% also underwent mitral valve repair. Mean age at surgery was 3 years and 3 months, with a median of 6 months. Left ventricular dysfunction was found in 38% of patients, with functional recovery in 59.2% of cases. Follow-up was lost in 26 cases; among those followed, 1 patient required heart transplantation and 4 died—3 in the first year of life and 1 at 59 years old, one year after diagnosis without surgery. These findings reinforce the importance of early diagnosis of ALCAPA. Despite its severity, most surgically treated patients had favorable outcomes, including ventricular function recovery. Mortality was 5.7%, mostly early, consistent with the literature. Loss to follow-up may have affected long-term mortality analysis.

Variable	Absolute number (n)	Percentage (%)
Sex		
Female	40	56.3
Male	31	43.7
Surgery		
Not operated	2	2.8
Repair without mitral valve repair	25	35.2
Repair with mitral valve repair	44	62.0
Age at surgical correction		
Not operated	2	2.8
Less than 6 months	28	39.4
6 months to 1 year	20	28.2
>1 year to 10 years	14	20.0
>10 years to 20 years	3	4.2
>20 Years	4	5.4

DIAGNOSTIC VALUE OF DUCTUS ARTERIOSUS PULSATILITY INDEX IN FETAL DUCTAL CONSTRICTION: A SYSTEMATIC REVIEW

FERNANDO JOSÉ PEREZ DA SILVA GRAÇA1; ARTUR DIAS PEREZ GRAÇA2; MARIA CLARA CHAGAS NEGRÃO DE ALMEIDA BARROS2; ISABELLE MORAES DE ARAÚJO3;

(1) UNIVERSIDADE FEDERAL DE RORAIMA - BOA VISTA - RR - BRASIL; (2) UNIVERSIDADE LUSÍADA - SANTOS - SP - BRASIL; (3) FACULDADES CATHEDRAL - BOA VISTA - RR - BRASIL;

Introduction/Background: Fetal ductal constriction is a clinically relevant condition associated with increased right ventricular afterload, altered fetal hemodynamics, and adverse perinatal outcomes. The Doppler-derived pulsatility index (PI) of the ductus arteriosus is widely used as a surrogate marker of ductal flow dynamics; however, its diagnostic performance as an isolated parameter remains uncertain. Objectives: To evaluate the diagnostic performance and clinical reliability of the ductus arteriosus pulsatility index as an isolated parameter for detecting fetal ductal constriction. Methods: A systematic review was conducted according to PRISMA guidelines and registered in PROSPERO 2026 CRD420261380023. A comprehensive search was performed in PubMed and Embase, complemented by manual reference screening. Eligible studies included original clinical investigations assessing fetal ductal constriction with Doppler echocardiographic evaluation of the pulsatility index. Data extraction included study design, population characteristics, diagnostic criteria, Doppler parameters, and clinical outcomes. Due to methodological heterogeneity, a qualitative synthesis was performed. Resultados e Conclusions: RESULTS Fetal ductal constriction was consistently associated with increased systolic and diastolic ductal flow velocities and reduced pulsatility index values. However, considerable overlap between normal and pathological PI ranges was observed. Pharmacological and dietary exposures, including non-steroidal anti-inflammatory drugs and polyphenol-rich substances, demonstrated a direct and reversible effect on PI values, confirming its sensitivity to ductal tone. PI variability was influenced by physiological and hemodynamic factors such as fetal heart rate, loading conditions, and right ventricular performance. Studies incorporating additional echocardiographic parameters, including ductal flow patterns and ventricular remodeling, showed improved diagnostic accuracy compared to isolated PI assessment. CONCLUSION The pulsatility index of the ductus arteriosus is a sensitive marker of fetal ductal hemodynamics but lacks sufficient specificity when used in isolation. A comprehensive echocardiographic approach integrating functional and structural parameters is essential to improve diagnostic accuracy and guide clinical decision-making.

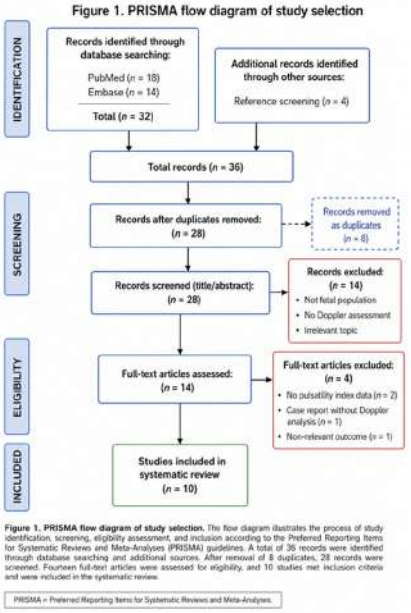

Figure 1. PRISMA flow diagram of study selection. The flow diagram illustrates the process of study identification, screening, eligibility assessment, and inclusion according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. A total of 36 records were identified through database searching and additional sources. After removal of 8 duplicates, 28 records were screened. Fourteen full-text articles were assessed for eligibility, and 10 studies met inclusion criteria and were included in the systematic review.

PRISMA = Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

ECHOCARDIOGRAPHIC ASSESSMENT OF HEMODYNAMIC REPERCUSSION IN VENTRICULAR SEPTAL DEFECT: THE ROLE OF VSD/LVD RATIO AND QUANTITATIVE DOPPLER.

ISABELLE MORAES DE ARAÚJO1; ANA CLARA MELO DA COSTA E SILVA2; BRENDA BASILIO BOAVENTURA2; CICERO MICHAEL OLIVEIRA DE SOUSA1; EDUARDA VITÓRIA ARAÚJO EMÍDIO2; FERNANDO J0SÉ PEREZ DA SILVA GRAÇA2; GUILHERME WEBBER PAULA1; JAQUES SONNTAG1; JOÃO VICTOR PEREIRA DA COSTA2; MARVIN FLORÊNCIO SARUBBY DO NASCIMENTO2; RICARDO AUGUSTO KONG ORMENO1; WESLLEY LOPES SOARES COSTA2;

(1) FACULDADES CATHEDRAL, BOA VISTA, RR, BRASIL - BOA VISTA - RR - BRASIL; (2) UNIVERSIDADE FEDERAL DE RORAIMA - BOA VISTA - RR - BRASIL;

Introduction/Background: Ventricular septal defect (VSD) is the most prevalent congenital heart disease and is frequently associated with pulmonary overcirculation and left ventricular (LV) volume overload. The definition of hemodynamic significance and the indication for intervention rely on complex echocardiographic and hemodynamic parameters, including the pulmonary-to-systemic flow ratio (Qp/Qs). In this context, simplified echocardiographic indices, such as the ratio between VSD diameter and left ventricular diameter (VSD/LVD), have been proposed as adjunctive tools for functional stratification. Objectives: To evaluate the applicability of echocardiographic parameters in the stratification of hemodynamic repercussion in isolated VSD, with emphasis on the VSD/LVD ratio and its association with Qp/Qs and cardiac chamber dilation. Methods: This systematic review was conducted according to PRISMA recommendations. Searches were performed in PubMed, LILACS, and SciELO databases, complemented by manual reference screening. Original clinical studies involving patients with isolated VSD undergoing echocardiographic assessment of hemodynamic repercussion were included. Evaluated parameters comprised ventricular structural measurements, quantitative Doppler methods, and proportional indices relating septal defect size to cardiac dimensions. Extracted data included population characteristics, echocardiographic findings, and markers of functional repercussion. Resultados e Conclusions: Quantitative Doppler methods demonstrated significant correlation with invasive pulmonary-to-systemic shunt measurements (Qp/Qs), with correlation coefficients ranging from r≈0.73 to r≈0.82, supporting their utility in hemodynamic stratification of VSD. Structural left ventricular measurements showed adequate reproducibility and interobserver reliability, reinforcing their role as indirect markers of volume overload. In addition, the VSD/LVD ratio demonstrated consistent association with traditional parameters of hemodynamic repercussion, suggesting potential applicability as a simplified echocardiographic index in functional assessment of VSD. Echocardiographic parameters demonstrated relevant association with the hemodynamic repercussion of VSD, particularly when integrated with structural and quantitative Doppler assessment. The VSD/LVD ratio showed potential as a complementary tool for functional stratification of isolated VSD, although prospective and standardized studies are still required for definitive validation of its clinical applicability.

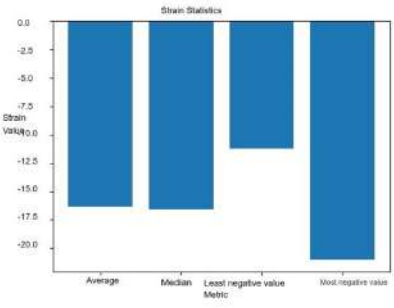
LONG-TERM ASSESSMENT OF MYOCARDIAL DEFORMATION (STRAIN) IN CHILDREN AND ADOLESCENTS WITH PEDIATRIC MULTISYSTEMIC INFLAMMATORY SYNDROME ASSOCIATED WITH COVID-19

NATHALIE JEANNE MAGIOLI BRAVO-VALENZUELA1; THIAGO T PANIZZI1; FLAVIO ROBERTO SZTAJANBOK1; ADRIANA FONSECA1; FERNANDA MARIA CORREIA LEMOS1; PEDRO LARANJEIRA DORNELES CORRÊA1;



(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Introduction/Background—In 2020, the World Health Organization (WHO) declared COVID-19 a pandemic. In children, systemic symptoms were observed to emerge approximately 2 to 4 weeks after infection, a clinical condition termed Pediatric Multisystem Inflammatory Syndrome (P-MIS), or Multisystem Inflammatory Syndrome in Children (MIS-C). In this context, cardiovascular repercussions were observed. Objectives: Objectives:To analyze the assessment of myocardial deformation using Global Longitudinal Strain (GLS) of the left ventricle (LV) one year after diagnosis to detect late subclinical ventricular dysfunction. To compare Global Longitudinal Strain (GLS) values of the left ventricle (LV) in vaccinated and unvaccinated patients, those with vaccinated and unvaccinated parents, and those with Kawasaki and non-Kawasaki phenotypes. Methods: Methodology: Prospective, observational, and longitudinal study in patients with MIS-C. Clinical follow-up was conducted for up to 3 years after diagnosis. Patients up to 18 years of age were included, according to WHO criteria, with informed consent. The primary focus of the echocardiographic analysis of LV GSL (Figure 1) was to detect late subclinical ventricular dysfunction. LVEF values between -18% and -22% were considered normal; borderline values: -16% to -17,9%; and abnormal values: less negative than -16% (severe dysfunction: less negative than -8%). Resultados e Conclusions: Results: A total of 38 patients (71.1% male) were analyzed, with a mean age at diagnosis of 4.29 years and an interquartile range (IQR) of 4.6. Of the total, SLG was assessed in 21 patients, revealing a mean of -16.35% and a median SLG of -16.6%, ranging from -11.2% to -21% (Figure 1). Of the total SLG sample, 40.9% had reduced SLG. Table 1 illustrates the results. No statistically significant difference was observed between SLG values in patients with and without the Kawasaki phenotype (p = 0.52). When comparing SLG values between patients with vaccinated and unvaccinated parents and between vaccinated and unvaccinated patients, no significant difference was found, with p-values of 0.68 and 0.83, respectively. Conclusions: Approximately 40% of the study sample presented reduced SLG values during long-term follow-up, indicating the presence of subclinical ventricular dysfunction, even after resolution of the acute inflammatory phase of MIS-C. The findings suggest that SLG is an important tool in late follow-up for MIS-C.

Table 1. Echocardiographic findings up to 3 years of follow-up:

Echocardiographic findings (ECHO)	Up to 3 years of follow-up
LVEF ≤ 55%: n, (%)	0/22 (0)
LVEF: Mean % (±SD)	-16.35 ± 2.56
SLGVE: Median %	-16.6
Reduced: n, (%).....	9/21 (40.9)

Values presented as n and (%) for categorical variables
n – number of individuals; SD – standard deviation;
LVEF – left ventricular ejection fraction

NEURODEVELOPMENTAL OUTCOMES AND COGNITIVE-MOTOR SCORES AFTER EARLY CARDIAC SURGERY IN COMPLEX CONGENITAL HEART DISEASE: A SYSTEMATIC REVIEW

ANA FLÁVIA VIANNA BERNARDI1; LUIZ GUILHERME STAIBANO GRANJA1; CLAUDIO EDUARDO LUIZ GRANJA JUNIOR2;

(1) FACULDADE DE MEDICINA DE MARILIA - MARÍLIA - SP - BRASIL; (2) UNICAMP - CAMPINAS - MT - BRASIL;

Introduction/Background: Improved survival among children with complex congenital heart disease (CHD) has highlighted neurodevelopmental outcomes as an important prognostic factor. These children present cerebral vulnerability from the neonatal period, including delayed brain maturation, reduced brain growth, and increased susceptibility to white matter injury associated with fetal hemodynamic alterations, chronic hypoxia, and perioperative factors. Consequently, motor, cognitive, and behavioral deficits may emerge early and persist throughout development. Objectives: To evaluate neurodevelopmental outcomes in children with complex CHD undergoing primary cardiac surgery within the first nine weeks of life, emphasizing motor (Bayley PDI), cognitive (Bayley MDI), and global intelligence (Wechsler scales) scores. Methods: A systematic review was conducted using the PubMed database, including studies published within the last 10 years following PRISMA guidelines. Prospective cohort studies and randomized clinical trials assessing neurodevelopmental outcomes after neonatal cardiac surgery in patients with complex CHD were included. The descriptors “Congenital Heart Disease,” “Neurodevelopmental Outcomes,” and “Cardiac Surgery” were used. Risk of bias was assessed using the ROB 2.0 and ROBINS-I tools, and evidence quality was evaluated using GRADE. Resultados e Conclusions: The included studies demonstrated significant neurodevelopmental delay during the first years of life, particularly in motor domains. PDI and MDI scores were approximately one standard deviation below age-expected population values. Children with single-ventricle physiology showed worse motor and cognitive outcomes compared with those with biventricular circulation. During school age and adolescence, cognitive deficits showed relative attenuation, although IQ scores remained slightly below population averages. The quality of evidence was considered low for infant outcomes and low to moderate for assessments at older ages due to methodological heterogeneity and the limited number of eligible studies. Overall, children with complex CHD undergoing early cardiac surgery present significant neurodevelopmental delay during the first years of life, especially in motor domains. Although some deficits show relative attenuation over time, differences compared with the general population persist, particularly among patients with single-ventricle physiology. Study heterogeneity reinforces the need for standardized longitudinal follow-up and neurodevelopmental monitoring.

PRENATAL DIAGNOSIS, SURGICAL TIMING, AND MORTALITY IN CRITICAL CONGENITAL HEART DISEASES: SYSTEMATIC REVIEW WITH SUBGROUP ANALYSIS

LETICIA ZDANSKI1; ISADORA MEDEIROS DE ALMEIDA2; LUCAS MARIANO PINHEIRO2; RAPHAEL BOESCHE GUIMARAES3;

(1) FEEVALE - NOVO HAMBURGO - RS - BRASIL; (2) PUCRS - PORTO ALEGRE - RS - BRASIL; (3) ICFUC - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Critical congenital heart diseases, especially single-ventricle anomalies and hypoplastic left heart syndrome, present the highest lethality rates among cardiac malformations. The standard management requires complex surgical palliation in multiple stages. However, the true clinical impact of the accuracy of fetal screening, the optimization of shunt techniques in the first stage, and the definition of the exact timing for surgical advancement remain widely debated challenges for improving survival. Objectives: To evaluate the accuracy of prenatal echocardiographic diagnosis and to analyze the impact of the surgical timing of the second stage of palliation, the shunt technique in the Norwood procedure, and predictors of extreme clinical severity on patient mortality and morbidity. Methods: A systematic review was conducted with searches in the PubMed, Embase, Scopus, and Web of Science databases. Six studies were included, totaling 5,371 patients with critical congenital heart diseases (predominantly single ventricle and hypoplastic left heart syndrome), stratified by treatment phase: prenatal screening, hospitalization for the Norwood procedure, and the interstage/second palliation period. Study selection and data extraction were performed by independent reviewers. The accuracy of fetal echocardiography, the impact of shunt type (RVPAS vs. MBTS), the surgical timing of the second stage, and clinical outcomes in severity subgroups, including ECMO indication, were analyzed. Methodological quality was assessed using the Newcastle-Ottawa Scale. Statistical analysis was conducted using RStudio software. Resultados e Conclusions: Fetal echocardiography showed high accuracy in screening for critical congenital heart diseases (sensitivity 92%; specificity 99.6%). Early progression to the second stage (<140 days) was associated with worse outcomes, doubling the risk of prolonged mechanical ventilation (OR 2.28; 95% CI: 1.07–4.84). Overall first-year mortality was 29.8% (95% CI: 26.1–33.8), concentrated during Norwood hospitalization (16.0%) and the interstage period (11.7%). RVPAS was a protective factor (OR 0.63), while non-elective surgery (OR 3.81) and prior ECMO (OR 7.59) were major predictors of mortality. Conclusion: Despite high diagnostic accuracy, mortality remains elevated in early phases. Early second-stage surgery does not improve survival and increases morbidity, requiring careful timing, risk stratification, and clinical optimization.

RISK FACTORS FOR ACUTE KIDNEY INJURY IN INFANTS UNDERGOING CARDIAC SURGERY: THE ROLE OF HEMODYNAMIC AND METABOLIC PARAMETERS

MARCELA TORRES DE MELO CAVALCANTE1; ANA BEATRIZ RIBEIRO FALCÃO1; ANA KAROLINE LOPES COELHO1; ANNA SAYURI ALBUQUERQUE SAWAKI1; FLORÊNCIA MONTENEGRO CAMPOS1; GRAZIELA MARTINS FÉRRER1; ISABELA FROHWEIN DE ALENCAR1; ISABELLE MOURÃO ALVES1; MARCELA MENDES DA PONTE1; REBECA COUTINHO QUEIROZ1; CANDICE TORRES DE MELO CAVALCANTE1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introduction/Background: Acute kidney injury (AKI) is a frequent complication after pediatric cardiac surgery and is associated with increased morbidity and worse clinical outcomes. Its development reflects a complex interplay between baseline vulnerability and postoperative hemodynamic instability. Objectives: To identify clinical and perioperative factors associated with AKI and to evaluate the role of lactate levels and vasoactive-inotropic score (VIS) in its early prediction. Methods: This retrospective cohort study included 1,264 infants (<2 years) undergoing cardiac surgery at a tertiary referral center (2018–2024). Patients were stratified by AKI occurrence. Demographic, preoperative, and postoperative variables were analyzed. Continuous variables were expressed as mean ± SD or median (IQR 25–75) and compared using Student's t-test or Mann–Whitney U test; categorical variables were compared using the chi-square test. A multivariable framework prioritized clinically relevant preoperative and early postoperative variables, including weight, baseline creatinine, preoperative mechanical ventilation, lactate levels, and VIS. ROC curve analysis evaluated predictive performance. Resultados e Conclusions: AKI occurred in 241 patients (19.1%). Those with AKI had lower weight (4.03 vs 5.64 kg, p<0.001), lower oxygen saturation (86.9% vs 89.7%, p<0.001), higher baseline creatinine (0.47 vs 0.36 mg/dL, p=0.029), and more frequent preoperative mechanical ventilation (36.9% vs 21.0%, p<0.001). Postoperatively, AKI was strongly associated with higher lactate levels (POI: 3.72 vs 2.37 mmol/L; POD1: 3.37 vs 1.70; POD2: 2.23 vs 1.40; p<0.001) and higher VIS (POI: 20.5 vs 11.6; POD1: 17.3 vs 8.6; POD2: 15.0 vs 6.5; p<0.001). Patients with AKI required longer mechanical ventilation [168 (72–432) vs 72 (22–240) h, p<0.001] and had prolonged ICU stay [480 (240–792) vs 324 (144–648) h, p<0.001]. Major complications were more frequent: low cardiac output syndrome (89.2% vs 37.6%), ventricular dysfunction (44.8% vs 19.6%), sepsis (19.1% vs 5.3%), SIRS (67.6% vs 14.3%), ECMO use (12.4% vs 2.0%), and open chest (24.2% vs 4.1%) (p<0.001). Lactate showed good discrimination for AKI (AUC 0.72), outperforming VIS alone (AUC 0.68). The combined model improved prediction (AUC 0.74), highlighting complementary metabolic and hemodynamic contributions. AKI affects nearly 1/5 of infants and is linked to hypoperfusion; lactate and VIS together may improve early risk stratification.

(1) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL; (2) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (3) UNIDAVI - CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL; (4) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL; (5) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (6) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL; (7) UNIVERSIDADE FEDERAL DO RIO GRANDE - RIO GRANDE - RS - BRASIL; (8) BETH ISRAEL DEACONESS MEDICAL CENTER, MASSACHUSETTS, UNITED STATES OF AMERICA - UNITED STATES; (9) MONTEFIORE EINSTEIN HOSPITAL, BRONX, NY, UNITED STATES OF AMERICA - UNITED STATES;

Introduction/Background: Heart failure with preserved ejection fraction (HFpEF) is highly prevalent and frequently underdiagnosed, owing to its heterogeneous presentation and reliance on advanced imaging and biomarker integration. Artificial intelligence (AI)–enabled electrocardiography (ECG) has emerged as a scalable, noninvasive approach for heart failure detection, but its diagnostic performance for HFpEF has not been systematically synthesized. Objectives: To evaluate the diagnostic accuracy of AI-enabled ECG models for the detection of HFpEF. Methods: We performed a systematic review and meta-analysis of three observational studies (25,239 patients) evaluating AI–based ECG algorithms for HFpEF detection. Eligible studies compared AI-ECG outputs with contemporary diagnostic reference standards. Pooled sensitivity, specificity, positive and negative predictive values, and area under the receiver-operating characteristic curve were estimated using a bivariate random-effects model, with summary receiver-operating characteristic analysis. Resultados e Conclusions: Three observational cohort studies were included in the quantitative synthesis. The pooled AUC for HFpEF detection was 0.81 (95% CI: 0.72–0.92). Pooled sensitivity was 90.4% (95% CI: 58.1–98.4), and pooled specificity was 72.9% (95% CI: 61.6–81.9). The pooled PPV was 58.6% (95% CI: 44.9–71.1), while the pooled NPV was 94.7% (95% CI: 79.3–98.8). SROC analysis demonstrated consistent overall diagnostic performance, with moderate dispersion of individual study estimates. Conclusions: These findings support AI-enabled ECG as a scalable, noninvasive imaging surrogate capable of enriching HFpEF diagnostic pathways and identifying patients who may benefit from targeted imaging evaluation.

ARTIFICIAL INTELLIGENCE FOR ELECTROCARDIOGRAM PRIORITIZATION IN THE EMERGENCY DEPARTMENT: A RETROSPECTIVE STUDY OF TWO BRAZILIAN COHORTS

CAMILA HELENA MACEDO COSTA1; ANDRE RICARDO DE ARAUJO QUADROS-JUNIOR1; FLAVIA PAIVA PROENÇA LOBO LOPES2; SERGIO HENRIQUE RODOLPHO RAMALHO3;

(1) HOSPITAL UNIVERSITARIO DE BRASILIA - BRASÍLIA - DF - BRASIL; (2) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (3) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introduction/Background: In emergency departments (ED), timely electrocardiogram (ECG) acquisition and accurate interpretation remain vital for acute cardiac care. Yet, ECG interpretation accuracy varies significantly among clinicians, potentially impacting prognosis. Artificial Intelligence (AI) has emerged as a promising technology to identify abnormal patterns and to reduce the misinterpretation gap across specialization levels in ED. However, the real-world impact of AI integration into ED ECG protocols on clinical outcomes is unclear. Objectives: To investigate the association of AI-enhanced ECG triage with clinical and quality outcomes, used in chest pain protocols at two Brazilian hospitals: a general ED and a specialized cardiology ED. Methods: We retrospectively analyzed 3,340 patients admitted with chest pain in two private hospitals: a specialized cardiology ED in São Paulo (SP) and a general ED hospital in Brasília (DF). Patients were divided into an AI-prioritized group (ECG-AI) with semi-automatic physician-validated report, and a standard care group (ECG-SC) with local reading. Primary metrics included door-to-ECG (DTE) time, door-to-medication time, intervention frequency, length of stay (LOS), and admission rates. Statistical analysis employed pairwise comparisons, with a significance level of 5%. Resultados e Conclusions: In the specialized hospital, ECG-AI showed no significant difference in median DTE (5.0 min for both, p=0.905) or LOS compared with ECG-SC (TABLE). In the general hospital, ECG-AI was associated with a statistically significant, though clinically modest, 1-minute reduction in median DTE (9.0 vs 10.0 min, p<0.001). Paradoxically, the ECG-AI group in the DF hospital had a longer median LOS than ECG-SC (269 vs 222 min, p=0.001). Notably, only in the general hospital, AI-assisted triage was associated with a greater frequency of anatomic stratification and angioplasty (3.5% vs 0.7%, p<0.001). No significant differences were found in mortality or ICU admission rates at either site. AI integration for ECG prioritization is clinically feasible and maintains high-quality temporal standards. Opposite to our hypothesis, ECG-AI was not associated with short-term clinical outcomes. Interestingly, in the general ED, ECG-AI had a greater rate of invasive procedures, closer to the rates in specialized EDs. ECG-AI may serve as a potential tool in less specialized settings to support decision-making, which must be validated in prospective clinical studies.

Table – Comparison between ECG-SC and ECG-AI findings in both hospitals

Variables	São Paulo Hospital (n = 1,865)			Distrito Federal Hospital (n = 1,468)		
	ECG-SC (n=1,387)	ECG-AI (n=478)	p-value	ECG-SC (n=844)	ECG-AI (n=634)	p-value
Hospitalization, n (%)

ARTIFICIAL INTELLIGENCE-ENABLED ECG FOR PRIORITIZING ECHOCARDIOGRAPHY AND ACCELERATING DIAGNOSIS OF STRUCTURAL HEART DISEASE

ALINE F. PEDROSO1; BRUNO R. NASCIMENTO2; LOVEDEEP DHINGRA1; SUMUKH V. SHANKAR1; WANESSA C. VINHAL3; RALDNER B. REGES3; CLARECI S. CARDOSO3; ISADORA V. B. S. SOUZA2; LUIZA H. DE PAULA2; GABRIEL R. ANGELO2; ANTÔNIO L. P. RIBEIRO2; ROHAN KHERA1;

(1) CARDSLAB, YALE UNIVERSITY - UNITED STATES; (2) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (3) UNIVERSIDADE FEDERAL DE SÃO JOÃO DEL REI, CÂMPUS DIVINÓPOLIS - DIVINÓPOLIS - MG - BRASIL;

Introduction/Background: Echocardiography (echo) is the gold standard for diagnosing structural heart disease (SHD), but in low-resource settings, limited capacity can delay its timely detection. Objectives: We hypothesize that AI applied to ECGs (AI-ECG) to identify those at SHD risk can enable resource-efficient prioritization for echo testing. Methods: We recruited a prospective cohort of 1831 consecutive individuals referred for echo based on clinical evaluation in Brazil, who had undergone an initial ECG. First, we deployed our validated AI-ECG tool for multiple SHDs, using subsequent echo to define its classification performance. Second, given the current echo capacity of 200/month, we examined the time to diagnosis of SHD after echo referral, comparing the standard vs a potential AI strategy, where echos for high AI-ECG are prioritized. For each scenario, we calculated the cumulative proportion of SHD diagnoses over a 6-month period. We also assessed the time to diagnosis of 50% of SHD cases within age and sex strata. Resultados e Conclusions: Among 1,475 patients with complete data (mean age 65±13 years, 54% women), 105 (7%) had SHD on echo. The AI-ECG achieved an AUROC of 0.83, and 22.9% were flagged high risk at Youden's J threshold. Based on the standard scheduling, 25%, 50%, 75%, and 90% of all SHD cases were diagnosed in 46, 81, 131, and 164 days. With AI prioritization, these milestones were reached at 6, 19, 54, and 96 days, with a median time to diagnosis reduced by 65 days (IQR 51-73). AI prioritization consistently reduced the time to diagnosis across age and sex groups. Therefore, AI-ECG-guided prioritization may substantially accelerate SHD detection within existing echo capacity, enabling earlier identification and treatment of high-risk patients.

ARTIFICIAL INTELLIGENCE–ASSISTED CARDIOLOGY CONSULTATIONS IMPROVE EFFICIENCY AND CLINICAL DOCUMENTATION QUALITY WHILE ENHANCING CONTINUITY OF CARE: A PROSPECTIVE PRE–POST STUDY

AUREO AUREO FILHO1; MAX KOPTI FAKOURY1; MATEUS ESTEVA MONTEIRO SALERNO1; EDUARDO MARINHO TASSI1; SEBASTIANA BESSA PORTO1;

(1) UNIVERSIDADE FEDERAL DO ESTADO DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: The integration of artificial intelligence (AI) into clinical workflows has been proposed as a strategy to address increasing demand and time constraints in cardiology outpatient care. However, evidence remains limited regarding whether gains in efficiency can be achieved without compromising the quality of clinical documentation and continuity of care, particularly in referral-based systems. Objectives: To evaluate the impact of an AI-based clinical support tool on consultation duration, structured documentation completeness, and perceived continuity of care in cardiology outpatient visits. Methods: This prospective pre–post study included 60 consecutive cardiology consultations in a university-affiliated outpatient setting, involving patients referred from primary care. The control group comprised 30 consultations conducted without AI assistance, while the intervention group included 30 consultations supported by an AI-based tool integrated into clinical workflow. Consultation duration was recorded in minutes. Documentation quality was assessed using the Structured Clinical Documentation Completeness Score (SCDCS), a multidimensional checklist encompassing history, physical examination, management plan, and follow-up. Continuity of care was evaluated through referring primary care teams using a Likert-based satisfaction scale (1–5). Continuous variables were expressed as mean ± standard deviation and compared using two-tailed t-tests, with statistical significance defined as $p < 0.05$. Resultados e Conclusions: AI-assisted consultations were associated with a substantial reduction in consultation time (27.3 ± 4.8 vs. 45.1 ± 6.2 minutes; $p < 0.001$), representing a 39.5% relative decrease. Documentation completeness significantly improved, with higher SCDCS scores in the intervention group (92.4 ± 5.1 vs. 74.6 ± 7.8; $p < 0.001$), reflecting consistent gains across all domains, particularly in follow-up planning. Satisfaction scores from primary care teams increased from 3.0 ± 0.6 to 4.3 ± 0.5 ($p < 0.001$), corresponding to a 43% relative improvement, indicating enhanced continuity and clarity of communication. These findings demonstrate that AI integration can simultaneously optimize efficiency and elevate the quality of cardiology consultations without trade-offs between speed and clinical rigor.

ARTIFICIAL INTELLIGENCE–BASED ECG AS A TRIAGE TOOL FOR ACUTE MYOCARDIAL INFARCTION: A DIAGNOSTIC SYSTEMATIC REVIEW AND META-ANALYSIS

GIULIA CALDEIRA GAELZER1; PEDRO GOMES BATISTA2; MARCELA VASCONCELOS MONTENEGRO3; RAILLA RAQUEL ALBINO DOS SANTOS SILVA4; MUSHRIN MALIK5; MARIA LETICIA CARNIELLI TEBET1; CAROLINE O FISCHER-BACCA6; JULIANA GIORGI7; GUSTAVO LENCI MARQUES1;

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (2) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (3) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL; (4) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL; (5) BETH ISRAEL DEACONESS MEDICAL CENTER - UNITED STATES; (6) CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL; (7) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introduction/Background: Rapid and accurate identification of acute coronary syndromes (ACS), particularly acute myocardial infarction (AMI), is essential in cardiovascular care. The 12-lead electrocardiogram (ECG) is central to early triage, but conventional interpretation lacks sensitivity, especially in non–ST-segment elevation presentations and occluded myocardial infarction (OMI), leading to delays in reperfusion and adverse outcomes. Artificial intelligence (AI) has enhanced ECG analysis by identifying complex patterns beyond human recognition. Across emergency and prehospital settings, AI-enabled ECG models have demonstrated improved diagnostic performance for STEMI, NSTEMI, and OMI compared with traditional criteria, with high negative predictive value supporting their use as triage tools. Objectives: To systematically evaluate the diagnostic performance of AI-enabled ECG algorithms for the detection of AMI, including ST-segment elevation myocardial infarction (STEMI) and non–ST-segment elevation myocardial infarction (NSTEMI), across diverse clinical settings. Methods: This diagnostic systematic review and meta-analysis was conducted in accordance with PRISMA guidelines and registered in PROSPERO (CRD420261292271). PubMed, Embase, and Cochrane CENTRAL were searched through January 2026. Studies evaluating AI-based ECG models for AMI detection and reporting sufficient data to reconstruct 2×2 contingency tables were included. Pooled sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were estimated using random-effects models (restricted maximum likelihood). Summary receiver operating characteristic (SROC) curves and area under the curve (AUC) were generated. Prespecified subgroup analyses were performed for STEMI and NSTEMI. Resultados e Conclusions: Ten observational studies comprising 94,510 participants were included. For overall AMI detection, AI-ECG demonstrated a pooled sensitivity of 89.4% (95% CI, 79.7–94.8) and specificity of 96% (95% CI, 91.2–98.2). The pooled NPV was 98.7% (95% CI, 94.1–99.7), and the pooled PPV was 73.3% (95% CI, 50.2–88.2). The SROC AUC was 0.97 (95% CI, 0.92–0.98). In STEMI, pooled sensitivity and specificity were 94.4% and 97.5%, respectively (AUC 0.98). In NSTEMI, pooled sensitivity was lower at 65.0%, with specificity of 87.5% and an AUC of 0.71. Heterogeneity was substantial, particularly among NSTEMI cohorts.

BEYOND TRADITIONAL RISK SCORES: AI-BASED PHENOMAPPING AS A NEW FRONTIER FOR RISK STRATIFICATION IN ISOLATED CABG

ÁLVARO RÖSLER1; GABRIEL CONSTANTIN1; VINICIUS WILLY PREDIGER1; JONATHAN FRAPORTTI1; MARCELA DA CUNHA SALES1; FERNANDO ANTÔNIO LUCCHESE1;

(1) HOSPITAL SÃO FRANCISCO - SANTA CASA DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Traditional surgical risk scores may fail to capture the biological heterogeneity of patients undergoing Coronary Artery Bypass Grafting (CABG), as they often combine objective physiology with subjective variables such as urgency or critical status. AI-based unsupervised learning may offer a clinically useful alternative by identifying natural phenotypes based on objective markers of physiological reserve. Objectives: To identify clinical phenotypes in patients undergoing isolated CABG using unsupervised Machine Learning applied to objective preoperative variables, and to assess their association with in-hospital mortality. Methods: This study included 4,000 consecutive patients undergoing isolated CABG. To reduce coding bias, acute contextual variables were intentionally excluded. Nine objective variables were selected: age, sex, body mass index, preoperative creatinine clearance, preoperative hemoglobin, left ventricular ejection fraction, prior atrial fibrillation, heart failure, and use of cardiopulmonary bypass. Data were normalized and analyzed using K-Means clustering. In-hospital mortality was compared across clusters ($p<0.001$). Resultados e Conclusions: The algorithm identified three distinct phenotypes with markedly different mortality. The “Preserved Reserve” cluster (n=1,822; mortality 1.7%) included younger patients (mean age 58 years) with preserved renal function (creatinine clearance >89 mL/min) and hemoglobin levels (>13.8 g/dL), showing excellent survival despite higher body mass index. The “Frail Elderly” cluster (n=2,455; mortality 4.3%) was characterized by older age (mean 67 years), reduced renal function (~56 mL/min), and lower hematologic reserve, suggesting chronic physiological vulnerability rather than acute instability. The “Arrhythmic-Inflammatory Phenotype” (n=176; mortality 9.1%) was defined by prior atrial fibrillation and moderate ventricular dysfunction, with mortality more than five times higher than the preserved reserve group. These findings indicate that mortality after isolated CABG is concentrated in recognizable vulnerability phenotypes rather than distributed linearly across isolated risk factors. AI-based phenomapping may complement traditional scores by offering a more intuitive and actionable framework for clinical cardiologists, highlighting patients who may benefit from renal optimization, anemia correction, and closer perioperative surveillance when atrial fibrillation is present.

CLONAL HEMATOPOIESIS AND RISK OF HEART FAILURE WITH PRESERVED EJECTION FRACTION: A SYSTEMATIC REVIEW

FELLIPE DEBACKER LADEIRA1; ARTHUR CHEDE CHAVES REIS1; IVENS MURAD GARCIA MAGALHÃES1; ANDRESSA PERON RESENDE CORRÊA2;

(1) UFJF - JUIZ DE FORA - MG - BRASIL; (2) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL;

Introduction/Background: Clonal hematopoiesis of indeterminate potential (CHIP) is increasingly recognized as a non-traditional cardiovascular risk factor mediated by chronic inflammation and adverse myocardial remodeling. Its role in heart failure with preserved ejection fraction (HFpEF) and mildly reduced ejection fraction (HFmrEF) remains incompletely characterized. Objectives: To systematically evaluate the association between CHIP and HFpEF/HFmrEF, focusing on gene-specific effects, cardiovascular outcomes, and inflammatory mechanisms. Methods: A PRISMA 2020-compliant systematic review was conducted using PubMed, Embase, Web of Science, Scopus, Cochrane Library, and LILACS. Observational studies evaluating adults with molecularly confirmed CHIP and reporting HFpEF/HFmrEF outcomes were included. Two reviewers independently screened studies, extracted data, and assessed risk of bias using an adapted Newcastle–Ottawa Scale. Due to methodological heterogeneity, findings were synthesized narratively. Resultados e Conclusions: Five studies involving approximately 19,950 participants were included. CHIP prevalence was consistently higher or characterized by larger clone size among HFpEF patients. TET2-driven CHIP demonstrated the strongest association with incident HFpEF, with adjusted hazard ratios ranging from 1.40 to 2.50 and a pooled estimate of 2.35 (95%CI 1.34–4.11). In contrast, composite CHIP and DNMT3A variants showed weaker or inconsistent associations, although the DNMT3A R882 hotspot variant predicted HFpEF in one cohort. CHIP was not consistently associated with heart failure with reduced ejection fraction, supporting a phenotype-specific inflammatory mechanism. CHIP carriers also presented worse diastolic function, higher natriuretic peptide levels, and increased cardiovascular hospitalization, particularly in the presence of elevated C-reactive protein. Experimental studies demonstrated that TET2 deficiency promotes myocardial fibrosis and diastolic dysfunction through NLRP3/IL-1β-mediated inflammatory signaling. No included study separately analyzed HFmrEF. Current evidence supports CHIP, especially TET2-related CHIP, as an independent modifier of HFpEF risk and prognosis, highlighting inflammatory pathways as potential therapeutic targets.

Study	Design	Cohort / N	Age (years)	CHIP method	Follow-up	Key outcomes

DEEP LEARNING–BASED ATRIAL FIBRILLATION SCREENING: REAL-WORLD NATIONWIDE VALIDATION USING OVER 818,000 ECGS INTEGRATED INTO A TELECARDIOLOGY WORKFLOW IN BRAZIL

DIANDRO MARINHO MOTA1; BRUNO FARIAS2; RAFAEL ALTOE2; GUSTAVO KUSTER2; JOSE HENRIQUE LOPES3; MARIANA LIRA2; MARLON CANDOTI2; LUIZ PAIVA2; MARIANA ALMEIDA2; EDUARDO SASSAKI1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (2) NEOMED HEALTHTECH - SAO PAULO - SP - BRASIL; (3) NEOMED HALTHTECH - SAO PAULO - SP - BRASIL;

Introduction/Background: Atrial fibrillation (AF) is the most common sustained cardiac arrhythmia worldwide and is associated with substantial morbidity, mortality, and nearly 20% of ischemic strokes. As population aging accelerates, scalable screening strategies capable of improving early AF detection have become increasingly relevant. Artificial intelligence (AI)–based electrocardiogram (ECG) analysis has emerged as a promising approach for large-scale cardiovascular screening and workflow optimization in real-world clinical practice. Objectives: To evaluate the diagnostic performance and real-world feasibility of a deep learning model for automated AF detection using a nationwide Brazilian ECG database integrated into a telecardiology workflow. Methods: We analyzed digital ECGs collected from public and private healthcare services across all five geographic regions of Brazil. All ECGs underwent standardized preprocessing and expert physician labeling. A one-dimensional convolutional neural network based on a ResNet architecture was developed for automated AF detection and prospectively integrated as an AI-assisted triage tool within a real-world telecardiology workflow. Resultados e Conclusions: A total of 818,176 ECGs were analyzed, including 457,004 (55.9%) from female patients and 361,172 (44.1%) from male patients. AF was identified in 25,096 ECGs, including 13,543 cases in men (54.0%) and 11,553 in women (46.0%). The model achieved an overall accuracy of 96.1%, with recall of 95.3% for AF detection and specificity of 96.1% for non-AF cases. Precision reached 99.8% for non-AF ECGs, while the area under the receiver operating characteristic curve (AUC) was 0.98. F1-scores were 0.597 for AF and 0.979 for non-AF cases, reflecting the marked class imbalance inherent to real-world screening datasets. A total of 55,039 ECGs were flagged by the AI model as AF-positive, supporting its operational feasibility as a scalable triage strategy in routine telecardiology practice. Deep learning–based AF detection demonstrated high diagnostic performance in a large-scale real-world Brazilian population exceeding 818,000 ECGs. Integration into routine telecardiology workflows supports the feasibility of AI-assisted AF screening as a scalable strategy to improve early diagnosis and expand access to cardiovascular care. Despite substantial class imbalance, the model maintained high sensitivity and robust discriminatory performance, reinforcing its potential for population-level implementation in contemporary cardiovascular medicine.

DEEP LEARNING–BASED PROBABILISTIC MODEL FOR IDENTIFICATION OF TRUE CARDIAC CHEST PAIN IN A TERTIARY CARE CENTER

EDUARDO PIETRE1; LARISSA FRANCO DE ANDRADE1; ANDRÉ LUIZ DIAS LIMA BONFIM1; EVANDRO SUZANO DA SILVA FILHO1; GUSTAVO DUTRA CAVALCANTI1; MARIA DE FATIMA MARTINS GIL DIAS1; JOÃO VICTOR PROVETI MORAES1; PAULO MACHADO PONTES1; MARCOS MORAIS DE MEIS1; MATIAS BRITO FLORIANI1; LUIS FILIPE AZEVEDO DE CARVALHO1; LEONARDO ANDRADE FERNANDES DE LUCA1;

(1) QUINTA D'OR - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Chest pain is a frequent emergency complaint with multiple etiologies. Differentiating between cardiac and non-cardiac pain remains complex. Traditional clinical scores rely on predefined variables and linear assumptions, limiting their performance, whereas machine learning can better capture complex data patterns and potentially improve diagnostic discrimination. Objectives: Develop and evaluate a deep learning-based model for classifying patients with chest pain into cardiac etiologies or not, using real-world data. Methods: Retrospective study using structured clinical dataset of chest pain patients from a tertiary center. Primary outcome was cardiac etiology (ST-elevation and non-ST myocardial infarction, unstable angina). Non-classifiable diagnoses were excluded. Demographics, comorbidities, HEART score and clinical presentation were the input. Data was processed using multiple imputation by chained equations (MICE) for both numerical and categorical variables, one-hot encoding for categorical features, and standardization of continuous variables, then split into training and testing subsets (85%/15%) with stratification by outcome. The neural network was defined according to image 1. Performance of the test was assessed using area under the receiver operating characteristic curve (ROC-AUC). Additionally, model behavior was analyzed across multiple probability thresholds to evaluate its clinical applicability under different decision strategies. The same was done to the HEART score in this population. Resultados e Conclusions: The model demonstrated adequate discrimination performance. With an AUC of 0.90 while HEART score showed 0.85. The probabilistic output enables flexible threshold selection. Lower probability thresholds favors high sensitivity, supporting strategies aimed at safely ruling out cardiac disease, whereas higher thresholds improve specificity, facilitating identification of high-risk patients. Despite promising results, limitations must be considered. Machine learning models performance depends on training data, which may limit external generalizability. Underrepresented populations may be at risk of misclassification, raising concerns regarding equity and fairness in clinical deployment. These considerations underscore the need for rigorous external validation, transparency in model development, and stronger regulatory frameworks governing the safe use of artificial intelligence in healthcare.

ELECTROCARDIOGRAPHY REIMAGINED: DIAGNOSTIC ACCURACY OF AI-ENABLED ECG FOR VALVULAR HEART DISEASE - A SYSTEMATIC REVIEW AND META-ANALYSIS

CAROLINE OLIVEIRA FISCHER-BACCA1; PEDRO GOMES BATISTA2; JUAN PERES OLIVEIRA1; RAILLA RAQUEL ALBINO SANTOS SILVA3; GIULIA GAELZER4; MARCELA VASCONCELOS MONTENEGRO5; LARISSA ARAUJO LUCENA6; RAMON HUNTERMANN1; MARIA EDUARDA MOLINARI1; MRUNALINI DANDAMUDI7; MUSHRIN MALIK8; JULIANA GIORGI9;

(1) UNIDAVI - CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL; (2) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (3) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL; (4) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (5) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL; (6) UNIVERSIDADE FEDERAL DO RIO GRANDE DO NORTE - NATAL - RN - BRASIL; (7) MONTEFIORE EINSTEIN HOSPITAL - UNITED STATES; (8) BETH ISRAEL DEACONESS MEDICAL CENTER - UNITED STATES; (9) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL;

Introduction/Background: Valvular heart disease (VHD) is a major and growing global health burden, frequently underdiagnosed due to reliance on transthoracic echocardiography, which is resource-intensive and unsuitable for population-level screening. Artificial intelligence–enabled electrocardiography (AI-ECG) has emerged as a scalable, noninvasive approach for detecting clinically significant valvular lesions, but its diagnostic performance has not been systematically quantified. Objectives: To evaluate the diagnostic accuracy of AI-ECG for the detection of clinically significant VHD. Methods: We conducted a systematic review and meta-analysis of studies assessing AI-ECG algorithms for VHD detection. Pooled sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and area under the receiver-operating characteristic curve (AUC) were estimated using random-effects models. Overall diagnostic performance was summarized using a summary receiver-operating characteristic (SROC) curve, with prespecified subgroup analyses by valve pathology. Resultados e Conclusions: Eight studies met inclusion criteria. For overall VHD detection, pooled sensitivity was 74.8% (95% CI: 68.2–80.4) and pooled specificity was 74.5% (95% CI: 69.7–78.8). The pooled NPV was high at 97.7% (95% CI: 96.4–98.5), whereas pooled PPV was 16.4% (95% CI: 10.7–24.3). SROC analysis demonstrated good overall discrimination with an AUC of 0.80 (95% CI: 0.78–0.81) (Figure 1). Valve-specific analyses showed the strongest performance for aortic stenosis and tricuspid regurgitation, with more modest accuracy for regurgitant lesions (Figure 2). Conclusions: AI-ECG demonstrates good diagnostic performance for detecting clinically significant VHD, characterized by consistently high NPV. These findings support its role as a scalable, noninvasive rule-out and triage tool to guide targeted echocardiography and facilitate earlier recognition of valvular disease.

EMPOWERING COMMUNITY HEALTH WORKERS WITH CLINICAL DECISION SUPPORT IN VULNERABLE SETTINGS: A MIXED-METHODS STUDY

MILENA SORIANO MARCOLINO1; LILIAN CRISTINA REZENDE1; SUELI FERREIRA FONSECA1; THIAGO BARBABELA DE CASTRO SOARES1; CHRISTIANE CORREA RODRIGUES CIMINI1; LUCAS BARROSO SANTOS1; MARCO AURÉLIO SALES SILVEIRA1; JAMES BATCHELOR2; ANTONIO LUIZ PINHO RIBEIRO1; CLARA RODRIGUES ALVES OLIVEIRA1;

(1) TELEHEALTH CENTER, UNIVERSITY HOSPITAL, UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) CLINICAL INFORMATICS RESEARCH UNIT, FACULTY OF MEDICINE, UNIVERSITY OF SOUTHAMPTON - ENGLAND;

Introduction/Background: Community health workers (CHWs) are essential in supporting continuity of care for individuals with hypertension and diabetes, particularly in underserved settings. Clinical decision support systems (CDSS) have the potential to enhance early recognition of clinical worsening and support appropriate referral within primary care services. Objectives: To describe the design, deployment, and assessment of a CDSS incorporated into a multicomponent intervention aimed at assisting CHWs during home visits for patients with hypertension and diabetes. Methods: This mixed-methods sub-analysis of the CHArMING Project was carried out in 5 low-resource municipalities in the Jequitinhonha and Mucuri Valleys, Brazil, following the RE-AIM framework. A tablet-based CDSS was developed for use during household visits, integrating automated blood pressure measurement and urine glucose testing, with prompts and care guidance triggered by predefined thresholds. The intervention also included standardized training and remote tele-mentoring to support clinical evaluation, lifestyle advice, and use of the tool. CHWs from 18 primary care facilities were involved. Quantitative data were summarized descriptively, while qualitative insights from focus groups explored adoption, usability, and implementation factors. Resultados e Conclusions: Between March/2024 and January/2025, 984 evaluations were completed across 680 individuals. Among 648 patients with hypertension, 26.2% presented uncontrolled blood pressure levels. Of 242 individuals with diabetes, 33.9% reported recent random glucose values above 250 mg/dL, 31.4% described symptoms consistent with hyperglycemia, and 24.8% had detectable urine glucose. Among 41 insulin-treated patients, 26.8% lacked access to a glucometer and 17.0% reported unavailability of test strips. Reported enablers of CDSS use included usability, availability of technical support, increased professional confidence, improved patient interaction, and better-informed decision-making. Challenges included time constraints, difficulties in referral coordination, uncertainty in interpreting urine glucose findings, limited internet connectivity, and occasional data synchronization failures. Overall, the CDSS proved feasible and showed promise in supporting early identification of clinical deterioration, strengthening communication, and facilitating timely referral. Overcoming infrastructure and workflow barriers will be critical for long-term sustainability and scalability in resource-limited contexts.

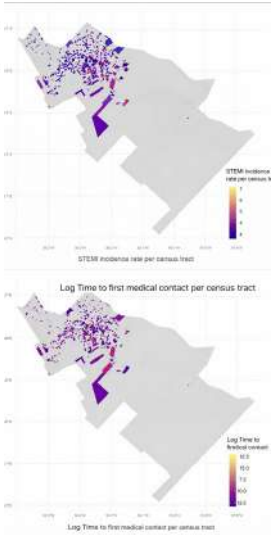
EPIDEMIOLOGICAL MODELING AND TERRITORIAL DETERMINANTS OF STEMI CARE IN A HEALTHCARE NETWORK IN THE PROVINCE OF BUENOS AIRES, ARGENTINA (2009–2025)

SANTIAGO LEANDRO TORROBA1; MARTIN LEDESMA1; GASTON CIRIO2; DANIELA ALVAREZ2; SEBASTIAN MANTEGNA3; TOMAS CATENA GALLO1; EZEQUIEL LERECH1; MAXIMILIANO DE ABREU1;



(1) HOSPITAL EL CRUCE - ARGENTINA; (2) UNIVERSIDAD NACIONAL ARTURO JAURETCHE - ARGENTINA; (3) UNIVERSIDAD NACIONAL DE LA PLATA - ARGENTINA;

Introduction/Background: ST-segment elevation myocardial infarction (STEMI) is a global health problem. Early diagnosis and treatment are associated with reduced mortality. It is well established that multiple social determinants, such as poverty, educational level, and access , individually influence delays in STEMI care. However, the impact of the unequal socio-spatial distribution of these determinants remains insufficiently explored. Objectives: To analyze incidence rate (IR) and time to first medical contact (TFMC) in a cohort of STEMI patients, and to develop an ecological explanatory model of incidence rates and delays in care times based on georeferenced sociodemographic variables at the census-tract level within a STEMI network in the metropolitan area of Buenos Aires, Argentina. Methods: A prospective study was conducted between 2009–2025 including all patients with STEMI. Cases were geocoded based on patients' home addresses and aggregated at the census-tract level, the smallest geostatistical unit in Argentina. Assessment of the association between IR and TFMC and area-level variables such as distance to the geographic center of the network, unmet basic needs, sewerage coverage, and related contextual indicators was made. These findings were displayed using choropleth maps, with spatial pattern exploration, cluster detection, and identification of critical areas with prolonged delays. Statistical analyses were performed in RStudio. The full set of variables was used to fit generalized additive models (GAMs) in order to identify nonlinear associations, incorporating penalization and shrinkage-based selection. Two main outcomes were evaluated: TFMC per census tract, modeled using a Gaussian distribution after log transformation, and IR adjusted for population size. Resultados e Conclusions: A total of 1,650 STEMI events were analyzed; the main clinical characteristics are shown in Table 1. The median TFMC was 97.5 minutes (IQR, 45–248 mins). TFMC was independently associated with mortality. Figures 1A and 1B illustrate the geographic distribution of IR and TMFC, respectively. The multivariable GAM using territorial mean TFMC delay showed limited explanatory performance (1% of deviance explained). In contrast, STEMI IR showed consistent associations in the GAM, explaining 30.6% of the deviance, with significant effects of distance, population density, sewerage coverage and number of households. These findings allow identification of spatial patterns and may help target interventions in order to improve STEMI care.

EVIDENCE OF VALIDITY OF A MOBILE APPLICATION PROTOTYPE FOR PATIENT SELF-MANAGEMENT AFTER ACUTE MYOCARDIAL INFARCTION.

RAFAELA VILELA ALVES DOS SANTOS1; PRISCILLA CAROLINY DE OLIVEIRA1;

(1) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL;

Introduction/Background: Cardiovascular diseases continue to be the leading cause of mortality worldwide, accounting for nearly 30% of all deaths. Within this group, acute myocardial infarction is particularly prominent due to its high incidence, clinical severity, and substantial contribution to morbidity and mortality related to coronary artery disease.Following the acute event, patients are required to adopt significant lifestyle modifications and engage in long-term clinical follow-up to minimize the risk of recurrence. Nevertheless, current evidence indicates that adherence to recommended therapeutic and behavioral interventions remains suboptimal, ultimately compromising clinical outcomes and negatively impacting quality of life. Objectives: To develop and validate, in collaboration with healthcare and technology experts, a prototype self-management application for patients diagnosed with Acute Myocardial Infarction (AMI), while generating evidence regarding its content validity and usability. Methods: This is a methodological, descriptive study with a quantitative approach, focused on the development of a mobile health application, following the software development stages proposed by Pfleeger. Content validation was conducted using the Content Validity Index (CVI), inter-rater agreement was assessed through the Intraclass Correlation Coefficient (ICC), and internal consistency was evaluated using Cronbach's alpha coefficient. Resultados e Conclusions: Twenty expert judges in the subject area participated in the study, resulting in an overall CVI of 0.78. The CCI was 0.87, indicating high agreement among the evaluators. The Cronbach's alpha coefficients obtained were greater than 0.70, demonstrating good internal consistency. And a score on the System Usability Scale (SUS) of 93.34 indicates that the application has a high level of usability. The prototype of the application developed for the management of patient care in the post-MI period presented robust validation results, both in relation to content and usability, demonstrating compliance with rigorous methodological standards and with the main international guidelines in cardiology. The combination of a satisfactory content validity index with an excellent score on the SUS indicates that the tool is reliable, functional and highly acceptable by the target audience.

EXPANDING TIMELY ACCESS TO CARDIOVASCULAR DIAGNOSIS THROUGH TELE-ECG IN BRAZILIAN PUBLIC PREHOSPITAL EMERGENCY CARE: A NATIONAL QUALITY IMPROVEMENT EXPERIENCE

FERNANDA RODRIGUES LIMA1; ARIANE SALLES PRADO1; CLÁUDIA ALVES DE ASSIS1; ANDRÉIA DA SILVA RIBEIRO1; FELIPE MENDES DELPINO1; SILVIA SCHOEUNAU DE AZEVEDO1; MARIA FERNANDA SOARES NAUFEL1; SABRINA GISELE TOBIAS DA SILVA1; CAMILA PEREIRA PINTO TOTH1; CAMILA ROCON DE LIMA1; PATRICIA VENDRAMIN1;

(1) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL;

Introduction/Background: Brazil is a continental country marked by significant regional inequalities in healthcare access. Cardiovascular diseases remain a leading cause of mortality, placing a substantial burden on health systems. In this context, fixed prehospital emergency care units are key entry points for cardiovascular emergencies, supporting early diagnosis and management. However, limited timely access to diagnostic tests and specialist electrocardiogram (ECG) interpretation remains an important barrier to the prompt identification and treatment of acute cardiac conditions. Objectives: This study aimed to describe the outcomes of a national tele-electrocardiography (Tele-ECG) and cardiology teleconsultation program implemented in fixed public prehospital emergency care units across Brazil. Methods: A descriptive, quantitative study was conducted as part a cardiological best-practices program implemented in partnership with the Brazilian Ministry of Health and a private tertiary hospital that provided access to Tele-ECG and cardiology teleconsultation services in 735 public fixed prehospital emergency care units across Brazil between 2024 and 2025. The study included patients whose ECGs were interpreted through the program and who were diagnosed with ST-elevation myocardial infarction (STEMI) or malignant arrhythmias. Resultados e Conclusions: A progressive increase in Tele-ECG assessments was observed, rising from 1.447,294 ECGs interpreted in 2024 to 1.794,684 in 2025, representing a 31.8% increase, with a 3-minute average report time with clinically relevant ECG abnormalities in 46.4% and 47.1% of exams, respectively . Cardiology teleconsultation adherence remained above the institutional target, increasing from 62% in 2024 to 75% in 2025. Among interpreted ECGs, 24,286 (1.35%) cases of malignant arrhythmia, 20,756 (1.16%) STEMI cases, and 1,352 (0.08%) other clinically relevant abnormalities were identified. Analysis of 48-hour outcomes showed inter-facility transfer as the most frequent disposition (n=16,610, 56.95%), followed by discharge from the prehospital unit (n=9,065, 31.08%). Other outcomes included in-unit mortality (n=1,296, 4.44%), continued stay (n=1,513, 5.19%), and left against medical advice (n=670, 2.30%). National implementation of Tele-ECG and cardiology teleconsultation proved to be feasible and enabled standardized specialist diagnosis in prehospital emergency care, enhancing early risk recognition, clinical decision-making, and ultimately patient safety.

20359

IMPACT OF BANGLA HEART MANUAL IN PEOPLE WITH CORONARY HEART DISEASE AND THEIR CAREGIVERS IN BANGLADESH: A FEASIBILITY STUDY

MD. JAMAL UDDIN1; ROD TAYLOR1; MITHILA FARUQUE2;

(1) UNIVERSITY OF GLASGOW - SCOTLAND; (2) BANGLADESH UNIVERSITY OF HEALTH SCIENCES - BANGLADESH;

Introduction/Background: Cardiac rehabilitation (CR) is essential for improving outcomes in people with coronary heart disease (CHD), yet access in Bangladesh is limited., in conclusion, The culturally adapted Bangla Heart Manual is home-based CR model offers a practical alternative to centre based CR to increase accessibility and patient engagement. Objectives: To assess the feasibility and acceptability of the home-based Bangla Heart Manual CR programme for people with CHD following revascularisation. Methods: This single-centre feasibility pilot study used a mixed-methods, single-arm pre–post design coordinated at a tertiary cardiac hospital. Thirty-three individuals with CHD undergoing coronary artery bypass grafting or percutaneous coronary intervention were recruited between June and July 2024. The Bangla Heart Manual intervention consisted of a 6-week home-based CR programme including exercise, education, self-care, psychological support and risk factor management, facilitated by healthcare professionals. Study primary outcomes were feasibility and acceptability study recruitment and retention and intervention adherence assessed by quantitative data and qualitative interviews with patients, caregivers and staff. Secondary Participant included health-related quality of life (HeartQoL, EQ-5D-5L), psychological well-being, exercise capacity and adverse events assessed before and after Bangla Heart Manual Intervention. . Resultados e Conclusions: Of 72 screened, 33 individual (46%) were recruited; of whom 30 (91%) completed follow-up and attended 6 session out of 8 (75%) adhered to the CR intervention. Participants were predominantly male (88%) with a mean age of 55 years. Improvements were observed in patient-reported outcomes and exercise capacity following the intervention. Two deaths and one rehospitalisation occurred during the study period, unassociated with the CR intervention. The Bangla Heart Manual was found to be feasible and acceptable for both people following revascularisation and healthcare providers. These findings support progression to a multicentre randomised controlled trial to formally evaluate the clinical and cost-effectiveness of the Bangla Heart Manual.

Table 1: Summary of feasibility outcome measures.

Outcomes	Definition	Prespecified success criteria	Study outcome
Recruitment	Number of consented participants relative to the total number of eligible patients approached for consent	Recruitment rate of ≥30%	33 patients were recruited/ 72 were screened over a 2 month period (33/2) ≥ 16 patients per months, 46%
Retention	Number of participants who complete the final study assessment relative to the total number of participants enrolled for pilot trial.	Retention rate of ≥80%	2 deaths and dropout 1 (30/33), 91%
Adherence	Percentage of completion of the Bangla Heart Manual intervention components according to training logs.	Intervention adherence of ≥75%	(6 session out of 8 session delivered in 6 weeks programme), 75%

Table 2: Secondary outcomes: HeartQoL physical and emotional subscale, HADS and EQ-5D-5L at baseline and 3-months follow up

HeartQoL physical and emotional subscale				
	Baseline (n=33) mean (SD)	Follow-up (n=30) Mean (SD)	Mean difference and 95% CI	P Value
Physical Subscale	1.69 (0.64)	2.62 (0.41)	0.94 (0.66 to 1.21)	<0.0001
Emotional Subscale	1.78 (.79)	2.67 (.55)	0.87 (0.47 to 1.27)	
HADS				
	Baseline (n=33) mean (SD)	Follow-up (n=30) Mean (SD)	Mean difference and 95% CI	P Value
Anxiety	6.79 (4.08)	1.55 (1.56)	5.24 (3.94 to 6.55)	
Depression	5.27 (3.39)	2.12 (2.30)	1.93 (1.14 to 2.72)	<0.0001
EQ-5D-5L dimensions				
	Baseline (n=30), Mean (SD)	Follow-up (n= 29) Mean (SD)	Mean difference and 95% CI	P-Value
Mobility	2.23 (1.15)	1.13 (0.35)	1.10 (0.64 to 1.56)	<0.0001
Self-care	1.74 (1.06)	1.2 (0.41)	0.52 (0.15 to 0.92)	0.01
Usual activities	1.84 (1.07)	1.1 (0.31)	0.76 (0.34 to 1.17)	0.0008
Pain or discomfort	2.19 (0.91)	1.5 (0.51)	0.66 (0.23 to 1.07)	0.004
Anxiety or Depression	2.29 (0.86)	1.3 (0.47)	1.03 (0.69 to 1.38)	<0.0001
EQ-5D-5L VAS				
EQ-VAS	Baseline (n=30), Mean (SD)	Follow-up (n= 29) Mean (SD)	Mean difference and 95% CI	P-Value
VAS score, Mean (SD)	66 (18)	86 (09)	17 (11.16 to 22.91)	<0.0001
EQ-5D-5L utility scores using Indian population health value norms				
EQ-5D-5L pre and post (value norms)	Baseline (n=30), Mean (SD)	Follow-up (n=29) Mean (SD)	Mean difference and 95% CI	P-value
EQ-5D-5L index score	0.69 (0.37)	0.94 (0.06)	0.25 (0.11 to 0.39)	0.00094

IMPACT OF CREATININE CLEARANCE ON OPERATIVE MORTALITY IN AORTIC ANEURYSM SURGERY: A NEW PERSPECTIVE THROUGH MACHINE LEARNING-ASSISTED NON-LINEAR ANALYSIS

ÁLVARO RÖSLER1; MARCELA DA CUNHA SALES1; JONATHAN FRAPORTTI1; VINICIUS WILLY PREDIGER1; GABRIEL CONSTANTIN1; FERNANDO ANTÔNIO LUCCHESE1;

(1) HOSPITAL SÃO FRANCISCO - SANTA CASA DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Traditional risk scores, largely based on logistic regression models, often oversimplify the physiological complexity of renal function. This restrictive approach may fail to adequately stratify patients with moderate renal dysfunction, masking important therapeutic windows. In contrast, Machine Learning techniques can detect hidden non-linear patterns and redefine the prognostic impact of creatinine clearance in high-complexity aortic surgery. Objectives: To build and apply advanced Machine Learning algorithms to investigate the non-linear relationship between renal function and operative mortality, identifying critical inflection thresholds and quantifying survival gains associated with each 5 mL/min increase in glomerular filtration rate. Methods: This cohort study included 610 patients undergoing thoracic aortic aneurysm repair between 2010 and 2025. The analytical strategy employed: 1) Ensemble Learning algorithms (ExtraTrees) for Feature Importance ranking, surpassing traditional logistic regression; and 2) Generalized Additive Models (GAM) with cubic splines for vectorized risk curve modeling. Analyses isolated the marginal effect of renal function while adjusting for multiple confounders, including cardiopulmonary bypass time, surgical complexity, and other perioperative variables. Resultados e Conclusions: Overall mortality was 5.6%. Non-linear modeling established a distinct risk hierarchy, with preoperative creatinine clearance emerging as the second strongest determinant of survival, surpassed only by cardiopulmonary bypass time. Contrary to the linear behavior assumed by traditional scores, AI-assisted analysis demonstrated an exponential risk profile with a critical inflection point at 60 mL/min. A “golden zone” for clinical optimization was identified between 40 and 70 mL/min, in which each 5 mL/min increase in renal function translated into a 22% relative reduction in mortality risk. Above 75 mL/min, the benefit reached a safety plateau, with persistently low operative risk even among patients with major comorbidities. These findings demonstrate that the kidney-mortality relationship is governed by non-linear dynamics and reveal a critical therapeutic window frequently underestimated by conventional models. AI-based approaches may therefore support a new paradigm of “Precision Surgery,” offering refined preoperative targets that static risk scores are unable to provide.

IMPROVING CARDIOVASCULAR RISK CONTROL THROUGH TELEHEALTH IN PRIMARY CARE: EVIDENCE FROM A REAL-WORLD INTERVENTION IN BRAZIL

MILENA SORIANO MARCOLINO1; JOÃO ANTONIO QUEIROZ OLIVEIRA1; CHRISTIANE CORREA RODRIGUES CIMINI1; ANTONIO LUIZ PINHO RIBEIRO1;

(1) TELEHEALTH CENTER, UNIVERSITY HOSPITAL, UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Hypertension and diabetes mellitus are major cardiovascular risk factors, yet control rates remain suboptimal in Brazil. Telehealth has been increasingly incorporated into primary care, with the potential to improve chronic disease management through clinical decision support systems (CDSS) and care reorganization. Objectives: To evaluate the impact of a multifaceted telehealth intervention on hypertension and diabetes control in primary care settings in a resource-constrained region of Brazil. Methods: This is a quasi-experimental sub-study of the HealthRise–Teófilo Otoni project. A multifaceted telehealth intervention was implemented in primary care across 10 municipalities in the Vale do Mucuri region, Minas Gerais, Brazil, from October/2017 to February/2020. The intervention included the implementation of a CDSS, training of primary care professionals, strengthening of multidisciplinary care processes, and improved access to diagnostic testing. Effectiveness was assessed by comparing baseline and final clinical parameters among patients with hypertension and/or diabetes, including systolic and diastolic blood pressure, LDL cholesterol, glycated hemoglobin (HbA1c), and body mass index. Resultados e Conclusions: A total of 3,095 patients were included (median age 56.0 years, 67.0% female), of whom 94.1% had hypertension and 32.1% had diabetes. Among hypertensive patients with at least two blood pressure measurements (n=2,111), there was a significant reduction in systolic and diastolic blood pressure (p<0.001), an increase in the proportion of patients with controlled blood pressure (48.1% vs 59.5%, p<0.001), and a reduction in LDL cholesterol levels (p=0.005), with improved attainment of LDL targets. Among patients with diabetes (n=463 with ≥2 HbA1c measurements), there was no significant change in median HbA1c; however, the proportion achieving HbA1c <8% increased (53.8% vs 59.0%, p=0.025). Significant reductions in blood pressure and LDL cholesterol were also observed, along with improved blood pressure control (51.3% vs 58.2%, p=0.004). No significant changes were observed in body mass index. In conclusion, the intervention was associated with improvements in blood pressure and lipid control among patients with hypertension and diabetes in a resource-limited setting. These findings support the potential of telehealth-enabled strategies to strengthen chronic disease management, although further efforts are needed to enhance glycemic control and ensure long-term sustainability and scalability.

21016

IMPROVING TIMELY ACUTE CORONARY SYNDROME CARE THROUGH IMPROVEMENT SCIENCE AND LEAN HEALTHCARE ACROSS 100 FIXED PRE-HOSPITAL CARE FACILITIES IN BRAZIL

ARIANE SALLES PRADO1; FERNANDA RODRIGUES LIMA1; ANDRÉIA SILVA DA RIBEIRO1; CAMILA PEREIRA PINTO TOTH1; FELIPE MENDES DELPINO1; SILVIA SCHOENAU DE AZEVEDO1; MARIA FERNANDA SOARES NAUFEL1; CAMILA ROCON DE LIMA1; SABRINA GISELE TOBIAS DA SILVA1; PATRICIA VENDRAMIM1;

(1) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL;

Introduction/Background: Care practices adopted in fixed pre-hospital services within Brazil's public health system directly influence patient safety and clinical outcomes. In the context of Acute Coronary Syndrome (ACS), failures in standardizing initial care, reflected in delays, care variability, and low adherence to evidence-based practices, represent significant challenges to care quality. The implementation of managed clinical protocols aligned with recognized guidelines, combined with Improvement Science and Lean Healthcare methodologies, constitutes a structured approach to minimize unwarranted variation and optimize care delivery. Objectives: To describe the impact of applying Improvement Science and Lean Healthcare on reducing care times and standardizing ACS care in fixed pre-hospital services within Brazil's public health system. Methods: A multicentre project was implemented across 100 fixed pre-hospital public health services in Brazil from June 2024 to December 2025, with June and July 2024 designated as the baseline period. Interventions were based on Improvement Science and Lean Healthcare and included implementing guideline-aligned ACS clinical protocols, team training, process standardization, and monthly monitoring of key indicators through Plan–Do–Study–Act (PDSA) cycles. Resultados e Conclusions: Following implementation involving 10,561 patients (mean age 63; 58.6% male), services showed a sustained reduction in door-to-ECG time, from 24 to 12 minutes (50% reduction). Door-to-physician time also improved from 20 to 17 minutes, a sustained 15% reduction. Finally, adherence to guideline-recommended pharmacological therapy for ACS increased from 33% to 67% during the monitoring period.

21056

SMARTPHONE-BASED CRANIOFACIAL AI SCREENING FOR OBSTRUCTIVE SLEEP APNEA IDENTIFIES INDIVIDUALS AT INCREASED HYPERTENSION RISK

LAURA SIQUEIRA CASTRO1; LUCAS FIGUEIREDO BARAÇAS1; JOSIMAR EDINSON CHIRE SAIRE1; FRANCIELI RUIZ1; CRISTINA SALLES2; ROSA HASAN1; DALVA POYARES3; FATIMA CINTRA3; TATIANA AGUIAR VIDIGAL3;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) ESCOLA BAHIANA DE MEDICINA E SAUDE PUBLICA (EBMSP) - SALVADOR - BA - BRASIL; (3) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL;

Introduction/Background: Obstructive sleep apnea (OSA) is strongly associated with hypertension and cardiovascular disease, yet remains markedly underdiagnosed due to limited access to polysomnography, particularly in large-scale and real-world settings. Objectives: To evaluate whether a smartphone-based craniofacial artificial intelligence (AI) model for OSA risk identification is associated with hypertension across clinical and real-world cohorts. Methods: We developed a machine learning model using frontal and profile facial photographs, age, and sex to estimate OSA risk without clinical questionnaire variables. Craniofacial features associated with upper airway anatomy were extracted from smartphone images to generate high- versus low-risk OSA classification.The model was developed and evaluated using multicenter clinical cohorts with polysomnography as the diagnostic reference standard, and subsequently assessed in real-world smartphone users. A total of 5,220 participants were included across a clinical cohort (n=846) and two independent real-world cohorts evaluated before (n=3,285) and after (n=1,089) deployment of the refined model. Logistic regression was used to evaluate associations between predicted OSA risk and self-reported hypertension. Resultados e Conclusions: Clinical validation demonstrated robust discriminative performance for OSA detection (AUC 0.83 for AHI≥5). Individuals with hypertension consistently showed higher prevalence of high OSA risk across all cohorts. In the clinical cohort, high-risk classification occurred in 92.4% of hypertensive versus 74.8% of non-hypertensive participants (OR 4.08, 95% CI 2.55–6.53; p<0.001). In the real-world cohort evaluated before deployment of the refined model, prevalence was 75.3% versus 45.1% (OR 3.71, 95% CI 2.93–4.69; p<0.001), with similar findings after deployment (73.2% vs 44.7%; OR 3.38, 95% CI 2.24–5.11; p<0.001). Smartphone-based craniofacial phenotyping identified individuals at increased risk for OSA and demonstrated consistent association with hypertension across clinical and real-world settings. These findings support scalable, non-invasive AI-based screening strategies for early cardiovascular risk identification while expanding access to OSA screening in underserved populations.

Supplementary Table 1 – Preliminary Testing Across AHI Thresholds

Preliminary performance of models across different AHI thresholds (≥5, ≥10, ≥15), using image-only, demographic, and Berlin 1 combinations as features.

Threshold	Features	Sens.	Spec.	Accuracy	AUC
AHI ≥ 5	Image only	0.9359	0.6364	0.8989	0.7861
	Image + Demographics	0.9231	0.7373	0.8989	0.8252
	Image + Demographics + Berlin 1	0.9326	0.7778	0.9065	0.8552
AHI ≥ 10	Image only	0.8280	0.6316	0.7865	0.7301
	Image + Demographics	0.8714	0.6842	0.8315	0.7778
	Image + Demographics + Berlin 1	0.7858	0.7368	0.7753	0.7613
AHI ≥ 15	Image only	0.8167	0.5852	0.7416	0.7014
	Image + Demographics	0.7167	0.7241	0.7191	0.7204
	Image + Demographics + Berlin 1	0.7167	0.7241	0.7191	0.7204

Note. AHI: Apnea-Hypopnea Index; AUC: Area Under the ROC Curve; Berlin 1: first version of the Berlin Questionnaire score used in feature combination.

Supplementary Table 2 – Cranial Feature Descriptions

Descriptions of the craniofacial features extracted from standardized frontal and lateral facial images. Features include linear distances, angular relationships, and proportional metrics used as input to image-based classification models.

View	Feature Name	Description
Front	Distance Eye Left Outer to Nose Left	Horizontal distance from the outer corner of the left eye to the left side of the nose.
Front	Distance Cheek Right to Cheek Left	Facial width between the right and left cheeks.
Front	Distance Nose Right to Nose Middle	Horizontal distance from the right side of the nose to its midpoint.
Front	Area Cheek and Chin	Area covering cheeks and chin, used as a proxy for facial shape.
Front	Distance Eye Right Width	Width of the right eye.
Front	Distance Eye Left Inner to Nose Left	Horizontal distance from the inner corner of the left eye to the left side of the nose.
Front	Proportion Jaw Width and Height	Ratio of jaw width to vertical jaw height.
Front	Proportion Jaw Width and Width	Ratio of jaw width to overall facial width.
Front	Distance Nose Middle to Nose Left	Horizontal distance from nose midpoint to left side.
Front	Proportion Interocular and Width	Ratio of distance between eyes to total facial width.
Front	Distance Chin Right to Chin Left	Horizontal chin width from right to left edge.
Front	Distance Eye Right Outer to Nose Right	Horizontal distance from the outer corner of the right eye to the right side of the nose.
Front	Distance Cheek Left to Eye Left Outer	Distance from left cheek to the outer corner of the left eye.
Front	Distance Nose Right to Nose Left	Overall nose width.
Front	Distance Eye Left Width	Width of the left eye.
Front	Distance Eye Right Inner to Nose Right	Horizontal distance from the inner corner of the right eye to the right side of the nose.
Front	Proportion Interocular and Height	Ratio of inter-eye distance to facial height.
Front	Proportion Mandibular Bottom Width and Width	Ratio of bottom mandibular width to total facial width.
Front	Proportion Mandibular Bottom Width and Height	Ratio of bottom mandibular width to mandibular height.
Front	Proportion Mandibular Top Width and Width	Ratio of top mandibular width to facial width.
Front	Distance Cheek Right to Eye Right Outer	Distance from right cheek to the outer corner of the right eye.
Side	Proportion Area Max and Area Rect	Ratio of maximum visible facial area to bounding rectangular area.
Side	Proportion Right Mandible Angle Bottom to Right Chin and Height	Ratio from mandible bottom angle to chin over total height.
Side	Proportion Right Chin to Nose Columella and Height	Ratio from chin to columella (nasal base) over height.
Side	Proportion Right Chin to Nose Columella and Width	Ratio from chin to columella over facial width.
Side	Proportion Right Ear Tragus to Right Chin and Width	Ratio from tragus to chin over width.
Side	Proportion Right Ear Tragus to Right Chin and Height	Ratio from tragus to chin over height.
Side	Proportion Right Ear Tragus to Right Mandible Angle Top and Width	Ratio from tragus to mandible top angle over width.
Side	Proportion Right Ear Tragus to Right Mandible Angle Top and Height	Ratio from tragus to mandible top angle over height.
Side	Proportion Right Mandible Angle Bottom to Right Chin and Width	Ratio from mandible bottom angle to chin over width.

USE OF MACHINE LEARNING TO IDENTIFY CRITICAL THRESHOLDS OF EXPONENTIAL RISK IN CORONARY ARTERY BYPASS GRAFT SURGERY

ÁLVARO RÖSLER1; MARCELA DA CUNHA SALES1; GABRIEL CONSTANTIN1; VINICIUS WILLY PREDIGER1; JONATHAN FRAPORTTI1; FERNANDO ANTÔNIO LUCCHESE1;

(1) HOSPITAL SÃO FRANCISCO - SANTA CASA DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Traditional statistical models often assume a gradual and linear increase in surgical risk. However, human homeostasis operates through complex functional reserve limits. In this context, non-linear models may identify “Breakpoints,” defined as thresholds beyond which compensatory mechanisms collapse and adverse outcomes become exponential. Machine learning may therefore provide a risk stratification approach more consistent with biological reality. Objectives: To build and apply Machine Learning algorithms to detect non-linear relationships between physiological variables and in-hospital mortality, aiming to rank predictor importance and identify critical risk thresholds in Coronary Artery Bypass Grafting (CABG). Methods: This retrospective observational cohort included 4,388 consecutive patients undergoing isolated elective CABG. Predictive modeling was performed using the Random Forest Classifier algorithm to map complex non-linear interactions beyond logistic regression limitations. “Gini Importance” was calculated to rank predictor relevance, while Partial Dependence Plot analysis with decile stratification was used to identify thresholds where risk curves showed significant positive inflection. Resultados e Conclusions: AI-based modeling identified a distinct risk hierarchy compared with traditional scores. Cardiopulmonary Bypass Time (29.9%) and Creatinine Clearance (27.2%) emerged as the dominant predictors, surpassing age (14.0%) and ejection fraction (13.4%). Partial dependence analysis exposed physiological cliffs in which mortality abruptly increased: mortality doubled (3.4% to 7.3%) when perfusion time exceeded 108 minutes and tripled (9.1%) when creatinine clearance fell below 41 mL/min. Preoperative anemia also demonstrated an exponential pattern, with mortality reaching 8.5% for hemoglobin levels below 10.6 g/dL. In contrast, age and ejection fraction showed stable safety curves up to thresholds of 75 years and 40%, respectively. These findings demonstrate that Machine Learning can refined the mathematical understanding of risk in elective cardiac surgery, demonstrating that risk progression is governed by breakpoints rather than linear behavior. Interpreting variables solely as linear averages may conceal zones of extreme vulnerability. Defining these breakpoints provides objective perioperative safety targets and may support earlier interventions before patients cross thresholds associated with exponential risk.

AMYLOIDOSIS MORTALITY IN BRAZIL, 2014–2024: NATIONAL OVERVIEW OF A RARE DISEASE AND TREND ANALYSIS USING JOINPOINT REGRESSION.

RAFAEL SOTO TABAJARA1; ROBERTO FRANCISCO MOURA GOMES SANTOS1; ANA JULIA FREITAS REZENDE1; GLÊNIO ALVES DE FREITAS1;

(1) UNIVERSIDADE FEDERAL DE UBERLANDIA - UBERLÂNDIA - MG - BRASIL;

Introduction/Background: Amyloidosis is a rare disease characterized by extracellular deposition of amyloid proteins, often with cardiac involvement and a significant impact on morbidity and mortality. In Brazil, there are still few studies on mortality related to this condition. Objectives: To analyze the temporal trend and epidemiology of mortality due to amyloidosis in Brazil from 2014 to 2024. Methods: This is an observational, ecological time-series study using data from the Mortality Information System (SIM-DATASUS) related to amyloidosis (ICD-10: E85). Variables included sex, age group, race/ethnicity, and region of residence. Mortality rates were calculated per 100,000 inhabitants, and temporal trends were evaluated using Joinpoint Regression, with calculation of Annual Percent Change (APC) and Average Annual Percent Change (AAPC). Resultados e Conclusions: Between 2014 and 2024, a total of 1,918 deaths due to amyloidosis were recorded in Brazil, with predominance of males (59.4%) compared to females (40.6%). Age distribution showed higher concentration among individuals aged 70–79 years (27.2%), followed by ≥80 years (25.7%) and 60–69 years (22.3%), indicating greater impact on older adults. Regarding race/ethnicity, there was predominance of White individuals (56.9%), followed by mixed-race (28.7%) and Black individuals (10.7%). In regional analysis, Southeast region accounted for highest proportion of deaths (52.7%), followed by Northeast (21.9%), South (16.5%), Midwest (6.9%), and North (2.0%), possibly reflecting greater availability of diagnostic resources and case identification. In temporal trend analysis, APC indicated stationary pattern in Brazilian regions. However, AAPC demonstrated increasing trend in national mortality (7.30%; 95% CI: 0.17–14.93) and Northeast region (11.14%; 95% CI: 0.06–23.45). Increase observed in Brazil and Northeast may be associated with improvements in diagnostic capacity over study period. Cardiovascular involvement stands out as main prognostic determinant, frequently associated with late diagnosis, advanced heart failure, and high lethality. These findings reinforce need to improve early recognition, diagnostic qualification, and organization of care for infiltrative cardiomyopathies in country.

CARDIOVASCULAR OUTCOMES IN LONG COVID: A TWO-YEAR OBSERVATIONAL FOLLOW-UP STUDY

RODRIGO DE CARVALHO MOREIRA1; VITORIA JABRE1; MARIA PIA DINIZ RIBEIRO1; ROBERTO M SARAIVA1; HUGO PERAZZO1; EMILIA JALIL1; MARCELO TEIXEIRA DE HOLANDA1; RONALDO ISMERIO MOREIRA1; BEATRIZ GRINSZTEJN1; DANIEL ARABE1; VALDILEA G VELOSO1; SANDRA WAGNER CARDOSO1;

(1) INSTITUTO NACIONAL DE INFECTOLOGIA EVANDRO CHAGAS - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Post-acute sequelae of SARS-CoV-2 infection (Long COVID) is associated with persistent clinical manifestations, including cardiovascular complications. However, the prevalence and factors associated with cardiovascular outcomes in Long COVID remain incompletely characterized. Objectives: We aimed to describe the prevalence of cardiovascular and non-cardiovascular outcomes and to identify factors associated with cardiovascular outcomes in people with Long COVID. Methods: Persons with persistent symptoms of dyspnea, chest pain, or tachycardia post COVID-19 were included and followed for up to two years with outpatient visits scheduled every 6 months. Routine assessments included electrocardiography (ECG) and echocardiography. Additional diagnostic tests such as Holter monitoring and cardiac catheterization, were performed at the discretion of the attending physician based on clinical judgment. Outcomes were classified as non-cardiovascular or cardiovascular, including heart failure, hypertension, coronary artery disease, arrhythmias, thromboembolic diseases, non-anginal chest pain, myocarditis or pericarditis, syncope or lipothymia. Multivariable logistic regression models were used to identify factors associated with cardiovascular outcomes, expressed as odds ratios (OR) and 95% confidence intervals (95% CI). The study was reviewed and approved by the local Ethics Review Board. All analyses were conducted with R 4.2.3 Resultados e Conclusions: A total of 266 participants were included. The median age was 58 years (IQR 50–66) Women reported palpitations/tachycardia more frequently than men (42% vs. 21%; p < 0.001). Non-cardiovascular outcomes were observed in 33.1% of patients. Among cardiovascular outcomes, heart failure was the most prevalent condition (21.4%), followed by hypertension (20.3%), coronary artery disease (16.2%), and arrhythmias (16.2%). In multivariable analysis, age (OR 1.04; 95% CI 1.01–1.08), dyslipidemia (OR 4.42; 95% CI 1.76–12), diastolic dysfunction (OR 2.35; 95% CI 1.01–5.55), left ventricular ejection fraction (OR 0.92; 95% CI 0.85–0.97) and low white blood cell count (OR 4.15; 95% CI 1.03–19.5) were associated with cardiovascular outcomes. Patients with Long COVID exhibited a high prevalence of cardiovascular outcomes, with heart failure, hypertension, coronary artery disease and arrhythmias as the most frequent conditions, highlighting the importance of systematic cardiovascular assessment in this population.

CLINICAL IMPACT OF CARDIOVASCULAR DIAGNOSTIC CAMPAIGNS ON RISK PRIORITIZATION IN SUS WAITING LISTS: EVIDENCE FROM MINAS GERAIS, BRAZIL

WANESSA CAMPOS VINHAL1; BRUNO RAMOS NASCIMENTO2; RALDNER BORGES E REGES1; ISABELY KAROLINE DA SILVA RIBEIRO1; LUIZA PONTES ABREU1; MATEUS HENRIQUE MARTINS GOMES1; GABRIELLA DE ALMEIDA SOARES1; ANA CAROLINA OLIVEIRA GONCALVES1; MARIA DO CARMO PEREIRA NUNES2; ANTONIO LUIZ PINHO RIBEIRO2; CLARECI SILVA CARDOSO1;

(1) UNIVERSIDADE FEDERAL DE SAO JOAO DEL REI - DIVINOPOLIS - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Background: In public health systems, chronologically organized waiting lists for cardiac testing may delay the identification of patients at imminent risk of severe cardiovascular events. Cardiovascular diagnostic campaigns may help overcome this limitation by expanding access to testing while enabling risk-based prioritization of care. Objectives: Objective: To assess the clinical impact of cardiovascular diagnostic campaigns on risk stratification and identification of priority cases among patients awaiting cardiac evaluation in the Brazilian Unified Health System (SUS). Methods: Methods: We performed a descriptive cross-sectional study using data from two cardiovascular diagnostic campaigns conducted in Divinópolis and Poços de Caldas, Minas Gerais, Brazil. Electrocardiograms and echocardiograms were obtained from patients previously registered on SUS waiting lists. During the campaigns, participants were classified in real time as normal, abnormal requiring outpatient follow-up, or clinical priority, defined as the need for urgent intervention. Clinical impact was assessed using the Number Needed to Screen (NNS) for abnormal findings, priority cases, and activations of the Mobile Emergency Care Service (SAMU). Resultados e Conclusions: Results: A total of 3,832 patients underwent electrocardiographic and echocardiographic evaluation. Median age was 66 years in both municipalities. Overall, 1,013 patients (26.4%) had abnormal findings and 273 (7.1%) were classified as clinical priority cases. Divinópolis showed a higher proportion of priority cases than Poços de Caldas (9.0% vs. 5.3%). Thirty-two SAMU activations for immediate hospital transfer were recorded and occurred on every day of the campaigns. The NNS was 4 (95% CI, 3.6–4.0) for abnormal findings, 14 (95% CI, 12.5–15.7) for priority cases, and 120 (95% CI, 84.7–169.4) for one SAMU-triggered hospital transfer. Conclusions: Cardiovascular diagnostic campaigns demonstrated meaningful clinical impact by identifying high-risk patients concealed within chronologically organized SUS waiting lists. Beyond expanding diagnostic access, this strategy may enhance risk-based prioritization, improve patient safety, and support more efficient organization of care delivery in resource-constrained public health settings.

Table 1. Distribution of screened patients and clinical outcomes

Indicator	Total	Divinópolis N (%)	Poços de Caldas N (%)
Patients screened	3,832	1,831 (47.8)	2,001 (52.2)
Abnormal findings	1,013 (26.4)	524 (28.6)	489 (24.4)
Clinical priority	273 (7.1)	166 (9.0)	107 (5.3)
SAMU activations	32 (0.8)	25 (1.4)	7 (0.4)

Table 2. Clinical yield of the diagnostic campaigns

Indicator	Identified cases (n)	Prevalence (%)	NNS	95% CI
Abnormal findings	1,013	26.43	4	3.6–4.0
Priority cases	273	7.12	14	12.5–15.7
SAMU activation	32	0.83	120	84.7–169.4

Abbreviations: NNS, Number Needed to Screen; SAMU, Mobile Emergency Medical Services.

COMPARATIVE ANALYSIS OF IN-HOSPITAL OUTCOMES FOLLOWING ADMISSIONS FOR COPD VERSUS ACUTE CORONARY SYNDROMES IN THE BRAZILIAN POPULATION.

JOSE AUGUSTO RIBAS FORTES1; GIOVANNA NOGAROLLI FARIA1; THYAGO PROENÇA DE MORAES1; JOSÉ ROCHA FARIA NETO1;

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL;

Introduction/Background: Chronic Obstructive Pulmonary Disease (COPD) and Acute Coronary Syndromes (ACS) are among the leading causes of hospitalization in Brazil, with a substantial impact on morbidity and mortality. Despite their distinct clinical trajectories, both are associated with a significant risk of readmission. Large-scale comparative analyses within the context of the Brazilian Unified Health System (SUS) remain limited. Objectives: To compare in-hospital outcomes, including readmissions, time to first event, and in-hospital mortality, between patients with a first hospitalization for COPD versus ACS in the Brazilian population. Methods: Retrospective cohort including 702,560 patients hospitalized in the Brazilian Unified Health System (SUS) between 2008 and 2024, using publicly available DATASUS data extracted via the TT Disease Explorer platform (Techtrials), which continuously integrates and updates epidemiological information. The system uses Microsoft Azure, SQL, M, DAX, and Power BI for data processing and visualization. Artificial intelligence (ETLs and web crawlers) enables collection of structured, encrypted, and de-duplicated data, ensuring unique patient identification. First hospitalizations for COPD or Acute Coronary Syndromes were included, defined as no prior admissions in the previous five years. Outcomes included readmission, time to event (Kaplan–Meier), and in-hospital mortality, analyzed using logistic regression and Cox models. Resultados e Conclusions: Among patients with COPD (n=35,478), 34.5% were readmitted, mainly due to COPD (43.8%) and pulmonary infection (32.8%). In the ACS group (n=201,008), 33.8% were readmitted, predominantly due to cardiovascular causes (77.7%). Time to readmission was longer in COPD (271 days; 95% CI 259–283) compared with ACS (84 days; 95% CI 82–87). Patients with ACS had a higher risk over time (HR 1.26–1.27) and a greater likelihood of 30-day readmission (OR 3.08; 95% CI 2.91–3.26). In-hospital mortality during the first admission was similar between groups (OR 0.98; p=0.44), but was higher during the second admission in COPD (10.0% vs 8.3%; OR 0.81 for cardiovascular; p<0.001). These findings highlight distinct patterns: the cardiovascular group shows a higher risk of early events and immediate recurrence, whereas COPD is associated with higher late mortality and readmissions related to disease progression. Therefore, care strategies should be tailored accordingly, prioritizing early transitional care in ACS and longitudinal management in COPD.

COULD ANGIOTENSINOGEN GENE POLYMORPHISM BE A RISK FACTOR FOR POOR CARDIOVASCULAR PROGNOSIS IN CHRONIC HEMODIALYSIS PATIENTS?

MAURO ALVES1; SONIA VELIHOVETCHI LAREDO1; BASÍLIO DE BRAGANÇA PEREIRA1;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Patients undergoing hemodialysis (HD) continue to experience a significant increase in morbidity and mortality, especially from cardiovascular diseases (CVD). The presence of risk factors (RF) may indicate a higher probability of a particular outcome occurring. A better understanding of RFs linked to the prognosis of patients undergoing dialysis treatment is relevant in predicting mortality. Traditional cardiovascular risk factors alone are not sufficient to explain the high mortality rate in the population with chronic kidney disease requiring dialysis in our region. Other factors, such as genetic factors, need to be investigated. In our view, the key to greater survival lies in a better understanding of the risk factors, traditional or otherwise, associated with the prognosis of this population. Objectives: Primary: To evaluate the association of the M235T polymorphism of angiotensinogen (AGT) with survival in a hemodialysis population in Hardy-Weinberg equilibrium. Secondary: To evaluate the main causes of mortality. Methods: This was an observational study designed to investigate the role of a RAS gene. Using the same cohort from our doctoral thesis, we decided in 2026 to analyze an arm of that study in a subpopulation that presented at the same time of hemodialysis treatment. Eighty-two patients treated with chronic hemodialysis in four dialysis units in the state of Rio de Janeiro were analyzed. The follow-up period was 11 years. Survival rates were calculated using the Kaplan-Meier method, and differences between the curves were evaluated using the Tarone-Ware, Peto-Prentice, and Log-rank tests. Logistic and multinomial regression models were also used. A p-value <0.05 was considered statistically significant. • Feedback Resultados e Conclusions: The survival rate was 44% over 11 years. The main causes of death were circulatory system diseases (41%), with atherothrombotic vascular disease (ischemic heart disease + stroke) accounting for 37% of cases, followed by infections (15%). Although not statistically significant, it is interesting to note that 22% of the deceased patients had diabetes, while only 14% of the surviving patients had this disease. Logistic regression analysis in relation to the TT angiotensinogen genotype, with a p-value of 0.0844, indicated a significant trend with an odds ratio of 3.931 (95% CI: 0.128 to 1.231) for higher lethality. The TT polymorphism of AGT M235T showed a trend towards association with mortality in these patients.

DESIGNING SUSTAINABLE MULTISECTOR GOVERNANCE FOR HYPERTENSION AND NCD CONTROL: A CO-CREATION AND IMPLEMENTATION SCIENCE APPROACH FROM BRAZIL

YARA BAXTER1; JOHANNES BOCH1; MARIANA NEGRÃO SILVEIRA2; GIOVANNA FERNANDES2; BARBARA SERVULO HERTHEL2; RENATO GAVIOLI2; DANIELE FIGUEIRA BEIRIZ MACHADO2; ANA LÍRIA SOUZA2; PATRÍCIA DÜTSCH3; THAIS JUNQUEIRA4; ANN AERTS1; ANDRÉ MENEZES LARA RESENDE5;

(1) NOVARTIS FOUNDATION - SWITZERLAND; (2) BENEFICENCIA PORTUGUESA - SAO PAULO - SP - BRASIL; (3) SWISS RE FOUNDATION - SWITZERLAND; (4) UMANE - SÃO PAULO - SP - BRASIL; (5) BAKKO - SÃO PAULO - SP - BRASIL;

Introduction/Background: Despite growing recognition of multisectoral collaboration for noncommunicable diseases (NCDs), health systems still struggle to translate this principle into structured and sustainable governance models. This gap is particularly evident in large public systems, where coordination remains fragmented, accountability unclear, and implementation capacity uneven. In low- and middle-income settings, these challenges are intensified by resource constraints and system complexity. Hypertension, a leading modifiable risk factor for cardiovascular disease, exemplifies this disconnect, as large-scale control depends on coordinated governance and sustained multisector engagement. Objectives: To evaluate the co-creation, design, and implementation of a multisector governance model ("Coalition") for hypertension and NCD control, analyzing its structure, coordination mechanisms, and scalability. Methods: A descriptive implementation research design was applied to analyze the coalition model. A structured co-creation process engaged 13 organizations from government, academia, civil society, philanthropy, and the private sector. The approach combined Human-Centered Design, implementation science, and participatory tools across iterative phases (situational analysis, stakeholder mapping, priority setting, and governance design). Analysis included stakeholder mapping with qualitative Social Network Analysis, SDG-aligned impact diagnosis, Impact Canvas modeling, and development of a Logical Framework/Theory of Change. Data were synthesized through inductive thematic analysis. Resultados e Conclusions: At the time of analysis, the initiative had expanded to 45 municipalities, reaching approximately 12.7 million people. Stakeholder mapping identified 70 organizations and 15 potential revenue streams, reflecting a diversified ecosystem for sustainability. The process generated three outputs: (1) a three-phase pathway from philanthropic to hybrid and impact-driven governance; (2) the GIFT-C framework (Governance, Impact, Financing, Technology, Communication); and (3) a coalition-specific Logical Framework linking inputs to long-term impact. Stakeholders reported high perceived impact (mean 4.3/5). These findings position the coalition as a governance innovation capable of integrating multisector actors, aligning incentives, and supporting long-term transformation of cardiovascular and NCD care.

19794

EPIDEMIOLOGIC DIFFERENCES AMONG PATIENTS ADMITTED DUE TO CARDIOLOGICAL PATHOLOGY TO A PUBLIC AND A PRIVATE INTENSIVE CARE UNIT IN BRAZIL'S COUNTRYSIDE

LUID CELENTE DOS SANTOS1; HENRIQUE MILLER BALIEIRO1; JULIANA MENDES DE MATTOS1; CARLOS DE JESUS MERELES AYALA1; LEONARDO LORENZO VENEGAS CARTES1; HENRIQUE GJORUP BARCELLOS1; MATEUS BARROS OLIVEIRA1; ANNA CRISTINA MARTINS CALDEIRA1; MARIA EDUARDA LEAL BALIEIRO1; SAULO RONI MORAES1;

(1) HOSPITAL MUNICIPAL DE EMERGENCIA HENRIQUE SERGIO GREGORI - RESENDE - RJ - BRASIL;

Introduction/Background: Cardiological pathology is one of the main causes of admission in the ICU. Understanding the epidemiologic profile of these patients is essential for developing health management policies. We seek to provide data that can contribute to improving the quality of intensive care in countryside regions of middle and low income countries. Objectives: Research Questions Assess the epidemiologic profile among patients admitted due to cardiological pathology to a public (PUB) and private (PVT) ICU in Brazil's countryside and identify the epidemiologic differences between the subgroups. Methods: Methods We conducted a prospective cross-sectional study between 2022 and 2024. Data was collected in the ICU from each patient admitted due to cardiological pathology. We analyzed the epidemiologic profile and the differences between the PUB and PVT subgroups. We used SPSS v20.0 for statistical analysis. We assessed quantitative variables using the Kolmogorov Smirnov test with mean and standard deviation, using the interquartile range in case of asymmetry. We compared quantitative variables using the Student's t-test for independent samples, and in case of asymmetry, using the Mann-Whitney test. We used the Chi-square test to compare proportions, and Fisher's exact test as appropriate. P<0,05 was considered statistically significant. Resultados e Conclusions: Results There were 1438 patients, of which 361 (25,1%) were in the PUB subgroup. The mean age in PUB was 65,3 +- 14,2 and in PVT 54,6 +- 17,1, p<0,0001; SAPS 3 in PUB was 63,3 +- 16,8 and in PVT 40,7 +- 9,0, p<0,0001; length of stay in PUB was 7,5 and in PVT 3,6, p<0,0001; mortality rate was 56 (3,9%), in PUB 33 (9,3%) and 23 (2,1%) in PVT, p<0,0001; HTN in PUB accounted for 274 (75,9%) patients and in PVT 589 (54,7%), p<0,0001; AF in PUB was 37 (10,2%) and in PVT 62 (5,8%), p=0,005; HF NYHA II-III in PUB was 102 (28,3%) and in PVT 88 (8,2%), p<0,0001; MI in PUB was 61 (16,9%) and in PVT 56 (5,2%), p<0,0001; sequelae of stroke in PUB was 12 (3,3%) and in PVT 15 (1,4%), p=0,025; and COPD in PUB was 32 (8,9%) and in PVT 28 (2,6%), p<0,0001. Sex, BMI, dialysis and HF NYHA IV were not statistically significant. Conclusion The comorbidities HTN, AF, HF NYHA II-III, MI, sequelae of stroke and COPD were more common in PUB patients, which were also older, had a higher mortality rate and SAPS 3 and had a longer length of stay. There were no statistical differences between the groups for sex, BMI, dialysis and HF NYHA IV.

EPIDEMIOLOGICAL PROFILE AND MORTALITY TRENDS OF HEART FAILURE HOSPITALIZATIONS IN PARAÍBA, BRAZIL

LUCAS IAN SOUSA QUEIROZ1;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL;

Introduction/Background: Heart failure (HF) is a clinical syndrome resulting from the heart's inability to eject blood to meet its metabolic needs. It affects more than 23 million people worldwide and, in Brazil, is considered the main cardiovascular cause of hospitalizations. State studies on the epidemiological profile of HF are limited. Objectives: The aim of this analysis is to assess the epidemiological and mortality profile of HF hospitalizations in the state of Paraiba, Brazil, between 2013 and 2023. Methods: This is an epidemiological, retrospective descriptive study with a quantitative approach, based on data from patients over 15 years old with HF, available from DATASUS. Resultados e Conclusions: In the period analyzed, there were 28,646 hospital admissions for HF in Paraiba, with a downward trend of 55.6% when comparing 2023 with 2013. It showed an average hospitalization time of 7.64 (± 1.29) and a total cost of R$47,486,508.03, with an increase in the average length of stay and average cost of 75% and 91.1%, respectively, over the last 10 years. Of the total number of cases, 52.2% were male patients and 73.4% were aged over 60, with the highest proportion in the 70-79 age group. In addition, the self-declared brown population accounted for 60% of hospitalizations. In addition, excluding data with no information, the type of care and its regime corresponded to 98% emergency care and 61% in private services, respectively. The number of deaths was 6,763 during the period, with an average population mortality rate of 676.3 (± 63.27) and an average population mortality rate of 13.68/100,000 (± 2.88) in Paraiba, resulting in a decline of 5.8% and 10.23%, respectively, from 2013 to 2022. The mortality rate in hospitalizations was 13.7%, with a higher proportion in the elderly over 80 years old. There was a 77.6% increase in the frequency of mortality in hospitalizations in 2023 compared to 2013. Even with the reduction in the absolute number of hospitalizations, HF persists as a public health problem due to the increase in the average length of stay, death rate and cost of hospitalization. The development of this study allowed us to learn more about the epidemiology of HF in the state of Paraiba, providing a better assessment of the evolution of this disease over time.

ETHICAL AND FEASIBILITY CONSTRAINTS UNDERLYING LEVEL C RECOMMENDATIONS IN ACC/AHA AND SBC CARDIOLOGY GUIDELINES: AN AI-ASSISTED MAPPING STUDY

LUCAS MANUEL PAGENKEMPER1; MARA LAURA SPRINGMANN1; LUIS GUSTAVO MORAIS PESSOA DOS SANTOS1; NORA SOPHIA HOFFMANN1; KAROLINE ILSE SIEGLINDE MANEGOLD1; BEATRIZ FORNARI FERNANDEZ1; ARIANA ESTER FERNANDEZ1; LUCIANA DORNFELD BICHUETTE1; MARCOS PITA LOTTENBERG1; FRANCISCO AKIRA MALTA CARDOSO1; DANIELLE MENOSI GUALANDRO2; BRUNO CARAMELLI1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) DEPARTMENT OF CARDIOLOGY AND CARDIOVASCULAR RESEARCH INSTITUTE BASEL (CRIB) UNIVERSITY HOSPITAL BASEL , UNIVERSITY OF BASEL, SWITZERLAND - SWITZERLAND;

Introduction/Background: ACC/AHA and SBC clinical practice guidelines grade recommendations by class and level of evidence. Level C recommendations often rely on expert consensus and may be interpreted as “low evidence”, although many remain untested because randomized controlled trials (RCTs) are ethically unacceptable and/or operationally impractical. Objectives: To quantify recommendation class and level of evidence across ACC/AHA and SBC guidelines and, among Level C recommendations, to map ethical and feasibility constraints for RCTs. Methods: Formal recommendations with explicitly stated class and level of evidence were extracted from 24 ACC/AHA (2011–February 2026) and 36 SBC (2015–2024) guidelines using an AI-assisted pipeline with predefined parsing rules, externally validated against human assessment. Native grading systems were preserved; for summary reporting, ACC/AHA B-R and B-NR were grouped as Level B, and C-LD and C-EO as Level C. Level C recommendations were classified into four RCT-constraint groups: Group 1, ethical and feasible; Group 2, ethical but not feasible; Group 3, feasible but not ethical; and Group 4, neither. Constraints were mapped using a predefined framework informed by the CONSORT extension for pilot/feasibility trials, the Declaration of Helsinki, and CIOMS. Resultados e Conclusions: Sixty guidelines were analyzed: 24 ACC/AHA and 36 SBC. In ACC/AHA, Class I, IIa, IIb, and III recommendations accounted for 46.5%, 29.8%, 16.2%, and 8.8%, respectively; Level C accounted for 35.3%. In SBC, the corresponding proportions were 44.7%, 30.5%, 13.8%, and 9.4%, with Level C accounting for 43.8%. Among Level C recommendations, ACC/AHA showed 46.5% in Group 1, 28.4% in Group 2, 22.3% in Group 3, and 3.9% in Group 4; SBC showed 46.1%, 25.7%, 22.8%, and 5.2%, respectively. Level C recommendations were frequent in both societies’ guidelines, with remarkably similar distributions. Many consensus-based recommendations may reflect ethical and feasibility constraints rather than lack of scientific rigor. This framework may help prioritize research and support alternative evidence-generation strategies when RCTs are not acceptable, while underscoring the continuing role of clinical judgment in guideline development and dissemination of good clinical practice.

19087

EVOLUTION OF MORBIDITY AND MORTALITY AND HOSPITAL EFFICIENCY IN THE MANAGEMENT OF ACUTE MYOCARDIAL INFARCTION IN BRAZIL: REGIONAL DISPARITIES AND THE IMPACT OF THE COVID-19 PANDEMIC (2016-2025)

AMANDA GABY DE OLIVEIRA1; EZIO DO AMARAL RODRIGUES2; JULIA SCHNEIDER SANTIAGO2; RAFAEL HEIDTMANN MONTEIRO MESSIAS DE BRITO1; RAMON CAIWAN SILVEIRA DA SILVA3; RONI OLIVEIRA PINHEIRO2; JOÃO CARLOS DA COSTA MENDES FILHO2; EDUARDO COIMBRA COELHO DE ASSIS2; VICENZO LORENZONI VALE3; ENRICO MAGELA BATALHA FALCAO2; JOÃO GABRIEL DUARTE DE LIMA2; GIOVANNA BARCELOS FONTENELE PEREIRA1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (3) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introduction/Background: Acute myocardial infarction (AMI) is the leading cause of cardiovascular death in Brazil. The COVID-19 pandemic impacted coronary syndrome management and epidemiological profile, suggesting pent-up demand and changes in clinical outcomes and hospital efficiency post-pandemic. Regional analysis is crucial to assess SUS resilience and cardiovascular care evolution in the last decade. Objectives: Analyze AMI morbidity, mortality, and hospital efficiency in Brazil, comparing pre- and post-COVID-19 periods, focusing on regional disparities. Methods: Epidemiological, descriptive, and analytical study, with an ecological and retrospective design, based on SIH/SUS data via DATASUS/TABNET (2016-2025). Hospitalizations, deaths, hospital mortality rate (HMR), and average length of stay were compared between the pre-pandemic (2016-2019) and post-pandemic (2021-2025) periods, using 2020 as the transition. Means were compared using Student’s t-test ($p < 0.05$). Percentage variations quantified the magnitude of regional changes. Resultados e Conclusions: A significant increase ($p < 0.001$) in the average volume of AMI hospitalizations occurred in all regions post-pandemic. The largest increase was in the Central-West (+73.3%), followed by the North (+57.5%) and Northeast (+47.0%), indicating high healthcare pressure. Concurrently, the average mortality rate (AMR) decreased nationwide, with sharp drops in the Central-West (-30.4%; $p = 0.0049$) and North (-29.9%; $p = 0.0007$), and significant reductions in the Southeast, South, and Northeast ($p < 0.05$). The average length of stay decreased in the Central-West (-19.5%; $p < 0.001$), Southeast (-13.7%; $p = 0.012$), and North (-7.1%; $p = 0.03$), remaining stable in the Northeast and South ($p > 0.05$). Despite the increased burden of ischemic heart disease post-pandemic, the healthcare system demonstrated resilience and greater efficiency in AMI management. The simultaneous reduction in mortality and length of stay suggests optimization of flows and protocols. The Northern region stands out for the largest proportional decrease in mortality compared to the increase in hospitalizations, indicating advances in the regional emergency network. The data reflect better clinical outcomes and cardiovascular management in Brazil, with demand absorbed through hospital efficiency. The study reinforces the importance of regionalized public policies for maintaining efficiency gains observed in the post-crisis scenario.

FOLLOW-UP OF ONE YEAR IN A NATIONAL COHORT OF ATHEROTHROMBOSIS: FINAL RESULTS FROM THE NETWORK TO CONTROL ATHEROTHROMBOSIS (NEAT) REGISTRY

PEDRO GABRIEL MELO DE BARROS E SILVA1; RENATO LOPES2; LUCAS TRAMUJAS1; CHARLENE TROIANI3; MARCELO ARRUDA NAKAZONE4; RONALD FLUMIGNAN5; ANA CAROLINE DE ALMEIDA SANTOS6; EDUARDO LOULY SANTOS DALLASTRA6; ISABELLA MARIA ZANELLA PATIÑO6; VITOR JOSÉ NUNES TOLEDO RAMOS6;

(1) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL; (2) DUKE UNIVERSITY - UNITED STATES; (3) UNIVERSIDADE DO OESTE PAULISTA - UNOESTE - PRESIDENTE PRUDENTE - SP - BRASIL; (4) FACULDADE DE MEDICINA DE SAO JOSE DO RIO PRETO - SÃO JOSÉ DO RIO PRETO - SP - BRASIL; (5) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL; (6) CENTRO UNIVERSITARIO SAO CAMILO - GUARULHOS - SP - BRASIL;

Introduction/Background: Atherothrombosis is a disruption of atherosclerotic plaque with superimposed thrombosis and, as a group, is the leading cause of death in Brazil and other developing countries. Contemporary prospective data from Latin America assessing prognostic factors in patients with atherothrombotic disease are limited. The Network to control atherothrombosis (NEAT) registry is a national prospective observational study of patients with known coronary artery disease (CAD) and/or peripheral arterial disease (PAD) in Brazil. After one year of follow-up, it highlights determinants observed in the study population. Objectives: To evaluate one-year clinical outcomes and identify independent prognostic factors among patients with established atherothrombotic disease enrolled in the Brazilian NEAT registry. Methods: The NEAT registry was a prospective, national, multicenter observational study including adults with CAD and/or PAD in Brazil. Outcomes at 1 year included all-cause mortality, cardiovascular mortality, total hospitalizations, and cardiovascular hospitalizations. Multivariable analysis was performed to identify independent prognostic factors in this very high-risk population. Resultados e Conclusions: Among 1,382 patients included in the one-year analysis, worsening renal function was linked to a progressive rise in hospitalizations or death. Event rates were 16% for those with CrCl ≥60 mL/min, 30% for CrCl 30–59 mL/min or albuminuria, and 51% for CrCl <30 mL/min. Compared with CrCl ≥60 mL/min, event risk was higher with CrCl 30–59 mL/min or albuminuria (HR 1.97; 95% CI 1.54–2.52) and with CrCl <30 mL/min (HR 4.27; 95% CI 2.99–6.09). After multivariable adjustment, renal dysfunction remained independently associated with adverse outcomes: CrCl 45–59 mL/min or albuminuria (HR 1.70; p<0.001), CrCl 30–44 mL/min (HR 1.79; p=0.001), and CrCl <30 mL/min (HR 3.15; p<0.001). Additional predictors were heart failure (HR 1.85), isolated PAD (HR 1.78), combined PAD/CAD (HR 1.73), and age (HR 1.15 per decade). In this very high-risk population with established atherothrombotic disease, chronic kidney disease was a major independent prognostic factor for one-year hospitalization or death. Renal dysfunction, along with age, heart failure, PAD, and combined PAD/CAD, should be considered in prognostic stratification.

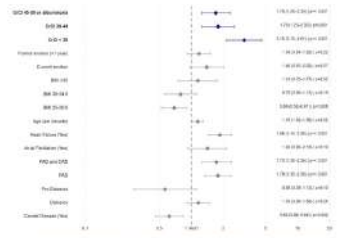

Figure 1: Independent predictors of one-year hospitalization or death in multivariable analysis

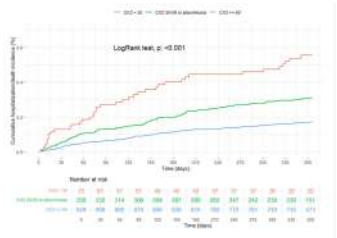

Figure 2: Cumulative one-year hospitalization or death according to renal function

FROM CO-CREATION TO SYSTEM TRANSFORMATION: THE IMPACT OF AN INTEGRATED PACKAGE OF SOLUTIONS ON CHRONIC DISEASE CARE IN BRAZIL

GIOVANNA FERNANDES1; ANA LÍRIA SOUZA1; ANN AERTS2; MARIANA NEGRÃO SILVEIRA1; YARA BAXTER2; JOHANNES BOCH2; LUCIANO DRAGER3; LUIZ BORTOLOTTO3; ALVARO AVEZUM4;

(1) BENEFICENCIA PORTUGUESA - SAO PAULO - SP - BRASIL; (2) NOVARTIS FOUNDATION - SWITZERLAND; (3) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (4) SBC - SAO PAULO - SP - BRASIL;

Introduction/Background: Isolated interventions have proven insufficient to sustainably improve care for chronic noncommunicable diseases (NCDs), particularly cardiovascular conditions, in complex health systems. Despite the availability of evidence-based guidelines, a persistent know–do gap limits large-scale effectiveness, especially in primary health care, where fragmentation, weak governance, and limited data use constrain implementation. Additionally, many individuals with cardiovascular risk factors remain outside health services, hindering early detection and continuity of care. Objectives: To describe the development and implementation of an integrated package of 10 solutions and analyze its role as a structuring mechanism for systemic transformation of cardiovascular and NCD care. Methods: The package was developed through a design thinking process grounded in implementation science, engaging multiple stakeholders (health managers, professionals, patients, and communities). Iterative cycles of diagnosis, co-creation, prototyping, and implementation generated over 80 solutions, of which 10 were selected based on essentiality, feasibility, and scalability. The package integrates actions across care organization, access, treatment adherence, governance, and data use. Implementation occurred in multiple Brazilian municipalities using a context-adaptive approach combining in-service strategies (e.g., opportunistic screening in primary care) and community-based outreach, including active case finding. Resultados e Conclusions: The package demonstrated high adaptability and acceptability across more than 45 municipalities. Impact resulted from the synergistic effect of integrated solutions rather than isolated interventions, reflected in improvements in care cascade indicators, strengthened primary health care capacity, enhanced governance, and increased use of data for decision-making. The model also improved alignment and standardization of existing practices and expanded reach to previously underserved populations. These findings suggest that coordinated implementation of a core solution set can bridge the know–do gap and enable scalable, sustainable transformation of cardiovascular care within health systems.

FROM LOCAL IMPLEMENTATION TO GLOBAL LEARNING: BRAZIL AS A LIVING LAB FOR URBAN HYPERTENSION CONTROL IN ALIGNMENT WITH THE WHO CALL TO ACTION

MARIANA SILVEIRA1; YARA BAXTER2; JOHANNES BOCH3; LUCIANO FERREIRA DRAGER4; ÁLVARO AVEZUM5; LUIZ APARECIDO BORTOLOTTO4; GIOVANNA FERNANDES1; RENATO GAVIOLI1;

(1) BENEFICENCIA PORTUGUESA - SAO PAULO - SP - BRASIL; (2) NOVARTIS FOUNDATION - SWITZERLAND; (3) NOVARTIS FOUNDATION - SWAZILAND; (4) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (5) SBC - SÃO PAULO - SP - BRASIL;

Introduction/Background: Hypertension remains the leading modifiable risk factor for cardiovascular disease and the second for premature mortality worldwide, with persistent gaps between evidence-based guidelines and implementation—especially in urban settings in low- and middle-income countries. In response to the World Health Organization Call to Action on hypertension control, the Initiative has evolved in Brazil as a “Living Lab,” integrating multisector governance, data-driven management, and scalable care models within public health systems. Objectives: To describe the development, implementation, and scale-up of the Initiative as a Living Lab in Brazil, and assess its contribution to translating global hypertension strategies into measurable population health outcomes.c Methods: A mixed-methods implementation science approach was applied across multiple urban contexts in Brazil. The Living Lab model integrates: (1) multisector coalitions involving public managers, private sector, and civil society; (2) standardized clinical and operational pathways aligned with strengthening primary health care; (3) data-driven management using care cascade indicators and real-time dashboards; and (4) continuous cycles of co-creation and adaptive learning. Quantitative data were obtained from routine health systems and program monitoring tools, including screening, diagnosis, treatment, and blood pressure control. Qualitative evidence was collected through stakeholder engagement and governance analysis. Resultados e Conclusions: Since its implementation, the Living Lab in Brazil has expanded from a single-city experience to a multiterritorial coalition, reaching over 45 municipalities and marking a shift from pilot interventions to a scalable model. Key advances include expanded hypertension screening and diagnosis through community strategies; strengthened care pathways within primary health care; improvements in care cascade indicators, particularly adherence and blood pressure control; and governance models enabling co-investment and multisector coordination. The Living Lab enabled rapid adaptation across diverse urban contexts while generating evidence to inform policy and planning. This experience shows that bridging the gap between global recommendations and local implementation is feasible, requiring integrated governance, data-driven decisions, and continuous learning. It also provides a replicable framework to operationalize the WHO Call to Action on hypertension, supporting sustainable scale-up in urban health systems globally.

HEAT WAVES AND CARDIOVASCULAR MORBIDITY AND MORTALITY: A SYSTEMATIC LITERATURE REVIEW

EDUARDA SONDA DE GODOY1; GABRIELLI BACCHI COLOMBO1; GUSTAVO SONDA DE GODOY1; MARIA GABRIELA PANIZ BACEDO1; BRENDA PELLIZZER RODRIGUES1; OLÍVIA PORTO TOSCAN1;

(1) UNIVERSIDADE DE CAXIAS DO SUL - CAXIAS DO SUL - RS - BRASIL;

Introduction/Background: Heat waves represent a growing threat to global cardiovascular health. Climate change has increased the frequency, intensity, and duration of these extreme events, amplifying their impact on vulnerable populations. Epidemiological evidence demonstrates an association between exposure to extreme heat and increased cardiovascular morbidity and mortality, especially among older adults and individuals with pre-existing cardiovascular diseases. Objectives: To systematically review the scientific literature on the association between heat waves and cardiovascular outcomes, identifying vulnerable populations and the main epidemiological findings. Methods: A systematic review was conducted in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. A search was performed in the PubMed database using the MeSH terms and keywords “heat waves,” “cardiovascular diseases,” “mortality,” and “climate change,” combined using the Boolean operators. We included observational studies, systematic reviews, and meta-analyses published in English between 1990 and 2026. The exclusion criteria were studies without specific cardiovascular outcomes, case reports, letters to the editor, and experimental studies. Of the 79 records identified, 18 studies met the eligibility criteria and were included in the final analysis. Resultados e Conclusions: A consistent association was observed between heat waves and increased cardiovascular morbidity and mortality across diverse geographic regions. The meta-analysis by Liu J et al. (comprising 266 studies) demonstrated a 2.1% increase in cardiovascular mortality for every 1°C rise above the minimum mortality temperature (RR 1.021; 95% CI 1.020–1.023), along with an 11.7% increase during heat-wave events (RR 1.117; 95% CI 1.093–1.141). Furthermore, the data indicated higher rates of hospitalizations and emergency admissions, particularly among adults aged ≥65 years, individuals with pre-existing cardiovascular diseases, and urban populations affected by the urban heat island effect. Adaptive strategies, including the expansion of urban green spaces and the implementation of extreme heat action plans, demonstrated significant protective potential. Current evidence shows a significant global association between extreme heat and adverse cardiovascular outcomes. In the context of climate change, targeted public health policies and adaptive strategies for vulnerable populations are essential to reduce the cardiovascular burden of extreme heat.

HOSPITAL MORTALITY DUE TO ACUTE MYOCARDIAL INFARCTION IN BRAZIL: EPIDEMIOLOGICAL ANALYSIS BY SEX AND AGE GROUP (2016–2025)

WALLISON SILVA TELES1; EMILY BITTENCOURT DE SOUZA MARTINS1; ANA ERCÍLIA OLIVEIRA REGO1; ONARA MAISA MELO ARAUJO1; MARIA FERNANDA PIMENTEL PIMENTEL1; GUSTAVO RODRIGUES SAMPAIO1; ANGÉLICA PAIXÃO DE MENEZES1; PAULA FRASSINETTI CASTELO BRANCO CAMURÇA FERNANDES1;

(1) UNIVERSIDADE ESTADUAL DO CEARÁ - FORTALEZA - CE - BRASIL;

Introduction/Background: Acute Myocardial Infarction (AMI) remains one of the leading causes of cardiovascular mortality in Brazil. Understanding the epidemiological profile, particularly regarding gender disparities and the temporal behavior of mortality rates, is essential for planning prevention policies as well as strategies aimed at case control. Objectives: This study analyzes the trend of hospital deaths from AMI in Brazil, focusing on the distribution between men and women throughout the decade from 2016 to 2025. Methods: Epidemiological, descriptive, and retrospective study, with a quantitative approach. Records were extracted from the "SUS Hospital Morbidity (SIH/SUS)" section via the TabNet/DATASUS platform. The study population comprised hospital deaths under the diagnosis of AMI, according to the "ICD-10 Morbidity List". The variables analyzed were the annual mortality rate (per 100,000 inhabitants), calculated based on population projections generated by "Demográficas e Socioeconômicas" from TabnetDATASUS, as well as sex, and age group throughout the national territory, covering the period from 2016 to 2025. Resultados e Conclusions: The temporal trend analysis using Simple Linear Regression demonstrated a progressive and statistically significant increase in the AMI mortality rates (per 100,000 inhabitants) over the decade (2016-2025). The estimated average annual growth was 0.10 deaths/100,000 inhabitants for males ($R^2 = 0.60$; $p = 0.008$) and 0.05 deaths/100,000 inhabitants for females ($R^2 = 0.41$; $p = 0.046$). Furthermore, the comparison of historical means by Student's t-test confirmed a highly significant predominance of mortality in males compared to females ($p < 0.001$), evidencing a consistently unequal epidemiological burden between genders even after adjusting for population growth. The AMI mortality in Brazil shows a statistically significant upward trend over the last decade, confirming an unequal epidemiological burden with a highly significant predominance in males. In 2020, there was a drop in the number of cases, which may have occurred as a consequence of the COVID-19 pandemic causing missed diagnoses. On the other hand, the jump in records from 2021 onwards highlights the need to strengthen prevention and control strategies for diseases such as hypertension, diabetes, and dyslipidemia, as they are risk factors for AMI. Furthermore, ensuring rapid access to reperfusion therapy in emergency networks is essential to mitigate the growing burden of cardiovascular deaths in the country.

Statistical Analysis:

Linear Regression Male:
Growth: +0.10 / 100 mil hab.
$R^2 = 0.60$ | $p = 0.008$

Linear Regression Female:
Growth: +0.06 / 100 mil hab.
$R^2 = 0.41$ | $p = 0.046$

T test (Male x Female):
$p < 0.001$

IMPACT OF CLIMATE SEASONALITY ON HOSPITALIZATIONS AND HEALTHCARE COSTS FOR HEART FAILURE IN RIO DE JANEIRO

ANA CAROLINA ALMEIDA DOS SANTOS1; ISABELE SESSA SOARES1; JENNIFER DA SILVA ALVES1; JOAO PEDRO POMIN FERNANDES COSTA1; LUCAS SILVA ALEXANDRE1; AUGUSTO OLIVEIRA PERES1;

(1) UNIRIO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Heart failure (HF) is one of the leading causes of hospitalization worldwide and imposes a substantial economic burden on the Brazilian Unified Health System. Environmental and climatic factors, particularly temperature variation, have been associated with HF decompensation and increased healthcare demand. However, local evidence exploring this relationship in large urban centers such as Rio de Janeiro remains limited, especially regarding its economic impact. Objectives: To analyze the association between HF hospitalizations and climate seasonality and to assess its impact on hospital costs in Rio de Janeiro. Methods: Ecological, longitudinal, retrospective, and quantitative study using data from the Brazilian Hospital Information System (SIH/SUS), the National Institute of Meteorology, and the Center for Weather Forecasting and Climate Studies. HF hospitalizations (ICD-10), length of stay, costs, and mean monthly temperature were analyzed between January 2015 and December 2025. Spearman and Pearson correlation tests were applied. Resultados e Conclusions: A total of 28,865 HF hospitalizations were recorded, with a mean length of stay of 14.64 days and an average of 218.6 admissions per month. Total costs reached R$83.1 million, with a mean cost of R$2,850.34 per hospitalization and R$198.18 per day. The mean temperature was 23.7°C. Hospitalizations were more frequent in winter (30.2%) and less frequent in summer (21.8%). A moderate negative correlation was observed between temperature and hospitalizations (Spearman ρ=-0.462; Pearson r=-0.391; $p<0.005$; R^2=0.153). A negative correlation was also found between length of stay and daily cost (R^2=0.0925). Lower temperatures were significantly associated with increased HF hospitalizations, indicating a relevant seasonal pattern. The high economic burden reinforces the importance of climate-informed planning strategies to optimize healthcare resource allocation.

IMPROVING EMERGENCY CARDIOVASCULAR CARE THROUGH CARE BUNDLES: ADHERENCE AND SYSTEM-LEVEL OUTCOMES OF A CITYWIDE PUBLIC HEALTH POLICY FOR ACUTE MYOCARDIAL INFARCTION AND STROKE IN A LARGE LATIN AMERICAN METROPOLIS

SMS MAISA FERREIRA DOS SANTOS1; JOSIANE MOTTA E MOTTA2; MAIRA CRISTHIANE BOGADO DA SILVA1; HAVILEY OLIVEIRA MARTINS3; ELIZANDRA IARA DE PAULA1; RUBIA JOSIANE MARQUES1; HENO FERREIRA LOPES1; MAURICIO AUGUSTO GONÇALVES AUGUSTO GONÇALVES1;

(1) SMS - SAO PAULO - SP - BRASIL; (2) OUTRA - SAO PAULO - SP - BRASIL; (3) SECRETARIA MUNICPAL DE SAUDE - SÃO PAULO - SP - BRASIL;

Introduction/Background: Cardiovascular diseases remain the leading cause of death in large urban centers. In the municipality of São Paulo, official epidemiological surveillance data indicate that diseases of the circulatory system account for approximately 30–33% of all deaths, with acute myocardial infarction (AMI) ranking as the leading specific cause and cerebrovascular diseases (stroke) among the second and third causes of mortality. In complex, high-demand public health systems, variability in emergency care processes contributes to avoidable delays, inequities in access, and worse clinical outcomes. The implementation of evidence-based care bundles, integrated into structured public health policies, represents a strategy to improve the reliability of care for time-sensitive cardiovascular conditions. Objectives: To describe the implementation of a municipal public health policy for emergency cardiovascular care based on care bundles for AMI and stroke, and to analyze early adherence data to these bundles as system-level performance indicators aimed at reducing avoidable cardiovascular mortality Methods: This quality improvement study was conducted within the municipal emergency care network of a large Latin American metropolis, using routinely collected care process indicators and epidemiological surveillance data. Evidence-based AMI and stroke care bundles were implemented in Emergency Care Units as a citywide public health policy. The bundles were aligned with national and international guidelines and organized according to the '5 Rs of Rescue' framework (Recognize, Rescue, Reassess, Refer, and Reflect). Implementation strategies included clinical governance, multiprofessional workforce training, standardized clinical pathways, and continuous monitoring using Plan–Do–Study–Act (PDSA) cycles. Bundle adherence was measured through key process indicators related to critical early phases of AMI and stroke care, analyzed across sequential monitoring rounds (R1 and R2). Resultados e Conclusions: The implementation of AMI and stroke care bundles as a structured municipal public health policy resulted in high adherence to critical care processes, even in high-pressure emergency environments. . For the AMI care bundle, adherence rates reached up to 91% in participating emergency units, with sustained adherence in subsequent monitoring cycles of approximately 89%.

MORTALITY TRENDS BY CARDIOVASCULAR DISEASE: DATA FROM BRAZIL AND REGIONS BETWEEN 2010–2024

ELIANA AQUINO BONILHA1; ANDRÉ LUIZ MORAIS LO FEUDO1; ANA PAULA QUEIROZ MELLO2; MARÍLIA LOURENÇO GUIMARÃES1;

(1) CENTRO UNIVERSITÁRIO SÃO CAMILO - SÃO PAULO - SP - BRASIL; (2) CENTRO UNIVERSITÁRIO SÃO CAMILO - SAO PAULO - SP - BRASIL;

Introduction/Background: Heart failure (HF) is a complex clinical syndrome defined by the heart's inability to maintain adequate cardiac output due to structural or functional abnormalities. Ischemic heart disease is the leading etiology, with hypertension, valvular disease, and myocarditis among other contributors. Objectives: To analyze trends in mortality by IHD among Brazilian population in the years 2010-2024. Methods: It was conducted a retrospective ecological study of deaths attributed to ischemic heart disease and related circulatory conditions (ICD 10: I20–I25; I00–I09; I11; I13) in Brazil from 2010 to 2024, using mortality records from the Mortality Information System (Ministry of Health) and population estimates from the Brazilian Institute of Geography and Statistics (IBGE). Age standardized mortality rates (reference: 2010 population) were calculated. Temporal trends were evaluated using Joinpoint regression to estimate Annual Percent Change (APC) for each segment and Average Annual Percent Change (AAPC) for the overall period. Multivariable regression models adjusted for age, sex, region, and year were used to estimate Mortality Rate Ratios (MRR). The study used exclusively aggregated, de identified, publicly available secondary data. Results are reported with 95% confidence intervals and p values< 0,05. Resultados e Conclusions: Age standardized mortality rates for 2010 declined in Brazil between 2010 and 2024 without identifiable inflection points; the overall AAPC was −1.809% per year (95% CI: −2.1359 to −1.4717; p < 0.001). Both sexes experienced significant declines without joinpoint changes: men AAPC = −1.571%/yr and women AAPC = −2.057%/yr. Regionally, the Central West, Southeast, and South showed significant continuous decreases (AAPC = −1.732%, −1.939%, and −2.975%/yr, respectively), with the South exhibiting the largest reduction. The North showed a non significant slight decline (AAPC = −0.1758%; 95% CI: −0.4566 to 0.1121; p = 0.237). The Northeast presented two joinpoints (2017, 2021): non significant trend 2010–2017, significant decline 2017–2021 (APC = −2.906%; 95% CI: −3.7022 to −1.9326; p = 0.006), and non significant trend 2021–2024; overall AAPC = −0.968% (95% CI: −1.2003 to −0.7341; p < 0.001). Age standardized mortality declined in Brazil (2010–2024), with heterogeneous regional and sex patterns. Standardization to the 2010 population controls for age structure changes, suggesting much of the rise in crude rates is attributable to population aging rather than increased age adjusted risk.

Graph Data Model Estimates Trends Model Selection

Annual Percent Change (APC)

Introduction/Background: Sub-Saharan Africa is experiencing a crisis of hypertension. Compared to high income settings, hypertension in SSA is characterised by younger onset, suboptimal control, and worse cardiovascular disease (CVD) outcomes. Rural SSA faces a particular challenge with lower awareness and poorer access to healthcare. Together, this may contribute to the earlier onset of target organ damage (TOD), a strong predictor of long-term CVD. However, population-level data on TOD prevalence in rural SSA are lacking. Objectives: To determine the prevalence of TOD in two rural SSA populations in Kenya and The Gambia. Methods: This cross-sectional, population-based study in Kilifi (Kenya) and Kiang West (The Gambia) ran from July 2023 to December 2024. An age-stratified random sample of adults aged ≥30 years underwent 24-hour ambulatory blood pressure measurement, electrocardiography, echocardiography, pulse-wave velocity measurement, and renal function assessment. TOD was defined as left ventricular hypertrophy (LVH), reduced global longitudinal strain (GLS), left ventricular systolic dysfunction (LVSD), arterial stiffness, or renal dysfunction. Resultados e Conclusions: Of 1819 participants screened,1379 were recruited, and 1212 were included in the analysis (mean age 56.8±14.8 years; 62.9% female). Elevated blood pressure was present in 56.6% and hypertension in 33.5%. Overall, 57.4% had at least 1 TOD marker, increasing from 35.0% for non-elevated blood pressure to 77.3% for hypertension (p<0.001). TOD prevalence rose from 32.7% in those 30–39 years to 77.0% in those >70 years (p<0.001). Common markers were electrocardiogram LVH (31.1%) and arterial stiffness (38.0%). Echocardiogram LVH was observed in 10.0%, reduced GLS in 16.7%, LVSD in 9.8%, and renal dysfunction in 3.8%. Prevalence was higher in The Gambia (64.8%) than Kenya (50.9%) (p<0.001). TOD clustering increased with blood pressure. No participants with non-elevated blood pressure had four TOD markers compared to 3.3% of those with hypertension (p<0.001). Target organ damage is common in rural SSA, including in younger individuals. These findings provide important information on how TOD assessment should be incorporated into cardiovascular care pathways and help determine optimal ages for CVD screening.

REGIONAL DISPARITIES IN CLINICAL AND ECONOMIC OUTCOMES OF HEART FAILURE HOSPITALIZATIONS IN BRAZIL: A 2021–2025 ANALYSIS

THALES PURIFICACAO VIEIRA1; PÂMELLA DE SÁ ANTUNES BEZERRA1; MARIA CLARA VIEIRA PIRES1;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL;

Introduction/Background: Heart Failure (HF) is a clinical syndrome characterized by the heart's inability to adequately meet the body's metabolic demands, representing a leading cause of global morbidity and mortality. In Brazil, it imposes high mortality rates and significant healthcare costs on the public health system. However, the unequal distribution of resources exacerbates regional disparities in quality of care and outcomes. Objectives: To evaluate regional disparities in financial investments, average length of stay, and in-hospital mortality rates associated with heart failure hospitalizations in Brazil from 2021 to 2025. Methods: This is an epidemiological, retrospective, and analytical study based on data from the Hospital Information System (SIH/SUS). Records of hospitalizations and in-hospital deaths due to heart failure across the five Brazilian regions between 2021 and 2025 were included. The variables analyzed were hospital costs, average length of stay, and in-hospital mortality. Regional comparisons were performed in JAMOVI software (v. 2.6.44.0), using Welch's ANOVA and Games-Howell post-hoc test ($p < 0.05$). Resultados e Conclusions: Statistical analysis showed significant regional differences across the three variables evaluated. The Southeast region had the highest average hospital costs (R$ 209.5 million), while the North had the lowest (R$ 25.5 million) (Welch's ANOVA, $F(4, 9.51) = 54.3$, $p < 0.001$). Mean length of hospital stay was highest in the Northeast (8.98 days) and lowest in the South (6.86 days) (Welch's ANOVA, $F(4, 9.65) = 59.9$, $p < 0.001$). The in-hospital mortality rate was highest in the Southeast (13.37%) and lowest in the Central-West (10.4%) (Welch's ANOVA, $F(4, 9.68) = 7.74$, $p = 0.005$). Post-hoc analysis showed consistent differences between the North, Northeast, and Central-West regions compared to the South and Southeast. This study demonstrates that regional disparities in public healthcare investment directly influence clinical and operational outcomes in heart failure care in Brazil. The concentration of costs and higher mortality in the Southeast, combined with longer hospital stays in the Northeast, suggest that resource distribution and healthcare efficiency are not uniform. These findings reinforce the need for targeted public policies that address regional vulnerabilities to optimize care and reduce mortality across Brazil.

Table 1. Total hospital costs (R$) for Heart Failure hospitalizations by Brazilian macro-regions, 2021–2025.

Regions	2021	2022	2023	2024	2025
North	15,627,873.27	23,905,279.29	28,691,010.03	27,797,581.08	31,635,703.2
Northeast	71,781,062.85	93,144,859.43	99,888,981.53	106,373,230.04	118,013,536.27

RESULTS OF MASSIVE ECHOCARDIOGRAPHIC SCREENING JOINT EFFORTS IN THE BRAZILIAN PUBLIC HEALTH SYSTEM: PREVALENCE OF STRUCTURAL HEART DISEASE AMONG PATIENTS IN WAITING QUEUES FOR CARDIOVASCULAR CARE

BRUNO R. NASCIMENTO1; WANESSA C. VINHAL2; CLARECI S. CARDOSO2; RALDNER B. REGES,2; GABRIELA M. DE M. PAIXÃO1; CLARA R. ALVES1; LUISA C. C. BRANT1; CRAIG SABLE3; ISADORA V. B. S. SOUZA1; FREDERICO T. C. DALL'ORTO4; BRUNA C. FREITAS5; ANTONIO L. P. RIBEIRO1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE SÃO JOÃO DEL REI, CAMPUS DIVINÓPOLIS - DIVINÓPOLIS - MG - BRASIL; (3) OCHSNER HEALTH - UNITED STATES; (4) HOSPITAL DO CORAÇÃO DE POÇOS DE CALDAS - POÇOS DE CALDAS - MG - BRASIL; (5) FACULDADE DE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Structural heart disease (SHD) is a major cause of morbidity and mortality in Brazil, with underserved populations facing prolonged waiting times for echocardiography (echo). Delayed diagnosis contributes to advanced disease at presentation. Objectives: We aimed to evaluate the feasibility of integrating comprehensive echocardiography with remote interpretation into public health through joint efforts, and to determine the prevalence of significant SHD among patients on waiting queues, to prioritize care. Methods: In 11 days, 15 certified cardiologists performed transthoracic echo at 2 public facilities of 2 mid-size cities of the state of Minas Gerais, southeast Brazil, during scheduled joint-efforts. Consented patients in waiting queues, referred for echo for clinical indications or found in screening, answered a clinical questionnaire and underwent a comprehensive echo protocol (GE Vivid Q and Vivid IQ), interpreted by the acquiring physician, with adjudication by a second expert. Significant SHD was defined as moderate/severe valve disease, left (LV) and right (RV) ventricular dysfunction/hypertrophy, pericardial effusion or wall-motion abnormalities. Clinical and demographic predictors of SHD on echo were assessed using multivariable logistic regression. Resultados e Conclusions: In March (5 days) and November (6 days) 2025, 3832 patients underwent echo; mean age was 64±14 years, 57% were females. At total 56.7% had cardiovascular symptoms, being the most frequent chest pain (33.7%) and dyspnea (29%); 74.9% had hypertension and 36.9% diabetes. SHD was found in 1186 (31.2%) patients, and 342 (9%) were considered top priorities for care. Moderate/severe SHD was observed in: LV dysfunction 185 (4.8%), LV hypertrophy 143 (3.8%), mitral regurgitation 118 (3.1%), mitral stenosis 61 (1.6%), aortic stenosis in 64 (1.7%), aortic regurgitation 77 (2.0%), tricuspid regurgitation 115 (3.0%), and any LV segmental wall-motion abnormalities in 537 (14%). Independent predictors of SHD were: age (every 10y) (OR=1.39 (95%CI 1.31-1.48), dyspnea (OR=1.37 (1.13-1.65), previous history of Chagas disease (OR=1.95 (1.06-3.60), coronary artery disease (OR= 2.42 (1.99-2.96), and heart failure (OR= 1.53 (1.27-1.85). In conclusion, large-scale integration of comprehensive echo in Brazilian public health settings is feasible and enables rapid identification of a high burden of SHD among patients on waiting lists, holding promise for improvement of timely access for high-risk individuals.

TEMPORAL TRENDS IN OBESITY MORTALITY IN BRAZIL, 2003–2023: REGIONAL AND DEMOGRAPHIC DISPARITIES

ELIANA AQUINO BONILHA1; ANDRE LUIZ MORAIS LO FEUDO1; ANA BEATRIZ SILVA SOUZA2; CLARA KORUKIAN FREIBERG1;

(1) CENTRO UNIVERSITARIO SAO CAMILO - GUARULHOS - SP - BRASIL; (2) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introduction/Background: Obesity is classified by the World Health Organization as a chronic disease resulting from complex interactions among genetics, neurobiology, eating behaviors, diet access, market forces, and the broader environment. It is strongly associated with increased risk of non-communicable diseases, particularly cardiovascular conditions, and with premature mortality. Objectives: To evaluate temporal trends in obesity mortality in Brazil from 2003 to 2023, stratified by sex, age group, and region. Methods: A retrospective ecological study analyzed deaths due to obesity (ICD-10 E66) from the Mortality Information System of the Ministry of Health and population data from the Brazilian Institute of Geography and Statistics (IBGE). Descriptive statistics were applied, followed by Joinpoint regression to assess temporal trends. Annual Percent Change (APC) was estimated for each segment, and Average Annual Percent Change (AAPC) summarized overall trends. Multivariable Poisson regression models with log(population) offset were fitted to estimate Mortality Rate Ratios (MRR), adjusted for age, sex, region, and year. Analyses were conducted in R 4.5.1 (R Core Team, 2025) with RStudio, using tidyverse, readxl, and MASS packages. Resultados e Conclusions: Results: Obesity mortality tripled (0.56 to 1.70 deaths/100,000), with an inflection in 2009: accelerated growth initially (APC = 10.6%) followed by slower but sustained increase (AAPC = 6.3%; p < 0.001). Adjusted analyses showed average annual growth of 4.5% (MRR = 1.045; 95% CI: 1.041–1.048; p < 0.001). Mortality rose in both sexes, but men had continuous growth (AAPC = 6.5%), while women showed inflection in 2009 (AAPC = 5.8%). Proportionally, increases were greater in men (230%) than women (188%). Age exerted the strongest effect: mortality in ≥80 years was ~195 times higher than in 0–19 years (MRR = 194.618; p < 0.001). Regionally, the North had 45% lower mortality than the Southeast (MRR = 0.550), while the South was 24% higher (MRR = 1.240). Conclusion: Obesity mortality increased significantly and unevenly across Brazil, driven largely by aging, with marked differences by sex and region. Findings highlight the need for targeted public health policies and preventive strategies adapted to demographic and regional disparities, reinforcing the cardiovascular burden of obesity

Table 1. Mortality Rate Ratio (MRR) for Obesity by Year, Sex, Age Group, and Region. Brazil, 2003–2023.

Variável	Category	MRR*	IC 95%	p-valor

TRENDS IN HEART FAILURE HOSPITALIZATIONS IN RIO DE JANEIRO BEFORE AND AFTER THE INTRODUCTION OF CARDIOPROTECTIVE THERAPIES

ANA CAROLINA ALMEIDA DOS SANTOS1; JULIA STHEFANNY SOARES FERNANDES DE SOUZA1; EMANUELLY DA SILVA ALEGRE1;

(1) UNIRIO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Heart failure is a major cause of hospitalization and cardiovascular mortality in Brazil. Recent advances, including angiotensin receptor-neprilysin inhibitors and SGLT2 inhibitors, have improved disease management and were incorporated into the public health system in 2022. Objectives: To analyze trends in HF hospitalizations and outcomes before and after the introduction of cardioprotective therapies in the public health system. Methods: Ecological time-series study using SIH/SUS data. HF hospitalizations (ICD-10: I50) in Rio de Janeiro between 2015 and 2025 were analyzed. Variables included hospitalization rates, in-hospital mortality, total and mean costs, and length of stay. Data were grouped into pre-implementation (2015–2021) and post-implementation (2022–2025) periods. Resultados e Conclusions: A total of 122,624 hospitalizations were recorded. Hospitalization rates increased from 62.9 to 67.8 per 100,000 inhabitants (+7.8%). In-hospital mortality also increased from 16.7% to 18.0% (+7.8%). The mean cost per hospitalization rose from R$1,476 to R$2,492 (+68.8%), while total costs increased from R$113 million to R$124 million (+9.7%). Length of stay remained stable (10.1 vs 10.5 days). Although a general downward trend in hospitalizations was observed over the full period, the post-implementation phase showed increases in hospitalization rates, mortality, and costs. These findings may reflect changes in disease severity and patient complexity, highlighting the importance of continuous epidemiological monitoring after the introduction of new therapies.

CHEMICAL PROFILING OF ANNONA SENEGALENSIS LEAF EXTRACT AND COMPUTATIONS WITH BETA-ADRENERGIC RECEPTOR AND YES-ASSOCIATED PROTEIN IMPLICATED IN CARDIOVASCULAR DISEASES

GBADEBO EMMANUEL ADELEKE1;

(1) LADOKE AKINTOLA UNIVERSITY OF TECHNOLOGY, OGBOMOSO,NIGERIA - NIGERIA;

Introduction/Background: Annona senegalensis (Figure 1), also known as the African custard apple or wild custard apple, is a plant native to Africa, with wide therapeutic applications for its several pharmacological compounds (Lawal et al., 2021). Cardiac organ is rich in Beta-blocker receptors, responsible for signaling in the sympathetic nervous system. Fu et al. (2022) documented that YES-Associated protein (YAP) induces proliferation of cardiomyocytes. Objectives: This study examined the chemical composition of Annona senegalensis leaf methanol extract and In-silico profile .of its selected phytochemicals against Beta-blocker receptor and YAP. Methods: Fresh leaves of Annona senegalensis were collected in May, 2024 at Obamoro village (7.760 N, 4.150 E), Iwo, Osun State, Nigeria. The leaves were air-dried and grinded to obtain powder (300 g), which was subjected to Soxhlet extraction with methanol. The mixture obtained was dried to obtain Annona senegalensis Leaf Methanol Extract (ASLME). Fourier Transform-Infra Red (FT-IR) spectroscopy and High-Performance Liquid Chromatography (HPLC) were carried out on the ASLME. Computational studies were carried out on some of the phytochemicals of ASLME identified via HPLC, using atenolol and metoprolol as standard beta -blockers, and verteporfin as a standard inhibitor of YAP using virtual screening Schrodinger. Resultados e Conclusions: The HPLC of ASLME identified compounds including annogalene, annosenegalin, kaurenoic acid, roemerine (Fig.1). The binding energies of annogalene, annosenegalin, kaurenoic acid, roemerine, atenolol and metoprolol with Beta-adrenergic receptor were found to be –11.0, -9.3, -8.8, -8.8, -7.9 and -7.5 (kcal/mol), respectively. However, the binding energies of annogalene, annosenegalin, kaurenoic acid, roemerine and verteporfin with YAP were -9.9, -10.0, -6.8, -7.7 and -6.4 (kcal/mol), respectively (Tables 1 and 2). In molecular docking, the four compounds from ASLME antagonized beta-adrenergic receptor better than atenolol and metoprolol, and inhibited YAP better than verteporfin (Figs 2 – 7) Annona senegalensis leaf extract has cardio-protective potential, hence could be a promising source of alternative agents for development of drugs against cardiomyopathy, hypertension and cardiac failure.

PYRIDOSTIGMINE FOR AUTONOMIC DYSFUNCTION SYMPTOMS IN POST-COVID-19 CONDITION: A RANDOMIZED CROSSOVER CLINICAL TRIAL.

JOELMA DOMINATO ROCHA CARVALHO1; ELIZA PRODEL1; HELENA N M ROCHA1; JOÃO DARIO MATTOS1; JOÃO PAULO MOREIRA CARVALHO1; NATALIA G ROCHA1; RENATA RODRIGUES TEIXEIRA DE CASTRO1; ANTONIO CLAUDIO LUCAS DA NOBREGA1;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL;

Introduction/Background: Fatigue is among the most prevalent and disabling manifestations in Post COVID-19 condition, impairing functional capacity and quality of life. Dysautonomia has been proposed as a potential mechanism underlying these symptoms, whereas pyridostigmine bromide, an acetylcholinesterase inhibitor, may improve autonomic function and alleviate fatigue in this population. Objectives: To determine whether pyridostigmine bromide could serve as a therapeutic strategy to alleviate fatigue, improve dysautonomia symptoms and enhance quality of life in individuals with post-COVID-19 condition. Methods: A randomized, double-blind, placebo-controlled, crossover clinical trial was conducted. Fifteen participants (age 41.8±9.1 years; 8 male, 7 female) received pyridostigmine bromide (60 mg, three times daily) or placebo for 30 days, respecting a washout period between treatments. Assessments included the Chalder Fatigue Scale, WHOQOL-Bref, and COMPASS-31 questionnaires; echocardiography; 12-lead electrocardiogram; cardiovascular autonomic tests (Valsalva maneuver, deep breathing, active standing); handgrip strength; maximal inspiratory pressure; spirometry; and cardiopulmonary exercise testing. Resultados e Conclusions: The pyridostigmine bromide administration improved fatigue (Chalder Fatigue Scale, p<0.01), dysautonomia symptoms (COMPASS-31, p<0.001), and quality of life (WHOQOL-Bref domains “perception of quality of life,” p=0.003; “satisfaction with health,” p=0.001) compared with placebo and baseline. Maximal inspiratory pressure (p=0.01) and peak expiratory flow (p=0.02) also improved with pyridostigmine bromide and placebo, while no changes were observed in autonomic test responses or aerobic capacity. CONCLUSIONS: Pyridostigmine bromide effectively reduced fatigue and dysautonomia symptoms and enhanced quality of life in patients with Post COVID-19 condition. These findings support its potential as a therapeutic strategy to promote functional recovery and reintegration into daily activities after COVID-19.

FALLS IN ANTICOAGULATED ELDERLY PATIENTS: SHOULD WE BE CONCERNED?

ÁLVARO CESAR CATTANI1; GABRIELA GABRIELA FISS SEITZ1; BEATRICCE ISABELLE GOEDERT FARINON1; KATLIN GABRIELE WOLLMER1; LÍVIA MARIA BARBIERI1; MARIA FERNANDA HAAS TONIAL1; RAYSSA MARINI REIS1;

(1) AFYA CENTRO UNIVERSITÁRIO DE PATO BRANCO - PATO BRANCO - PR - BRASIL;

Introduction/Background: Concerns regarding major bleeding often lead to the underprescription or discontinuation of anticoagulants in patients with a history of falls. This systematic review, focusing on evidence from the past 5 years, evaluated whether fall risk should influence the decision to initiate, continue, or discontinue anticoagulation in this population. Objectives: To evaluate whether fall risk should influence clinical decision-making regarding the use of anticoagulants in older adults, analyzing safety, risk of intracranial hemorrhage, mortality, and the clinical benefit of anticoagulation. Methods: A PubMed search was conducted for the past 5 years (2021–2026) using the Boolean terms: elderly AND falls AND anticoagulation AND risk. Of the 31 studies identified, abstracts were screened and 16 were selected for inclusion. Eligible studies involved patients aged >65 years using oral anticoagulants (DOACs or VKAs) with a known risk or history of falls. Primary outcomes were major bleeding, intracranial hemorrhage (ICH), mortality, and clinical benefit. Resultados e Conclusions: Analysis demonstrated that fall risk, in isolation, is not an independent predictor of ICH or mortality when adjusted for age or frailty. The incidence of post-fall ICH in anticoagulated patients remains low (0.9–6.2%), and DOACs demonstrated a superior safety profile compared to VKAs, with a consistent reduction in ICH risk (OR 0.63; 95% CI 0.43–0.91). Interestingly, one study evaluating antiplatelet therapy found it was associated with an equal or higher risk of traumatic ICH compared to anticoagulation (RR 1.72 vs. 1.08). Decision models suggest that a patient would need to fall between 35 and 458 times per year for the bleeding risk to outweigh the benefits of anticoagulation, depending on the agent. Furthermore, discontinuing anticoagulation after a single fall increases thromboembolic risk without a clear benefit in reducing major bleeding events. Fall risk alone should not contraindicate anticoagulation in elderly patients. Clinical management should prioritize thromboembolic prevention, prefer DOACs when appropriate, implement multifactorial fall prevention strategies, and individualize the risk-benefit assessment to avoid unnecessary treatment discontinuation.

OLDER WOMEN WITH HEART FAILURE WALK 62 M LESS THAN MEN: A BODY-COMPOSITION-INDEPENDENT GAP THAT PERSISTS AFTER SEX-SPECIFIC NORMALIZATION IN 180 OUTPATIENTS

RODRIGO CHAVES DA SILVA CHAVES DA SILVA1; BEATRIZ NICOLAU NICOLAU NASSIF1; YSIS BARRETO DONATI2; LEANDRO BRASIL REGO2; LUIS FERREIRA NETO1; TAÍNA COSTA NONATO2; JOÃO PAULO PINTO2; FRANCISCO LUCIANO PONTES JUNIOR2; FELICIO SAVIOLI NETO1; NEIRE NIARA ARAUJO1; CAROLINA MARIA NOGUEIRA PINTO1; LAÍS ALMEIDA SOUZA2;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (2) UNIVERSIDADE DE SÃO PAULO - SP - SP - BRASIL;

Introduction/Background: Heart failure (HF) is a leading cause of morbidity and functional limitation among older adults, with impaired exercise capacity being a central feature associated with poor prognosis and reduced quality of life. The six-minute walk test (6MWT) is a widely used, simple, and reliable tool to assess functional capacity in this population, reflecting the integrated response of cardiovascular, pulmonary, and musculoskeletal systems. Sex differences in HF have been increasingly recognized, with women often presenting distinct clinical profiles and outcomes compared to men. In particular, previous studies have consistently shown that women tend to walk shorter distances on the 6MWT. However, the mechanisms underlying this disparity remain uncertain. Differences in body composition, especially body mass index (BMI), are frequently proposed as a potential explanation, yet few studies have formally evaluated this hypothesis using robust analytical approaches such as mediation analysis. Objectives: We aimed to quantify the sex gap in 6MWT distance in elderly heart-failure outpatients, test whether body mass index (BMI) mediates it, and check whether the gap remains after normalization to sex-specific predicted values. Methods: Cross-sectional analytical study (STROBE) of 180 outpatients aged 60 years or older with heart failure (97 men, 83 women). The primary outcome was 6MWT distance. We fitted multiple linear regression adjusted for age, BMI, LVEF, log-BNP, NYHA class and comorbidities; logistic regression for 6MWT <300 m; and a causal mediation analysis with 2,000 bootstrap samples for the indirect effect of BMI on the sex–6MWT pathway. Distances were normalized to Enright's sex-specific predicted 6MWT, with subgroup analysis by ejection-fraction phenotype Resultados e Conclusions: Women walked 62 m less than men (300 ± 102 vs 362 ± 69 m; p < 0.001). Adjustment for age, BMI, LVEF, BNP, NYHA class and comorbidities had minimal impact (β = −55.1 m; p < 0.001). Women had higher odds of walking <300 m (OR 3.95). The gap persisted across HF phenotypes and BMI mediated only 1.4% of the effect. After normalization to sex-specific predicted values, women still achieved lower performance (66% vs 74%; p = 0.003). These findings indicate a consistent, body-composition-independent disadvantage, supporting the need for sex-tailored cardiac rehabilitation.

THREE MARKERS, THREE DIFFERENT PATIENTS: LOW AGREEMENT BETWEEN FRAILTY, DYNAPENIA AND PHYSICAL PERFORMANCE ASSESSMENTS IN COMMUNITY-DWELLING OLDER ADULTS

YSIS BARRETO DONATI1; RODRIGO CHAVES SILVA2; BEATRIZ NICOLAU NASSIF2; LUIS FERREIRA NETO2; LUCAS MARQUES VIEIRA1; ANA PAULA SOUZA LIMA1; LEANDRO BRASIL REGO1; FRANCISCO LUCIANO PONTES JUNIOR1; FELICIO SAVIOLI NETO2; NEIRE NIARA ARAUJO2;

(1) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction/Background: Frailty, dynapenia and low physical performance each predict adverse cardiovascular outcomes in older adults, and cardiogeriatric guidelines now recommend functional vulnerability screening as part of routine assessment. But which one to use? If the three instruments tag the same patients, single-instrument screening is enough; if they tag distinct subgroups, single-instrument screening misses vulnerable older adults. Objectives: We estimated the prevalence and pairwise agreement of three functional vulnerability markers in older adults seen at a cardiogeriatric outpatient clinic, and looked for clinical predictors of combined vulnerability. Methods: Cross-sectional retrospective analysis of 71 consecutive community-dwelling adults aged 60 years or older with complete records. Three markers were assessed: Fried frailty phenotype (frail or pre-frail vs robust); EWGSOP2 dynapenia (handgrip <27 kgf in men, <16 kgf in women; Jamar dynamometer with standardized protocol); and low physical performance (five-times sit-to-stand ≥15 s). Pairwise agreement was quantified with Cohen's κ, and combined vulnerability was defined a priori as ≥2 positive markers. Predictors were tested by multivariable logistic regression adjusted for age, sex, BMI, COPD and smoking; α = 0.05. Resultados e Conclusions: Half of the older adults (50.7%) screened positive for two or more functional vulnerability markers, and 11.3% scored positive on all three. Among 71 patients (median age 69 years; 52% male; median BMI 27.9 kg/m²), prevalence was 78.9% (95%CI 68.0–86.8) for frailty or pre-frailty, 27.8% (18.8–39.0) for dynapenia and 35.6% (25.6–47.1) for low physical performance. Pairwise agreement was uniformly low: frailty × dynapenia κ = 0.13, frailty × low performance κ = 0.27, dynapenia × low performance κ = 0.07. Older adults with triple vulnerability were older (median 78.5 vs 69.0 years; p = 0.022), had weaker handgrip (p = 0.032), worse sit-to-stand (p = 0.001) and lower MMSE (p = 0.015). In multivariable analysis, age (aOR 1.61 per 5 years; 95%CI 1.03–2.51; p = 0.036) and COPD (aOR 3.52; 95%CI 0.99–12.57; p = 0.052) predicted combined vulnerability. The three instruments tag overlapping but largely distinct individuals, so a single-instrument screen will miss vulnerable older adults; a brief multi-instrument battery deserves prospective evaluation as a bedside tool in cardiogeriatric care.

ALDOSTERONE SYNTHASE INHIBITORS VERSUS MINERALOCORTICOID RECEPTOR ANTAGONISTS FOR BLOOD PRESSURE REDUCTION: A NETWORK META-ANALYSIS

GERMANO TOSCANO1; BRUNA MONTENEGRO1; MILTON LIRA2; PEDRO PIRES3; DAVI CHAVES1; LUCAS BRUNET1; WERTON ROQUE1; SAMUEL ROCHA1; MARIA LUIZA MIRANDA1; ANA GERTRUDES NEVES1; YASMIN FERNANDES1; ARTHUR CICUPIRA4;

(1) FAMENE - JOÃO PESSOA - PB - BRASIL; (2) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (3) UNIPE - JOÃO PESSOA - PB - BRASIL; (4) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction/Background: Mineralocorticoid receptor antagonists (MRAs) are recommended for resistant hypertension but limited by antiandrogen effects. Aldosterone synthase inhibitors (ASIs) represent a novel class that suppresses aldosterone production upstream without steroid receptor blockade. Objectives: We aimed to perform a network meta-analysis to indirectly compare these drug classes for systolic blood pressure (SBP) reduction. Methods: PubMed, Cochrane Library, and ClinicalTrials.gov were searched up to March 2026 for randomized clinical trials (RCTs) comparing ASIs (baxdrostat, lorundrostat) or MRAs (spironolactone) versus placebo in adults with resistant or uncontrolled hypertension. ASI trials enrolled both populations, whereas MRA trials enrolled exclusively resistant hypertension. Blood pressure (BP) measurement methods varied across trials. Pooled effect estimates across active doses were used to represent overall drug effect per study. Mean difference (MD) with 95% confidence intervals (CIs) was computed. Heterogeneity was assessed using I² statistics. Network meta-analysis used a random-effects model with placebo as common comparator. Statistical analyses were performed using R version 4.5.3. Resultados e Conclusions: Eight RCTs were included: five ASI trials (n=1,990) and three MRA trials (n=793), comprising 2,783 participants. Follow-up ranged from 8 to 12 weeks. Both ASIs (MD −9.54 mmHg; 95%CI −10.69 to −8.40; p0.001; I²=0%) and MRAs (MD −8.56 mmHg; 95%CI −10.64 to −6.49; p0.001; I²=0%) significantly reduced SBP versus placebo. Indirect comparison showed no significant difference between ASIs and MRAs (MD −0.98 mmHg; 95%CI −3.13 to +1.17; p=0.372). Sensitivity analyses confirmed result robustness; transitivity was supported by similar placebo responses despite heterogeneity in population severity and BP measurement methods. Hyperkalemia rates were comparable between classes, and gynecomastia was not reported with ASIs (0%), whereas MRAs are associated with rates of 6–10% in longer-term use due to their antiandrogen mechanism. No significant difference was detected between classes, suggesting comparable antihypertensive efficacy. ASIs emerge as a promising alternative for patients requiring potent aldosterone modulation without the risk of steroid-related adverse effects. Head-to-head randomized trials with longer follow-up are warranted to confirm these findings and evaluate cardiovascular outcomes.

ARTIFICIAL INTELLIGENCE–DERIVED INDIVIDUALIZED BLOOD PRESSURE TARGETS TO MINIMIZE MAJOR ADVERSE CARDIOVASCULAR EVENTS

TRACEY H TAVEIRA1; YAN CHENG1; YING YIN1; YIJUN SHAO2; ALI AHMED3; QING ZENG1; WEN-CHIH H WU4;

(1) UNITED STATES VETERANS HEALTH ADMINISTRATION - UNITED STATES; (2) UNITES STATES VETERANS HEALTH ADMINISTRATION - UNITED STATES; (3) UNITED STATES VETERANS HEALTHS ADMINISTRATION - UNITED STATES; (4) UNITED STATES VETERANS HEALTH ADMINISTRATION - MA - UNITED STATES;

Introduction/Background: Hypertension is the leading modifiable risk factor for major adverse cardiovascular events (MACE), yet current guidelines recommend uniform blood pressure (BP) targets despite substantial heterogeneity in cardiovascular risk, co-morbidities, life expectancy and treatment response. Excessive lowering of diastolic BP (DBP) during systolic BP (SBP) lowering may increase cardiovascular risk, yet composite measures such as mean arterial pressure (MAP) are underutilized. Objectives: To develop and evaluate an artificial intelligence (AI)-based approach to identify individualized BP ranges associated with the lowest future risk of MACE. Methods: We developed BP-GPS, a transformer-based AI model integrating longitudinal data and cross-linked electronic health records data from 673,694 Veterans with hypertension receiving anti-hypertensive therapy within a national integrated healthcare system from 2000-2024. Eligible patients had documented outpatient SBP and DBP measurements from a randomly selected hypertension encounter (index date). The model incorporated SBP, DBP, MAP, demographic, and clinical variables to estimate individualized BP ranges associated with minimized 1-year MACE risk. Analyses were stratified by prior myocardial infarction (MI), stroke, diabetes and life expectancy categories (>10 years, 5-10 years, <5 years). Life expectancies were estimated using observed survival among the 428,809 patients who died during the follow-up. Resultados e Conclusions: BP-GPS demonstrated strong discrimination for predicting individualized BP targets associated with lower MACE risk (AUC 0.84). Median (interquartile ranges) optimal individualized SBP values were 125 (105-140), 135 (110-155) and 150 (120-190) mmHg, while optimal individualized MAP values were 90 (85-100), 95 (85-105), and 100 (85-125) mmHg among patients with a life expectancy >10 years, 5-10 years, <5 years, respectively. Among patients with life expectancy >10 years, prior MI or stroke had median optimal SBP values 25 mmHg lower and optimal MAP values 15mmHg lower versus patients without these conditions, while patients with diabetes had SBP and MAP values 5mmHg lower. Patients whose SBP was within their AI-predicted optimal range had lower MACE rates versus those outside range (7.7 vs. 15.5%; OR 0.72 [0.7-0.74];p<0.001). Similarly, patients within optimal MAP range had lower MACE rates than those outside the range (7.1 vs. 16.4%;OR 0.68 [0.67-0.70];p<0.001). These findings support a precision medicine framework for hypertension management.

EFFECT OF BEETROOT EXTRACT SUPPLEMENTATION ON BLOOD PRESSURE IN PATIENTS WITH RESISTANT HYPERTENSION

PATRICIA REGINA THOMÉ MARTINS1; STELLA CORRÊA BARRIAS NARA ROCHA1; GRAZIELLE VILAS BOAS HUGUENIN1; EDUARDO TIBIRIÇÁ1; VALERIA VERRI1; ELISA MAIA DOS SANTOS1; ANDREA ROCHA DE LORENZO1;

(1) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Resistant hypertension (RH) is defined as the failure to achieve blood pressure (BP) values < 140/90 mmHg despite the use of triple therapy with different classes of antihypertensive drugs, including a diuretic, at maximum tolerated doses, and is associated with increased complications and mortality. In addition to pharmacological treatment, diet plays a key therapeutic role, and dietary supplements have been investigated for better BP control without the need for increasing medications. Beetroot is a source of inorganic nitrate, known for its vasodilatory effects; thus, its use in RH in association with pharmacologic treatment is potentially beneficial. Objectives: To evaluate the effect of beetroot-derived nitrate on the BP of patients with RH. Methods: Double-blind, randomized, placebo-controlled, crossover study of adult patients with RH. Participants received 10g of beetroot extract (BE) (400mg of inorganic nitrate) or 10g of maltodextrin as a placebo (PL) for 60 days, followed by a 30-day washout period, and then crossed over to BE or PL for an additional 60 days. Office BP was recorded at each study visit, and ambulatory BP monitoring (ABPM) was performed at baseline and after each intervention. Comparisons were performed using the Student's t-test, with a significance level of 5%. Resultados e Conclusions: Forty-four patients were evaluated (50% male; mean age 61.8±8.6 years). Patients´ medications were vasodilators (79.5%), ACE inhibitors (77.3%), thiazide diuretics (77.3%), calcium channel blockers (31%), non-thiazide diuretics (56.8%), beta-blockers (50%), and alpha-2 adrenergic agonists (45.4%). Mean pre-intervention BP was 147.6 x 86.3 mmHg. After 60 days of BE or placebo use, there was no significant difference in office systolic BP (SBP): BE=147.6 mmHg vs. PL=149.6 mmHg (p=0.661); in office diastolic BP (DBP): BE=86.3 mmHg vs. PL=87.3 mmHg (p=0.638); in ABPM SBP: BE=133.2 mmHg vs. PL=134.8 mmHg (p=0.642); and in ABPM DBP: BE=78.5 mmHg vs. PL=79.0 mmHg (p=0.814). No significant reduction in either office or ABPM pressures was observed after 60 days of BE supplementation when compared to placebo. In this high-risk population, dietary supplementation with BE may be insufficient to promote clinically detectable effects. Further evaluation of a larger patient cohort is necessary, though, to confirm this absence of effect.

Introduction/Background: Despite established guidelines, blood pressure (BP) control remains suboptimal worldwide. Poor implementation of guidelines is identified as a contributing factor. Implementation of guidelines has been challenging, especially in low-middle-income countries (LMIC). The World Health Organization(WHO) has proposed protocol-based BP management (PB-BPM) to mitigate this. However, the efficacy of PB-BPM from South Asia is sparse. Therefore, we assessed the efficacy of PB-BPM in improving BP control among patients with hypertension followed up for 6 or more months at outpatient clinics (primary, secondary, and tertiary care hospitals) where PB-BPM is implemented in Sri Lanka. Objectives: General objective To study the efficacy of guideline based blood pressure control using the data of blood pressure programme proposed by Ministry of health. Specific objectives To study the mean change in blood pressure over 6, 12 and 18 months period. To study the change in percentage with controlled blood pressure over 6,12 and 18 months period Methods: PB-BPM was initiated stepwise from November 2023, and BP data of all patients with 6 or more months' follow-up by 31st December 2025 were analysed. Controlled BP was defined as <140/90 mmHg per the WHO guideline. We compared mean BP and the percentage with controlled BP between baseline and the end of follow-up, stratified into three cohorts based on follow-up duration (Cohorts 1, 2, and 3 with follow-up durations of 6, 12, and 18 months, respectively). Resultados e Conclusions: Results We studied BP control in 13 097 patients (male 3 480(26.6%, mean age 64(SD 10.2) years, 7 679(58.6%) from primary and 5 418(41.4%) from secondary/tertiary healthcare facilities. Mean Systolic BP (SBP p<0.001), diastolic BP(DBP p<0.001), and the percentage with controlled BP (p<0.001) improved significantly at follow-up compared to baseline, in all three cohorts. Mean reductions in SBP/ DBP were better at primary compared to secondary/tertiary care facilities (p<0.001/ p<0.001) and with higher baseline SBP/ DBP (r=0.671, p<0.001/ r=0.639, p<0.001). Conclusion PB-BPM improved BP control among outpatients managed in primary, secondary, and tertiary healthcare facilities in Sri Lanka, with greater efficacy at primary healthcare facilities and among patients with high baseline BP.

FIXED-DOSE TRIPLE ANTIHYPERTENSIVE THERAPY IN WOMEN: CONSISTENT EFFICACY REGARDLESS OF MENOPAUSAL STATUS

ADRIANO PETROLINI-MATEUS1; JULIANA DINEIA PEREZ BRANDÃO1; MAURA GONZAGA LAPA1; AUGUSTO THEODORO DE FIGUEIREDO1; PAULA BONILHA FERNANDES1; ÉRIDA APARECIDA PINTO MAGATON1; CAROLINA DE OLIVEIRA RODINI ZILIO1; FELIPE CELLONI BLAYA MARTINEZ1; MILLENA SOARES DE ALMEIDA1; LAIANA JANUSE DE ARRUDA CORDEIRO MATOS1; VAGNER MADRINI JÚNIOR1; VIVIENNE CARDUZ CASTILHO1;

(1) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL;

Introduction/Background: Hypertension in women is a dynamic condition influenced by multiple factors, including hormonal transitions, which are associated with distinct cardiovascular risk profiles and specific therapeutic needs. In this context, the impact of hormonal changes on antihypertensive treatment, particularly with the use of fixed-dose triple combination therapy, remains underexplored. Objectives: To characterize the clinical profile of hypertensive women and to evaluate the influence of menopausal status on the antihypertensive response to a fixed-dose triple combination. Methods: The OPTION TREAT study was a randomized, double-blind, controlled, multicenter clinical trial including 703 participants in Brazil (NCT05920005). In this subanalysis, women participants were evaluated by analyzing the change in systolic blood pressure (ΔSBP) from baseline to week 12, stratified by menopausal status as as fixed effects, the treatment–menopause interaction, and baseline SBP as a covariate. Resultados e Conclusions: A total of 441 women were included, with a mean age of 58 ± 10.2 years and a mean BMI of 31.5 ± 5.9 kg/m². The most prevalent comorbidities were menopause and dyslipidemia (54.0%), obesity (37.6%), and type 2 diabetes mellitus (21.1%). Among women of reproductive age (n = 203), the experimental treatment (candesartan cilexetil 16 mg, chlortalidone 12.5 mg, and amlodipine 5 mg) achieved a significantly greater reduction in SBP compared with the reference treatment (valsartan 160 mg, hydrochlorothiazide 12.5 mg, and amlodipine 5 mg), with a least-squares mean difference of −4.94 mmHg (95% CI: −8.2 to −1.6; p = 0.004). In postmenopausal women (n = 238), SBP reduction was also greater with the experimental treatment (−3.30 mmHg; 95% CI: −6.3 to −0.3; p = 0.034). In the overall population, the experimental treatment resulted in a significantly greater SBP reduction (−4.11 mmHg; 95% CI: −6.4 to −1.9; p < 0.001). After adjustment for menopausal status, non- menopause women exhibited a significantly greater SBP reduction (p = 0.038), regardless of treatment group. The novel fixed-dose triple combination demonstrated consistent antihypertensive efficacy across menopausal status groups, with greater systolic blood pressure reductions observed in non-menopausal women.

FROM GLOBAL RECOMMENDATIONS TO NATIONAL POLICY: SINGLE-PILL COMBINATION ANTIHYPERTENSIVES IN SUB-SAHARAN AFRICA

MILENA SORIANO MARCOLINO1; ISABELLA VIANA GOMES SCHETTINI1; BRUNO VALDIZAN PEREIRA RODRIGUES2; LUCAS ROCHA VALLE1; CHIAMAKA OMOYELE3; MAYANK DALAKOTI4; ANDRES ROSENDE5; MUNDIH NOELAR NJOHJAM6; HUEIMING LIU7; JAFESI PULLE8; ALEXANDER D PERKINS9; MICHELLE RALIL DA COSTA1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) FACULDADE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) WORLD FOOD PROGRAMME - NIGERIA; (4) UNIVERSITY OF CAMBRIDGE - UNITED KINGDOM; (5) PAN AMERICAN HEALTH ORGANIZATION - UNITED STATES; (6) CHEIKH ANTA DIOP UNIVERSITY - SENEGAL; (7) THE GEORGE INSTITUTE - AUSTRALIA; (8) UGANDA HEART INSTITUTE - UGANDA; (9) LONDON SCHOOL OF HYGIENE & TROPICAL MEDICINE - UNITED KINGDOM;

Introduction/Background: Blood pressure control rates in Sub-Saharan Africa (SSA) remain among the lowest worldwide. Single-pill combinations (SPCs) are endorsed by the World Health Organization (WHO) and major international guidelines as an effective strategy to improve treatment adherence and cardiovascular outcomes. However, access to SPCs in SSA is largely shaped by national policy decisions, particularly their inclusion in Essential Medicines Lists (EMLs), clinical guidelines, and national health policy (NHP) documents. Objectives: To evaluate how SPC antihypertensive therapies are incorporated, positioned, and recommended across these policy instruments in SSA. Methods: We conducted a comparative document review of national EMLs, hypertension clinical guidelines, and NHP documents retrieved from official government sources, WHO repositories, and regional institutional platforms. Analyses were performed across countries using a descriptive and comparative approach, informed by the WHO Health System “Leadership and Governance” framework. Resultados e Conclusions: All countries had an identifiable EML, but only 21 (42.9%) included at least one antihypertensive SPC. Uptake was higher in Eastern and Southern Africa and remained limited in Central Africa. SPC inclusion was more frequent in recently updated EMLs, particularly after the 2019 revision of the WHO Model List of Essential Medicines. National hypertension guidelines were identified in only 15 countries; among these, four mentioned SPCs, and only Kenya provided detailed, actionable recommendations. Concordance between EMLs and clinical guidelines was generally poor, with most countries either listing SPCs without corresponding guideline endorsement or recommending them without including them in EMLs. In conclusion, the adoption of SPC antihypertensive therapies across SSA remains inconsistent and incomplete. The observed gaps and lack of alignment between medicines selection and clinical guidance suggest limitations in national governance processes that may hinder access to WHO-recommended treatments. Improving policy coherence represents a key opportunity to enhance hypertension care and expand access to effective therapies in the region.

HIGH DISCORDANCE BETWEEN OFFICE AND OUT-OF-OFFICE BLOOD PRESSURE PHENOTYPES IN INDIVIDUALS DIAGNOSED WITH HYPERTENSION

AMOR SAYOKO DE LINDA FESTO1; MALACHIAS VINICIUS BOLIVAR MALACHIAS1;

(1) FACULDADE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Background: The diagnosis and management of hypertension have traditionally relied on office blood pressure (BP) measurements. However, substantial differences may exist between office and out-of-office BP values. Objectives: Objectives: To evaluate the concordance between office BP phenotypes and ambulatory blood pressure monitoring (ABPM), and to assess BP control according to antihypertensive treatment strategy. Methods: Methods: This prospective observational study included 455 individuals (mean age 55.2 years; 59.6% women), of whom 51.2% were not receiving antihypertensive treatment. All participants had altered office BP and were referred for ABPM using a validated device (SpaceLabs 90217). BP phenotypes of sustained hypertension (SH) and uncontrolled sustained hypertension (USH) established by office measurements were compared with ABPM findings. BP control rates were also evaluated according to monotherapy, dual therapy, or multiple-drug therapy. Fisher's exact test, Chi-square test, Shapiro–Wilk test, Student's t-test, and Wilcoxon Mann–Whitney test were performed using RStudio 2025.09.1, adopting p<0.05 as statistically significant. Resultados e Conclusions: Results: Concordance between office and ABPM hypertension phenotypes was observed in 274 individuals (60.2%; 95% CI 55.7%–64.7%). However, 181 individuals (39.8%; 95% CI 35.3%–44.3%; p<0.001) showed normal or normalized BP values on ABPM, consistent with white coat hypertension or white coat effect phenotypes, and discordant with the office-based diagnosis. Among untreated individuals, 37.8% (95% CI 23.6%–52.0%) were normotensive on ABPM. Among treated individuals, BP control rates were similar across therapeutic strategies: 42.5% with monotherapy, 40.5% with dual therapy, and 42.9% with multiple-drug therapy (p=0.958). Clinical characteristics of individuals with concordant and discordant phenotypes were similar to those of the overall sample. Conclusions: Nearly 40% of individuals with altered BP (SH and USH) based on office measurements were reclassified after ABPM evaluation. BP control rates were similarly low regardless of treatment strategy. These findings reinforce the importance of out-of-office BP assessment to improve the accuracy of hypertension diagnosis and management.

Percentages of concordance and discordance (altered blood pressure) between Office or Out-of-Office Blood messurements. The line segment indicates the upper limit of the 95% confidence interval. p<0.001.

IMPACT OF HYPERTENSION ON COGNITIVE PERFORMANCE IN DIABETIC PATIENTS AT THE LUANDA DIABETES CLINIC CENTER, ANGOLA

SILKE WEZA JOSÉ ANTÓNIO1; JOÃO HOUARI AFONSO ADELAIDE1; ROSÁRIA EPANDI LUCANDA CAIANGULA1; ISAURA CONCEIÇÃO ALMEIDA LOPES1; HENRIQUE COTCHI SIMBO MUELA1;

(1) FACULTY OF MEDICINE, AGOSTINHO NETO UNIVERSITY, LUANDA - ANGOLA;

Introduction/Background: Hypertension (HTN) in diabetic patients significantly accelerates cognitive decline, resulting in poorer memory, slower thinking speeds, and increased dementia risk compared to either condition alone. Objectives: To evaluate the impact of HTN on cognitive performance in diabetic patients followed up at the Diabetic Clinic Center in Luanda. Methods: A cross-sectional study was carried out, including 148 patients (aged ≥18 years or older and followed up at the center). HTN was defined as systolic blood pressure (SBP) and/or diastolic blood pressure (DBP) ≥140/90 mmHg or the use of anti-hypertensive drugs. HTN control was defined as BP <130/80 mmHg. Physical activity (PA) was assessed using the IPAQ questionnaire. Cognitive function was assessed using the MoCA test. The Smirnov-Kolmogorov test was used for variable distribution analysis. The Spearman coefficient for bivariate correlation and multivariable regression to determine the predictors of cognitive performance. Statistical significance was set at 5%. Resultados e Conclusions: HTN prevalence was 73.0%; among HTN patients, 82.4% were aware, and 92.1% were undergoing treatment, but only 12.8% had BP under control. HTN patients were older (60.5±12.5 vs. 49.2±11.9 yrs; p<0.001) and had also a lower level of education (10.6±3.8 vs. 13.1±3.4; p<0.001). The duration of DM was longer in HTN patients (median: 12 vs. 8 years; p<0.001). Cognitive dysfunction was more prevalent in HTN patients (82.7% vs. 17.3%; p<0.001); 80.9% of HTN patients were sedentary/irregularly active. HTN diagnosis had a negative correlation with cognitive performance (r= -0.374; p<0.001); the risk of cognitive impairment was 5-fold higher compared to the normotensive (OR: 5.916, CI: 2.637-13.276). PA was positively correlated with cognitive performance (r=0.327; p<0.001), and the risk of cognitive impairment in the less active group (sedentary/irregularly active) was 4-fold higher compared to the more active (OR: 4.789; CI: 2.140-10.717). HTN diagnosis was a predictor of worse cognitive performance (B: -0.204; CI: -0.340 to -0.060), while a higher educational level was a predictor of better cognitive performance (B: 0.227; CI: 0.008-0.042). The prevalence of HTN was high; most HTN patients were aware and being treated, but BP control was low. Cognitive dysfunction was high and exacerbated by HTN. HTN diagnosis was a predictor of worse cognitive performance, while higher education level was a predictor of better cognitive performance.

LONGITUDINAL BLOOD PRESSURE PATTERNS AND CARDIOVASCULAR RISK IN THE SLEEP HEART HEALTH STUDY

KAROLINA STEPHANY PEREIRA FERREIRA1; PALOMA RODRIGUES ROCHA2;

(1) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction/Background: Cardiovascular risk stratification traditionally relies on isolated blood pressure (BP) measurements, which may not reflect longitudinal control patterns. Persistent elevation or worsening BP status may provide additional prognostic information beyond a single cross-sectional assessment. Objectives: This study aimed to evaluate whether different clinical patterns of BP change across three time points were associated with subsequent cardiovascular risk in the Sleep Heart Health Study (SHHS). Methods: A longitudinal analysis was conducted using participants from the SHHS with BP measurements obtained at three time points: Visit 1, an interim follow-up, and Visit 2. Participants were classified into five clinical trajectory groups based on BP control status at each wave: always controlled, improving, worsening, persistently elevated, and mixed pattern. The primary outcome was the first cardiovascular event occurring after Visit 2, defined as the earliest occurrence of myocardial infarction, stroke, congestive heart failure, or cardiovascular death. Follow-up for the survival analysis started at Visit 2. Cox proportional hazards models were adjusted for age, sex, and body mass index, and, in a sensitivity analysis, additionally adjusted for baseline systolic BP. Resultados e Conclusions: A total of 3,161 participants were included; mean age was 62.7 years, 55.3% were women, 20.4% had uncontrolled BP at Visit 1, and 403 (12.7%) experienced a cardiovascular event after Visit 2. Compared with the always controlled group, cardiovascular risk was higher in the worsening (HR 1.36; 95% CI 1.04-1.78; p=0.026), persistently elevated (HR 1.70; 95% CI 1.24-2.32; p<0.001), and mixed pattern trajectories (HR 1.57; 95% CI 1.12–2.21; p=0.009) in the model adjusted for age, sex, and body mass index. In the sensitivity analysis with additional adjustment for baseline systolic BP, these associations were attenuated and no longer statistically significant: improving, HR 0.72 (95% CI 0.48–1.08; p=0.110); worsening, HR 1.23 (95% CI 0.94–1.62; p=0.134); persistently elevated, HR 0.89 (95% CI 0.58-1.37; p=0.597); and mixed pattern, HR 1.22 (95% CI 0.85–1.75; p=0.287). In the SHHS, clinical patterns of worsening BP and persistent elevation across three time points were associated with higher subsequent cardiovascular risk. These findings suggest that the clinical evolution of BP control may refine cardiovascular risk stratification beyond a single cross-sectional assessment.

Introduction/Background: Out-of-office blood pressure (BP) measurement plays an increasingly important role in the diagnosis of hypertension. In community pharmacies, cutoff values are adapted from home and ambulatory measurements, without specific validation based on clinical outcomes. Standardization of the measurement method may significantly impact the accuracy of these estimates. Objectives: To evaluate the impact of different BP thresholds on the prevalence of hypertension using standardized measurements performed in community pharmacies. Methods: A cross-sectional observational study was conducted in 2025 within a large pharmacy chain in the state of Minas Gerais, Brazil. Measurements were obtained by previously trained pharmacists using a validated device (HEM-7349T, Omron) with TruRead technology (three consecutive measurements at 60-second intervals, with the average of the last two readings used for analysis). The prevalence of hypertension was estimated according to three BP thresholds: ≥140/90 mmHg, ≥135/85 mmHg, and ≥130/80 mmHg. Comparisons between proportions were performed using McNemar's test. Resultados e Conclusions: A total of 49.068 standardized BP measurements were analyzed. The population comprised 57.2% women and 42.8% men, with a mean age of 54.5 ± 17.7 years. The mean systolic BP was 126.6 ± 19.0 mmHg and the mean diastolic BP was 80.7 ± 11.8 mmHg. The prevalence of hypertension was 31.1% at the diagnostic threshold of BP ≥ 140/90 mmHg, 45.0% at BP ≥ 135/85 mmHg, and 60.5% at BP ≥ 130/80 mmHg. There were statistically significant differences across all thresholds analyzed (p<0.001 for all comparisons). Conclusions: The prevalence of hypertension in measurements obtained in community pharmacies varies substantially according to the BP threshold applied, even under standardized measurement conditions. These findings underscore the need to establish setting-specific cutoff values for this environment and have important implications for population screening strategies and public health policies.

Table 1. Characteristics of the study population and prevalence of hypertension across different blood pressure thresholds

Variables	n = 49.068
Age, years	54.5 ± 17.7
Male sex, %	21,013 (42.8%)
SBP, mmHg	126.6 ± 19.0
DBP, mmHg	80.7 ± 11.8
BP ≥140/90 mmHg	15.273 (31.1%)
BP ≥135/85 mmHg	22.066 (45.0%)†
BP ≥130/80 mmHg	29.692 (60.5%)†#

Plus–minus values are means ±SD. BP denotes blood pressure, SBP systolic blood pressure , DBP diastolic blood pressure and mmHg millimeters of Mercury.
†p<0.001 compared with the prevalence of hypertension considering BP ≥140/90 mmHg.
#p<0.001 compared with the prevalence of hypertension considering BP ≥135/85 mmHg.

Introduction/Background: Sex differences in awareness, treatment, and control of hypertension are well documented in the literature, with men demonstrating lower utilization of healthcare services and a higher burden of undiagnosed disease. However, it remains unclear whether these disparities persist or are further accentuated in screening settings conducted in community pharmacies. Objectives: To assess sex differences in blood pressure (BP) measurements and in the prevalence of hypertension according to different cutoff thresholds within a structured measurement program in community pharmacies. Methods: A cross-sectional observational study was conducted in 2025 within a large pharmacy chain in the state of Minas Gerais, Brazil. Measurements were obtained by previously trained pharmacists using a validated device (HEM-7349T, Omron) with TruRead technology (mean of the last two of three consecutive measurements obtained at 60-second intervals). The prevalence of hypertension was estimated according to three BP thresholds: ≥140/90 mmHg, ≥135/85 mmHg, and ≥130/80 mmHg. Comparisons between sexes were performed using the unpaired Student's t-test and the chi-square test. Age-adjusted linear and logistic regression models were used for additional analyses. Resultados e Conclusions: A total of 49.068 standardized BP measurements were analyzed. The population comprised 57.2% women and 42.8% men, with mean ages of 54.2 ± 18.2 and 54.8 ± 17.0 years, respectively. Mean systolic and diastolic BP were higher in men (p < 0.001), as was the prevalence of hypertension across all diagnostic thresholds (see Table 1). After adjustment for age, men had a higher risk of hypertension compared with women, with an odds ratio (OR) of 1.50 (95% confidence interval [CI] 1.44–1.58) for ≥140/90 mmHg (p < 0.001), OR 1.57 (95% CI 1.52–1.63) for ≥135/85 mmHg (p < 0.001), and OR 1.68 (95% CI 1.61–1.74) for ≥130/80 mmHg (p < 0.001). Conclusions: Men have a higher prevalence of hypertension compared with women in the community pharmacy setting. The widening of this difference with lower BP thresholds suggests a greater burden of unrecognized hypertension in this group, underscoring the role of community pharmacies as a relevant strategy for early detection of this condition.

Table. Sex-based differences in blood pressure and prevalence of hypertension according to diagnostic thresholds

Variables	Women (*n*=28,055)	Men (*n*=21,013)	*p*-value
Age, years	54.2 ± 18.2	54.8 ± 17.0	<0.001
SBP, mmHg	123.4 ± 19.3	130.8 ± 17.7	<0.001
DBP, mmHg	79.7 ± 11.7	82.1 ± 11.9	<0.001
Prevalence of hypertension, n (%)			
BP ≥140/90 mmHg	7.679 (27.4%)	7.594 (36.1%)	<0.001
BP ≥135/85 mmHg	11.263 (40.1%)	10.803 (51.4%)	<0.001
BP ≥130/80 mmHg	15.512 (55.3%)	14.180 (67.5%)	<0.001

Plus–minus values are means ±SD. BP denotes blood pressure, SBP systolic blood pressure, DBP diastolic blood pressure and mmHg millimeters of Mercury.

THE EFFICACY OF RENAL DENERVATION SURGERY COMPARED TO SIMULATED PROCEDURES IN LOWERING BLOOD PRESSURE IN PATIENTS WITH RESISTANT HYPERTENSION: A SYSTEMATIC REVIEW

ISABELA MARQUES QUEIROZ1; PIETRA TABOSA CABRAL1; GUILHERME MODESTO NEVES1; LUNA FURTADO CUTRIM SOUZA2; MARIA EDUARDA ALVES MIRANDA BARBOSA1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA), SANTARÉM, PA, BRASIL - SANTARÉM - PA - BRASIL;

Introduction/Background: Resistant hypertension is defined as blood pressure that remains above normal levels despite the use of antihypertensive medications. Renal denervation surgery has emerged as a therapeutic alternative because it is a minimally invasive procedure that aims to lower blood pressure by modulating the sympathetic nervous system. Objectives: To evaluate the efficacy of renal denervation surgery in controlling resistant hypertension, compared to sham procedures. Methods: A systematic literature review following the PRISMA guidelines. The databases PubMed, Medline, Lilacs, Cochrane, and Scielo were used with the following search terms: ("Renal denervation" AND "Sham"). Articles published in the last 5 years were included, provided the full text was publicly available and the study had a Qualis Capes A1 impact factor. Studies not directly related to the research question or with inadequate methodology were excluded. Resultados e Conclusions: Results: After data processing, 6 articles were selected for inclusion in the review, resulting in a sample size of 1,173 patients. The randomized clinical trials comparing renal denervation surgery with a sham procedure, notably the studies by Xiongjing Jiang et al. and Michel Azizi et al., reported a reduction in blood pressure with renal denervation surgery, which lowers the risk of major cardiovascular complications. Regarding safety, hematomas were observed in patients treated with the aforementioned surgery, with full recovery and no major complications. Conclusion: The included studies demonstrated the advantages of renal denervation surgery compared to the simulated procedure in terms of blood pressure reduction, a factor that lowers the risk of clinical complications.

Introduction/Background: Ambulatory blood pressure monitoring (ABPM) is the gold standard for assessing the circadian pattern of blood pressure. Home blood pressure monitoring (HBPM) using wrist devices with nocturnal measurements has emerged as a more comfortable and potentially applicable alternative; however, its ability to accurately reflect the physiological sleep–wake blood pressure decline remains uncertain. Objectives: To compare the sleep–wake blood pressure decline obtained by ABPM and wrist HBPM and to evaluate the impact of sleep quality on this parameter. Methods: We conducted a pragmatic multicenter study including 172 hypertensive patients (mean age 57.6 ± 15.5 years; 56% women) who underwent both ABPM and HBPM while on the same antihypertensive regimen, with a median interval of 26 [12–96] days between assessments. The sleep–wake decline was calculated as the percentage reduction from wakefulness to sleep. Sleep quality was categorized as good or impaired (fair/poor). Blood pressure (BP) data are presented as median [interquartile range]. Comparisons were performed using nonparametric tests (Wilcoxon, McNemar, and Kruskal–Wallis, as appropriate), and correlations were assessed using Spearman's test. A p-value <0.05 was considered statistically significant. Resultados e Conclusions: Systolic (SBP) and diastolic (DBP) BP values during wakefulness and sleep were 121 [113–129]/76 [71–83] and 110 [102–119]/65 [58–74] mmHg with ABPM, and 125 [118–135]/79 [71–87] and 117 [109–127]/71 [63–79] mmHg with HBPM, respectively. Patients reported good sleep quality more frequently during HBPM than during ABPM (74% vs. 24%; p<0.001). The sleep–wake BP decline was significantly greater with HBPM compared with ABPM (SBP: 10.5 [3.9–15.8]% vs. 7.1 [0.8–12.9]%; DBP: 15.7 [8.0–21.9]% vs. 9.0 [2.7–17.0]%; p<0.001). In analyses stratified by sleep quality, the decline did not differ significantly between patients with good versus impaired sleep in either method (ABPM: p>0.05; HBPM: p>0.05). Correlation of the sleep–wake decline between methods was weak (r=0.14, p=0.06 for SBP; r=0.017, p=0.029 for DBP). These findings indicate that HBPM is more comfortable and potentially more applicable. The sleep-wake BP decline was greater but not equal to ABPM, meaning that we can assess circadian BP profile with HBPM but the reference values may be different.

ACUTE EFFECT OF NON-INVASIVE NEUROSTIMULATION ON DISTANCE WALKED IN PEOPLE WITH HEART FAILURE: A RANDOMISED CONTROLLED CLINICAL TRIAL.

KAIO EMANUEL SOUZA NUNES1; JOSÉ HERISTON MORAIS LIMA2; EDUARDO ERIKO TENÓRIO FRANÇA2; RAFAELA PEDROSA2; TATIANA ONOFRE GAMA2; SUELLEN MARY MARINHO SANTOS ANDRADE2;

(1) UNIPE - JOÃO PESSOA - PB - BRASIL; (2) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL;

Introduction/Background: Introduction: Heart failure is a chronic condition associated with high morbidity and mortality rates. Clinically, HF manifests through a series of debilitating symptoms, including dyspnea, extreme fatigue, peripheral edema, and exercise intolerance, significantly impacting individuals' quality of life. The six-minute walk test (6MWT) is a simple method to investigate exercise capacity in cardiac patients. When compared to a traditional cardiopulmonary exercise test, it is found that, as a rule, patients performing the 6MWT do not reach predicted maximum ventilation or heart rate levels, therefore being considered a submaximal test. High-definition transcranial direct current stimulation (HD-TDCS) has emerged as a promising neuromodulatory approach, with potential influence on cardiovascular function, However, its effects on heart failure are still poorly understood Objectives: Objective: To evaluate the effects of HD-TDCS on the distance covered in the 6MWT, heart rate, and subjective perception of effort in individuals with heart failure Methods: Methods: A randomized clinical trial was conducted in individuals diagnosed with NYHA class II and III heart failure. Participants underwent three 20-minute HD-TDCS sessions (stimulation, inhibition, and sham), applied to the left temporal cortex at an intensity of 3 mA. After each session, a six-minute walk test was performed. The variables analyzed included the distance covered in the 6MWT, heart rate, and Borg's rating of perceived exertion scale. Data were analyzed using the Shapiro-Wilk test and the Friedman test, considering the non-normal distribution of the data Resultados e Conclusions: Results: Twenty-four individuals participated in the study, with a mean age of 53.46 ± 10.92 years, a minimum age of 31 years, and a maximum age of 70 years. Males predominated (62.5%, n=15). The average distance covered for stimulation, inhibition, and sham was 393.0, 414.5, and 399.5 meters, respectively. The final heart rate was 92, 85, and 91 bpm for stimulation, inhibition, and sham, and the hand-grip results after HD-TDCS application were 29.55, 31.40, and 29.74 for stimulation, inhibition, and sham. Conclusion: The findings suggest that HD-TDCS may influence autonomic modulation. Although no significant effects were observed in the analyzed variables, the results indicate a therapeutic potential for the technique in autonomic regulation in heart failure.

17804

AN IN-HOSPITAL RISK AND OUTCOMES COST ESTIMATE MODEL FOR HEART FAILURE PATIENTS IN BRAZIL

ANA PAULA BECK DA SILVA ETGES1; PEDRO POLANCZYK ROHDE2; MARCIANE ROVER3; MARIANA MOTTA DIAS DA SILVA3; GABRIEL PIANTA2; CARISI ANNE POLANCZYK3;

(1) UNIVERSIDADE FEDERAL DO RIO GRANDE - RIO GRANDE - RS - BRASIL; (2) PUCRS - PORTO ALEGRE - RS - BRASIL; (3) HOSPITAL MOINHOS DE VENTO - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Heart failure (HF) represents an important burden in the Brazilian healthcare system, the self-reported prevalence of heart failure (HF) is estimated at 1.1% among adults aged 18 years and older and 3.3% among individuals aged 60 years and older. Total expenditures by the Brazilian Unified Health System (SUS) on HF exceeded R$ 3,03 billion between 2015 and 2024, with a peak in 2023 (R$ 315,69 million), and although several cost and burden studies have been conducted, a model that provides more accurate real-world cost estimates and serves as an instrument to drive resource allocation and financial predictability is scarce. Objectives: This study introduces an in-hospital risk-and-outcomes cost estimate model for heart failure patients in Brazil. Methods: This is a real-world data Brazilian study developed in the context of the private health system that included clinical and hospital cost data -without profit margin and medical fees-, for HF patients treated at a tertiary care hospital from 2017 to 2025. The ADHERE served as a parameter for clinical risk adjustment, and cost descriptions were stratified by the low (0), medium (1), and high scores (2+). The analysis used multiple regression models (GLM) to identify the risk and outcome variables individually associated with cost. By confirming the variables, the model outputs were used as the parameters of the cost-estimate model. The analysis considered the assumptions to confirm the regression at the 95% confidence level. Resultados e Conclusions: Clinical and in-hospital cost data for 1,328 HF patients, with a mean age of 80.8±12.4 years. Most of the sample presented low ADHERE (58%), and only 13% a high score (2+). The GLM explained 73.6% of cost variability, with length of stay as the dominant predictor (+5,1% cost per day, p<0.001), followed by hemodialysis, ICU admission, and in-hospital death for all ADHERE scores. Female sex contributes to a cost decrease in ADRHRE low-score patients. By applying the model, the median cost estimate per ADHERE score ranges from R$24,143 to R$42,738, and can reach R$101,403 and R$180,012, respectively, for patients who confirm all cost predictors. Table 1 contains the influence of each predictor variable on the cost estimate and the suggested model. By introducing a risk- and outcomes-adjusted cost tool for HF patients, this study can contribute to improving HF financial predictability and support clinicians, hospitals, and payer managers in working closely to reduce the HF burden in Brazil.

BETA-BLOCKER DISCONTINUATION OR NON-INITIATION IN STABLE POST-MYOCARDIAL INFARCTION PATIENTS WITH PRESERVED EJECTION FRACTION: A CONTEMPORARY SYSTEMATIC REVIEW AND META-ANALYSIS (2024-2026)

LUIS HENRIQUE ARAUJO EVARISTO SOARES1; DAVI NOGUEIRA JARLES1; REBECA FREITAS COSTA ARAÚJO1; EUCÁRIO LEITE MONTEIRO ALVES1;

(1) UNICET - TERESINA - PI - BRASIL;

Introduction/Background: Beta-blocker (BB) therapy has been a cornerstone in post-myocardial infarction (MI) management. However, its long-term necessity in stable patients with preserved ejection fraction (EF) has been questioned in the modern reperfusion era. Recent large-scale randomized controlled trials (RCTs) published between 2024 and 2026 have provided conflicting or neutral results, necessitating an updated synthesis. Objectives: To conduct a systematic review and meta-analysis evaluating the safety and efficacy of BB discontinuation or non-initiation compared to therapy continuation in stable post-MI patients with preserved EF, incorporating the latest data from 2024 to 2026. Methods: We searched PubMed, Embase, and ClinicalTrials.gov for RCTs published between January 2024 and March 2026. Inclusion criteria (PICO): (P) Adult patients with post-MI and preserved EF (≥40% or ≥50%); (I) BB discontinuation or non-initiation; (C) BB continuation or initiation; (O) Major adverse cardiovascular events (MACE), mortality, and reinfarction. We excluded observational studies, reviews, and trials with reduced EF (<40%). Meta-analysis used a random-effects model to calculate pooled Relative Risks (RR) and 95% confidence intervals (CI). Heterogeneity was assessed via I^2 statistic. Resultados e Conclusions: Five high-quality RCTs (ABYSS, REDUCE-AMI, REBOOT-CNIC, BETAMI-DANBLOCK, and SMART-DECISION) were included, totaling 25,500 patients. The overall meta-analysis for MACE demonstrated a pooled RR of 0.95 (95% CI 0.86-1.05; p=0.32), indicating that BB discontinuation or non-initiation was non-inferior to continuation. Heterogeneity was low to moderate (I^2 = 32.7%). Subgroup analysis for discontinuation trials (ABYSS and SMART-DECISION) showed a pooled RR of 1.00 (95% CI 0.73-1.37), while non-initiation trials (REDUCE-AMI, REBOOT-CNIC, BETAMI-DANBLOCK) showed an RR of 0.96 (95% CI 0.86-1.08; I^2 = 12.2%). Secondary outcomes showed no significant differences. In stable post-MI patients with preserved EF, beta-blocker discontinuation or non-initiation is safe and non-inferior to therapy continuation regarding MACE. These findings, incorporating recent 2026 evidence, suggest that long-term BB therapy may not be necessary for all post-MI patients with preserved EF, supporting a more personalized approach.

Introduction/Background: Chagas Cardiomyopathy (ChC) has been associated with increased mortality in patients with HF, accounting for up to 22% of deaths in Brazil. However, most evidence derives from studies conducted more than a decade ago, and the impact of contemporary therapies on this association is uncertain. Objectives: This study evaluated the current population attributable risk (PAR) of ChC for one-year all-cause mortality among outpatients with chronic HF. Methods: In this prospective multicentric, the Rosa do Ventos cohort study, including 30 Brazilian centers, we studied adult patients with left ventricular ejection fraction (LVEF) < 50% from June/2021 to June/2025, comparing patients with and without ChC and estimated the PAR of ChC for one-year all-cause mortality. Resultados e Conclusions: Results: Of the 2,379 patients enrolled (36% women, 25% white, age 61+14 years and LVEF 34+9%), 263 (11%) had ChC. Regarding baseline treatment, ChC patients were more likely to use spironolactone (80% vs 74%) and amiodarone (33% vs 10%)(p<0.001), less likely to use SGLT2i (19% vs 41%, p<0.001), with no difference in ACEi/ARB(64%), ARNI(25%) and betablockers(92%) use compared to those without ChC (NChC). The use of implantable cardioverter-defibrillator was also higher in ChC than NChC (14% vs 6%, p=0.001). There were 147 deaths (44 in ChC). One-year survival was significantly lower in ChC (Figure; log-rank p<0.001), with an incidence rate of 18.3(95%CI, 13.6–24.6) deaths/100 person-years compared with 7.0(95%CI, 6.0–8.3) per 100 person-years in NChC. In multivariable Cox-regression analysis adjusted for age, sex, LVEF, heart rate, body mass index, hypertension, diabetes mellitus, systolic blood pressure and ischaemic/valvar aetiology, ChC was associated with increased risk of death: HR (95%CI)=2.66 (1.81–3.90), p<0.001. In fully adjusted analysis, PAR of ChC for mortality was high [PAR (95%CI) =14.8% (11.2 to 18.0)]. Conclusions: In this contemporary cohort of patients with chronic HF, ChC remained independently associated with increased mortality, accounting for approximately 15% of deaths.

DIAPHRAGMATIC FUNCTION CORRELATES WITH AEROBIC POWER AND VENTILATORY EFFICIENCY IN HEART FAILURE WITH REDUCED EJECTION FRACTION

PABLO MARINO CORREA NASCIMENTO1; MARIO LUIZ RIBEIRO1; BERNARDO NASCIMENTO LOURENÇO1; HUMBERTO VILLACORTA1; ANTONIO JOSE LAGOEIRO JORGE1; NAZARETH DE NOVAES ROCHA1; WOLNEY DE ANDRADE MARTINS1;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL;

Introduction/Background: Heart failure (HF) is a clinical syndrome characterized mainly by dyspnea and exercise intolerance. Inspiratory muscle weakness has been proposed as one of the mechanisms contributing to these symptoms. The diaphragm is the primary inspiratory muscle, and its function has recently begun to be assessed in HF using ultrasound imaging. Objectives: To investigate the relationship between diaphragmatic function, aerobic capacity, and ventilatory efficiency in individuals with heart failure with reduced ejection fraction (HFrEF). Methods: Patients with HFrEF underwent diaphragmatic ultrasound, echocardiography, and cardiopulmonary exercise testing. Results were compared with those of a control group without HF. Continuous variables were compared using Student's t-test or the Mann–Whitney test, and categorical variables using Fisher's exact test. Associations between variables were assessed using Pearson's or Spearman's correlation coefficients. Statistical significance was defined as $p < 0.05$. Resultados e Conclusions: Eleven individuals with HFrEF and eleven controls were included. The groups were similar in age (HFrEF: 61.8±10.7 years; control: 60.4±5.9 years; p=0.697) and sex distribution (p=1.0), but differed significantly in left ventricular ejection fraction (HFrEF: 33.4±8.0%; control: 62.7±6.2%; p<0.001). Amplitude of diaphragmatic excursion (ADE) was significantly lower in the HFrEF group (1.73 [1.28–2.75] vs 6.03 [5.42–6.50]; p<0.001). Patients with HFrEF also showed lower peak oxygen consumption (peak VO_2) (12.9±4.0 vs 24.4±6.8 mL·kg^{-1}·min^{-1}; p<0.001) and lower oxygen uptake efficiency slope (OUES) (1.24±0.78 vs 1.96±0.42; p=0.01), as well as a higher cardiorespiratory optimal point (COP) (23.0 [21.95–28.30] vs 17.30 [15.20–18.0]; p<0.001). ADE correlated positively with peak VO_2 (ρ=0.715; p=0.001) and OUES (ρ=0.450; p=0.037), and negatively with COP (ρ=−0.611; p=0.003). Individuals with HFrEF exhibited markedly reduced diaphragmatic excursion compared with controls. Diaphragmatic function showed a strong association with peak VO_2, the gold-standard measure of aerobic capacity, and with ventilatory efficiency parameters such as OUES and COP. These findings suggest that diaphragmatic dysfunction may contribute, at least in part, to the dyspnea and exercise intolerance observed in patients with HFrEF.

DISCRIMINATORY ABILITY OF NT-PROBNP AND PASP FOR MORTALITY IN PATIENTS WITH ACUTE HEART FAILURE

MARIA XIMENA SANANGO JARA1; EDUARDA MORARI JESKE2; JOÃO PAULO BEILNER HOLZ2; GABRIELA FELICIANO POTRICH2; PEDRO AUGUSTO LUCCA DALLAZEN2; PEDRO LUCAS BEILNER HOLZ2; JOÃO VITOR REBELATTO BIANCHI2; PAULO ERNESTO LEÃES1; FERNANDO ANTONIO LUCCHESE1; LUIZ CLAUDIO DANZMANN1;

(1) UFCSPA - PORTO ALEGRE - RS - BRASIL; (2) UNIVERSIDADE LUTERANA DO BRASIL- ULBRA - CANOAS - RS - BRASIL;

Introduction/Background: Acute heart failure (AHF) is a leading cause of hospitalization and mortality in Brazil. Congestion, reflected by both hemodynamic parameters (filling pressures) and humoral markers (biomarkers), is the main determinant of symptoms and adverse outcomes. Objectives: To evaluate the association and discriminatory ability of humoral congestion (NT-proBNP) and hemodynamic congestion (pulmonary artery systolic pressure [PASP]) in predicting in-hospital mortality among patients with AHF. Methods: This retrospective cross-sectional study included 95 patients admitted to a hospital in southern Brazil between 2023 and 2024. The areas under the receiver operating characteristic curve (AUC) were analyzed, and optimal cutoff points for NT-proBNP and PASP for predicting mortality were determined using the Youden index. Resultados e Conclusions: The sample (n = 95) had a mean age of 70.2 ± 15.2 years, with a predominance of males (60%) and ischemic etiology (50.5%). Most patients (90.5%) had acutely decompensated chronic heart failure, and 56.8% had heart failure with reduced ejection fraction (HFrEF). NT-proBNP demonstrated discriminatory ability for in-hospital mortality, with an AUC of 0.710 (95% CI: 0.563–0.857; p = 0.005). A cutoff value >4,977.5 pg/mL was associated with higher mortality (29.3% vs. 6.3%; p = 0.029), with a sensitivity of 85.7% and specificity of 51.8%. PASP showed an AUC of 0.696 (95% CI: 0.549–0.842; p = 0.009), with a cutoff >44.5 mmHg associated with increased mortality risk (31.0% vs. 8.3%; p = 0.043), sensitivity of 75%, and specificity of 62.3%. In the multivariable model, there was a trend toward an independent association with increased mortality risk for both NT-proBNP (RR 3.47; p = 0.081) and PASP (RR 3.08; p = 0.062), although this did not reach statistical significance, possibly due to the limited sample size. No significant association was observed between these markers and length of hospital stay or need for intensive care unit admission. Elevated NT-proBNP and PASP levels at admission are associated with in-hospital mortality in AHF. The identified cutoff values (>4,977.5 pg/mL and >44.5 mmHg) demonstrate high sensitivity and may assist in early risk stratification of high-risk patients. Although the study suggests a trend toward independent association, statistical confirmation was limited by sample size.

DYNAMIC MORTALITY PREDICTION FOR RISK STRATIFICATION IN CHAGAS CARDIOMYOPATHY

MARIA DO CARMO PEREIRA NUNES1; ARIELA MOTA FERREIRA1; LÉA CAMPOS DE OLIVEIRA DA SILVA1; LUZ MARINA TACURI CHAVEZ1; DANIELLY RAMOS PEREIRA1; JOÃO GABRIEL FRANCISCO RODA1; ESTER CERDEIRA SABINO1; ANTÔNIO LUIZ PINHO RIBEIRO1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Chagas cardiomyopathy (CCM) remains a major cause of heart failure and premature mortality in endemic regions, with prognostic assessment complicated by disease heterogeneity and limited access to specialized care. Most existing models rely on static, single time-point data and may not reflect evolving risk profiles in contemporary practice. Objectives: This study aimed to develop and validate a dynamic mortality prediction model in patients with CCM by incorporating longitudinal clinical, and biomarker data. Methods: This was a prospective cohort study using data from the SaMi-Trop cohort, which enrolled patients with Chagas disease from 21 municipalities in a highly endemic region of Brazil between 2013 and 2014. Participants were followed for a median of 7.2 years and underwent standardized cardiovascular assessments at three time points, including NYHA classification, ECG, and NT-proBNP measurements. For the primary analysis, a landmark approach was applied at the second visit, restricting the cohort to participants who were alive and under follow-up at that time. Resultados e Conclusions: Results: Among 1,989 enrolled patients, 1,586 were included in the landmark analysis (Figure 1); 252 deaths occurred after Visit 2 (incidence rate of 32.8 per 1,000 person- years). In multivariable analysis, independent predictors of mortality included older age, male sex, absence of prior benznidazole therapy, persistently severe NYHA functional class, and sustained or worsening NT-proBNP levels. ECG abnormalities were not independently predictive after adjustment for NT-proBNP. The model demonstrated good discrimination (C statistic, 0.821; optimism-corrected, 0.814) and good calibration (shrinkage factor, 0.959; R^2 = 0.219). Risk stratification using model-derived profiles showed marked differences in 5-year survival: 93% in low-risk, 74% in intermediate-risk, and 21% in high-risk patients. Conclusions: In this cohort of patients with CCM, a dynamic modeling approach incorporating longitudinal changes in NYHA functional class and NT-proBNP levels provided accurate prediction of mortality risk. These findings highlight the prognostic utility of time-updated models to inform clinical decision-making, particularly in resource-limited settings where optimized heart failure therapy may be delayed.

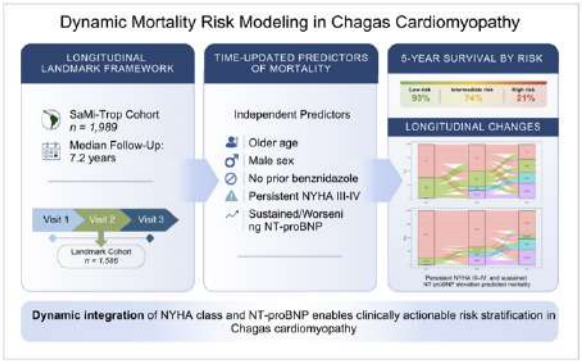

Figure 1: In a prospective cohort of patients with Chagas cardiomyopathy followed longitudinally for a median of 7.2 years, a landmark analysis incorporating time-updated NYHA functional class and NT-proBNP levels identified dynamic predictors of mortality.

EMERGENCY DEPARTMENT VISIT FOLLOWED BY HOSPITALIZATION INDEPENDENTLY PREDICTS ALL-CAUSE MORTALITY IN HEART FAILURE: A REAL-WORLD COHORT ANALYSIS

CARLOS HENRIQUE DEL CARLO1; MUCIO TAVARES OLIVEIRA JR1; ANTONIO DE PADUA MANSUR1; SERGIO JALLAD1; ALFREDO JOSE MANSUR1; ANDRÉ BARBOSA DE ABREU1; JOSE ANTONIO RAMOS NETO1; ANTONIO CARLOS PEREIRA-BARRETTO1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction/Background: Heart failure (HF) is a chronic condition associated with high morbidity, mortality and healthcare resource utilization, which may reflect disease trajectory beyond isolated events in HF. Whether a combined pattern of emergency department (ED) visit followed by hospitalization independently predicts mortality, after adjustment for ejection fraction, etiology, and comorbidities, remains unknown. Objectives: To determine whether an ED visit followed by hospitalization constitutes an independent predictor of all-cause mortality in a long-term HF cohort. Methods: Retrospective cohort of 11,763 HF patients followed 2017–2021 (median follow-up 1,224 days). Patients were stratified into four mutually exclusive utilization groups: no ED or hospitalization (n=7,858); ED only (n=1,365); hospitalization only (n=581); ED followed by hospitalization (high-utilization phenotype, n=1,959). All-cause mortality was the primary outcome. Kaplan–Meier survival analysis and log-rank test were used. A multivariable Cox model (forward stepwise, Wald) included the high-utilization phenotype and 16 covariates: age >60, sex, HF etiology (ischemic, Chagas, valvular, hypertensive, idiopathic dilated), prior MI, diabetes, anemia, chronic kidney disease (CKD), stroke, atrial fibrillation (AF), and HF phenotype by ejection fraction. Resultados e Conclusions: All-cause mortality was 21.8% (n=2,567). The high-utilization phenotype had 37.2% mortality vs. 16.9 to 19.8% in other groups (p<0.001) - Figure. Kaplan–Meier curves showed early and sustained survival separation (log-rank p<0.001). On univariable Cox analysis, the high-utilization phenotype predicted mortality (HR 1.74; 95%CI 1.60-1.90; p<0.001). In the final multivariable model, it remained an independent predictor after full adjustment (HR 1.21; 95%CI 1.11-1.32; p<0.001). Additional independent predictors included CKD (HR 2.61), stroke (HR 2.36), diabetes (HR 2.05), AF (HR 1.83), Chagas cardiomyopathy (HR 1.74), HFrEF (HR 1.53), valvular etiology (HR 1.49), anemia (HR 1.48), age >60 (HR 1.31), and prior MI (HR 1.27). An ED visit followed by hospitalization independently predicts all-cause mortality in HF beyond traditional risk factors. The strong prognostic impact of Chagas cardiomyopathy highlights a distinct epidemiological burden. Early identification of this high-utilization phenotype may support targeted risk stratification to improve long-term outcomes.

ETIOLOGY-SPECIFIC DETERMINANTS OF EXERCISE CAPACITY IN CHAGAS AND NON-CHAGAS HEART FAILURE

NOEME MADEIRA MOURA FÉ SOARES1; ENRICO ENRICO DE FRANCISCO MAGNANI2; DENISE MAYUMI TANAKA2; JULIO CESAR CRESCÊNCIO3; EDUARDO ELIAS VIEIRA CARVALHO1; LEONARDO PIPPA GADIOLI3; EDUARDO RUBIO AZEVEDO3; LUCIANA DUARTE NOVAIS SILVA1; HENRIQUE SILVEIRA COSTA2; MARCUS VINICIUS SIMÕES3; LUCIANO FONSECA LEMOS OLIVEIRA1;

(1) UNIVERSIDADE FEDERAL DO TRIANGULO MINEIRO - UBERABA - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) HOSPITAL DAS CLINICAS DA FACULDADE DE MEDICINA DE RIBEIRAO PRETO - USP - RIBEIRAO PRETO - SP - BRASIL;

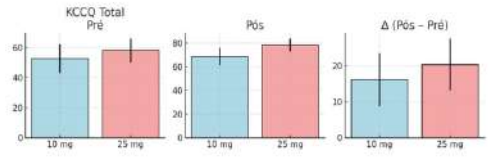
Introduction/Background: Heart failure (HF) is heterogeneous, and mechanisms of exercise intolerance may differ by etiology. Chronic Chagas cardiomyopathy has a distinctive pathophysiology, yet its functional determinants remain incompletely clarified. Objectives: To compare cardiopulmonary exercise testing (CPET) and echocardiographic parameters between patients with Chagas and non-Chagas HF, and identify etiology-specific determinants of exercise capacity and ventilatory efficiency. Methods: This cross-sectional study included 145 patients with HF and left ventricular ejection fraction (LVEF) <50%, divided into Chagas HF (n=78) and non-Chagas HF (n=67). All underwent clinical assessment, echocardiography, and symptom-limited CPET. Multiple linear regression models identified determinants of peak oxygen uptake (peak VO_2), percentage of predicted peak VO_2, and VE/VCO_2 slope. Resultados e Conclusions: Patients with Chagas HF had lower body mass index (24.98 vs. 28.71 kg/m²; p<0.001) and lower absolute peak VO_2 (821.54 vs. 1116.00 mL/min; p=0.02), but higher relative peak VO_2 [17.15 (12.32–22.77) vs. 15.00 (12.00–17.80) mL/kg/min; p=0.007] and higher predicted peak VO_2 (59.93% vs. 49.55%; p<0.001). In Chagas HF, peak VO_2 was independently associated with age, sex, NYHA class, LVEF, and mitral E-wave velocity (adjusted R²=0.744; p<0.001). Predicted peak VO_2 was mainly determined by LVEF, NYHA class, and E-wave velocity (adjusted R²=0.460; p<0.001), whereas VE/VCO_2 slope was associated with NYHA class and LVEF (adjusted R²=0.304; p<0.001). In non-Chagas HF, peak VO_2 was associated only with sex and NYHA class (adjusted R²=0.378; p<0.001), while VE/VCO_2 slope was determined by NYHA class and left atrial diameter (adjusted R²=0.212; p<0.001). Determinants of exercise capacity differed by HF etiology. In Chagas HF, functional limitation was strongly linked to central cardiac parameters, especially systolic function and transmitral flow. In non-Chagas HF, clinical status and left atrial remodeling were more relevant. The higher relative peak VO_2 in Chagas HF should be interpreted cautiously because this group had lower body mass index and lower absolute oxygen uptake.

15699

EVALUATION OF THE USE OF EMPAGLIFLOZIN IN OUTPATIENTS WITH HEART FAILURE WITH IMPROVED/PRESERVED EJECTION FRACTION.

CONRADO ROBERTO HOFFMANN FILHO1; GABRIEL ERZINGER1; ANA CAROLINA JUNQUEIRA BORNSCHEIN1; LAURA LUIZ1; YASMIN HOFFMANN2; GILMAR ERZINGER1; RENATO DELASCIO LOPES3;

(1) UNIVERSIDADE DA REGIAO DE JOINVILLE - JOINVILLE - SC - BRASIL; (2) UNIVERSIDADE LUTERANA DO BRASIL- ULBRA - CANOAS - RS - BRASIL; (3) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL;



Introduction/Background: Heart failure (HF) is a heterogeneous syndrome with high morbidity and mortality. The prevalence of HF with preserved (HFpEF) and improved ejection fraction (HFimpEF) has increased, accounting for ~50% of cases. Sodium–glucose cotransporter 2 inhibitors (SGLT2i), such as empagliflozin, are now part of HF treatment. Prior studies in high-risk diabetic patients showed reduced HF-related mortality with both 10 mg and 25 mg doses. As a result, 10 mg has been adopted for HF, while 25 mg remains indicated for diabetes. Objectives: Objective: To compare empagliflozin 10 mg versus 25 mg regarding quality of life, assessed by the Kansas City Cardiomyopathy Questionnaire-12 (KCCQ-12), and functional capacity, assessed by the 6-minute walk test (6MWT) Methods: Methods: Ninety patients from a heart failure outpatient clinic were randomized in a double-blind, active-controlled trial to receive empagliflozin 10 mg or 25 mg for eight weeks. Study follow-up occurred between March 7, 2023, and April 29, 2024, with protocol-defined assessments performed at baseline and study completion. The study was registered on ClinicalTrials.gov under the title: “Evaluation of the Use of Empagliflozin in Patients with HFpEF in a Cardiology Outpatient Department (ADDEMFEP)”, identifier NCT06683053. Resultados e Conclusions: The cohort included 46 men and 44 women, with mean ages of 69.3 and 68.8 years, and similar distribution between groups (10 mg: n=45; 25 mg: n=45). Comorbidities included hypertension (90%), coronary artery disease (44%), diabetes (37.8%), and atrial fibrillation (33%). Baseline KCCQ-12 scores were comparable (53.17 vs 58.38; p=0.415). After eight weeks, both groups showed significant improvement: 10 mg (Δ16.85; 95% CI 9.27–24.44; p<0.01) and 25 mg (Δ21.19; 95% CI 14.46–27.92; p<0.01), with higher final scores in the 25 mg group (79.57 vs 70.03; difference 9.54; 95% CI 0.68–18.42; p=0.035), indicating greater quality-of-life benefit. In the 6MWT (n=85), improvement was observed only in the 10 mg group (+20.1 m; p=0.023), with no between-group difference (p=0.781). Both groups showed reductions in HbA1c and increases in hematocrit, while fasting glucose, creatinine, sodium, and potassium remained stable. Conclusions: Empagliflozin at both 10 mg and 25 mg doses improved quality of life, with superior KCCQ-12 outcomes at 25 mg, suggesting incremental benefit. Functional capacity improved modestly only with 10 mg. Laboratory findings indicate metabolic benefit without short-term renal or electrolyte toxicity.

Tabela 8 - KCCQ 12 Summary Score

Comparação	n (10 / 25)	Média 10 (Pré/Pós)	Média 25 (Pré/Pós)	Δ médio (pareado)	IC95% (Δ/Dif)	p
Baseline: 10 vs 25	43 / 42	53.17	58.38	nan	[-7.45, 17.86]	p=0.4152
10 mg: Pré vs Pós	43	53.17 → 70.03		16.85	[9.27, 24.44]	p<0.01
25 mg: Pré vs Pós	42		58.38 → 79.57	21.19	[14.46, 27.92]	p<0.01
Final: 10 vs 25	43 / 42	70.03	79.57	nan	[0.68, 18.42]	p=0.0353

EVOLUTION OF FUNCTIONAL CAPACITY AND LABORATORY PARAMETERS IN PATIENTS WITH ADVANCED HEART FAILURE TREATED WITH INTERMITTENT LEVOSIMENDAN INFUSION

SERGIO JALLAD1; KELLY REGINA NOVAES VIEIRA1; DEBORA CONSUELO GONÇALVES PEREIRA1; CARLOS HENRIQUE DEL CARLO1; ANA CAROLINA REZENDE1; AGATHA CAROLINE FARIA ROCHA RODRIGUES1; DEBORA SILVA BIRAL1; ELOISA SASSÁ CARVALHO NOTTOLI1; INDIRA SAMANTHA VALLEJOS CERRATO1; MUCIO TAVARES OLIVEIRA JR.1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction/Background: Patients with advanced heart failure (HF), even those who are candidates for heart transplantation or a ventricular assist device, have poor quality of life, a worse prognosis, and a higher likelihood of hospitalisation. Therapeutic options are scarce, and even doses of GDMT often need to be reduced or discontinued because of hypotension, what may worse prognosis. Outpatient inotropic intermittent support with levosimendan demonstrated benefits. Objectives: The aim of this study is to evaluate the results of clinical outcome parameters, functional capacity, and laboratory parameters in patients with advanced HF referred for intermittent levosimendan infusion and treated at a Day Hospital and Infusion Centre. Methods: Patients defined as having advanced HF (presence of significant ventricular dysfunction, low functional capacity, recurrent episodes of hospitalisation or need for emergency care) underwent levosimendan infusion therapy at 0.1 mcg/kg/minute for 4 hours for 4 consecutive weeks, with reassessments after each cycle at 7, 15 or 30 days to determine the need to restart a new infusion cycle according to the patient's clinical status. Each patient could be prescribed as many cycles as necessary. Clinical, laboratory parameters and the 6-minute walk test were accessed. Resultados e Conclusions: From June 2020 to March 2026, 52 patients (31 men) were treated, mean age 65±16.1 years, 67% had ischaemic aetiology. Hypertension was present in 41 (80%), diabetes in 26 (50%) and atrial fibrillation in 22 (43%); 33 patients (64%) had been hospitalised for acute HF and needed , inotropic therapy in the last year. Ejection fraction on echocardiogram ranged from 13% to 35% (mean 24.6±6.3%). Performance on the walk test before the first infusion and after the after the second cycle showed a significant difference, increasing from 267.5±67.3 to 345.5±73.2 metres (p=0.014). There was no difference in renal function, other laboratory parameters, or BNP (1288 vs. 1080 pg/mL, p=NS) before and after all cycles for each patient. More patients moved from NYHA class III to II after the levosimendan cycles. In conclusion, in patients with advanced HF, intermittent levosimendan infusion improved functional class and significantly improved physical performance measured by the 6-minute walk test.

FRAILTY SYNDROME IN PATIENTS WITH HEART FAILURE: PREVALENCE, CLINICAL PROFILE, AND ASSOCIATED FACTORS IN A REFERENCE OUTPATIENT CENTER

FABRÍCIO ALVES ARAÚJO1; SALVADOR RASSI1; DANIELA DO CARMO RASSI FROTA1; CAIO RASSI JUNQUEIRA2; SALVADOR RASSI FILHO2; ANDERSON OLIVEIRA ESTEVAN3;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL; (2) UNIEVANGELICA - ANÁPOLIS - GO - BRASIL; (3) UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL;

Introduction/Background: Heart failure (HF) is a chronic syndrome associated with progressive functional decline and high morbidity. Frailty syndrome — characterized by reduced physiological reserves and increased vulnerability to stressors — is prevalent in HF and independently linked to worse clinical outcomes, including hospitalization and mortality. Systematic frailty assessment remains underutilized in Brazilian outpatient practice. Objectives: To determine the prevalence of frailty in HF outpatients using the Fried Phenotype criteria and to describe the sociodemographic, clinical, and pharmacological profile of this population. Methods: Cross-sectional study conducted at a HF reference outpatient center. Frailty was assessed by the Fried Phenotype (weakness, slowness, exhaustion, weight loss, low physical activity). Patients were classified as robust (0 criteria), pre-frail (1–2), or frail (≥3). Sociodemographic data, comorbidities, HF etiology, ejection fraction, and medications were recorded. Resultados e Conclusions: 68 patients were included. Mean age was 61.0 years (SD ±12.2); 57.4% were male; mean LVEF was 38.7%. Frailty distribution: 26.5% robust, 52.9% pre-frail, and 20.6% frail — indicating that over 73% presented some degree of frailty. The most prevalent criteria were low physical activity (36.8%), weight loss (32.4%), and weakness (29.4%). Women showed significantly higher frailty rates than men (34.5% vs. 10.3%). Chagas disease etiology predominated (50%), followed by ischemic (27.9%). Hypertension was the most common comorbidity (70.6%). The results highlight the high prevalence of frailty in patients with heart failure and reinforce the need for integrated detection methods to improve patient care.

HEALTH STATUS TRAJECTORY AFTER HEART FAILURE HOSPITALIZATION IN AN ICHOM COHORT FROM SOUTHERN BRAZIL

GIORDANO GATTI DE GIACOMO1; CARISI ANNE POLANCZYK1; MARCIANE MARIA ROVER1; ANA PAULA BECK DA SILVA ETGES2;

(1) HOSPITAL MOINHOS DE VENTO - PORTO ALEGRE - RS - BRASIL; (2) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: The Kansas City Cardiomyopathy Questionnaire Clinical Summary Score (KCCQ-CSS) is a validated patient-reported measure of symptoms and functional status in heart failure (HF). Post-discharge health status after HF hospitalization remains underdescribed in Brazilian cohorts. Objectives: Evaluate post-discharge health status trajectory in heart failure using KCCQ-CSS in an ICHOM cohort from southern Brazil. Methods: We screened consecutive patients hospitalized for HF in a private tertiary hospital in Southern Brazil, between May 2017 and November 2025. The source cohort included 1,478 patients. The analytic baseline cohort included 697 patients with valid KCCQ-CSS at 30 days (T30). Longitudinal change analyses were restricted to 483 patients with observed follow-up KCCQ-CSS at 180 and/or 360 days. A sensitivity analysis included 555, incorporating 101 patients who died within 360 days and were assigned a KCCQ-CSS of 0. Clinically meaningful change was defined by a minimal clinically important difference of 5 points. Multivariable logistic regression was used to identify predictors of improvement. Resultados e Conclusions: The cohort was markedly elderly, with a median age of 81 years, and nearly half of patients had HF with preserved ejection fraction. Mean KCCQ-CSS was 71.1±24.0 at T30, 72.4±24.0 at 180 days, and 74.1±23.1 at 360 days, indicating only modest improvement among patients with observed follow-up. In the main analysis, 218/483 patients (45.1%) improved by at least 5 points, 84/483 (17.4%) remained stable, and 181/483 (37.5%) worsened. When mortality was incorporated in the sensitivity analysis, mean KCCQ-CSS declined to 65.2 at 180 days and 55.6 at 360 days; 209/555 patients (37.7%) improved, whereas 265/555 (47.7%) worsened. Prior myocardial infarction (OR 0.28, 95% CI 0.13-0.62; p=0.002) and advanced NYHA class (OR 0.68, 95% CI 0.50-0.94; p=0.020) were associated with lower odds of improvement in the main analysis, whereas male sex was associated with higher odds of improvement (OR 1.80, 95% CI 1.01-3.19; p=0.045). In sensitivity analysis, renal dysfunction emerged as an additional negative predictor (OR 0.46, 95% CI 0.23-0.91; p=0.025). In this Brazilian HF cohort, post-discharge health status improved only modestly over time and showed substantial heterogeneity across patients. Better identification of patients more likely to achieve clinically meaningful recovery may help guide follow-up, support, and quality-improvement programs after HF hospitalization.

IMPACT OF A STRUCTURED MULTIDISCIPLINARY CARE PROGRAM ON CLINICAL OUTCOMES AND PRE-DISCHARGE THERAPEUTIC OPTIMIZATION IN ACUTE HEART FAILURE

MARCELO WESTERLUND MONTERA1; ANA MOTTA DE CARVALHO1; ANDRE VOLSHAN1;

(1) HOSPITAL PRO CARDIACO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: In acute heart failure (AHF), the reduction of in-hospital and early post-discharge outcomes is influenced by structured in-hospital care, including pre-discharge therapeutic optimization and multidisciplinary educational interventions, highlighting the need to demonstrate their impact on the implementation of organized care models. Objectives: To evaluate the impact of a structured multidisciplinary care program (SMCP) on the reduction of clinical outcomes and optimization of guideline-directed medical therapy at hospital discharge in patients with AHF. Methods: Retrospective observational cohort study including patients with AHF and left ventricular ejection fraction <50% admitted between 2005–2015 (G1; n=797) and 2018–2025 (G2; n=799). In G2, an SMCP was implemented, including a multidisciplinary team, structured protocol, and educational program with post-discharge follow-up. Outcomes were length of stay (LOS), in-hospital mortality (IHM), and 30-day readmission (R30). Discharge prescriptions were analyzed in eligible patients: beta-blockers (BB), ACEI/ARB/ARNI, mineralocorticoid receptor antagonists (MRA), and SGLT2 inhibitors (SGLT2i). Dual therapy was BB + ACEI/ARB/ARNI; triple therapy added MRA. SGLT2i were not used in G1. Comparisons used Student's t-test and chi-square test (p<0.05). Resultados e Conclusions: Results: SMCP was associated with reduced LOS (14±27 vs 11±13 days; p<0.001), IHM (9.2% vs 5.4%; p=0.002), and R30 (27.4% vs 8.0%; p<0.0001), and higher IV furosemide dose (50±25 vs 110±50 mg; p<0.0001). Prescriptions increased for BB (75% vs 96.3%), ACEI/ARB/ARNI (65% vs 77%), and MRA (39% vs 67.4%) (all p<0.0001), with greater dual (48.4% vs 92.8%) and triple therapy (35.3% vs 60%) (both p<0.0001). SGLT2i were used in 70% only in G2. Conclusion SMCP was associated with significant reduction in in-hospital and early post-discharge outcomes, likely driven by optimized care, increased use of guideline therapies—especially combined strategies—and incorporation of SGLT2i, supporting structured multidisciplinary care models.

IMPACT OF COMBINED DIURETIC THERAPY ON DECONGESTION IN PATIENTS WITH HEART FAILURE AND ACUTE KIDNEY INJURY: A PILOT RANDOMIZED CLINICAL TRIAL

LUIS ALBERTO FRANCO RAMIREZ1; DANIELA PONCE1; FLAVIO DE SOUZA BRITO1; SILMEIA GARCIA ZANATI BAZAN1; CAROLINE FERREIRA DA SILVA MAZETO1; MILDRED VIVIANA AGUILAR VASQUEZ1; JULIO CESAR GARCIA DE ALENCAR2; LUIS ALEXANDRE FILIPPI CICCHETTO1; PEDRO HENRIQUE DELLA LIBEIRA2; INARA CRISTINA MARCIANO FRINI2; GUILHERME TRIPOLI2; RUI PIERI NETO1;

(1) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL; (2) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL;

Introduction/Background: Diuretic resistance is common in decompensated heart failure (DHF), sequential nephron blockade has emerged as potential strategy to optimize decongestion. However, comparative data on different diuretic combinations in patients with DHF and acute kidney injury (AKI) are limited. Objectives: Compare the efficacy and safety of three diuretic strategies: IV furosemide alone, IV furosemide+oral acetazolamide, and furosemide+oral hydrochlorothiazide in patients with DHF, clinical signs of volume overlode, and AKI. Methods: Randomized controlled pilot clinical trial conducted in 2 centers, including 55 patients with DHF and KDIGO stage 1- 2 AKI, allocated into: furosemide +acetazolamide (19), furosemide +hydrochlorothiazide (21), and furosemide alone (15). Exclusion criteria were vasoactive drug use, systolic BP<90 mmHg, stage 5 chronic kidney disease, or KDIGO stage 3 AKI at admission. Clinical and laboratory parameters were assessed on days 1-3. The primary outcome was congestion improvement at 72 hours (weight, clinical score, dyspnea). Secondary outcomes included AKI progression, electrolyte disturbances, hospital stay, and 90-day mortality. ANOVA/Kruskal-Wallis and ANOVA/Friedman tests were used. Resultados e Conclusions: Mean age was 65.6±14.9 years; 69.1% male; 80% hypertensive, and ejection fraction of 43.6±20.1%. Mortality was 12.7% and 90-day readmission 25%. All groups showed significant reductions in weight and dyspnea (p<0.001), with no difference between strategies (p=0.26 and p=0.85), indicating similar decongestion. There were no differences in hospital stay, renal support, or mortality. The acetazolamide group showed progressive increase in creatinine (1.4→1.5→1.8 mg/dL), unlike the others. It also had decrease potassium (p<0.001) and increase in magnesium (p=0.016), with no relevant changes in the other groups. NT-proBNP decreased significantly with hydrochlorothiazide (p=0.018), showed a trend with acetazolamide (p=0.06), and was unchanged with furosemide. Conclusion: Sequential nephron blockade with acetazolamide or hydrochlorothiazide did not increase decongestion versus loop diuretic monotherapy. This contrasts with ADVOR and CLOROTIC trials, possibly due to AKI-related pathophysiology limiting response. Acetazolamide was associated with increased creatinine and metabolic disturbances, without added benefit. In DHF with KDIGO 1-2 AKI, optimizing loop diuretics remains a reasonable initial strategy, with no clear advantage of combination therapy.

ISCHEMIC TIME DOES NOT PREDICT ECMO REQUIREMENT AFTER HEART TRANSPLANTATION: A SINGLE-CENTER EXPERIENCE

JULIA ALMEIDA SAADI1; EDUARDO KELLER SAADI2; JESSICA DOMINGUEZ TRINDADE2; FELIPE ABATTI SPADINI3; MARCUS VINICIUS PRZEPIORKA VIEIRA2; LUIZE MASCHIO MARQUES2; ALEXIA FARIAS GEYER2; DANIEL DO NASCIMENTO SILVA2; PIETRA DIONISI DE CARVALHO1; ANA GABRIELA CANALI1;

(1) UNIVERSIDADE LUTERANA DO BRASIL- ULBRA - CANOAS - RS - BRASIL; (2) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL; (3) UNIVERSIDADE FEDERAL DO RIO GRANDE - RIO GRANDE - RS - BRASIL;

Introduction/Background: Extracorporeal membrane oxygenation (ECMO) is sometimes required after heart transplantation and is associated with high morbidity and mortality. Ischemic time has been proposed as a potential risk factor, although its role remains controversial. Objectives: To evaluate the association between ischemic time and postoperative ECMO requirement after heart transplantation. Methods: This retrospective study included 47 patients who underwent heart transplantation at a tertiary center between 2021 and 2026. The primary outcome was postoperative ECMO use. Group comparisons were performed using the Mann–Whitney U test. Multivariable logistic regression was used to evaluate the association between ischemic time and ECMO requirement, adjusting for sex, age, ejection fraction, and underlying heart disease. Resultados e Conclusions: Among 47 patients, 8 (17%) required ECMO in the postoperative period. There were 3 in-hospital deaths (6.4%), and all occurred in patients who had required ECMO. Ischemic times in the ECMO group were mainly concentrated between 180 and 240 minutes, with one outlier exceeding 300 minutes. There was no significant difference in ischemic time between patients with and without ECMO (p=0.90). In multivariable analysis, ischemic time was not associated with ECMO requirement (OR 1.008; 95% CI 0.9 In this single-center cohort, ischemic time was not associated with postoperative ECMO requirement after heart transplantation. These findings suggest that factors beyond ischemic time alone may play a more relevant role in determining the need for postoperative mechanical circulatory support.

16375

LIVER STIFFNESS AS AN INDEPENDENT PREDICTOR OF SUBCLINICAL HFPEF IN MASLD PATIENTS

BRUNO REZNIK WAJSBROT1; CAROLINA CASTRO BIGNO2; CARLOS TERRA1; DANIEL XAVIER DE BRITO SETTA2; FLÁVIA FERREIRA FERNANDES1; JORGE EDUARDO DA SILVA SOARES PINTO2; LUIZ GUILHERME KRAEMER-AGUIAR2; JULIA BRUNO VIEIRA2; MARCELO IMBROINISE BITTENCOURT1; ROBERTO ESPORCATTE1; RICARDO MOURILHE-ROCHA1;

(1) HOSPITAL UNIVERSITARIO PEDRO ERNESTO - RIO DE JANEIRO - RJ - BRASIL; (2) UNIVERSIDADE ESTADUAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Heart Failure with Preserved Ejection Fraction (HFpEF) and Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) belong to a group of highly prevalent cardio-hepatic-inflammatory conditions that share common pathophysiological mechanisms. Given their substantial societal burden and the limited effectiveness of current treatments for advanced cases, early identification and targeted management of well-established risk factors may be critically important. Objectives: This pilot cross-sectional observational study was conducted to evaluate the association between Liver Stiffness (LS) and elevated left atrial pressure (LAP) in individuals with MASLD. Methods: Asymptomatic patients with diabetes or obesity and MASLD, without alcoholic liver disease or positive hepatitis C serology, were recruited. After providing informed consent, participants underwent a comprehensive evaluation including transthoracic echocardiography according to the American Society of Echocardiography diastolic guidelines, transient hepatic elastography using the FibroScan® method, and complete laboratory testing. The study was approved by the Local Ethics Committee (protocol 7.172.537). The primary endpoint was to evaluate the association between the presence of significant LS and elevated LAP on echocardiography in patients with MASLD and preserved systolic function. A binary logistic regression model was used incorporating clinically rational predictors, including liver stiffness ≥8 kPa, age, sex, body mass index, and the presence of hypertension, diabetes, and dyslipidaemia. For all variables, the odds ratio (OR), 95% confidence interval (CI) and p-value were calculated. Resultados e Conclusions: A total of 111 patients were evaluated. Only age showed a normal distribution, with a mean of 60.0 years (SD 11.9). Hypertension was present in 74.6% of patients, while diabetes was observed in 70.3% of the sample. Median BMI was 31.9 kg/m² (IQR 28.2–36.3), haemoglobin A1c 6.9% (IQR 6.0–8.2), NT-proBNP 66 pg/mL (IQR 36–162) and C-reactive protein 2,2 mg/dL (IQR 0,9–5,9). Elevated HS and LAP were present in 41,6% and 23.9% of patients, respectively. Age (OR 1.25; p=0.016), BMI (OR 1.20; p=0.015), and hepatic stiffness ≥8 kPa (OR 9.88; p=0.049) were independently associated with elevated LAP. Other variables, including sex, hypertension, dyslipidaemia, and HbA1c, were not significant. The model explained approximately 34% of the variance in elevated LAP.

MYOCARDIAL WORK ANALYSIS FOR THE DIFFERENTIAL DIAGNOSIS OF ATTR AND AL CARDIAC AMYLOIDOSIS

VIVIANE TIEMI HOTTA1; NATHALIA CONCI SANTORIO1; NATALIA DE MELO PEREIRA1; GARDENIA DA SILVA LOBO OISHI1; BRUNO VAZ KERGES BUENO1; FABIO FERNANDES1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction/Background: Recently, patients diagnosed with cardiac amyloidosis (CA) have increased and impressive development of effective therapies was achieved. However, early diagnosis and defining the subtype of CA is essential for patient management. Myocardial work (MW) analysis by echocardiography is a promising tool and may add incremental value for this purpose. Objectives: To characterize myocardial work parameters in patients with transthyretin amyloidosis without cardiac involvement (ATTR), transthyretin cardiac amyloidosis (ATTR-CA), and light-chain cardiac amyloidosis (AL-CA). Methods: Fifty-seven patients were prospectively evaluated: ATTR (n=20), ATTR-CA (n=25), and AL-CA (n=12). All patients underwent clinical evaluation and comprehensive TTE, strain and MW analysis. Echocardiographic studies were acquired using the Vivid E95 system and analyzed offline with EchoPAC v203. Resultados e Conclusions: Results: Patients with ATTR were younger (p<0.001). Most patients were male. Atrial fibrillation was more prevalent in ATTR-CA. Compared with AL-CA, patients with ATTR-CA showed greater interventricular septal and posterior wall thickness, higher left ventricular (LV) mass index, and increased relative wall thickness. Conventional TTE parameters remained normal in ATTR. ATTR-CA patients also presented larger indexed biatrial volumes and higher right atrial pressure. Right ventricular (RV) systolic function, assessed by TAPSE and RV S' wave, was more impaired in ATTR-CA, while RV wall thickness was increased in both ATTR-CA and AL-CA compared with ATTR without CA. Despite preserved conventional TTE findings, ATTR exhibited mildly reduced LV global longitudinal strain (GLS). RV free-wall strain and RV GLS were significantly reduced in ATTR-CA and AL-CA. Global myocardial work index and global constructive work were more severely impaired in ATTR-CA than in AL-CA. Both ATTR-CA and AL-CA demonstrated increased LV and RV relative apical sparing indexes. Left atrial reservoir, conduit, and pump strain values were significantly lower in ATTR-CA compared with AL-CA. Conclusions: Although conventional TTE is insufficient for differentiating CA subtypes, integration of strain-derived cardiac mechanics and myocardial work parameters with clinical findings may improve discrimination between ATTR-CA and AL-CA. ATTR-CA patients demonstrated more advanced cardiac remodeling and greater impairment of LV, RV, and left atrial function, suggesting a more severe cardiac phenotype compared with AL-CA.

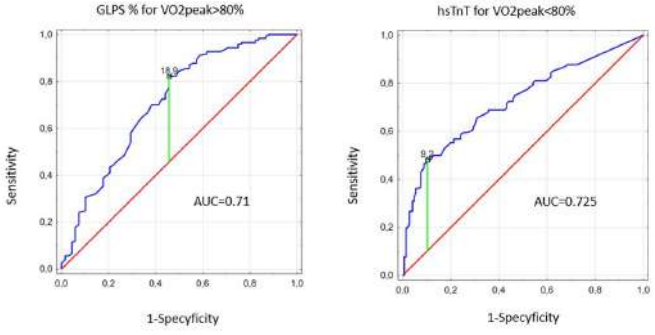
PHENOTYPING OF ANABOLIC-ANDROGENIC STEROID–INDUCED CARDIOMYOPATHY: EARLY MYOCARDIAL DYSFUNCTION AND ACCELERATED CORONARY DISEASE

EDUARDO RIBEIRO GOULAT ALVES1; JOÃO VITOR REBELATTO BIANCHI1; PEDRO AGUSTO LUCCA DALLAZEN1; ELISA DA SILVA FOLETTO1;

(1) UNIVERSIDADE LUTERANA DO BRASIL- ULBRA - CANOAS - RS - BRASIL;

Introduction/Background: Anabolic-androgenic steroid (AAS) misuse is an emerging cardiovascular risk factor. Unlike physiological athletic remodeling, AAS exposure induces a maladaptive phenotype driven by myocardial toxicity and chronic vascular injury, frequently undetected in early stages. Objectives: o define the imaging phenotype of AAS-induced cardiomyopathy and identify sensitive markers of early myocardial dysfunction. Methods: Structured review of studies from PubMed and LILACS including Speckle Tracking Echocardiography and Cardiac Magnetic Resonance. Parameters of cardiac geometry, myocardial strain, diastolic function, and coronary plaque burden were comparatively analyzed between chronic AAS users and controls. Resultados e Conclusions: AAS use is consistently associated with concentric remodeling, increased left ventricular (LV) mass, and focal fibrosis on cardiac magnetic resonance. Subclinical systolic dysfunction is a central feature, with significantly reduced global longitudinal strain (GLS) (−17.4% vs. −22.9%; p<0.01), despite only mildly reduced LV ejection fraction (49–52% vs. 63%).Left atrial (LA) dysfunction emerges as an early and robust marker, with LA strain <40% achieving 83.3% sensitivity and 92.1% specificity. Diastolic dysfunction is evident, with elevated filling pressures (E/e' 7.2 vs. 4.5), persisting even during off-cycle periods.Exposure burden is a key determinant of myocardial injury: annual duration of AAS use (β = −0.54; p<0.001) and LA volume independently predict strain impairment. Notably, cumulative exposure is associated with accelerated coronary atherosclerosis, with each 10 years of use corresponding to a 0.60 SD increase in plaque volume (p=0.008). AAS exposure defines a distinct cardiomyopathic phenotype characterized by early impairment in myocardial mechanics, atrial involvement, and premature coronary disease. Left atrial strain emerges as a highly sensitive marker of subclinical dysfunction. Multimodality imaging enables early detection and may redefine risk stratification in this population.



16561

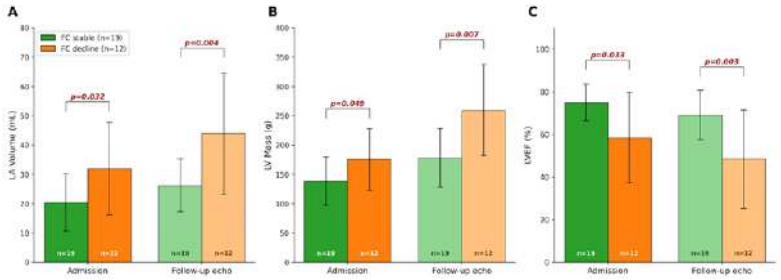
PREDICTORS OF REDUCED EXERCISE CAPACITY IN PATIENTS WITH HEART FAILURE AND PRESERVED EJECTION FRACTION

AGATA MAGDALENA BIELECKA DABROWA1; AGATA SAKOWICZ1; MACIEJ BANACH1;

(1) MEDICAL UNIVERSITY OF LODZ - POLAND;

Introduction/Background: Background: Heart failure with preserved ejection fraction (HFpEF) is a highly heterogeneous syndrome. A significant proportion of these patients suffer from severely impaired exercise tolerance, which is a key clinical feature affecting their quality of life and prognosis. Objectives: Objective: To compare markers of functional impairment and identify clinical and biochemical predictors that differentiate HFpEF patients with reduced exercise capacity from those with preserved capacity. Methods: Methods: The study included 269 hospitalized patients diagnosed with HFpEF: 150 patients with non-reduced exercise capacity (VO2max >80% in spiroergometry; mean age 55 years) and 119 patients with reduced capacity (VO2max <80%; mean age 57 years). During hospitalization, patients underwent detailed clinical examination, echocardiography (Vivid E95), and non-invasive body composition analysis (Tanita). Laboratory assessments included NT-proBNP and modern biomarkers: Growth/differentiation factor 15 (GDF-15), galectin-3, fatty-acid-binding protein (FABP), copeptin, and Vascular Endothelial Growth Factor (VEGF), alongside ferritin and hsCRP. All patients completed symptom-limited cardiopulmonary exercise testing (CPET) on a cycle ergometer with metabolic gas analysis. Resultados e Conclusions: Compared with non-reduced exercise capacity, those with reduced VO2 max <80% exhibited increased left atrial volume index (LAVI; mediana 36 vs 31 mL/m², p=0.005), lower LVEF (mediana 63 vs 54%, p<0.0001) worse GLPS -18 vs -20, p<0,0001), lower TAPSE (24 vs 19 mm, p<0.0001) and higher E/E' (mediana 7.6 vs 8.7, p=0.004). Patients with markedly reduced exercise capacity revealed higher total body water (TBW mediana 39 vs35 kg, p<0.001), but no significant differences regarding BMI and fat. Metabolic and inflammatory markers were also higher in HFpEF patients with VO2max<80%: galectin (10 vs 8 ng/ml p=0.003), hsTnT (8,2 versus 4,6 ng/L p<0.0001) and NT-proBNP (264 vs 75 pg/ml, p<0.001). In multivariate logistic regression, global longitudinal peak strain (GLPS) <-18% (OR 2.9, 95% CI: 1.4–6.3, p=0.004) and hsTNT >9.2 (OR 4.8, 95% CI: 1.9–12.1, p=0.001) independently distinguished HFpEF patients with preserved and significantly reduced physical activity. Conclusions: The GLPS and hsTnT were identified as the strongest independent predictors of significant functional impairment underscoring the clinical utility of advanced echocardiographic strain analysis and biomarkers like hsTnT in the precise phenotyping of HFpEF.

20132



PROGRESSIVE ATRIOVENTRICULAR REMODELING DETERMINES FUNCTIONAL DECLINE AND SURVIVAL IN CHRONIC CHAGAS CARDIOMYOPATHY

ANA CAROLINA LOAYZA BENCHMOL BARBOSA1; PAULO PAULO BENCHIMOL-BARBOSA2; BHARAT K KANTHARIA3;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) HOSPITAL UNIVERSITARIO PEDRO ERNESTO - RIO DE JANEIRO - RJ - BRASIL; (3) ICAHN SCHOOL OF MEDICINE AT MOUNT SINAI - UNITED STATES;

Introduction/Background: Chagas cardiomyopathy (CC) is driven by a persistent, low-grade inflammatory and fibrotic cascade that results in inexorable biventricular and atrial structural deterioration. Objectives: We hypothesized that progressive morphofunctional remodeling determines the rate of clinical decline, manifested as NYHA functional class (FC) worsening, serving as a direct putative mechanistic pathway to survival. Methods: We longitudinally evaluated 50 patients with chronic CC (age 51±9 years, 70% female), strictly in sinus rhythm at baseline, over an extensive follow-up at a tertiary center (mean 83.5±40.7 months). Serial echocardiographic assessments (parasternal long-axis) were utilized to derive LA volume (spherical model), LV mass (Devereux), and LVEF (Teichholz) at admission and at the study's conclusion, with paired data available for 34 patients. NYHA functional class (FC) worsening was defined as an increase of at least one class from baseline to final follow-up (ΔFC≥1). Clinical trajectories represented by ΔFC were mapped in 44 patients. LV dysfunction was defined a priori as LVEF <50%. Univariate logistic regression analysis identified predictors of survival, and the Spearman (ρ) coefficient assessed intervariable correlations. Resultados e Conclusions: At baseline, 82% had preserved LVEF. The incidence of de novo LV dysfunction was 0.94/100 person-years (95%CI [0.19–2.74]); of 9 patients with baseline dysfunction, 7 (78%) died. LVEF declined at 2.7±4.8%/year (p<0.001) while LV mass increased at 6.9±23.6 g/year (p=0.027). FC worsened in 18/44 patients (41%). Patients who worsened had larger final LA volume (44.0±20.7 mL vs 26.2±9.0 mL; p=0.004), lower final LVEF (47.4±22.4 % vs 69.1±11.7 %; p=0.003), and higher final LV mass (253.6±77.0 g vs 177.9±50.0 g; p=0.007) than those who remained stable (Figure). Per 1-NYHA class FC increase, ΔFC correlated with final LA (ρ=0.56, p=0.001), final LVEF (ρ=–0.61, p<0.001), and final LV mass (ρ=0.48, p=0.005). Non-survivors worsened FC faster than survivors (0.050±0.042 FC-class/year vs 0.003±0.006 FC-class/year; p<0.001), and any FC worsening was associated with increased mortality (OR=7.64; p=0.021). In Chagas cardiomyopathy, progressive ventricular and atrial remodeling is related to functional class worsening, which is strongly associated with survival. Integrating serial echocardiographic assessment with NYHA FC monitoring may improve early identification of high-risk patients.

Figure 2 — Cardiac Remodeling: FC Stable vs FC Decline (paired echocardiograms with FC data)

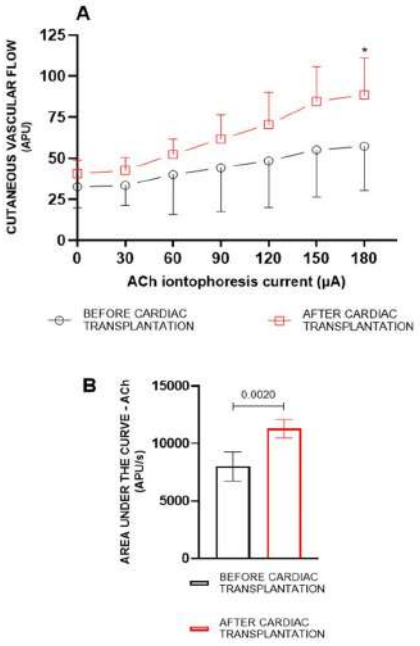
SEX DIFFERENCES IN RESTING HEART RATE MODULATE PREDICTORS OF MORTALITY IN HEART FAILURE.

ERNESTO AMARAL BRAGA1; ANTONIO PADUA MANSUR1;

(1) INSTITUTO DO CORACAO (INCOR) - HOSPITAL DAS CLINICAS DA FACULDADE DE MEDICINA DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction/Background: Heart failure (HF) is associated with high morbidity and mortality. Persistent atrial fibrillation (PAF) adds further risk in these patients. However, sex differences in resting heart rate (RHR) and prognosis remain limited. Objectives: To evaluate how RHR modulates predictors of mortality in propensity-matched HF cohorts (RHR 1, 2, and 3). Methods: We conducted a retrospective cohort study of patients with HF evaluated between February 2017 and January 2024. Of 2,817 patients screened, propensity score matching yielded a final cohort of 1,662 patients: 1,059 men (63.7%), 603 women (36.3%). Baseline data included clinical characteristics and echocardiographic parameters. The left ventricular ejection fraction (LVEF) was categorized as improved (Grade 1), stable (Grade 2), or worsened (Grade 3). RHR was analyzed as continuous and categorical: RHR1 (<70 bpm), RHR2 (70–89 bpm), and RHR3 (≥90 bpm). The primary endpoint was all-cause mortality, analyzed using multivariable Cox regression. Resultados e Conclusions: In the RHR1 group (Figure: Group 1), lack of LVEF improvement (Grade 2 vs. Grade 1) was associated with increased mortality risk (HR = 2.13; p < 0.001), as was worsening (Grade 3) (HR = 1.41; p = 0.005). Chronic kidney disease (CKD) (HR = 1.67; p < 0.001), age (HR = 1.03; p < 0.001), and left atrial diameter (LAD) (HR = 1.03; p < 0.001) were independent predictors. LVEF had a protective effect (HR = 0.98; p < 0.001). In the RHR2 group (Figure: Group 2), unchanged LVEF (Grade 2 vs. 1) remained strongly associated with mortality (HR = 1.98; p < 0.001). CKD (HR = 1.45; p < 0.001), age (HR = 1.03; p < 0.001), and LAD (HR = 1.03; p < 0.001) were also significant, while LVEF had a protective effect (HR = 0.98; p < 0.001). In the RHR3 group (Figure: Group 3), unchanged LVEF (Grade 2 vs. 1; HR = 2.02; p < 0.001), and age remained associated with mortality (HR = 1.03; p < 0.001), and LVEF continued to be protective (HR = 0.98; p < 0.001). Females had lower mortality (HR = 0.71; p = 0.042), while CKD and other variables lost statistical significance. Conclusion: RHR modulates mortality predictors in HF. While LVEF variation remains a determinant across groups, the prognostic relevance of comorbidities such as CKD and LAD varies according to RHR profile. These findings support the incorporation of HR into risk stratification and clinical decision-making.



17666

SYSTEMIC MICROVASCULAR IMPROVEMENT IN PATIENTS UNDERGOING HEART TRANSPLANTATION

ANTONIO FATORELLI1; DANIEL ARTHUR KASAL1; MAÍRA DUQUE DE ABREU1; EDUARDO VERAS TIBIRIÇA1;

(1) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Heart failure (HF) is a multifactorial syndrome characterized by structural or functional impairment of ventricular filling, resulting in significant morbidity and mortality. At the vascular level, endothelial dysfunction progresses in parallel with ventricular impairment. For patients who progress to refractory disease, advanced therapies such as heart transplantation (HT) or mechanical circulatory support become the only viable options. There is scarce evidence from patients evaluating the pattern of microvascular endothelial function after HT. Objectives: This study evaluated patients diagnosed with advanced HF, investigating the pattern of systemic microvascular dysfunction, assessed noninvasively both before and after HT. Methods: This was a prospective, cross-sectional study conducted at a quaternary referral center for advanced HF and HT, between March 2022 and April 2026. Six adult patients with advanced HF referred for HT were included. Cutaneous microvascular function was assessed both before and after HT, on the ventral forearm skin, using laser speckle contrast imaging (LSCI) coupled with pharmacological micro-iontophoresis. Drug delivery employed electrodes containing 200 µl of 2 % acetylcholine (ACh) solution for endothelial-dependent vasodilation. Incremental doses of ACh were delivered, and vasodilatory responses were expressed in arbitrary perfusion units (APU). Resultados e Conclusions: Patients listed for HT were aged 40.3 ± 12.7 years; 3 male. All patients had reduced left ventricular ejection fraction (LVEF), and the HF etiologies of HF were idiopathic (n=3), valvar (n=1), and post-myocarditis (n=1). Post-HF LVEF was 60.2±14.7%, and microvascular evaluation was performed 564.8±379.4 days after HT. The microvascular vasodilation induced by Ach iontophoresis (functional and endothelium-dependent) was 8,000 ± 1,264 APU/s before and 11,288 ± 817,3 APU/s after transplantation (P=0.002). The peak values of microvascular flow were higher after (93 ± 27 APU) than before (57 ± 27 APU) transplantation (P=0.027) (Figure 1A and 1B). The delta (peak-baseline) values of microvascular flow were also higher after (48 ± 19 APU) than before (25 ± 15 APU) transplantation (P=0.015). These data show for the first time with the employment of LSCI, a significant improvement in systemic microvascular endothelial function after HT. Additional patient recruitment will provide more robust and refined evaluation of the systemic microvascular effects of HT.

19870

THE HEART UNDER ATTACK IN DENGUE: CARDIOVASCULAR BURDEN, PREDICTORS OF SEVERITY, AND MORTALITY RISK

EDUARDO RIBEIRO GOULAT ALVES1; JOAO VITOR REBELATTO BIANCHI1; PEDRP AGUSTO LUCCA DALLAZEN1; ELISA DA SILVA FOLETTO1;

(1) UNIVERSIDADE LUTERANA DO BRASIL- ULBRA - CANOAS - RS - BRASIL;

Introduction/Background: Dengue is a rapidly expanding global disease with important cardiovascular implications. Beyond hypovolemia, systemic inflammation, endothelial dysfunction, and direct myocardial injury contribute to a broad and often underrecognized spectrum of cardiac involvement. Objectives: To delineate the cardiovascular phenotype associated with acute dengue infection and determine predictors of clinical severity and in-hospital mortality. Methods: Structured review of studies from PubMed, SciELO, and LILACS (2016–2026), excluding animal studies and reports without primary cardiovascular outcomes. Data on prevalence and predictors of adverse outcomes were analyzed, focusing on cardiac biomarkers (troponin I), electrocardiographic, and echocardiographic findings. Resultados e Conclusions: Cardiovascular events occur in 27.2% of dengue cases, with higher myocarditis prevalence in patients <20 years (33.8%). Acute infection markedly increases the risk of arrhythmias (aOR 18.4) and major adverse cardiovascular events (aOR 2.9). Myocarditis affects 4.2% of hospitalized patients and may progress to fulminant disease.In severe presentations, troponin I elevation is observed in 100% of cases, with ECG abnormalities in 59.5%. Echocardiography reveals right ventricular dilation (57%), left ventricular dilation (21%), and reduced ejection fraction (<55%) in 24%.Troponin I emerges as the strongest prognostic marker, independently predicting prolonged hospitalization (aOR 5.2) and conferring an eightfold increase in in-hospital mortality (aOR 8.2). Abnormal echocardiographic findings also independently predict adverse outcomes (aOR 4.3).Dengue-related mortality appears to involve not only hypovolemic shock but also direct cardiovascular involvement. Cardiac complications are frequent and clinically relevant, with potential prognostic implications. Troponin I may facilitate early identification of high-risk patients and should be incorporated into clinical assessment. Multimodal evaluation may improve risk stratification and clinical outcomes.

Introduction/Background: Most evidence on heart failure (HF) derives from high-income settings and may not reflect the heterogeneity in socioeconomic conditions, healthcare access within a universal system, and HF etiology in Brazil. Contemporary nationwide data on treatment patterns and prognosis remain scarce. Objectives: To evaluate the use of HF-modifying therapies and clinical outcomes in patients with HF and reduced or mildly reduced ejection fraction in Brazil, and to assess regional variation. Methods: Prospective, multicenter cohort including patients ≥18 years with chronic HF and left ventricular ejection fraction (LVEF) <50%, enrolled from June 2021 to June 2024 across 30 sites in all five Brazilian macro-regions. Baseline characteristics and guideline-directed medical therapy (GDMT) were collected during outpatient visits. Follow-up was performed at 6 and 12 months. Endpoints were all-cause mortality and the composite of HF hospitalization or CV death at one year. Cox models assessed associations between geographic region and outcomes, adjusting for potential confounders. Resultados e Conclusions: Among 2,379 patients (age 61±14 years, 36% women, 25% White, LVEF 34%±9%), ischemic etiology was present in 37%, and Chagas cardiomyopathy in 11%. Socioeconomic burden was high (66% with low education level; median income US$ 243.00/month). Quadruple GDMT (renin-angiotensin system inhibitor, beta-blocker, mineralocorticoid receptor antagonist, and sodium-glucose cotransporter-2 inhibitor) was used in 28% (95% CI: 26%–30%) of patients and was similar across regions. All-cause mortality was 8.2 (95% CI: 7.1–9.5; Figure 1) and the rate of the composite endpoint 19.5 (95% CI: 17.7–21.5; Figure 2) per 100 person-years. Geographic region was not independently associated with all-cause death (p=0.15) or with the composite endpoint (p=0.33). In this nationwide contemporary cohort of chronic HF in Brazil, only one-quarter of patients received quadruple GDMT and approximately one in five experienced HF hospitalization or CV death at one year, with no significant regional differences. These findings reveal substantial gaps in HF care and highlight the need for strategies to improve implementation of evidence-based therapies.

TWO-PATHWAY MORTALITY IN DECOMPENSATED HEART FAILURE: SOCIAL VULNERABILITY—FROM STRUCTURAL INEQUALITY TO MARITAL DISRUPTION—DRIVES POST-DISCHARGE DEATH

GIOVANNI POSSAMAI DUTRA1; BRUNO FERRAZ DE OLIVEIRA GOMES1; DAVI DE VASCONCELLOS DIAS2; FABIANA CARDOSO DE OLIVEIRA2; LUCAS DE SOUZA MARTINS PEREIRA1; LUAN CAVALCANTE VILAÇA LIMA2; JOÃO LUIZ FERNANDES PETRIZ1; PLINIO RESENDE DO CARMO JUNIOR1; EMILIA MATOS DO NASCIMENTO3; BASILIO DE BRAGANÇA PEREIRA2; GLAUCIA MARIA MORAES DE OLIVEIRA2;

(1) BARRA D`OR - RIO DE JANEIRO - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (3) UNIVERSIDADE ESTADUAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Decompensated heart failure (DHF) mortality encompasses two competing events—in-hospital and post-discharge death—driven by potentially distinct biological and social mechanisms. Standard survival models that censor one event overestimate cumulative incidence and obscure the true prognostic architecture. Whether social determinants of health (SDH) and clinical variables differentially drive each competing outcome has not been established. Objectives: To disentangle the differential contributions of SDH and clinical variables to in-hospital versus post-discharge mortality in DHF, and to identify granular social vulnerability markers beyond broad contextual determinants. Methods: From 1,023 consecutive DHF patients at two centers (West Zone HDI 0.959 vs. North Zone HDI 0.814; median follow-up 6.9 years, IQR 4.4–9.9), Fine–Gray subdistribution hazard models were fitted separately for in-hospital death (n=110; 10.8%) and post-discharge death (n=656; 64.1%), with 26 covariates (α=0.10). Concurrently, Elastic Net logistic regression assessed granular SDH determinants of total mortality. Survival trees identified intersecting vulnerability phenotypes. Resultados e Conclusions: Post-discharge mortality was predominantly driven by social/structural variables: North Zone hospital (SHR 2.01, 95%CI 1.61–2.51; P<0.001), female sex (protective, SHR 0.79, 95%CI 0.68–0.91; P=0.001). In-hospital mortality was driven by clinical severity: severe LV dysfunction (SHR 2.25, 95%CI 1.35–3.77; P=0.002), chronic AF (SHR 1.85, 95%CI 1.24–2.75; P=0.003), prior HF (SHR 1.79; P=0.006). Severe dysfunction appeared “protective” post-discharge (SHR 0.62), reflecting survivor bias from early competing death. Elastic Net logistic regression identified granular SDH as powerful independent determinants: widowhood (OR 2.59, 95%CI 1.45–4.65; P=0.001), separation/divorce (OR 2.09; P=0.031), and middle/technical-level occupation (OR 1.85, 95%CI 1.15–2.96; P=0.011). Survival trees identified Brown/Black patients at the North Zone hospital as the highest-risk post-discharge node. This two-pathway model reveals that clinical severity determines early death whereas socioeconomic context—from broad structural inequality to granular social disruption—shapes long-term survival, supporting phase-specific and equity-informed interventions.

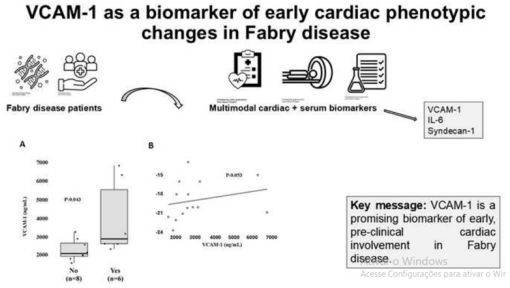
VCAM-1 AS A BIOMARKER FOR EARLY CARDIAC PHENOTYPIC CHANGES IN FABRY DISEASE PATIENTS CARRYING THE GLA P.ARG363HIS VARIANT.

DANIELLI OLIVEIRA DA COSTA LINO1; GDAYLLON CAVALCANTE MENESES2; ALICE COSTA MARTINS2; IGOR MOREIRA DE ALMEIDA2; RICARDO PAULO DE SOUSA ROCHA1; CARLOS JOSE MOTA DE LIMA1; JEAN CARLOS DANIELLI MACHADO1; SUELLEN BERGAMIM TAVARES1; FELIPE BRINGEL LANDIM1; GERALDO DA SILVA BEZERRA JUNIOR3;



(1) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL; (2) UFC - FORTALEZA - CE - BRASIL; (3) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introduction/Background: Fabry Disease (FD) is a rare, X-linked inherited disorder caused by a deficiency of the enzyme alpha-galactosidase A, which results in the cellular and tissue accumulation of glycosphingolipids (Gb3/Lyso-Gb3). The most classic cardiac phenotype is Left Ventricular Hypertrophy, though this is a later marker of the disease. Biomarkers are measurable substances that indicate biological processes signaling pathological involvement, with early detection being a key desirable characteristic. Early detection of cardiac involvement in FD is necessary given the possibilities for early therapeutic intervention and the reduction of morbidity and mortality. Objectives: This study aims to compare the levels of biomarkers associated with inflammation/endothelial dysfunction versus the cardiac phenotype in a group of FD patients diagnosed after family cascade screening associated with a variant not previously described in the Brazilian population. Methods: This is a cross-sectional study for the clinical evaluation of patients carrying the GLA variant. Evaluations included cardiac screening exams such as electrocardiogram, echocardiogram, and cardiac magnetic resonance imaging to assess structural and functional changes. Additionally, biomarkers for inflammation and endothelial dysfunction—vascular cell adhesion molecule-1 (VCAM-1), IL-6, and Syndecan-1—were measured and compared to 30 control individuals. Resultados e Conclusions: Results: 14 patients were evaluated, consisting of 3 males (21.4%) and 11 females (78.6%). Patients had a mean age of 30 years, with a median of 6 (3-14) years of symptoms. The neurological system was identified as the primary symptomatology in 71.4% of cases, while the cardiovascular system accounted for 14.3%. Palpitations (50%) were the most common CV symptom. Only one patient presented a concentric LVH pattern (with a septum < 12mm). Diastolic dysfunction was present in 42.9%. Global longitudinal strain (GLS) was altered in 28.6%. Among the biomarkers, VCAM-1 was significantly higher compared to the control group (2,634.2 (2,048.7 - 3,173.6) ng/mL vs. 671.7 (490.3 - 765.1) ng/mL; p < 0.001). It was also elevated in patients with ventricular remodeling (p = 0.045) and showed a possible linear correlation with GLS (Rho = 0.526, p = 0.053). Conclusion: Elevated levels of VCAM-1 were found in FD patients compared to the control group, as well as higher levels in patients with ventricular remodeling and a trend toward correlation with GLS in patients with a pre-hypertrophic phenotypic pattern.

Table 3. Serum and urine biomarkers of patients with Fabry disease from the same family and control group.

	Control (n=31)	Fabry (n=14)	p-Value
Sex			0.11
Female	16 (51.60%)[2]	11 (78.60%)[2]	
Male	15 (48.40%)[2]	3 (21.40%)[2]	
Age (years)	29.00 (24.00 – 41.00)[1]	30.50 (24.00 – 48.00)[1]	0.649
Serum Creatinine (mg/dL)	0.70 (0.60 – 0.80)[1]	0.69 (0.59 – 0.77)[1]	>0.9
Albumin/creatinine ratio (mg/g-Cr)	7.04 (3.48 – 17.95)[1]	2.72 (1.65 – 19.31)[1]	0.868
Serum Syndecan-1 (ng/mL)	46.50 (36.80 – 66.80)[1]	58.10 (46.90 – 71.10)[1]	>0.9
Serum VCAM-1 (ng/mL)	671.70 (490.30 – 765.10)[1]	2,634.2 (2,048.70 – 3,173.60)[1]	**<0.001**
Serum IL-6 (pg/mL)	ND	15.0 ± 4.70[3]	**<0.001**

19790

A NOVEL AI - DERIVED FORWARD-VALIDATED PREDICTION SCORE (“BASE- BALLOON SUCCESS EVALUATION SCORE) FOR OUTCOMES IN BALLOON MITRAL VALVOTOMY– LOOKING BEYOND THE WILKINS’!!

PRAYAAG KINI1;

(1) SRI SATHAY SAI INSTITUTE ,BENGALURU - INDIA;

Introduction/Background: Determining the success of BMV has been attempted by many authors but risks cores to determine both BMV success and risk predictionm for post BMV Mitral regurgitation are not available Objectives: Aims: (1) To determine predictors of BMV success at our high-volume centre and (2) Generate an indigenous score for predicting BMV outcomes and validate it for accuracy. Methods: We are amont the largest BMV providing centres in the world with a database of 35000-plus procedures Material and methods: Data from 2625 patients (Males=1390) undergoing BMV was analysed and parameters studied for “success” of BMV and occurrence of post-BMV regurgitation. Predictors of success and MR were determined using both Multivariate regression and Machine learning. A composite score was generated and prospectively applied to 450 patients for determining accuracy. Resultados e Conclusions: Results: SEVEN predictors of success were determined by stepwise logistic regression and weighted as per their strength of association to create a prediction model. We categorised SIX as Binary variates: LA diameter > 55 mm with IAS septal bulge> 25 mm from midline:1, without the same as 2;Mobile leaflets in diastole as 2: lack of mobility as 1; Severe subvalve disease upto leaflet tip as 1, without as 2; ICDS v/s HBBS as 2 and 1 respectively, Rhythm: AF :0, SR:2 and RV systolic pressure for PAH: 0 if RVSP>70 mm, 2 if <70 mm Hg. Bicommissural fusion was graded as continuous variable: Both commissures fused without calcium:0,Partial fusion:1,commissural calcium nodule: 2.Of total score of 14, there was linear increase in immediate BMV success as the score increased in tertiles of < 7, 8-10 and > /=11. We used Precision-Recall curves for forward Validation analysis in 450 patients. The score could predict successful BMV outcomes (77% chance of success) as well as showed good prediction of MR: 86% accuracy in last tertile compared with only 21% patients in first (p < 0.001). It improvised upon Wilkins score in that in patients with Wilkins score >8, BASE score > 11 predicted BOTH positive and negative outcomes. This aspect is NOT COVERED by any existing score in literature Conclusion: Our clinical + echo-based score improvises upon current scores for successful BMV outcomes, ALONG WITH additionally good predictability of post – BMV possibility of MR. This is the first such score in rheumatic MS patients in world literature.

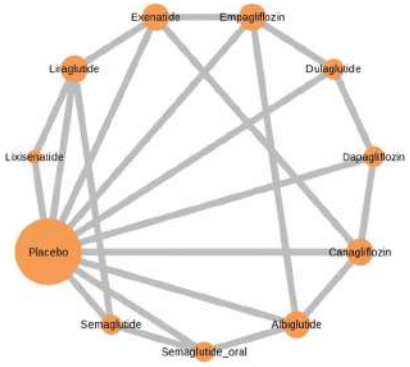
CLINICAL OUTCOMES AND HEMODYNAMIC PERFORMANCE OF SELF-EXPANDING VERSUS BALLOON-EXPANDABLE VALVES IN TAVI: A SYSTEMATIC REVIEW AND META-ANALYSIS

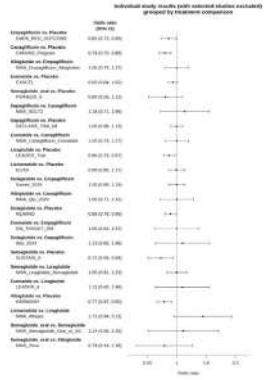
OTAVIO AUGUSTO OLIVEIRA DE ARAGAO ARAGAO ARAGAO1; LEO NOANH CONSOLI CONSOLI2; ANDRE BASTOS PAIXAO PAIXAO1; SERGIO COSTA TAVARES FILHO TAVARES3; LAWRENCE ANDRADE ARAUJO ARAUJO1; WERSLEY ARAÚJO SILVA ARAUJO1; RAFAEL ALEXANDRE MENEGUZ-MORENO MENEGUZ MORENO1; ANTONIO TERCIO OLIVEIRA DE ALMEIDA OLIVEIRA1; ALLYSSON MATOS PORTO SILVA PORTO SILVA1; RICARDO F.O SURUAGY-MOTTA SURUAGY-MOTTA4; TATIANA BASTOS TATIANA1;

(1) ANGIOCOR / HOSPITAL CIRURGIA - ARACAJU - SE - BRASIL; (2) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL; (3) HOSPITAL PRIMAVERA - ARACAJU - SE - BRASIL; (4) CESMAC - MACEIÓ - AL - BRASIL;

Introduction/Background: The choice of transcatheter heart valve platform remains a clinically relevant debate for transcatheter aortic valve implantation (TAVI). Balloon-expandable (BEV) and self-expanding valves (SEV) differ in implantation mechanism, hemodynamic profile, and complication rates. Head-to-head randomized controlled trials (RCTs) are scarce, and quantitative synthesis of available data may guide individualized device selection. Objectives: To compare clinical and hemodynamic outcomes between BEVs and SEVs in patients undergoing TAVI. Methods: We searched Pubmed, Embase and the Cochrane Library for RCTs comparing BEVs versus SEVs from inception to March 2026. Binary outcomes were synthesized as risk ratios (RRs) if short-term, or hazard ratio (HR), if long-term, with 95% confidence intervals (CIs). Continuous endpoints were estimated as mean difference (MD). Pooled estimates were calculated using a random-effects meta-analysis model. Statistical significance was defined as a two-tailed p-value<0.05. Between-study heterogeneity was assessed by the I² statistic. R studio was used for all analyses. Resultados e Conclusions: Four RCTs were included (CHOICE, SOLVE-TAVI, SCOPE I, SMART; n=1,852). No significant difference was observed in all-cause mortality (HR 1.04; 95% CI 0.90–1.20; p=0.625; I²=0%) or stroke (HR 1.33; 95% CI 0.66–2.66; p=0.423; I²=). BEV was associated with lower rates of permanent pacemaker implantation (RR 0.77; 95% CI 0.60–0.99; p=0.039; I²=24.6%) and moderate/severe paravalvular regurgitation (RR 0.47; 95% CI 0.25–0.87; p=0.016; I²=49.4%). Hemodynamically, effective orifice area was similar between platforms, but BEV demonstrated higher mean transvalvular gradients compared to SEV, reflecting the intra-annular implantation design of balloon-expandable devices. Device selection in TAVI should be individualized, favoring BEV when paravalvular leak or pacemaker risk is a concern, and SEV in patients at risk for prosthesis-patient mismatch.



15826



COMPARATIVE CARDIOVASCULAR EFFICACY OF SGLT2 INHIBITORS AND GLP-1 RECEPTOR AGONISTS: A BAYESIAN NETWORK META-ANALYSIS OF 22 RANDOMIZED TRIALS

SUELEN QUEIROZ1; NOOR HUSAIN2;

(1) UNIVERSIDADE ESTADUAL DE PONTA GROSSA - PONTA GROSSA - PR - BRASIL; (2) - INDIRA GANDHI INSTITUTE OF MEDICAL SCIENCES - INDIA;

Introduction/Background: SGLT2 inhibitors and GLP-1 receptor agonists reduce major adverse cardiovascular events (MACE) in patients with type 2 diabetes. However, no large-scale head-to-head trials have directly compared these two classes. A network meta-analysis that jointly synthesizes evidence from both classes enables indirect comparisons and provides a probabilistic ranking of treatment efficacy Objectives: To indirectly compare the efficacy of SGLT2 inhibitors and GLP-1 receptor agonists in reducing MACE in patients with type 2 diabetes, and to rank treatments by their probability of being the most effective. Methods: Bayesian network meta-analysis of 22 two-arm RCTs (N=124,112) from cardiovascular outcome trials. Compared 11 treatments: three SGLT2 inhibitors (canagliflozin, dapagliflozin, empagliflozin), seven GLP-1 agonists (albiglutide, dulaglutide, exenatide, liraglutide, lixisenatide, subcutaneous semaglutide, oral semaglutide), and placebo. Primary outcome: MACE (cardiovascular death, nonfatal MI, nonfatal stroke). Random-effects model. Ranking by SUCRA. Resultados e Conclusions: Versus placebo, significant MACE reduction was seen with subcutaneous semaglutide (OR 0.773; 95% CrI 0.631–0.931), albiglutide (0.807; 0.703–0.939), canagliflozin (0.816; 0.716–0.934), liraglutide (0.822; 0.702–0.943), and empagliflozin (0.855; 0.747–0.978). Dulaglutide (0.880) and exenatide (0.899) had CrIs crossing unity. Dapagliflozin, lixisenatide, and oral semaglutide were not superior. SUCRA ranking: subcutaneous semaglutide (81.4%), oral semaglutide (76.1%), albiglutide (71.9%), canagliflozin (70.2%), liraglutide (66.9%), empagliflozin (55.7%), dulaglutide (46.1%), exenatide (40.3%), dapagliflozin (18.8%), placebo (11.3%), lixisenatide (11.3%). Heterogeneity low (sd=0.05). Subcutaneous semaglutide, albiglutide, canagliflozin, liraglutide, and empagliflozin significantly reduced MACE odds versus placebo. Subcutaneous semaglutide ranked highest in efficacy. This mixed-class approach supports therapeutic choice when either class is indicated.

18704

COMPLICATIONS AFTER TRANSCATHETER AORTIC VALVE IMPLANTATION AND THE IMPORTANCE OF SPECIALIZED CARE

ISADORA HAETINGER ANDRIOTTI ALVES1; CLAUDIA SEVERGNINI EUGENIO1; BRENDA GONÇALVES DONAY ALVES1; MELINA MARIA TROJAHN1; TANIA MARIA MASSUTI1; LETICIA PEREIRA DE SOUZA1; SIMONE DE SOUZA FANTIN1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Transcatheter aortic valve implantation (TAVI) has emerged as an effective therapeutic option for patients with severe aortic stenosis, particularly those at high surgical risk. Despite technological advances, cardiovascular and systemic complications may occur in the peri-operative period, requiring intensive monitoring and specialized care in a coronary intensive care unit (ICU). Objectives: To describe patient characteristics and the main complications associated with TAVI in a coronary ICU. Methods: This cross-sectional, descriptive study was conducted from May to December 2025, including patients undergoing TAVI in a high-complexity cardiovascular referral center and admitted to a coronary ICU. Sociodemographic and clinical variables, peri-operative complications, ICU and hospital length of stay, and clinical outcomes were analyzed. The study was approved by the Institutional Research Ethics Committee (CAAE: 91641525.0.0000.5327) Resultados e Conclusions: : A total of 62 patients were included, with a mean age of 81±2 years and a predominance of males (53.7%). Most patients were white (88.1%), had incomplete elementary education (46.8%), and were from the interior of the state (44.8%) or Porto Alegre (30.6%). The majority were treated through the Brazilian Unified Health System (85.1%). Systemic arterial hypertension was present in 68.7% of cases. The mean procedural time was 78±3 minutes. Intra-procedural complications occurred in 28.4% of patients. Left bundle branch block was the most frequent event (25.4%), followed by vascular access site bleeding (11.9%). Early ambulation within 24 hours occurred in 71.7% of cases. Mean length of stay was 2±1 days in the coronary ICU and 5±2 days in the hospital. In-hospital mortality was 6.5%. Although most patients had favorable outcomes, branch conduction disturbances and vascular complications remain clinically relevant after TAVI. In this context, nursing care in the coronary ICU plays a key role in early detection of clinical changes, continuous monitoring, and timely interventions, contributing to patient safety and improved outcomes. These findings also reinforce the importance of structured post-procedural education strategies to enhance continuity of care, prevent complications, and support safer recovery.

14483

DISTAL RADIAL ACCESS IN THE ANATOMICAL SNUFFBOX VERSUS CONVENTIONAL RADIAL ACCESS FOR CORONARY ANGIOGRAPHY AND PCI: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED TRIALS

DAVID GARCIA DE ALCARAZ CONTI1;

(1) FACULDADE DE MEDICINA DO ABC (FMABC) - SANTO ANDRÉ - SP - BRASIL;

Introduction/Background: Distal radial access (DRA) through the anatomical snuffbox has emerged as an alternative to conventional transradial access (TRA) for coronary angiography and percutaneous coronary intervention, with potential benefits in radial artery preservation and access-site safety. Objectives: To compare distal radial access (DRA) versus transradial access (TRA) for efficacy and safety in invasive coronary procedures. Methods: A PRISMA 2020 systematic review was performed using randomized evidence identified in PubMed and related indexed sources. Placebo is not applicable; therefore, only randomized head-to-head trials of DRA versus TRA for coronary angiography with or without PCI were considered. Quantitative estimates were based on a random-effects meta-analytic framework (DerSimonian–Laird). Effect measures were risk ratios (RR) for dichotomous outcomes and standardized mean differences (SMD) or mean differences (MD) for continuous outcomes. Between-study heterogeneity was assessed using I^2 and τ^2 statistics. Prespecified subgroup analyses (including STEMI and procedural setting) and leave-one-out sensitivity analyses were performed to explore robustness. Risk of bias was assessed using RoB 2, and certainty of evidence was judged using GRADE. Resultados e Conclusions: Fourteen randomized trials enrolling 6,208 patients were synthesized. Key trials included DAPRAO (Eid-Lidt, 2021), DISCO RADIAL (Aminian et al., 2022), the STEMI RCT by Wang et al. (2022), ANTARES (Koziński et al., 2023), and RAPID III (Li et al., 2025). DRA reduced radial artery occlusion at the longest follow-up (RR 0.36, 95% CI 0.23-0.56; p<0.001; I^2=28.3%) and in-hospital occlusion (RR 0.32, 95% CI 0.19-0.53; p<0.001; I^2=29.0%), and lowered EASY ≥II hematoma (RR 0.51, 95% CI 0.27-0.96; p=0.04). By contrast, DRA increased crossover (RR 3.08, 95% CI 1.88-5.06; p<0.001), puncture attempts (SMD 0.59, 95% CI 0.48-0.69; p<0.001), puncture time (SMD 3.56, 95% CI 0.96-6.16; p<0.001), and sheath insertion time (SMD 0.37, 95% CI 0.16-0.58; p<0.001). In emergency/STEMI subgroup analyses, the reduction in occlusion remained consistent overall, with shorter hemostasis time and no clear penalty in procedural success or safety. We judged certainty as moderate for radial artery occlusion and low-to-moderate for procedural efficiency outcomes. Overall, DRA offers a vessel-preserving strategy with lower occlusion and hematoma rates, at the cost of more challenging cannulation; it appears particularly attractive when radial preservation is clinically relevant.

GENDER DISPARITIES IN CORONARY ARTERY BYPASS GRAFTING IN RIO DE JANEIRO: ADMISSIONS, LENGTH OF STAY, AND MORTALITY

GUILHERME MACHADO OLIVEIRA VALLE1; JOÃO PEDRO POMIN FERNANDES COSTA2; LUCA PINHEIRO PINHEIRO2; GABRIEL RANGEL COSTA DA SILVA CARDOSO2; AUGUSTO DE OLIVEIRA PERES2; JOÃO VICTOR DINIZ DE ANDRADE2;

(1) UNIRIO - RIO DE JANEIRO - DF - BRASIL; (2) UNIRIO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Coronary artery disease imposes a substantial burden of morbidity and mortality in Brazil, and coronary artery bypass grafting (CABG) remains a cornerstone therapeutic approach for complex cases within the Unified Health System (SUS). Although literature indicates worse outcomes in women, who are frequently subjected to intervention at more advanced stages, there is a gap in real-world data quantifying this inequity in large urban centers over historical series. Rio de Janeiro, located in the Southeast region — responsible for 45.9% of CABG admissions in the country between 2008 and 2026 — represents a strategic setting to assess these asymmetries and inform public health policy. Objectives: To evaluate sex disparities in the in-hospital outcomes of patients undergoing CABG through the SUS in Rio de Janeiro, with an emphasis on admission volume, in-hospital mortality, and length of stay. Methods: A descriptive ecological study with time-series analysis, based on secondary data from the SUS Hospital Information System (SIH/SUS). All CABG admissions in the municipality of Rio de Janeiro between January 2008 and February 2026 were analyzed and stratified by sex. The variables admission frequency, deaths, and length of stay were organized and analyzed descriptively, with a comparison between sexes over the study period. Resultados e Conclusions: Of 12,293 CABG admissions in Rio de Janeiro (2008-2026), 8,594 were men (69.9%) and 3,699 were women (30.1%), yielding a persistent 2.3:1 ratio. This disparity was consistent across all surgical modalities. Female mortality reached 11.0% (406 deaths), 54.9% higher than the male rate of 7.1% (606 deaths). Mean hospital stay was also significantly longer for women (20.29 vs. 18.43 days). These results underscore a marked sex asymmetry in surgical outcomes. Lower female volume, coupled with higher mortality and prolonged stay, suggests that women are often referred later with more advanced disease and complex clinical profiles. Such disparities likely stem from atypical symptom presentation, diagnostic delays, and unequal access to cardiovascular interventions within the Brazilian Unified Health System (SUS). These findings highlight urgent gaps in equitable care in large urban centers. Targeted public health strategies, including gender-sensitive referral protocols and early detection programs, are essential to mitigate these inequities, optimize resource allocation, and improve survival and recovery for female patients undergoing CABG.

INTERATRIAL SHUNT DEVICES IN HEART FAILURE WITH PRESERVED AND MILDLY REDUCED EJECTION FRACTION: A SINGLE-ARM SYSTEMATIC REVIEW AND META-ANALYSIS OF HEMODYNAMIC AND CLINICAL OUTCOMES

MARINA AZEVEDO AMARAL1; MARCILIO MARCÍLIO DE OLIVEIRA FILHO1; RAFAELA AZEVEDO AMARAL2; GIOVANNA ABREU DE SOUZA1; ANISIO UCHOA LEITE SANTANA3; EDUARDO BELLO MARTINS4; ANTONIO ESCAMILLA GARCIA5; FLAVYANNE SALLES1; MARIA FERNANDA REZENDE PIERONI6; RENATO LABOISSIERE7; MIGUEL CHAVES LENZI8; SUELEN QUEIROZ9;

(1) FACULDADE DE MEDICINA DE BARBACENA - BARBACENA - MG - BRASIL; (2) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL; (3) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (4) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (5) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (6) UNIVERSIDADE JOSÉ DO ROSÁRIO VELLANO - ALFENAS - MG - BRASIL; (7) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (8) UNIVERSIDADE ESTADUAL DO RIO GRANDE DO NORTE - MOSSORÓ - RN - BRASIL; (9) UNIVERSIDADE ESTADUAL DE PONTA GROSSA - PONTA GROSSA - PR - BRASIL;

Introduction/Background: Heart failure with preserved and mildly reduced ejection fraction (HFpEF/HFmrEF) is characterized by elevated left atrial pressure and limited therapeutic options. Interatrial shunt devices have emerged as a novel strategy to reduce left-sided filling pressures and improve symptoms. However, evidence remains fragmented across early-phase studies. Objectives: To evaluate the safety, hemodynamic effects, and clinical outcomes of interatrial shunt devices in patients with HFpEF and HFmrEF through a systematic review and single-arm meta-analysis. Methods: This systematic review and meta-analysis followed PRISMA guidelines. PubMed, Embase, and Cochrane Library were searched from inception to April 9, 2026, for studies evaluating interatrial shunt therapies in HFpEF/HFmrEF. Eligible studies included cohorts and clinical trials reporting safety, hemodynamic, or functional outcomes. The primary outcome was change in pulmonary capillary wedge pressure (PCWP), with secondary outcomes including major adverse events, 6-minute walk distance (6MWD), and KCCQ score. Random-effects models (REML) were used; proportions were pooled with logit transformation and continuous outcomes as mean differences. Resultados e Conclusions: A total of 311 patients across five studies were included in this analysis. Interatrial shunt therapy demonstrated a low pooled major adverse event rate (~3–4%), with no significant heterogeneity ($I^2 \approx 0\%$), supporting procedural safety. Significant improvements were observed in functional capacity, with a pooled increase in 6-minute walk distance, as well as in quality of life, reflected by clinically meaningful gains in KCCQ scores. Hemodynamic outcomes consistently showed reductions in pulmonary capillary wedge pressure, indicating effective left atrial decompression across studies. Collectively, these findings suggest that interatrial shunt devices represent a promising, mechanism-based therapeutic strategy targeting elevated left atrial pressure in HFpEF/HFmrEF, with a favorable safety profile and consistent improvements in symptoms and hemodynamics.

INTRAVASCULAR ULTRASOUND (IVUS) VERSUS ANGIOGRAPHY-GUIDED PERCUTANEOUS CORONARY INTERVENTION FOR UNPROTECTED LEFT MAIN CORONARY ARTERY DISEASE (ULMCA): AN UPDATED SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS.

CAMILLY PATRICIO DA SILVA1; DOUGLAS MOREIRA DE SA1; JOSE ALEXANDRE NETO2; LUIS FERREIRA NETO3; GUSTAVO ANDREOLLA MAIA4; ISABELA CARVALHAL5;

(1) UNIG - NOVA IGUAÇU - RJ - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (3) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (4) UNIVERSIDADE DO OESTE PAULISTA - UNOESTE - PRESIDENTE PRUDENTE - SP - BRASIL; (5) PUCRS - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Percutaneous coronary intervention (PCI) for unprotected left main coronary artery disease (ULMCA) is associated with substantial procedural complexity and major prognostic implications. Intravascular ultrasound (IVUS) guidance may optimize stent deployment and improve clinical outcomes, yet evidence from randomized controlled trials (RCTs) remains inconclusive in this specific anatomical subset. Objectives: To evaluate the efficacy and safety of IVUS-guided versus angiography-guided PCI in patients with ULMCA disease. Methods: RCTs comparing IVUS-guided with angiography-guided PCI in ULMCA patients were eligible. Outcomes of interest included mortality from cardiovascular causes (cardiovascular mortality) and myocardial infarction (MI). The longest available follow-up from each trial was analyzed. Pooled risk ratios (RR) with 95% confidence intervals (CI) were calculated using Mantel-Haenszel random-effects models. Confidence intervals were computed by the Hartung-Knapp-Sidik-Jonkman method. Between-study heterogeneity was assessed using I^2 statistics and Tau^2 estimated by the Restricted Maximum-Likelihood method. Statistical analysis was performed using Review Manager (version 5.4). This study was prospectively registered in PROSPERO and conducted following PRISMA guidelines. Resultados e Conclusions: Four RCTs were included (BENDARY, MING, TAN and TESTA), comprising 719 patients in the IVUS-guided arm and 727 in the angiography-guided arm (total N = 1,446). For cardiovascular mortality, the pooled RR was 0.66 (95% CI: 0.18–2.40), with no statistically significant difference between groups (of note, for BENDARY we used all-cause mortality due to a lack of data of on cardiovascular mortality). Moderate heterogeneity was observed (I^2 = 34%; Tau^2 = 0.27; Chi^2 = 4.52, P = 0.21). For myocardial infarction, the pooled RR was 0.86 (95% CI: 0.50–1.46), also non-significant with negligible heterogeneity (I^2 = 0%; Tau^2 = 0.00; Chi^2 = 1.85, P = 0.60). Total MI events were 37 (IVUS) versus 45 (angiography). In conclusion, in patients undergoing PCI for ULMCA disease, IVUS guidance did not demonstrate a statistically significant reduction in cardiovascular mortality or myocardial infarction compared with angiography guidance. The point estimates favored IVUS for mortality (RR 0.66), though confidence intervals were wide, reflecting limited statistical power. These findings underscore the need for larger, adequately powered RCTs to better establish the role of IVUS guidance in this high-risk anatomical subset.

Long Term Clinical Outcomes of a Bioresorbable Scaffold Pilot Study with Complete Intravascular Imaging Use

COSTANTINO ROBERTO COSTANTINI1; SERGIO GUSTAVO TARBINE1; COSTANTINO ORTIZ COSTANTINI1; MARCOS ANTONIO DENK1; VINICIUS SERGIO SHIBATA1; ELDER JOSE DE SA1; RAFAEL SERGIO DE MACEDO1; EVERTON CARDOSO DOMBECK1; MARCIO MORENO LUIZE1; LEONARDO IEZZI1;

(1) HOSPITAL CARDIOLOGICO COSTANTINI - CURITIBA - PR - Brasil;

Introduction/Background: Background: The safety and performance of the absorb bioresorbable vascular scaffold (brs) (Abbott vascular, santa clara, ca) has been previously demonstrated with clinical data. However, these trials included patients with simple lesions. Absorb III, IV and AIDA trials demonstrated an excess of adverse events following brs implantation, though scarce was intravascular imaging use in these studies. Objectives: Objetctives: Aiming to evaluate clinical outcomes, we analyzed 9 years clinical follow up of a pilot study from a single center, including real world patients treated with brs implantation using optimal technique and complete intravascular image guidance in all cases. Methods: Methods: Observational prospective pilot study, including 100 patients treated with brs implantation from 12/2014 to 10/2016. Safety and efficacy outcomes were analyzed for in-hospital and 10 years follow-up . Resultados e Conclusions: Results: Mean age was 58.1 years; 88% were male, 31% had diabetes, and 28% presented with acute coronary syndromes. A total of 171 lesions in 141 vessels were treated with 190 brs (mean 1.9 scaffolds/patient). Further intervention following intravascular imaging to optimize brs implantation was required in 31% of patients. Procedure success was 100%. Median follow up 9.5 (25 th percentile 9.2, 75th percentile 10.1) years. Through latest follow-up no patient experienced a cardiac death or definite scaffold thrombosis. Major adverse cardiac events (the composite of all-cause death, any MI, or any revascularization) occurred in 29 patients (Kaplan-Meier estimated 10-year rate 29.4%); target vessel failure (TVF) (the composite of cardiac death, TVMI, or ischemia-driven target-vessel revascularization) occurred in 15 patients (10-year rate 15.0%); and target lesion failure (TLF) (the composite of cardiac death, TVMI or ischemia-driven target-lesion revascularization) occurred in 10 patients (10-year rate 10.0%). In landmark analysis, TVF between 3 and 10 years occurred in 7 patients (7.6%). Conclusions: In this real-world experience from this single center, long-term outcomes of BVS implanted in simple and complex coronary lesions with optimal technique including routine IVI guidance, were favorable, with no scaffold thrombosis.

LONG-TERM DURABILITY OF TRANSCATHETER AORTIC VALVE IMPLANTATION VERSUS SURGICAL AORTIC VALVE REPLACEMENT IN PATIENTS WITH LOW-RISK AORTIC STENOSIS: A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

OTAVIO AUGUSTO OLIVEIRA DE ARAGAO ARAGAO1; SERGIO COSTA TAVARES FILHO TAVARES2; ANDRE BASTOS PAIXAO PAIXAO1; WERSLEY ARAÚJO SILVA ARAUJO SILVA1; LEO NOANH CONSOLI CONSOLI3; LAWRENCE ANDRADE ARAUJO ANDRADE ARAUJO1; RAFAEL ALEXANDRE MENEGUZ-MORENO MORENO1; ANTONIO TERCIO OLIVEIRA DE ALMEIDA ALMEIDA1; ALLYSSON MATOS PORTO SILVA PORTO SILVA1; RICARDO F.O SURUAGY-MOTTA SURUAGY-MOTTA4; TATIANE CRISTINA SANTOS SANTOS1;

(1) ANGIOCOR / HOSPITAL CIRURGIA - ARACAJU - SE - BRASIL; (2) HOSPITAL PRIMAVERA - ARACAJU - SE - BRASIL; (3) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL; (4) CENTRO UNIVERSITARIO CESMAC - MACEIO - AL - BRASIL;

Introduction/Background: Transcatheter aortic valve implantation (TAVI) has emerged as a standard alternative to surgical replacement (SAVR), yet its late durability in low-risk patients remains under investigation. We aimed to systematically evaluate valve integrity and reintervention in low-surgical-risk patients after long-term follow-up. Objectives: To compare long-term valve durability between TAVI and SAVR in low-risk patients with severe aortic stenosis through a systematic review and meta-analysis of randomized controlled trials. Methods: We searched Pubmed, Embase and the Cochrane Library from inception to March 2026 for randomized trials meeting eligibility criteria. We synthesized outcomes as hazard ratio (HR) or risk ratio (RR) with 95% confidence intervals (CIs) using a random-effects meta-analysis model. A two-tailed p-value <0.05 was considered statistically significant. Between-study heterogeneity was estimated with the I2 statistic. All analyses were performed in R studio. Resultados e Conclusions: We included three randomized trials encompassing 2639 patients (follow-up 7 to 10 years). No statistically significant difference was observed for a composite of bioprosthetic valve failure or reintervention (HR 1.06; 95% CI 0.63-1.79; P=0.82; I2= 67.4%), for reintervention alone (HR 1.42; 95% CI 0.96-2.12; P=0.08; I2=24.5%), bioprosthetic valve failure alone (HR 0.82; 95% CI 0.55-1.22; P=0.33; I2=0.0%) or structural valve deterioration (HR 0.84; 95% CI 0.58-1.23; P=0.37; I2=0.0%). Moderate or greater paravalvular leak at 5-years was more frequent in the TAVI group (RR 5.54; 95% CI 1.25-24.54; P=0.02; I2=0.0%). In low-risk patients with severe aortic stenosis, TAVI and SAVR demonstrated comparable rates of bioprosthetic valve failure, structural valve deterioration, and reintervention at mid-to-long-term follow-up. However, paravalvular leak of at least moderate severity was significantly more frequent after TAVI at 5-years, and a non-significant trend towards more reinterventions was observed.

OUTCOMES OF ALTERNATIVE ACCESS ROUTES IN PATIENTS WITH CONTRAINDICATIONS TO TRANSFEMORAL ACCESS IN TAVI: A SYSTEMATIC REVIEW.

ZILFRAN CARNEIRO TEIXEIRA FILHO1; MEL LEÃO FIDANZA SALGUEIRO1; MARIA CECÍLIA ARAÚJO DE NEGREIROS MELO1; ANA BEATRIZ SOUSA COSTA1; ANDRÉ BARBOSA CARVALHO1; SANDRO SALGUEIRO RODRIGUES2;

(1) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL; (2) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introduction/Background: Transcatheter aortic valve implantation (TAVI) is a minimally invasive procedure for the treatment of severe aortic stenosis, in which a prosthetic valve is implanted via a catheter. The transfemoral approach is the most commonly used. However, there are contraindications that include inadequate valve anatomy, active infection (endocarditis), the presence of intracardiac thrombi, and the inability to achieve safe vascular access, such as in highly calcified or small-diameter arteries, as these conditions increase the risk of complications, hinder proper prosthesis implantation, or reduce the clinical benefit of the procedure. Objectives: To compare stroke and mortality outcomes among different alternative TAVI techniques in patients with contraindications to the transfemoral approach. Methods: Following the PRISMA protocol. A search was conducted in the PubMed and Scopus databases using the search terms “Transcatheter Aortic Valve Replacement AND Vascular Access Devices AND Peripheral Arterial Disease” applied to title, abstract, and keywords. Full-text articles published in the last 10 years in English and Portuguese were included. Eligible studies included patients with contraindications to transfemoral access in TAVI. Primary outcomes were stroke and mortality; secondary outcomes included vascular complications, bleeding, and procedural success. Three reviewers independently selected the studies and extracted data using Rayyan, with a fourth reviewer resolving any discrepancies. Resultados e Conclusions: Of the 87 records identified, 9 met the inclusion criteria, all of which were clinical trials. The studies demonstrate that transcatheter aortic valve implantation (TAVR) is a safe and effective procedure, even in complex situations. The incidence of stroke ranges from 1% to 3% in large studies, while smaller series report no events, likely due to small sample sizes. Thirty-day mortality has decreased over time, from approximately 8% in earlier studies to about 4–5% in more recent analyses. Stroke stands out as the primary adverse prognostic factor, being associated with a significant increase in mortality. Thus, its prevention is essential. In addition, new approaches and devices have expanded the applicability of TAVR in patients with unfavorable anatomy. Taken together, the data indicate good clinical outcomes with low complication rates, although studies with larger patient cohorts are needed to confirm these findings.

PHARMACOINVASIVE STRATEGY VERSUS PRIMARY PCI IN STEMI: A VIABLE ALTERNATIVE WHEN TIMELY PPCI IS NOT ACHIEVABLE

ANTONIO DA SILVA MENEZES JUNIOR1; ALEXANDRE HIDEO KAJITA2; REMO HOLANDA DE MENDONÇA FURTADO2; PEDRO GABRIEL M DE BARROS E SILVA3; RENATO DELASCIO LOPES3;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL; (2) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (3) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction/Background: Primary percutaneous coronary intervention (PPCI) is the guideline-recommended reperfusion strategy for ST-segment elevation myocardial infarction (STEMI) when performed within recommended time frames. However, timely access to PPCI remains inconsistent across regionalized systems of care, supporting the continued role of pharmacoinvasive strategies. Objectives: To compare the efficacy, reperfusion profile, and safety of a pharmacoinvasive strategy versus PPCI in patients with STEMI. Methods: We performed a systematic review and meta-analysis of comparative studies evaluating a pharmacoinvasive strategy versus PPCI in STEMI. The primary endpoint was major adverse cardiac events (MACE). Secondary outcomes included all-cause death, nonfatal reinfarction, stroke, heart failure, ischemia-driven revascularization, any bleeding, and major bleeding. Reperfusion outcomes included TIMI flow, post-PCI TIMI myocardial perfusion grade (TMPG), ST-segment regression ≥70%, and system delay. Pooled estimates used random-effects models, and heterogeneity and small-study effects were assessed. Resultados e Conclusions: The pharmacoinvasive strategy was associated with a borderline reduction in MACE compared with PPCI (risk ratio [RR]: 0.73; 95% confidence interval [CI]: 0.53-1.00; p = 0.0475). The pharmacoinvasive strategy also improved TIMI 3 flow, post-PCI TMPG 3, and ST-segment regression ≥70%. Major bleeding was increased (RR: 1.63; 95% CI: 1.07-2.50; p = 0.024), whereas any bleeding showed a nonsignificant excess (RR: 1.43; 95% CI: 0.94-2.18; p = 0.091), as shown in Figures 1 and 2. No significant differences were observed for all-cause death (RR: 0.92; 95% CI: 0.71-1.19), nonfatal reinfarction (RR: 1.19; 95% CI: 0.59-2.40), total stroke (RR: 1.70; 95% CI: 0.87-3.33), disabling stroke (RR: 1.53; 95% CI: 0.68-3.45), heart failure (RR: 0.79; 95% CI: 0.59-1.06), or ischemia-driven revascularization (RR: 0.74; 95% CI: 0.37-1.45). In summary, the pharmacoinvasive strategy was associated with improved reperfusion markers and a possible reduction in MACE, at the cost of increased major bleeding, with otherwise similar clinical outcomes compared with PPCI. These findings support the pharmacoinvasive strategy as a pragmatic alternative when timely PPCI cannot be achieved.

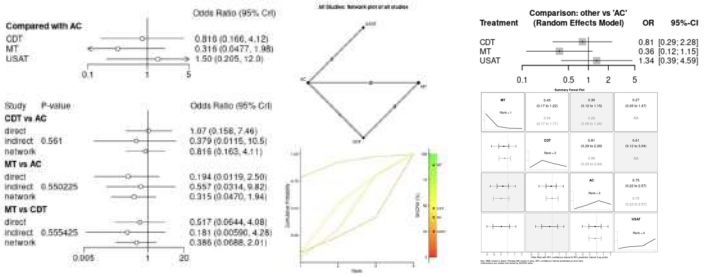
REDEFINING ANTITHROMBOTIC PRECISION AFTER PCI IN ATRIAL FIBRILLATION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF DIRECT ORAL ANTICOAGULANTS VERSUS VITAMIN K ANTAGONIST–BASED STRATEGIES

MARCILIO MARCÍLIO DE OLIVEIRA FILHO1; MARINA MARCÍLIO AZEVEDO AMARAL1; ANISIO UCHOA LEITE SANTANA2; MIGUEL CHAVES LENZI3; MARIA EDUARDA SANTOS LUNA1; SUELEN QUEIROZ4; RAFAELA AZEVEDO AMARAL5; EDUARDO BELLO MARTINS6; ANTONIO ESCAMILLA GARCIA7;

(1) FACULDADE DE MEDICINA DE BARBACENA - BARBACENA - MG - BRASIL; (2) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (3) UNIVERSIDADE ESTADUAL DO RIO GRANDE DO NORTE - MOSSORÓ - RN - BRASIL; (4) UNIVERSIDADE ESTADUAL DE PONTA GROSSA - PONTA GROSSA - PR - BRASIL; (5) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL; (6) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (7) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL;

Introduction/Background: The optimal antithrombotic strategy for patients with atrial fibrillation undergoing percutaneous coronary intervention (PCI) remains challenging due to the trade-off between bleeding and ischemic risks. Direct oral anticoagulant (DOAC)–based regimens have emerged as potential alternatives to vitamin K antagonist (VKA)–based triple therapy. Objectives: To compare the safety and efficacy of direct oral anticoagulant (DOAC)–based dual therapy versus vitamin K antagonist (VKA)–based triple therapy in patients with atrial fibrillation undergoing percutaneous coronary intervention, focusing on bleeding, ischemic outcomes, and net clinical benefit. Methods: A systematic review and meta-analysis of randomized controlled trials was conducted according to PRISMA guidelines. Trials comparing DOAC-based dual therapy versus VKA-based triple therapy in patients with atrial fibrillation undergoing PCI were included. The primary outcome was major or clinically relevant nonmajor (CRNM) bleeding. Key secondary outcomes included major adverse cardiovascular events (MACE), defined as cardiovascular death, myocardial infarction, or stroke, and net adverse clinical events (NACE). Random-effects models (REML) with Knapp–Hartung adjustment were applied. Resultados e Conclusions: A total of 10,969 patients across 4 randomized controlled trials were included. DOAC-based dual therapy significantly reduced major or clinically relevant nonmajor bleeding (HR 0.65, 95% CI 0.52–0.83; p=0.021; I²=69.2%), without increasing major adverse cardiovascular events (HR 1.00, 95% CI 0.93–1.08; p=0.99; I²=0%). This translated into a significant reduction in net adverse clinical events (HR 0.85, 95% CI 0.80–0.95; p=0.017; I²=0%). These findings demonstrate that DOAC-based dual therapy provides a superior safety profile without compromising ischemic protection, resulting in a favorable net clinical benefit and supporting its preferential use over VKA-based triple therapy in patients with atrial fibrillation undergoing PCI.



19647

REDEFINING REPERFUSION IN INTERMEDIATE-RISK PULMONARY EMBOLISM: A 2026 UPDATED BAYESIAN AND FREQUENTIST NETWORK META-ANALYSIS OF CONTEMPORARY CATHETER-BASED STRATEGIES

MARCÍLIO DE OLIVEIRA FILHO1; MARIA EDUARDA SANTOS LUNA1; MARINA AZEVEDO AMARAL1; ANISIO UCHOA LEITE SANTANA2; MIGUEL CHAVES LENZI3; SUELEN QUEIROZ4; EDUARDO BELLO MARTINS5; ANTONIO ESCAMILLA6;

(1) FACULDADE DE MEDICINA DE BARBACENA - BARBACENA - MG - BRASIL; (2) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (3) UNIVERSIDADE ESTADUAL DO RIO GRANDE DO NORTE - MOSSORÓ - RN - BRASIL; (4) UNIVERSIDADE ESTADUAL DE PONTA GROSSA - PONTA GROSSA - PR - BRASIL; (5) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (6) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL;

Introduction/Background: The optimal reperfusion strategy for intermediate-risk pulmonary embolism (PE) remains controversial. While catheter-based therapies have expanded rapidly, comparative effectiveness across modalities in the contemporary era is not well established. Objectives: To compare the efficacy of contemporary catheter-based reperfusion strategies versus anticoagulation using an updated network meta-analytic framework. Methods: A systematic search of PubMed, Embase, Cochrane Library, and Web of Science was performed from inception through March 2026, capturing the most recent randomized and comparative evidence in the modern device era. Studies evaluating catheter-directed thrombolysis (CDT), ultrasound-assisted thrombolysis (USAT), and mechanical thrombectomy (MT) in intermediate-risk PE were included. Both Bayesian and frequentist network meta-analyses were conducted using odds ratios (ORs). Consistency was assessed with node-splitting models. Resultados e Conclusions: A total of 12 studies including 3,331 patients were analyzed, forming a well-connected network across four treatment strategies (AC, CDT, USAT, and MT). In the Bayesian framework, MT showed the strongest signal toward reduction in adverse clinical events compared with AC (OR 0.32, 95% CrI 0.05–1.47), followed by CDT (OR 0.82, 95% CrI 0.17–4.12), while USAT showed no benefit (OR 1.50, 95% CrI 0.21–12.0). Frequentist analysis demonstrated consistent findings, with MT numerically outperforming AC (OR 0.36, 95% CI 0.12–1.15), and CDT showing a neutral effect (OR 0.81, 95% CI 0.29–2.28). Head-to-head comparisons suggested a numerical advantage of MT over CDT (Bayesian OR 0.39, 95% CrI 0.07–2.01). Ranking analyses consistently favored MT as the top-ranked strategy, followed by CDT, AC, and USAT. Node-splitting analysis demonstrated no evidence of inconsistency (all P > 0.5), supporting the validity of indirect comparisons. Overall, in this updated 2026 network meta-analysis integrating Bayesian and frequentist approaches, contemporary catheter-based strategies, particularly mechanical thrombectomy, demonstrate a consistent signal toward improved outcomes compared with anticoagulation alone in intermediate-risk PE, although wide confidence intervals highlight persistent uncertainty and the need for adequately powered randomized trials.

TARGETING MICROVASCULAR DYSFUNCTION IN STEMI: A NETWORK META-ANALYSIS OF PHARMACOLOGIC AND MECHANICAL STRATEGIES TO PREVENT NO-REFLOW

MARINA AZEVEDO AMARAL1; MARCILIO MARCÍLIO DE OLIVEIRA FILHO1; SUELEN QUEIROZ2; ANISIO UCHOA LEITE SANTANA3; MIGUEL CHAVES LENZI4; MARIA EDUARDA SILVA DE FARIA CANUTO1; NATÁLIA OLIVEIRA CORDEIRO5; EDUARDO BELLO MARTINS6; ANTONIO ESCAMILLA GARCIA7;

(1) FACULDADE DE MEDICINA DE BARBACENA - BARBACENA - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE PONTA GROSSA - PONTA GROSSA - RR - BRASIL; (3) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (4) UNIVERSIDADE ESTADUAL DO RIO GRANDE DO NORTE - MOSSORÓ - RN - BRASIL; (5) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL; (6) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (7) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL;

Introduction/Background: Microvascular obstruction (MVO) and the no-reflow phenomenon remain major determinants of adverse outcomes following primary percutaneous coronary intervention (PCI) in ST-elevation myocardial infarction (STEMI). The comparative effectiveness of pharmacologic and mechanical strategies remains unclear. Objectives: To compare the efficacy of pharmacologic and mechanical strategies in preventing no-reflow/MVO in patients with STEMI undergoing primary PCI using a network meta-analytic framework. Methods: A systematic review and network meta-analysis of randomized controlled trials was conducted according to PRISMA guidelines. Patients with STEMI undergoing primary PCI were included. The primary outcome was incidence of no-reflow/MVO. A frequentist random-effects model was used for the primary analysis, complemented by Bayesian analysis for treatment ranking (SUCRA). Resultados e Conclusions: A total of 6 randomized trials encompassing 12,044 patients formed a connected treatment network. In the frequentist analysis, compared with control, verapamil significantly reduced the risk of no-reflow (OR 0.17, 95% CI 0.04–0.72), whereas adenosine showed a non-significant trend toward benefit (OR 0.49, 95% CI 0.23–1.05) and nitroprusside demonstrated no significant effect (OR 0.73, 95% CI 0.36–1.47). Bayesian analysis confirmed these findings, with verapamil consistently ranking as the most effective strategy, followed by adenosine, nitroprusside, and control. Mechanical strategies, including thrombectomy and deferred stenting, did not demonstrate consistent benefit across analyses. These findings suggest that targeted pharmacologic modulation of microvascular dysfunction—particularly with verapamil—may represent the most effective strategy for preventing no-reflow in STEMI, outperforming mechanical approaches and supporting a mechanism-based shift in contemporary PCI practice.

TRANSCATHETER AORTIC VALVE IMPLANTATION (TAVI) VERSUS SURGICAL AORTIC VALVE REPLACEMENT (SAVR) IN WOMEN WITH AORTIC STENOSIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS.

DOUGLAS MOREIRA DE SÁ1; CAMILLY PATRÍCIO DA SILVA1; LUIS FERREIRA NETO2; JOSÉ ALEXANDRE NETO3; ISABELA CARVALHAL4; GUSTAVO ANDREOLLA MAIA5;

(1) UNIVERSIDADE IGUACU - NOVA IGUAÇU - RJ - BRASIL; (2) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (3) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (4) PUCRS - PORTO ALEGRE - RS - BRASIL; (5) UNIVERSIDADE DO OESTE PAULISTA - UNOESTE - PRESIDENTE PRUDENTE - SP - BRASIL;

Introduction/Background: Women with severe aortic stenosis represent a distinct biological and clinical subgroup, with evidence suggesting differential outcomes following transcatheter (TAVI) versus surgical aortic valve replacement (SAVR). Despite this, sex-disaggregated data from randomized controlled trials (RCTs) remain underreported, limiting sex-specific recommendations in current clinical practice. Objectives: To evaluate the comparative efficacy and safety of TAVI versus SAVR in women with aortic stenosis through a systematic review and meta-analysis of RCTs. Methods: A systematic review and meta-analysis of RCTs was conducted and prospectively registered in the PROSPERO, following PRISMA guidelines. The review included women with aortic stenosis undergoing TAVI or SAVR. The primary analysis was all cause mortality at 1 year. The pooled effect measure was the risk ratio (RR), estimated using a random-effects model with the Mantel-Haenszel method. Confidence intervals were calculated using the Hartung-Knapp-Sidik-Jonkman (HKSJ) method. Heterogeneity was assessed using the I² statistic, Chi² test, and Tau² (DerSimonian and Laird method). Statistical analysis was performed using Review Manager (version 5.4). Resultados e Conclusions: Five RCTs were included: CORE VALVE US, DEDICATE, PARTNER 1, RHEIA, and SURTAVI, comprising 1,217 patients in the TAVI group and 1,182 in the SAVR group (total N = 2,399). Total events were 85 in the TAVI arm and 128 in the SAVR arm. The pooled analysis demonstrated a statistically significant reduction in the primary outcome of all-cause mortality at 1 year favoring TAVI over SAVR (RR 0.65 [95% CI 0.48–0.88]; p = 0.02). Individual study estimates ranged from RR 0.41 (DEDICATE) to RR 0.87 (SURTAVI). Heterogeneity was negligible (I² = 0%; Chi² = 2.79, df = 4, P = 0.59; Tau² = 0.00), indicating high consistency across trials. The SURTAVI trial contributed a composite endpoint of death or disabling stroke due to unavailable sex-specific mortality data at 1 year and was therefore included as a sensitivity-supportive estimate. In conclusion, in women with aortic stenosis, TAVI was associated with a significant 35% relative risk reduction in all-cause mortality compared to SAVR across five randomized controlled trials, with no between-study heterogeneity. These findings suggest that TAVI may represent a favorable therapeutic strategy in female patients and highlight the importance of sex-specific analyses in valve disease research.

Patients Characteristics

VASOSPASTIC ANGINA IN ANOCA AND MINOCA: DIAGNOSTIC CRITERIA DEBATE AND REAL-WORLD IMPLICATIONS FROM A BRAZILIAN QUATERNARY CENTER

GABRIEL SEIXAS CARVALHO1; LUIZ ALBERTO RIBEIRO SIMÕES1; GIOVANINE PIRES DE CAMARGOS1; LUCAS QUEIROZ FERNANDES CAMPOS1; GUILHERME RAFAEL SANTANNA ATHAYDE1; FERNANDO GUSMÃO CÂMARA1; RAFAELA DE SOUZA FURTADO CAMPOS1; LUCAS LODI JUNQUEIRA1;

(1) REDE MATER DEI DE SAUDE - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Vasospastic angina (VSA) is a recognized endotype in ANOCA and MINOCA, but its diagnosis remains challenging because current criteria may not capture all clinically relevant vasomotor responses. COVADIS defines definitive VSA during acetylcholine testing by the simultaneous presence of epicardial spasm (>90% diameter reduction), symptom reproduction, and ischemic ECG changes. However, severe epicardial constriction associated with either typical symptoms or ECG changes is frequently encountered in routine care Objectives: To evaluate VSA prevalence and diagnostic implications in patients with ANOCA and MINOCA undergoing invasive coronary function testing (ICFT), comparing strict COVADIS criteria (3/3) with a clinically adapted approach (2/3) Methods: Single-center retrospective study (May 2025–April 2026). Patients with ANOCA or MINOCA (stenosis <50% or FFR >0.80) underwent ICFT including bolus thermodilution-derived CFR and IMR, intracoronary acetylcholine testing, and dobutamine-dFFR for myocardial bridging when indicated. Endotypes were classified according to COVADIS/AHA-ACC 2023 criteria adapted to the clinical context. Definitive VSA required all three criteria, whereas clinically relevant/probable VSA required severe epicardial spasm (>90%) plus symptom reproduction or ischemic ECG changes. Resultados e Conclusions: Twenty-two patients were included (mean age 53.6 years; 68.2% female): ANOCA 63.6%, MINOCA 36.4%. Sixteen patients (72.7%) underwent acetylcholine testing. Using the clinically adapted approach, VSA was the predominant endotype (37.5%), particularly in ANOCA (50%). Myocardial bridging was identified in 36.4%, representing a potential mechanical trigger for coronary hyperreactivity. Applying strict 3/3 criteria would reclassify cases, altering endotype distribution and therapeutic guidance. This uncertainty affects management, since VSA-directed therapy—calcium channel blockers and nitrates—was initiated based on alternative criteria. These findings underscore that heterogeneity in VSA thresholds affects prevalence estimates, treatment decisions, and study comparability. Prospective studies with harmonized criteria and quality-of-life assessment are needed to define the true burden and optimal management of VSA in ANOCA and MINOCA.

BEYOND SYSTOLIC DYSFUNCTION: REDEFINING PALLIATIVE CARE ELIGIBILITY IN ADVANCED HEART FAILURE

MARIA DE FATIMA MARTINS GIL DIAS1; FLÁVIO ANDRADE CAMACHO2; GABRIELLE DE SOUZA ROCHA2; ANA BEATRIZ DOS SANTOS RIBEIRO3; EDUARDO PIETRE4; RODRIGO SILVA GAMMERDINGER3; ANDRE CASARSA MARQUES1; PEDRO BASTOS DE MEDEIROS1; LARISSA FRANCO DE ANDRADE4; RAYANE FARIAS AUGUSTO PENNA3; LEONARDO ANDRADE FERNANDES DE LUCA4; LUIS FILIPE AZEVEDO DE CARVALHO4;

(1) UNIVERSIDADE FEDERAL DO ESTADO DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL; (3) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (4) HOSPITAL QUINTA D'OR - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Advanced heart failure (HF) is characterized by refractory symptoms, progressive functional decline, and frequent hospitalizations, with mortality rates comparable to many malignancies despite optimal guideline-directed therapy. Palliative care emerges as an essential complementary approach, aimed at relieving suffering and aligning treatment with patient values throughout the disease trajectory. Nevertheless, despite recommendations from the American Heart Association, palliative care remains significantly underutilized in this population, with late and inconsistent referrals driven by prognostic uncertainty and the lack of structured integration between cardiology and palliative care teams. Identifying the clinical profile of patients who would most benefit from early palliative care integration. Objectives: To describe the demographic and clinical profile of patients with advanced HF in a tertiary hospital who received exclusive palliative care. Methods: This retrospective cohort study included 373 patients with advanced heart failure, of whom 20 died during hospitalization. Patients were stratified according to whether they received exclusive palliative care (yes vs. no). Demographic data, comorbidities, heart failure phenotype, previous hospitalizations, and time to death were analyzed using descriptive statistics. The software used were Python 3.9.6 and other. Due to the sample size and low expected frequencies, the association with ejection fraction was assessed using the Fisher-Freeman-Halton exact test. Resultados e Conclusions: The average age was 85.5 years. Patients who received palliative care were older (86.3 vs. 82.2 years), had more hospitalizations in the previous year (2.8 vs. 1.5), and shorter intervals between admission and death. Delirium was identified in 35% of cases. A statistically significant association was found between the reduced ejection fraction phenotype and referral to palliative care (Fisher-Freeman-Halton exact test, p = 0.0035). Referral to palliative care appears to be driven by worsening ejection fraction, potentially neglecting patients with preserved ejection fraction or in the intermediate range who may equally benefit from this approach. Despite the high prevalence of multimorbidity and recurrent hospitalizations, the integration of palliative care remains late and phenotype-dependent in this population. Earlier referral strategies are needed to optimize symptom control, support goal-directed care planning, and improve quality of life.

Introduction/Background: Chagas disease (CD) remains a neglected condition with a substantial unmet demand for diagnosis, despite the availability of diagnostic resources within the Brazilian public healthcare system (SUS). Novel approaches combining artificial intelligence analysis with electrocardiographic tracings (AI-ECG) have been developed to optimize the identification of seropositive individuals. Objectives: To compare the screening model recommended by the Clinical Protocol and Therapeutic Guidelines for Chagas Disease (PCDT-DCh) with an AI-ECG-based model for the screening and diagnosis of patients with chronic Chagas disease. Methods: A study was conducted in two health macro-regions of Minas Gerais, Brazil: the northern region, hyperendemic for Chagas disease (CD), and the western region, endemic for CD. The PCDT-DCh strategy was compared with the AI-ECG approach as alternative methods for CD screening and diagnosis using Decision Curve Analysis (DCA) within the context of the Brazilian public healthcare system. The primary outcome was serological confirmation of CD. Net benefit was calculated for threshold probabilities (TP) of 5%, 10%, 15%, and 20%, considering both screening strategies in comparison with the "test-all" approach and the "no-intervention" scenario. Resultados e Conclusions: Results: The AI-ECG strategy outperformed the PCDT-DCh approach across all scenarios, with net benefit values ranging from 0.149 to 0.092, while universal testing proved unfeasible. Regional heterogeneity was observed. In the hyperendemic northern region of Minas Gerais, AI-ECG achieved the highest net benefit (0.168). In the western endemic region, AI-ECG remained superior up to a 10% probability threshold (0.025), but values fell below the x-axis at thresholds ≥15% (-0.002), indicating the need for stricter thresholds in this setting. Increasing probability thresholds further amplified the net benefit advantage of AI-ECG over comparator strategies. Conclusions: Decision curve analysis suggests that opportunistic screening using AI-ECG is an effective strategy, particularly in highly endemic regions, and may improve timely diagnosis of chronic Chagas Disease within the Brazilian public health system. Further economic evaluations are needed to confirm its long-term superiority and sustainability.

DEPRESSIVE SYMPTOMS AND SELF-REPORTED FUNCTIONAL CAPACITY ARE DETERMINANTS OF QUALITY OF LIFE IN PATIENTS WITH CHAGAS CARDIOMYOPATHY.

HENRIQUE SILVEIRA COSTA1; CHEYENNE ALVES FONSECA1; CATARINA SAUSEN REBOLLAL1; GUILHERME RIBEIRO LIMA1; DIANA NAIARA CASAS VÁSQUEZ1; SOFIA CORDEIRO DE CARVALHO1;

(1) UFVJM-DIAMANTINA - DIAMANTINA - MG - BRASIL;

Introduction/Background: Chagas cardiomyopathy affects multiple dimensions of health, including functional capacity, mental health, and quality of life. In addition to cardiac impairment, patients often experience social vulnerability, progressive physical limitation, and psychological burden, all of which may influence their perceived health status. The Minnesota Living with Heart Failure Questionnaire (MLHFQ) is widely used to assess quality of life in patients with heart disease, including those with Chagas cardiomyopathy; however, the main determinants of this outcome in this population remain insufficiently understood. Objectives: To investigate the determinants of quality of life, assessed by the MLHFQ, in patients with Chagas cardiomyopathy. Methods: This cross-sectional study included 57 patients with Chagas cardiomyopathy (64.18 ± 8.94 years), of whom 25 (43.9%) had systolic dysfunction, and 24 (42.1%) were female. Participants underwent assessment with the Human Activity Profile (HAP), the Duke Activity Status Index (DASI), the Beck Depression Inventory (BDI), the Cardiac Anxiety Questionnaire, the five-repetition sit-to-stand test, the 60-second sit-to-stand test, handgrip strength, and the MLHFQ. Correlations between MLHFQ score and the studied variables were initially tested. Variables showing significant associations were subsequently entered into a multivariable regression model. Resultados e Conclusions: MLHFQ score was significantly correlated with HAP (r=-0.461; p<0.001), DASI (r=-0.420; p=0.001), BDI (r=0.697; p<0.001), and cardiac anxiety (r=0.532; p<0.001), but not with five-repetition sit-to-stand performance (p=0.993), 60-second sit-to-stand performance (p=0.551), or handgrip strength (p=0.435). In the multivariable model, BDI (B=1.04; p<0.001) and maximum HAP score (B=-0.55; p=0.004) remained independent determinants of quality of life, together explaining 43% of the variance in MLHFQ score (R^2=0.43). These findings indicate that worse quality of life in patients with Chagas cardiomyopathy is primarily associated with greater depressive symptom burden and lower self-reported functional capacity, rather than with simple measures of muscle strength or sit-to-stand performance. This reinforces the importance of integrated care strategies that address both psychosocial and functional domains in the clinical management of this population.

EFFECTS OF COLCHICINE ON MYOCARDIAL FIBROSIS IN CHAGAS CARDIAC DISEASE: LABORATORY AND STRUCTURAL ANALYSIS

LUIZ MARIO BAPTISTA MARTINELLI1; MARIA CRISTINA DONADIO ABDUCH1; KEILA CARDOSO BARBOSA FONSECA1; FELIX JOSE RAMIRES1; CARLOS EDUARDO ROCHITTE1; RAFAEL ALMEIDA FONSECA1; BARBARA MARIA IANNI1; GIULIANO GENEROSO2; JULIANO NOVAES CARDOSO1; WILSON MATHIAS JUNIOR1; FABIO FERNANDES1; VIVIANE TIEMI HOTTA1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

INTRODUCTION: Chagas disease (CD) is a neglected chronic condition with potential for progressive cardiac involvement. Myocardial fibrosis, mediated by a persistent inflammatory process, represents one of the main pathophysiological mechanisms underlying disease progression. Colchicine has been investigated for its possible effect in reducing fibrosis and modulating chronic inflammation. Objectives: OBJECTIVES: This study aimed to assess the effect of colchicine on the inflammatory profile and myocardial fibrosis in patients with stage B1 CD, through laboratory analysis, myocardial deformation assessed by speckle tracking echocardiography (STE), and cardiac magnetic resonance (CMR). Methods: METHODS: This was a prospective, double-blind, randomized study with 12 months of follow-up, including 24 patients with stage B1 CD and evidence of myocardial fibrosis or edema on CMR. Participants were randomly assigned to a control group (n=8) or to a colchicine group (n=16; 0.5 mg every 12h). Inflammatory markers (IL-1β, IL-6, IL-8, IL-10, TNF-α, IFN-γ, Gal3), STE, and CMR were performed at baseline and after 12 months of colchicine therapy. Resultados e Conclusions: RESULTS: The colchicine group demonstrated a significant reduction in IL-6 (p=0.002) and Gal3 (p=0.043), as well as a trend toward reduction in TNF-α (p=0.065) and IFN-γ (p=0.086). IL-1β levels increased in both groups, with lower magnitude in the colchicine group. CMR revealed no significant differences in myocardial fibrosis between groups, and no significant variations were observed in Global Longitudinal Strain on STE. CONCLUSION: Colchicine showed a potential beneficial effect on the modulation of inflammatory markers in stage B1 CD patients, although without significant impact on myocardial fibrosis progression. Larger studies are warranted to further evaluate its influence on fibrotic evolution in CD.

EVALUATION OF THE REDUCTION IN CARDIAC INFLAMMATION AFTER SPECIFIC TREATMENT WITH BENZNIDAZOLE IN CHAGAS DISEASE BY CARDIAC PET.

SILVANA DE ARAÚJO SILVA1; MARIA DO CARMO PEREIRA NUNES1; ANTÔNIO LUIZ PINHO RIBEIRO1; ESTER CERDEIRA SABINO2; LEA CAMPOS DE OLIVEIRA DA SILVA2; HERIKA MARTINS MENDES1; ELOA SERPA NUNES1; LIVIA SPADER CAMARGO1; RAFAELA OLIVEIRA TORRES1; BRUNA VIEIRA GUARÇONI1; ARTHUR SOUZA LIMA1; LÍVIA VILELA GONCALVES1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (2) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL;

Introduction/Background: Chagas disease (CD) remains a neglected endemic disease with high morbidity and mortality in our setting. Myocardial inflammation is the most important mechanism associated with the pathogenesis of chronic Chagas cardiomyopathy (CCC). Fluorodeoxyglucose positron emission tomography (F-FDG PET-CT) detects the inflammatory process and quantifies the response to treatment. Demonstrating the benefit of specific treatment with benznidazole, a medication approved since the 1970s, in reducing the inflammatory process in CD may improve understanding of the disease progression mechanism and its prognosis, especially in CCC. Objectives: Compare myocardial FDG uptake in patients with Chagas disease before and after completing benznidazole treatment. Methods: This observational study included patients followed at the medical service, aged over 18 years, with Chagas disease confirmed serologically by two different tests, without symptoms or signs of heart failure, and with Doppler echocardiography showing no severe ventricular dysfunction (LVEF >45%). All patients underwent medical consultation, electrocardiography, echocardiography, laboratory tests, and cardiac PET-CT before treatment and six months after completion of the full benznidazole regimen (300 mg/day for 60 to 80 days). For PET-CT analysis, regions of interest (ROI) were defined on the images and standardized uptake values (SUV) were calculated, reflecting the degree of inflammatory activity adjusted for body weight and tracer dose. Resultados e Conclusions: Seventy-four patients were included. The mean age was 55 ± 10 years, the majority were female (61%), and 53% were in the indeterminate chronic form of the disease. So far, 64 patients have undergone the second PET-CT scan. Overall, 69% showed no abnormal myocardial F-FDG uptake or demonstrated reduced uptake (Figure 1), 28% showed increased uptake, and 3% showed no change in uptake. PET-CT appears to be a useful and promising tool for monitoring the inflammatory response to benznidazole in patients with Chagas disease. Correlation with clinical outcomes may clarify the impact of these metabolic changes on disease progression.

18264

EVALUATION OF THE REDUCTION OF CARDIAC INFLAMMATION BY RESONANCE AFTER SPECIFIC TREATMENT WITH BENZNIDAZOLE IN CHAGAS DISEASE.

SILVANA ARAÚJO SILVA1; MARIA DO CARMO PEREIRA NUNES1; ANTÔNIO LUIZ PINHO RIBEIRO1; ESTER CERDEIRA SABINO2; LEA CAMPOS DE OLIVEIRA DA SILVA2; MÁRCIO VINÍCIUS LINS BARROS3; GIOVANNA SIMÕES PARRELA1; GRAZIELA RUSSO1; PAULA GRANDA1; GABRIELA LANÇA1; LÍVIA VILELA GONÇALVES1; LEONARDO SILVA SANTOS1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (2) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (3) REDE MATER DEI DE SAUDE - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Chagas disease (CD) remains endemic throughout Latin America, with high morbidity and mortality. The benefit of specific treatment with benznidazole in the chronic phase of the disease still needs to be better established, although myocardial inflammation is already well documented as the main factor associated with chronic Chagas cardiomyopathy (CCC). Assessing the reduction of this inflammatory process with benznidazole treatment may help elucidate the mechanisms of disease progression. Objectives: To assess the reduction of cardiac inflammation and fibrosis using Cardiovascular Magnetic Resonance (CMR). Methods: This is an observational study including patients followed at this center, aged over 18 years, with Chagas disease confirmed serologically by two distinct techniques, without symptoms or signs of heart failure, and with echocardiography (echo) showing no severe ventricular dysfunction (i.e., with LVEF >45%). All patients underwent medical consultation, electrocardiogram, echocardiography, laboratory tests, and CMR before treatment and six months after completing full treatment with benznidazole (300 mg/day for 60 to 80 days). Biventricular volumes and function, resting perfusion, and tissue characterization were assessed using late gadolinium enhancement, T1 mapping, T2 mapping, and extracellular volume (ECV). For statistical significance, an estimated p-value < 0.05. Resultados e Conclusions: Of the 57 patients included, 4 did not complete treatment—two due to severe adverse effects (dermopathy) and two due to withdrawal. The mean age was 52.4 years; most were women (47, 82%), and 25 patients (44%) had electrocardiographic abnormalities. T1 mapping, T2 mapping, and ECV analysis showed a reduction in fibrosis/inflammation after treatment compared to pre-therapy findings in T1 mapping (fibrosis assessment), anterior wall values decreased from 1029.51 ± 41.39 to 1010.82 ± 51.68, septal wall from 1051.57 ± 52.82 to 1005.78 ± 38.14, and lateral wall from 1042.06 ± 55.08 to 1018.87 ± 43.97. In T2 mapping (edema assessment), septal wall values decreased from 53.36 ± 3.54 to 51.74 ± 2.98. These results were statistically significant (p < 0.05). Treatment with benznidazole (BZN) reduces fibrosis/inflammation in the cardiac tissue of patients with Chagas disease and may impact disease progression, which is of great importance for the prognosis of these patients.

19227

FUNCTIONAL AND PSYCHOSOCIAL DIFFERENCES IN PATIENTS WITH CHAGAS CARDIOMYOPATHY LIVING IN A CAPITAL CITY VERSUS AN ENDEMIC REGION

HENRIQUE SILVEIRA COSTA1; CHEYENNE ALVES FONSECA1; DIANA NAIARA CASAS VASQUEZ1; SOFIA COREDEIRO DE CARVALHO1; CATARINA SAUSEN REBOLLAL1;

(1) UNIVERSIDADE FEDERAL DOS VALES DO JEQUITINHONHA E MUCURI - DIAMANTINA - MG - BRASIL;

Introduction/Background: Chagas cardiomyopathy (CCC) is associated with substantial functional impairment and psychosocial burden. These outcomes may be influenced not only by cardiac involvement but also by the territorial and social context in which patients live. Comparing patients from a capital city and from an endemic region may help identify health disparities and support more context-sensitive care strategies. Objectives: To compare functional status, quality of life, and depressive symptoms in patients with CCC living in a capital city versus an endemic region for Chagas disease. Methods: This cross-sectional study included 95 patients with CC: 35 (36.8%) living in the capital city (HDI 0.797) and 60 (63.2%) living in an endemic region (mean HDI 0.616). Overall, 59 patients (62.1%) were male. Depressive symptoms were assessed using the Beck Depression Inventory (BDI), self-reported physical activity using the Human Activity Profile (HAP; maximum activity score), and quality of life using the Minnesota Living with Heart Failure Questionnaire (MLHFQ). Echocardiographic variables included left ventricular ejection fraction and left ventricular end-diastolic diameter. Outcomes were compared between groups. Resultados e Conclusions: Patients from the endemic region were older than those from the capital city (67.89 ± 9.21 vs. 47.81 ± 8.27 years; p<0.001). They also showed higher depressive symptom scores on the BDI (14.15 ± 10.99 vs. 8.42 ± 8.28; p=0.002), lower self-reported physical activity on the HAP (53.63 ± 11.45 vs. 83.58 ± 7.21; p<0.001), and worse quality of life on the MLHFQ (30.07 ± 22.74 vs. 20.45 ± 21.11; p=0.008). In contrast, no significant between-group differences were observed in left ventricular ejection fraction (p=0.306) or left ventricular end-diastolic diameter (p=0.266). These findings indicate that patients living in the endemic region had a worse functional and psychosocial profile despite similar echocardiographic parameters. This pattern suggests that factors beyond cardiac structural impairment, including territorial and social context, may influence disease burden. Considering these determinants may help guide more comprehensive and equitable care strategies for patients with Chagas disease.

19361

MEASURED VERSUS ESTIMATED PEAK OXYGEN UPTAKE IN PATIENTS WITH CHAGAS CARDIOMYOPATHY: INSIGHTS FROM EXERCISE TESTING

HENRIQUE SILVEIRA COSTA1; CHEYENNE ALVES FONSECA1; GUILHERME RIBEIRO LIMA1; DIANA NAIARA CASAS VASQUEZ1; CATARINA SAUSEN REBOLLAL1; SOFIA CORDEIRO DE CARVALHO1;

(1) UNIVERSIDADE FEDERAL DOS VALES DO JEQUITINHONHA E MUCURI - DIAMANTINA - MG - BRASIL;

Introduction/Background: Chagas disease remains a major public health challenge in Latin America, and Chagas cardiomyopathy is its most frequent and most severe clinical presentation. Functional capacity may decline early in the course of cardiac involvement, making regular assessment especially important in this population. Cardiopulmonary exercise testing (CPET) is the gold standard for measuring peak oxygen uptake (VO2peak), but its high cost and limited availability restrict its use in low-resource and endemic settings. Treadmill exercise testing is more accessible; however, VO2peak is indirectly estimated, and the accuracy of commonly used prediction equations in patients with Chagas cardiomyopathy remains uncertain. Objectives: To compare VO2peak measured by CPET with VO2peak estimated by treadmill exercise testing in patients with Chagas cardiomyopathy. Methods: Sixty patients with Chagas cardiomyopathy (48.8 ± 10.4 years; NYHA class I–III) underwent CPET using the Bruce protocol. Estimated VO2peak was calculated using the equations VO2max = (2.9 × exercise time in minutes) + 8.33 and, for women, VO2max = (2.74 × exercise time in minutes) + 8.03. Differences between measured and estimated values were assessed using the Wilcoxon test. The association between methods was analyzed using Pearson's correlation, and agreement was evaluated using Bland-Altman analysis. Resultados e Conclusions: Measured VO2peak was 24.4 ± 8.3 mL/kg/min, whereas estimated VO2peak was 33.5 ± 7.4 mL/kg/min, showing a significant difference between methods (p<0.001). Estimated values overestimated measured VO2peak by 27%. Although a statistically significant correlation was observed between the two measures (r = 0.302; p = 0.020), the strength of the association was modest. Bland-Altman analysis showed that most observations remained within the limits of agreement, with a mean difference of 4.5 mL/kg/min, equivalent to 1.3 METs. In patients with Chagas cardiomyopathy, treadmill-based prediction equations substantially overestimated directly measured VO2peak, potentially limiting their clinical applicability. These findings support cautious interpretation of estimated functional capacity and highlight the need for disease-specific prediction models, particularly in settings where CPET is not readily available.

19301

PERFORMANCE OF CARDIOPULMONARY EXERCISE TESTING FOR DETECTING PULMONARY HYPERTENSION IN DILATED CHAGAS CARDIOMYOPATHY

HENRIQUE SILVEIRA COSTA1; CHEYENNE ALVES FONSECA1; SOFIA CORDEIRO DE CARVALHO1; CATARINA SAUSEN REBOLLAL1; DIANA NAIARA CASAS VÁSQUEZ1;

(1) UFVJM - UNIVERSIDADE FEDERAL DOS VALES DO JEQUITINHONHA E MUCURI - DIAMANTINA - MG - BRASIL;

Introduction/Background: Background: Dilated Chagas cardiomyopathy is the most severe clinical manifestation of Chagas disease and is associated with poor prognosis. Pulmonary hypertension (PH) is a frequent complication in these patients and contributes to adverse clinical outcomes, including fatigue and dyspnea. Cardiopulmonary exercise testing (CPET) may help identify PH; however, no previous studies have comprehensively evaluated the accuracy of CPET-derived ventilatory parameters for detecting PH in patients with dilated Chagas cardiomyopathy. Objectives: Objectives: To assess the diagnostic accuracy of ventilatory variables obtained during CPET for identifying PH in individuals with dilated Chagas cardiomyopathy, with the potential to improve early diagnosis and therapeutic strategies. Methods: Methods: This diagnostic accuracy study included 41 patients with dilated Chagas cardiomyopathy (mean age 53.3 ± 10.6 years), of whom 9 had PH. All participants underwent echocardiography and CPET. PH was defined as a systolic pulmonary artery pressure greater than 40 mmHg. The following CPET variables were analyzed: peak oxygen uptake (VO2peak), the minute ventilation/carbon dioxide production slope (VE/VCO2 slope), and peak end-tidal carbon dioxide pressure (PETCO2peak). Diagnostic accuracy was determined using receiver operating characteristic (ROC) curves. Resultados e Conclusions: Results and Conclusions: The area under the curve for VO2peak, VE/VCO2 slope, and PETCO2peak was 0.802 (95% CI 0.63–0.97), 0.703 (95% CI 0.48–0.93), and 0.730 (95% CI 0.53–0.92), respectively. The optimal cutoff values were 17.0 mL/kg/min for VO2peak, 37.0 for VE/VCO2 slope, and 31.0 mmHg for PETCO2peak. Patients with abnormal VO2peak and VE/VCO2 slope values were 8.7 and 10.8 times more likely, respectively, to have PH. These findings suggest that VO2peak, VE/VCO2 slope, and PETCO2peak have acceptable accuracy for identifying PH in patients with dilated Chagas cardiomyopathy. CPET may therefore represent a valuable screening tool in this population, particularly in patients with ventilatory abnormalities, and may support earlier recognition of PH in clinical practice.

QRS DURATION AS AN EARLY ELECTROCARDIOGRAPHIC MARKER OF RIGHT VENTRICULAR SYSTOLIC IMPAIRMENT IN CHRONIC CHAGAS CARDIOMYOPATHY WITH PRESERVED LEFT VENTRICULAR FUNCTION

FLÁVIO HILTON FEIJÓ CAVALCANTI SILVA1; LUANA DO AMARAL DIAS1; ISABELLE CONCEIÇÃO ALBUQUERQUE MACHADO MOREIRA1; CAMILA NOGUEIRA LEANDRO LIRA1; MARIA DAS NEVES DANTAS DA SILVEIRA BARROS1; CRISTINA DE FATIMA VELOSO CERRAZONE1; MARIA DA GLORIA AURELIANO DE MELO CAVALCANTI1; LUIZ EDUARDO SAMPAIO GROSSI1; MARIA ELIZA LUCENA SALES DE MELO ASSUNÇÃO1; MONALIZA EVELYN PEREIRA DE SOUZA1; WILSON DE OLIVEIRA JUNIOR1; SILVIA MARINHO MARTINS ALVES1;

(1) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL;

Introduction/Background: Right ventricular (RV) dysfunction in chronic Chagas cardiomyopathy (CCC) is associated with worse prognosis and reduced survival. Electrocardiography remains an important diagnostic and prognostic tool in CCC, with the advantages of low cost and wide availability. In this context, QRS duration, obtained from a standard electrocardiogram, may serve as a simple and accessible marker of early right ventricular involvement. Objectives: To evaluate the association between QRS duration and right ventricular systolic impairment in patients with CCC and preserved left ventricular ejection fraction (LVEF). Methods: This cross-sectional study included 138 patients with CCC and preserved LVEF, defined as LVEF >50%, followed at a tertiary referral center. Left and right ventricular systolic function were assessed by cardiac magnetic resonance imaging. The association between QRS duration and right ventricular ejection fraction (RVEF) was examined using multivariable linear regression analysis adjusted for age and sex. Results are expressed as beta coefficients, 95% confidence intervals (CI), and p values. Resultados e Conclusions: Results: The study population was predominantly female (70%), with a mean age of 59.8 years (median, 61 years). Mean LVEF was 66.4% (SD 8.56), and mean RVEF was 68.2% (SD 7.0). Right axis deviation was identified in 1.4% of patients. Mean QRS duration was 117 ms (SD 27.2). Longer QRS duration was independently associated with lower RVEF (β = -0.51 per 10-ms increment; 95% CI, -0.94 to -0.08; p = 0.021), after adjustment for age and sex. Conclusion: In patients with chronic Chagas cardiomyopathy and preserved LVEF, each 10-ms increase in QRS duration was associated with a mean 0.5-percentage-point reduction in RVEF, suggesting a potential role for electrocardiography as a simple and widely accessible marker of early right ventricular systolic impairment.

Introduction/Background: Chagas disease (ChD) remains an important cause of cardiomyopathy in Latin America and is associated with substantial morbidity and impaired quality of life (QoL). Cardiac involvement and functional limitation may adversely affect perceived health status, but evidence on QoL patterns across follow-up remains limited. Objectives: To evaluate QoL and its association with clinical characteristics using repeated cross-sectional assessments of individuals with chronic ChD. Methods: We analyzed data from individuals with confirmed chronic ChD enrolled in the SaMi-Trop cohort. QoL was assessed at baseline (2013–2014), follow-up 1 (2015–2016), and follow-up 2 (2019–2021). Associations were estimated using mixed-effects models with a random intercept for individuals, focusing on time-specific effects. QoL was measured using the Brazilian-validated WHOQOL-Bref, which includes four domains: physical, psychological, social relationships, and environment. Higher scores indicate better perceived QoL. Resultados e Conclusions: A total of 623, 611, and 907 participants were included at baseline, follow-up 1, and follow-up 2, respectively. Participants were predominantly women and mostly middle-aged or older adults. Chagas cardiomyopathy prevalence exceeded 50% at all time points. QoL remained relatively stable over time, with modest increases in physical, psychological, and environmental domains at follow-up (Figure 1). Worse functional class was consistently associated with poorer QoL across all domains. Chagas cardiomyopathy was associated with worse physical domain scores. Higher income and educational attainment were positively associated with QoL at some time points. QoL remained relatively stable over time but was influenced by clinical severity and socioeconomic conditions. Functional limitation was the factor most consistently associated with poorer QoL.

ADVERSE EVENTS IN CARDIOVASCULAR MEDICATION ADMINISTRATION: ANALYSIS OF NURSING PRACTICE AND CONTRIBUTING FACTORS

GISELE ADAO SANTOS1; LUIZ GUSTAVO TORRES DIAS1;

(1) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Adverse events related to cardiovascular medication administration represent a major challenge to patient safety, particularly due to the use of high-risk drugs. Failures in communication, workload, and process organization may increase the likelihood of errors in clinical practice. Objectives: o analyze adverse events related to cardiovascular medication administration and identify contributing factors associated with nursing practice. Methods: This cross-sectional observational study was conducted in a hospital inpatient unit between January and March 2026. Data were collected through structured questionnaires administered to nursing professionals. Variables included medication administration practices, communication among healthcare professionals, workload, and adherence to safety protocols. Descriptive statistical analysis was performed. Resultados e Conclusions: Preliminary findings suggest that adverse events are associated with communication failures, high workload, and lack of adherence to double-checking procedures for high-risk medications. Interruptions during medication preparation were also identified as relevant contributing factors. These findings highlight the impact of organizational and communication factors on patient safety and reinforce the need for strategies focused on effective communication and adherence to safety protocols in nursing practice.

AGILE PROCESSES AND DIGITAL COMMUNICATION TOOLS IN ST-SEGMENT ELEVATION MYOCARDIAL INFARCTION CARE: IMPACT ON DOOR-TO-BALLOON TIME

LARISSA LUMA TOMASI FEBRAS1; CINTIA LAZZARI1; DANIEL LUFT MACHADO1; BELISA MARIN ALVES1; CASSIA CRISTINA DAMASIO DE LIMA1; FABIANA DOS SANTOS JOAQUIM1; VICTORIA REINA CAMINHA1;

(1) HOSPITAL MOINHOS DE VENTO - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: ST-segment elevation myocardial infarction (STEMI) represents one of the leading causes of cardiovascular morbidity and mortality in Brazil. Early reperfusion through primary percutaneous coronary intervention (pPCI) within 90 minutes is decisive in reducing myocardial damage and improving clinical outcomes. Strategies to optimize intra-hospital flow and digital communication tools between teams have the potential to reduce door-to-balloon time, yet local evidence regarding their impact remains limited. Objectives: To evaluate the impact of the physical presence of the hemodynamics team and the implementation of a digital communication group (WhatsApp) on door-to-balloon time in patients with STEMI. Methods: This is an observational analytical study involving 149 consecutive cases of STEMI treated at a hemodynamics service. Door-to-balloon time was compared between two groups: on-site team (Group 1) and on-call team requiring travel (Group 2). Additionally, door-to-balloon time was evaluated during the periods before and after the implementation of a WhatsApp group between the emergency and hemodynamics teams. Comparisons were performed using appropriate statistical tests, with $p < 0.05$ considered significant. Resultados e Conclusions: The mean door-to-balloon time was significantly lower in Group 1 (55 min) compared to Group 2 (70 min) ($p < 0.01$). Temporal analysis showed a significant reduction in door-to-balloon time following the implementation of the WhatsApp group: from 84 min in the pre-intervention period to 58 min in the post-intervention period ($p < 0.01$). Both strategies were associated with achieving the institutional goal of 60 minutes and improving clinical care indicators. The physical presence of the hemodynamics team and the adoption of a real-time digital communication tool were associated with clinically relevant reductions in door-to-balloon time for STEMI patients. These findings reinforce that investments in agile operational flows and effective communication between teams constitute cost-effective strategies for improving STEMI outcomes.

AN INTRODUCTION TO NURSING CARE FOR PATIENTS UNDERGOING CARDIAC SURGERY WITH CARDIOPULMONARY BYPASS

NAILA CAROLINE BARBOSA MORAIS1; RAPHAELY SOUSA FEITOSA MORAIS1; WONESKA RODRIGUES PINHEIRO1; JOSE DIOGO BARROS1;

(1) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL;

Introduction/Background: Cardiopulmonary bypass is an invasive technique, used primarily during cardiac surgery, that diverts the patient's blood to a machine that oxygenates it and pumps it back into the body, temporarily replacing the functions of the heart and lungs, and requiring a multidisciplinary approach to ensure the safety and comprehensiveness of care. In this context, nurses play a fundamental role, which involves thorough assessment and clinical management during the pre-, intra-, and postoperative periods. Objectives: The study aimed to analyze the nursing approach to patients in the perioperative period of cardiac surgery with cardiopulmonary bypass based on the literature. Methods: This is a systematic review conducted using the journal directory of the Scientific Electronic Library Online (SciELO), the Latin American and Caribbean Health Sciences Literature (LILACS) databases, the Nursing Database (BDENF), accessed through the Virtual Health Library (VHL), as well as the Medical Literature Analysis and Retrieval System Online (MEDLINE), via the National Library of Medicine (PubMed), by cross-referencing the Descriptors in Health Sciences (DeCS) and their respective Medical Subject Headings (MeSH), namely: Thoracic Surgery (Thoracic Surgery) AND Extracorporeal Circulation AND Cardiovascular Nursing AND Nursing Care, using the Boolean operator AND. Original articles, available in full text and published between 2018 and 2024, were included. Duplicate articles, integrative review articles, theses, dissertations, or those unrelated to the study's objective were excluded. The search and selection process was illustrated using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flowchart. Resultados e Conclusions: The final sample consisted of 9 articles. The study highlighted essential nursing practices in the perioperative period of cardiac surgeries with cardiopulmonary bypass, with an emphasis on the postoperative period and the prevention of complications. Among the main care measures identified are the monitoring of vital signs and hemodynamics, physical examination, evaluation of laboratory tests, and preventive measures for postoperative complications. The results reinforce the importance of multidisciplinary collaboration and the systematization of nursing care to ensure safety, quality of care, and a reduction in complications. Furthermore, they highlight the need for continuous training and evidence-based protocols to improve clinical practice and patient outcomes.

21868

ASSESSMENT OF QUALITY OF LIFE AND CLINICAL ASPECTS OF PATIENTS HOSPITALIZED FOR DECOMPENSATED HEART FAILURE

BRENDA GONÇALVES DONAY ALVES1; TAINÁ MEDEIROS SANTANA1; THAYS DA SILVA RODRIGUES1; ELLEN HETTWER MAGEDANZ1; ANDRÉIA DA SILVA GUSTAVO1; LUIZ CARLOS BODANESE1;

(1) PUCRS - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Heart failure (HF) is associated with several comorbidities and complex treatment regimens, compromising patients' quality of life (QoL). Objectives: To evaluate the association between clinical profile and quality of life in patients with decompensated HF at the time of enrollment in a health educational intervention. Methods: Cross-sectional study nested within a randomized clinical trial. Patients aged ≥18 years who were hospitalized at a hospital in Porto Alegre were included. Participants completed the Kansas City Cardiomyopathy Questionnaire (KCCQ) and the Hospital Anxiety and Depression Scale (HADS). Associations were analyzed using the Mann–Whitney and Kruskal–Wallis tests, in addition to Spearman's correlation coefficient. The study was approved by the Scientific Committee of the Research Ethics Committee of PUCRS, under opinion 6.220.119 – CAAE 71836423.4.0000.5336. Resultados e Conclusions: A total of 65 patients were evaluated, with a mean age of 64.5±13.1 years, predominance of males (56.9%), BMI of 27.0±5.2 kg/m², and abdominal circumference of 98.8±15.1 cm. Ischemic etiology was the most frequent (50.8%), with a mean left ventricular ejection fraction (LVEF) of 38.1±18.0%. Patients with heart failure with reduced ejection fraction (HFrEF) predominated (66.2%), as well as New York Heart Association (NYHA) functional class III (47.7%) and the warm and wet clinical-hemodynamic profile (84.6%). In the KCCQ score, patients with a previous diagnosis of HF presented higher scores in the Social Limitation domain (p=0.043) compared with those diagnosed during hospitalization. Patients classified as NYHA IV presented lower scores in the Physical Limitation domain (p=0.003), Symptoms subitems — Frequency (p=0.022) and Severity (p=0.044) —, Total Symptom Score (p=0.014), and Quality of Life (p=0.030), compared with NYHA I patients. Most participants were classified as without anxiety (55.4%) and without depression (75.4%). Patients classified as NYHA IV presented worse quality of life, evidenced by lower scores in the domains of Physical Limitation, Symptoms (Frequency and Severity), Total Symptom Score, and Quality of Life. LVEF, as well as anxiety and depression levels, showed no significant association with quality of life in patients with HF.

20248

CARDIOVASCULAR EMERGENCIES HANDLED BY THE MOBILE EMERGENCY CARE SERVICE IN A CAPITAL CITY IN NORTHEASTERN BRAZIL

GABRIEL SANTANA DA SILVA1; LUIS FERNANDO SANTOS SOEIRO2; TAYNARA DE JESUS COSTA CONCEIÇÃO2; GIOVANNA GARCIA VIEIRA2; YASMIN ROCHA ALBINO3; FLÁVIA DANYELLE OLIVEIRA NUNES2; ROSILDA SILVA DIAS2; LISCIA DIVANA CARVALHO SILVA2;

(1) INSTITUTO DO CORACAO (INCOR) - HOSPITAL DAS CLINICAS DA FACULDADE DE MEDICINA DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) UFMA - CAMPUS SAO LUIS - SÃO LUÍS - MA - BRASIL; (3) FACULDADE SANTA LUZIA (FSL) - SANTA INÊS - MA - BRASIL;

Introduction/Background: The majority of cases handled by the Mobile Emergency Care Service (SAMU) involve cardiovascular emergencies, including hypertensive crises, angina, acute myocardial infarction, and cardiopulmonary arrest. Analyzing the sociodemographic profile of patients treated by SAMU—particularly given the heterogeneity of the regions surveyed—is essential for the development and management of public policies. Objectives: To analyze the sociodemographic profile of victims of cardiovascular emergencies attended by SAMU in São Luís, Maranhão (MA). Methods: A retrospective, documentary study conducted at the Dispatch Center and Mobile Units of SAMU in São Luís, MA. The sample included 70 cardiovascular emergency calls recorded in 2017. Data were collected from medical dispatch records and analyzed using descriptive statistics in the Statistical Package for the Social Sciences (SPSS), including frequencies, means, and standard deviations. The study was approved by the Research Ethics Committee (CEP) of the Federal University of Maranhão (UFMA). Resultados e Conclusions: A total of 82 incidents were identified, resulting in 70 calls. A predominance of males (54.3%) over females (38.6%) was observed, with missing records in 7.1% of cases. Regarding age group, there was a higher incidence among the elderly (≥60 years), accounting for 57.1% of the cases, followed by individuals aged 40–59 years (31.4%). The remaining age groups were underrepresented. The main pre-existing conditions were hypertension (55.7%), heart disease (24.3%), and diabetes (20.0%). The most frequent complaints were malaise (21.4%), cardiorespiratory arrest (15.7%), and precordial pain (11.4%). Regarding geographic distribution, the highest number of cases occurred in the Coroadinho health district (20.0%), followed by Bequimão (17.1%). As for place of residence, the Bequimão district stood out (10.0%), although a high rate of missing records was observed (57.1%). The profile of cardiovascular emergencies highlights greater vulnerability among elderly men with hypertension, reflecting the impact of population aging and inequalities in access to healthcare. The spatial concentration of cases suggests territorial disparities in care, reiterating the urgency of strategies targeting these groups to promote equity and effectiveness in the emergency care network.

20671

DEVELOPMENT AND IMPLEMENTATION OF A TELEMONITORING PROTOCOL FOR POST-DISCHARGE CARE OF PATIENTS WITH HEART FAILURE

NAILA CAROLINE BARBOSA MORAIS1; BEATRIZ LANFERINI FARTES1; ADANY SANTOS CASTRO1; PEDRO LUNA FLORES SILVA1; PEDRO AUGUSTO SANTOS SILVA1; ANA ELISA FATIMA ALVES1; SHAYANE CORREIA WEISS1; RAFAELLY STAVALE1; ISIS BEGOT KRAINER1; SOLANGE GUIZILINI1; RITA SIMONE LOPES MOREIRA1;

(1) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL;

Introduction/Background: heart failure (hf) is a complex, multifactorial syndrome. Patients have a 75% chance of readmission within 30 days of hospital discharge, with a high impact on morbidity and mortality. Poor treatment adherence and the patient's difficulty in recognizing signs of decompensation are the main factors contributing to this scenario. Telemonitoring emerges as an effective strategy in the post-discharge period, optimizing remote care and patient safety. Objectives: to report on the experience of developing a telemonitoring protocol and its application in patients with hf in the post-discharge period, focusing on the systematization of continuity of care and the early identification of warning signs. Methods: this is an experience report, based on the situational strategic planning (ssp) methodology, which identified weaknesses in treatment adherence during the most critical period following hospital discharge and the need for a protocol to guide telemonitoring and. The protocol was developed by integrating guidelines from the brazilian society of cardiology, the aha, and the esc, in addition to using the kansas city cardiovascular questionnaire (kccq) and validated medication adherence scales. Practical implementation was carried out by a resident nurse via voice calls (whatsapp®), with data collection and systematization performed via google forms®. Resultados e conclusions: the protocol was structured as a digital form containing multiple-choice questions and open-ended fields to assess signs of decompensation (edema, fatigue, weight gain), medication adherence, fluid restriction, and lifestyle habits. It proved to be a complementary tool that assists healthcare professionals, in line with guidelines, particularly during the first days following hospital discharge until the outpatient follow-up visit. Furthermore, it demonstrated itself to be a low-cost, feasible, and replicable intervention, utilizing accessible technological resources. The development of this structured protocol improves the transition from hospital to home care, promotes patient-centered self-care, and establishes telemonitoring as an essential complementary tool for maintaining clinical stability and optimizing post-discharge outcomes.

14264

DEVELOPMENT OF EDUCATIONAL TECHNOLOGY AS A SELF-CARE STRATEGY IN THE TREATMENT OF CHAGAS DISEASE IN NORTHEAST BRAZIL

CAROLINA DE ARAUJO MEDEIROS1; REBEKA DA COSTA TEIXEIRA MELO1; VANESSA MARIA SILVA MUNIZ1; THAISSA OLIVEIRA MUNIZ1; REBECA VITÓRIA FERREIRA MARQUES1; LUCIANA PATRICIA COELHO DE AGUIAR2; MARIA MARIANA BARROS MELO DA SILVEIRA1; VIVIANE TANNURI FERREIRA LIMA FALCÃO1; MARIA BEATRIZ ARAÚJO SILVA1; SÍLVIA MARINHO MARTINS ALVES2; IZABEL BARROS DE ARRUDA1; THAISA REMIGIO FIGUEIREDO1;

(1) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL; (2) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL;

Introduction/Background: Chagas disease is a chronic condition caused by Trypanosoma cruzi and remains a neglected disease associated with high morbidity and mortality and major challenges for diagnosis, treatment and therapeutic adherence (World Health Organization, 2026). In this context, health education and self-care promotion strategies become fundamental, especially when associated with the use of accessible educational technologies, such as educational videos, capable of promoting understanding and stimulating behavioral changes. Objectives: To develop educational technology as a self-care strategy for the treatment of chronic Chagas disease in a public reference service in Northeast Brazil. Methods: This is a methodological study conducted at a Chagas disease reference outpatient clinic in Northeast Brazil. The development of the educational technology by the nursing team began with a literature review, using as one of its primary references the didactic material titled “Supported Self-Care Exercise Workbook”. The Canva® platform was utilized, employing animation features and graphic elements centered on themes of healthy eating, stress management, and physical exercises. Resultados e Conclusions: Educational videos regarding self-care in Chagas disease were developed by the nursing staff, featuring accessible narration and illustration, which gave the material an attractive cartoon-like aesthetic, fostering comprehension and interest among the target audience in the figure. Complementarily, illustrative charts were developed to enable self-assessment of lifestyle habits and to encourage the setting of individual goals, representing a playful and inclusive resource to support patient’s reflection on self-care. The study demonstrated that the use of educational technology, such as educational videos, constitutes an accessible and low-cost strategy to support self-care for patients with chronic Chagas disease. In addition to promoting understanding and engagement, the material has the potential for replication in other health services, including contexts of greater social vulnerability, reinforcing the importance of incorporating health education technologies into the treatment of Chagas disease.

16093

DIGITAL EDUCATIONAL TECHNOLOGY AS AN ENHANCEMENT OF HEALTH LITERACY IN HEART TRANSPLANT PATIENTS.

EVELYN GOMES OSÓRIO1; BEATRIZ DA SILVA PINHEIRO1; TEREZA CRISTINA FELIPPE GUIMARAES1; LILIAN MOREIRA DO PRADO1;

(1) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Heart transplantation is the gold standard treatment for advanced heart failure; however, the post-transplant period requires strict adherence to immunosuppressive therapy, continuous follow-up, and lifestyle changes. In this context, health literacy is fundamental for self-care and prevention of complications. Digital educational technologies emerge as strategies to enhance understanding of health information and support the autonomy of transplant patients. Objectives: To develop and test a digital educational technology to support health literacy in post–heart transplant patients, based on evidence and expert co-creation. Methods: Methodological study with a qualitative approach and quantitative components, aimed at developing a digital educational technology for heart transplant patients. The process was based on Design Thinking, with stages of immersion, ideation, prototyping, and testing. During immersion, a scoping review of the literature and an investigation with patients and professionals were conducted to identify needs related to self-care and health literacy. Ideation was carried out through brainstorming with a multidisciplinary team. In the prototyping phase, an educational video was developed and validated by specialists. The testing phase involved heart transplant patients to evaluate usability using the System Usability Scale (SUS). Resultados e Conclusions: The scoping review identified a scarcity of studies on health literacy in the post-heart transplant setting, with 15 articles included after screening according to PRISMA recommendations. The analysis of the literature and the investigation with transplant patients and professionals revealed difficulties in understanding guidance related to continuous use of immunosuppressive therapy, recognition of rejection signs, and self-care management, in addition to anxiety and fear of graft rejection. A preference for audiovisual resources was observed, especially interviews with healthcare professionals and explanatory animations. Based on these findings and a brainstorming workshop with specialists, thematic axes were defined, including therapeutic adherence, warning signs, lifestyle, and prevention of complications, guiding the development of an educational video with accessible language.

15255

EVALUATION OF THE EUROPEAN SELF-CARE SCALE IN CHRONIC CHAGAS DISEASE IN NORTHEAST BRAZIL

CAROLINA CAROLINA MEDEIROS1; THAISSA OLIVEIRA MUNIZ1; VANESSA MARIA SILVA MUNIZ1; REBEKA DA COSTA TEIXEIRA MELO1; ALANNA MIKAELLA DE ARAÚJO SILVA1; LUCIANA PATRÍCIA COELHO DE AGUIAR2; MARIA MARIANA BARROS MELO DA SILVEIRA1; THAISA REMIGIO FIGUEIREDO1; VIVIANE TANNURI FERREIRA LIMA FALCÃO1; IZABEL BARROS DE ARRUDA1; SÍLVIA MARINHO MARTINS ALVES2; MARIA BEATRIZ ARAÚJO SILVA1;

(1) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL; (2) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL;

Introduction/Background: Described by the Brazilian researcher Carlos Chagas, Chagas disease affects approximately 7 to 8 million people globally. Endemic in Latin America but also present in countries across Europe, North America, and Asia due to the immigration processes Self-care emerges as a non-pharmacological tool, mainly in reducing hospitalizations and when combined with health education actions led by nursing, it can improve quality of life and expand knowledge. Objectives: To evaluate the European Self-Care Scale in patients with chronic Chagas disease followed at a reference service in Northeast Brazil. Methods: A cross-sectional study with a quantitative approach, conducted at a Chagas disease reference outpatient clinic in the Brazilian Northeast region in 2025. The nursing team utilized the “European Heart Failure Self-care Behaviour Scale (EHFScBS),” validated for Brazil , which contains 12 self-care questions related to the perception of heart failure decompensation signs, nutritional habits, physical exercise, and vaccination. The higher the score on an item, the lower the self-care. Resultados e Conclusions: A total of 53 patients were evaluated, with a higher prevalence of females 75.5%, an average age of 66 years, 60% with incomplete primary education, 26.4% illiterate, 34% with an income of up to one minimum wage; 90.5% presented systemic arterial hypertension and 37.5% diabetes mellitus. Regarding the clinical classification of Chagas disease , 43.5% presented heart failure. As for polypharmacy, 60% reported using more than five daily medications, and 75.5% reported receiving the flu vaccine annually. Regarding the scale item “I weigh myself every day,” 34% stated they do not measure their weight daily, on the item “I limit the amount of fluids I drink,” 49% stated they restrict their daily fluid intake; regarding medication use, 81% demonstrated adequate adherence, and the item “I exercise regularly” showed 45% for “strongly disagree.” The average value obtained from the scale was 27.09, indicating a vulnerability in self-care.The population presented weaknesses regarding body weight control, fluid and salt intake, and the incorporation of physical exercise into their routine, essential factors for preventing decompensation episodes.Nevertheless, the discrepancy between medication adherence and non-pharmacological habits highlights the need for integrated strategies that consider not only the clinical dimension, but also the social determinants of health that affect patients with Chagas disease.

21017

INCIDENCE OF PRESSURE INJURY BEFORE AND AFTER THE IMPLEMENTATION OF EXCLUSIVE DIRECT NURSING CARE IN A CARDIAC INTENSIVE CARE UNIT

KAROLINE RAZIMAVICIUS BARBADO1; ANDRÉ ALMEIDA DE MOURA1; RENATA LOURENZEN DE OLIVEIRA2; BEATRIZ SANTANA PRADO2; HENRIQUE MATHEUS FERNANDES2; CAMILLA FERRARI PASTORELLI2; HERCULES DE OLIVEIRA CARMO1;

(1) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introduction/Background: Introduction: Critically ill cardiac patients admitted to the Intensive Care Unit (ICU) exhibit high vulnerability to adverse events, including pressure injuries (PI), which are associated with increased morbidity, prolonged hospital stays, and higher hospital costs. In this context, nursing care plays a strategic role in promoting patient safety. However, evidence regarding the impact of exclusive care provided by registered nurses on quality indicators in cardiac ICUs remains limited. Objectives: Objective: To analyze the incidence of pressure injuries before and after the implementation of an exclusive direct nursing care model in a cardiac ICU. Methods: Methods: A quantitative, retrospective, quasi-experimental study conducted in a cardiac ICU of a philanthropic hospital in São Paulo, Brazil. The intervention consisted of implementing a model of exclusive direct care provided by nurses, replacing the previous care model composed of both nurses and nursing technicians. Monthly indicators were compared for the pre-intervention (March 2023 to February 2024) and post-intervention (June 2024 to May 2025) periods. The analyzed outcome was the incidence of unit-acquired stage ≥2 PI. Clinical and care variables were also analyzed, including the number of patients per month, length of stay, and SAPS III. Comparisons between periods were performed using the Mann-Whitney test, with a significance level of 5%. The study was approved by the Research Ethics Committee (Opinion No. 7,981,946). Resultados e Conclusions: Results: A total of 1,357 patients admitted to a cardiac ICU were analyzed, comparing monthly indicators before and after the implementation of exclusive direct nursing care. The periods were similar regarding the median number of patients per month (57.5 vs. 56.5; p=0.762) and median length of stay (2 vs. 2 days; p=0.514). An increase in clinical severity was observed in the post-intervention period, evidenced by a higher median SAPS III (45 vs. 42 points; p<0.001). Despite this, the incidence of stage ≥2 pressure injuries decreased from 0.6% to 0.2%, representing a statistically significant difference (p=0.045). Conclusion: Notwithstanding the increase in patient severity, exclusive direct nursing care in the cardiac ICU was associated with a reduction in the incidence of pressure injuries. This demonstrates that the model contributes to patient safety and the quality of care in critical environments.

18376

INVOLVING PEOPLE WITH HEART DISEASE IN THE VALIDATION PROCESS FOR HEALTH EDUCATION TECHNOLOGY CONTENT

MARIA LUIZA DE ALMEIDA SALVATTORI PEREIRA1; GABRIELE DE ARAUJO ANACLETO1; GABRIELLA CASSINO SILVINO1; JENNIFER CAROLINE PEREIRA MARANHÃO1; JULIANNE FABIANO MOURA1; CAMILA PEIXOTO GIORDANO1; TAINA BIGIO NOGUEIRA1; VICTORIA KATHELLIN DOS SANTOS DE ALMEIDA1; LILIAN MOREIRA DO PRADO2; RENATA FLAVIA ABREU DA SILVA1;

(1) UNIRIO - RIO DE JANEIRO - RJ - BRASIL; (2) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Health education technologies must undergo scientific analysis before being incorporated into professional practice. The first step — validating content — must take the target audience into account, despite many researchers considering only so-called experts in this process. This overlooks the varying levels of health literacy among different populations, particularly people with heart disease who have conditions that can be managed without medication. Objectives: To describe the process of validating the content of a technology with people who have heart disease. Methods: A descriptive study with a quantitative approach was conducted at a leading cardiology hospital in Rio de Janeiro between December 2025 and February 2026. Participants were selected through non-probability sampling based on the following criteria: adults over 18 years of age, regardless of gender, who were hospitalized in clinical units. The instrument contained data on participant characteristics and on the technology. The Content Validity Ratio (CVR) was used to assess the essentiality of items in the content validity data, with a one-tailed test (α = 0.05) based on the critical CVR according to the number of participants defined by Lawshe. The study adhered to all stages pertaining to research involving human subjects. Resultados e Conclusions: A total of 12 participants took part in the study. The mean age of the participants was 58 years (range 35–80 years). The majority of participants were male (66.7%; n = 8). Of the participants, 16.7% (n = 2) had not completed elementary school, 33.3% (n = 4) had completed high school, 16.7% (n = 2) had not completed high school and 33.3% (n = 4) had completed college. Eighty-one per cent (n = 9) of participants had a religious affiliation, with 55.6% (n = 5) identifying as Catholic and 44.4% (n = 4) identifying as Evangelical. Family income ranged from one minimum wage for 50% (n = 6) to between two and five minimum wages for the remaining 50% (n = 6). The critical CVR was 0.47 and of the 97 items analysed by the participants, 13 did not reach the critical CVR. Participants reported difficulty reading sentences on coloured pages or in highly stylised fonts, low identification with certain motivational phrases, low acceptance of activities based on textual records, and the necessity of changes to the humour section. The participation of people with heart disease was essential to validate the content of the developed technology.

MEASURING COMFORT IN PATIENTS WITH ACUTE MYOCARDIAL INFARCTION: INSTRUMENT VALIDITY OF A TOOL TO EVALUATE COMFORT

PEDRO LUNA FLÔRES SILVA1; AMINNE OLIVEIRA DA SILVA BASTOS1; CAMILA OLIVEIRA VALENTE1; FERNANDA CARNEIRO MUSSI2; JOSELICE ALMEIDA GÓIS1; POLLYANA PEREIRA PORTELA1; KÁTIA SANTANA FREITAS1;

(1) UNIVERSIDADE ESTADUAL DE FEIRA DE SANTANA - FEIRA DE SANTANA - BA - BRASIL; (2) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL;

Introduction/Background: Comfort is a phenomenon conceptualized as holistic and desired at different moments in the life cycle, especially during the hospitalization process(HP). The survival after an acute event provenient from cardiovascular diseases is an outcome provenient from epidemiological|demographic transition. In that way, the HP for acute myocardial infarction (AMI) is positive once the individuals survive the event, in turn, brings with it sensations and meanings capable of interfering with the comfort in the face of fear of death, finitude and worry, in addition to imposing changes in the physical, psychological and social spheres. For this reason, investigating the psychometric properties of a tool for measuring the comfort experienced by people with an AMI becomes relevant, providing properties that will confer validity and reliability on the measurement obtained. Objectives: The objective of this study is to evaluate the evidence of validity of the internal structure of the General Comfort Questionnaire-IAM. Methods: This is a cross-sectional psychometric study, which included a sample of 332 people hospitalized in an intensive care unit or inpatient units due to AMI in a cardiology specialized hospital in a city in the interior of Bahia. Data collection was conducted using the sociodemographic, clinical collection instrument and the instrument for measuring patient comfort, the GCQ-IAM. To the data analysis, it was used factorial exploratory (EFA) and confirmatory analysis (CFA). This study is allowed in conformity to Ethical Research Comity n° 1.374.838. Resultados e Conclusions: Originally, the GCQ-IAM was developed with 63 items with answers in a likert type scale 1 - totally disagree to 4 - totally agree, which had them inserted in four contexts. The factor analyzes (EFA and CFA) inferred a two-dimensional instrument model with 9 items, which have satisfactory psychometric characteristics regarding factor loadings (-0.476 - 0.724), CFI (0.927), TLI (0.899) and RMSEA (0.065) suitable. However, when analyzing the reliability results in terms of internal consistency, the ω (0.571) and the VME (0.3160) showed incipient results. Therefore, it is pertinent that there is a certain degree of caution regarding the use of the GCQ-IAM, being important to carry out new analyses to achieve better psychometric measurements, which indicates the necessity to be reevaluated with a bigger sample in a multicentric study, mainly in relation to the degree of reliability and internal consistency.

ANEXO B - Questionário Geral de Conforto para Pessoas com Infarto Agudo do Miocárdio (GCQ-IAM)

Muitíssimo obrigada por nos auxiliar neste estudo sobre o conceito de Conforto. Existem algumas afirmações abaixo as quais talvez possam descrever seu estado de conforto momento em que você responde estas questões.

Por exemplo:

Eu estou feliz por responder este questionário sobre o meu conforto.

Concordo totalmente (4); Concordo (3); Discordo (2) e Discordo totalmente (1)

1. Seu corpo está relaxado agora?	4	3	2	1
2. Você é capaz de ajudar com seu tratamento?	4	3	2	1
3. Você tem muita privacidade?	4	3	2	1
4. Quando você precisa de ajuda e atendido pelos profissionais?	4	3	2	1
5. Voce nao quer se exercitar?	4	3	2	1
6. Seu problema de saúde te deixa pra baixo?	4	3	2	1
7. Você se sente confiante em sua recuperação?	4	3	2	1
8. Você se sente dependente dos outros?	4	3	2	1
9. Você sente que sua vida é importante agora?	4	3	2	1
10. Você se sente valorizado(a) por saber que é amado(a)?	4	3	2	1

NURSING CARE AT ADMISSION OF POSTOPERATIVE VASCULAR SURGERY PATIENTS ANS ITS IMPACT ON THE INCIDENCE OF ADVERSE EVENTS

ELAINE MACHADO DE OLIVEIRA1; JEAN FRANÇOIS GIGUÈRE1; MARIA CECILIA GALLANI1; KAREN ST-PIERRE1; JANAÍNA OLIVEIRA GOIS2; GIOVANNA MARIA CAMARGO CAMPANELLA2; MEIRE CRISTINA NOVELLI CASTRO2; CLAUDIA MARIA SILVA CYRINO2;

(1) UNIVERSITÉ LAVAL - CANADA; (2) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL;

Introduction/Background: The nursing care required at admission of postoperative vascular surgery patients can be measured using the Nursing Activities Score (NAS) to identify patients' specific needs, guide targeted nursing interventions, and improve patient safety. The NAS is one of the most comprehensive tools for the prospective assessment of nursing care, as it covers 81% of nursing activities. Objectives: To analyze the association between the intensity of nursing care at admission in postoperative vascular surgery patients and the incidence of adverse events. Methods: This prospective cohort study was conducted in vascular surgery units in Brazil and Canada, from October to November 2025. The NAS instrument consists of 23 items to measure the intensity of nursing care and can be applied at admission. Spearman's correlation test was used to assess the relationship between the number of adverse events, NAS at admission and patients' variables. The linear regression model was used to assess the association between NAS at admission and the number of adverse events. The significance level was $p<0.05$. Resultados e Conclusions: In Brazil, this study included 95 patients and found 176 adverse events. The mean NAS at admission was 41.70 (SD8.74), and 100% of patients experienced at least one adverse event. In Canada, the study included 210 patients and recorded 449 adverse events; 42.00% of patients experienced at least one adverse event. The mean NAS at admission was 70.15 (SD 10.63). The most frequent adverse event in both countries was severe pain (>8.0 on a 0-10 pain intensity scale), with 309 events (64.5%) in Brazil and 93 (51.70%) in Canada. In Brazil, a correlation indicated that as age and length of stay increased, the number of adverse events also increased. There was no association between NAS at admission and the number of adverse events. In Canada, higher NAS at admission and longer length of stay, higher incidence of adverse events. Moreover, the association test confirmed a statistically significant association between NAS at admission and the number of adverse events. Each point increase in NAS at admission was associated with a 0.4 increase in the incidence of adverse events ($p<0.05$). Thus, this study highlights that the intensity of nursing care at admission may influence the incidence of adverse events. Nurses have a crucial role at the admission of postoperative vascular surgery patients, implementing targeted interventions that may help reduce the incidence of adverse events.

NURSING CARE INTENSITY AT DISCHARGE OF POSTOPERATIVE VASCULAR SURGERY PATIENTS AND 30-DAY READMISSION IN BRAZIL AND CANADA

ELAINE MACHADO DE OLIVEIRA1; JEAN FRANÇOIS GIGUÈRE1; MARIA CECILIA GALLANI1; KAREN ST-PIERRE2; JANAÍNA OLIVEIRA GOIS3; GIOVANNA MARIA CAMARGO CAMPANELLA3; MEIRE CRISTINA NOVELLI CASTRO3; CLAUDIA MARIA SILVA CYRINO3;

(1) UNIVERSITÉ LAVAL - CANADA; (2) CHU DE QUÉBEC UNIVERSITÉ LAVAL - CANADA; (3) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL;

Introduction/Background: The assessment of nursing care intensity using the Nursing Activities Score (NAS) at discharge for vascular surgery patients enables nurses to identify specific patient needs on the last day of hospitalization and supports nursing decision-making regarding appropriate care strategies to address these needs prior to discharge and reduce 30-day readmission. The NAS instrument captures 81% of nursing activities, making it one of the most comprehensive tools currently available for measuring nursing care intensity. Objectives: To evaluate the association between NAS at discharge in postoperative vascular surgery patients and 30-day readmission. Methods: This prospective cohort study was conducted in cardiovascular surgery units in Brazil and Canada during October and November 2025. The NAS instrument was used to measure the intensity of nursing care at discharge in postoperative vascular surgery patients. Readmitted and non-readmitted patients were compared in both countries. A logistic regression model was used to assess the association between NAS at discharge and 30-day readmission in Brazil and Canada. The significance level was $p<0.05$. Resultados e Conclusions: The 30-day readmission rate was 22.10% in Brazil and 10.00% in Canada. In Brazil, NAS scores at discharge for readmitted and non-readmitted patients were 60.35 (±9.93) and 57.51 (±10.42), respectively, which were higher than those observed in Canada (56.02 ± 10.82 and 54.46 ± 8.66, respectively). The most frequent postoperative nursing activities at discharge in both countries involved medication, basic hygiene, basic mobilization, multidisciplinary communication and medical record management, as well as assistance with patient transport out of the unit (NAS items 3, 4.a, 6.a, 8.b and 23). No significant association was found between NAS at discharge and 30-day readmission in either Brazil or Canada. Even so, this study makes important contributions to the management of nursing care at discharge in postoperative vascular surgery patients. The main care demands at discharge were similar in both countries, and the higher 30-day readmission rate in Brazil than in Canada may be influenced by sociocultural factors that also contribute to higher NAS at discharge. This study provides innovative insights into the management of postoperative nursing care in vascular surgery and identifies potential interventions to reduce 30-day readmissions.

NURSING WORKFORCE RECONFIGURATION FOLLOWING THE IMPLEMENTATION OF EXCLUSIVE DIRECT NURSING CARE IN A CARDIAC ICU

KAROLINE RAZIMAVICIUS BARBABADO1; ANDRÉ ALMEIDA DE MOURA1; HERCULES DE OLIVEIRA CARMO1;

(1) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction/Background: Introduction: Exclusive nursing care models are promising strategies to enhance quality and safety in critical care. In Cardiac Intensive Care Units (ICUs), clinical complexity demands workforce reorganization. However, evidence on the impact of these models on human resource indicators, such as composition, absenteeism, and turnover, remains limited. Analyzing these metrics helps understand the organizational impact of nurse-centered models in high-complexity services. Objectives: Objective: To analyze changes in workforce composition and human resource indicators following the implementation of exclusive direct nursing care in a cardiac ICU. Methods: Method: A quantitative, retrospective, quasi-experimental study conducted in a cardiac ICU of a philanthropic hospital in São Paulo, Brazil. The intervention replaced the model composed of nurses and technicians with exclusive direct care by registered nurses. Monthly indicators from pre-intervention (Mar/2023–Feb/2024) and post-intervention (Jun/2024–May/2025) periods were compared, including staff composition, absenteeism, and turnover. The Mann-Whitney test was used (5% significance level). Approved by the Ethics Committee (No. 7,981,946). Resultados e Conclusions: Results: A total of 1,198 records were analyzed. The workforce was predominantly composed of mid-level nursing technicians (49.9%), mid-level registered nurses (39.4%), and females (62.1%). A significant staff reconfiguration occurred post-intervention, with a reduction in total professionals (52.0 vs. 46.0; p=0.004), an increase in nurses (17.5 vs. 31.0; p<0.001), and a reduction in technicians (35.0 vs. 15.0; p<0.001). No significant difference was found in total absenteeism (0.01 vs. 0.01; p=0.671), nor among nurses (p=0.242) and technicians (p=0.443). Total turnover increased post-intervention (0.01 vs. 0.03; p=0.004), with no significant difference for nurses (p=0.068) or technicians (p=0.443). Conclusion: Exclusive direct nursing care led to workforce reconfiguration with more nurses and fewer technicians, without affecting absenteeism. The findings highlight relevant organizational impacts of this model on nursing human resource indicators.

RISK SCORES FOR PREDICTING MEDIASTINITIS IN CARDIAC SURGERY: AN INTEGRATIVE REVIEW

ELLEN GRANDO BLANGER1; RAFAELA HERTZOG MÖLLER1; ELLEN HETTWER MAGEDANZ1;

(1) PUCRS - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Cardiovascular diseases are one of the leading causes of death in Brazil and often require cardiac surgery. In this context, mediastinitis is a serious postoperative complication associated with high mortality, despite its low incidence. It is related to risk factors such as obesity, diabetes, and advanced age. The use of predictive risk scores allows the identification of high-risk patients, supporting prevention and reducing clinical impacts and hospital costs. Objectives: To conduct an integrative review of risk scores used to predict mediastinitis in patients undergoing cardiac surgery, considering their accuracy and the methodological quality of the studies. Methods: An integrative literature review was carried out, with searches conducted between February and April 2025 in the PubMed, LILACS, SciELO, Cochrane, Scopus, Omnis PUCRS, Web of Science, and Epistemonikos databases. Original studies published between 2010 and 2025, in Portuguese, English, or Spanish, were included. Methodological quality was assessed using the Methodological Index for Non-Randomized Studies (MINORS) instrument. Resultados e Conclusions: Of the 54 studies identified, only four met the inclusion criteria. Obesity (BMI >30 kg/m²) was the only variable common to all analyzed scores. The studies demonstrated good methodological quality and accuracy, with Med-Score 24 showing the highest MINORS score. Mediastinitis prediction scores are useful tools for identifying high-risk patients, contributing to infection prevention and the promotion of safe care. Their application in nursing practice enables individualized, evidence-based interventions, strengthening the quality of postoperative care in cardiac surgery.

TRAINING NURSING STAFF IN INPATIENT UNITS FOR ELECTROCARDIOGRAM PERFORMANCE: AUTONOMY, AGILITY, AND QUALITY OF CARE

CINTIA LAZZARI1; LARISSA LUMA TOMASI FEBRAS1; BELISA MARIN ALVES1; CASSIA CRISTINA DAMASIO DE LIMA1;

(1) HOSPITAL MOINHOS DE VENTO - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Performing electrocardiograms (ECGs) in the hospital setting is essential for the early detection of cardiac alterations. In contexts where this activity is centralized in specialized laboratories, logistical challenges emerge due to high demand and the need for rapid response in critical situations. Training nursing staff for autonomous bedside ECG performance represents a promising strategy for improving care quality and operational decentralization, a topic still underreported in national literature. Objectives: To technically train the nursing staff of inpatient units for the autonomous performance of ECGs, promoting agility in care, qualification of clinical practice, and decentralization of operational workflows. Methods: A pilot educational intervention project structured in two stages. The theoretical stage was conducted by a nurse specialist in cardiology, covering the technical fundamentals of ECG, patient care, and primary electrocardiographic alterations. The practical stage took place under supervision in a cardiology laboratory. Participants included 42 nursing professionals (nurses and technicians), who were also prepared as knowledge multipliers within their teams. Technical-operational training with a representative from the ECG equipment manufacturer was also included. Resultados e Conclusions: Forty-two professionals were trained to perform ECGs directly in the inpatient units. The intervention resulted in greater agility in emergency care, reduced demand on the centralized cardiology laboratory, and optimization of the outpatient schedule. An improvement in clinical resolution and response time to clinical occurrences was observed, alongside the strengthening of permanent education as a strategy for professional qualification and the promotion of nursing leadership. Training the nursing staff to perform ECGs contributed to the technical autonomy of the units, optimizing workflows and strengthening multidisciplinary action. The decentralization of the process represented a significant advancement in care, combining safety, efficiency, and quality of care.

13994

VARIATIONS IN POSTOPERATIVE NURSING CARE AT THE ADMISSION AND DISCHARGE OF VASCULAR SURGERY PATIENTS IN BRAZIL AND CANADA

ELAINE MACHADO DE OLIVEIRA1; JEAN FRANÇOIS GIGUÈRE1; MARIA CECILIA GALLANI1; KAREN ST-PIERRE2; JANAÍNA OLIVEIRA GOIS3; GIOVANNA MARIA CAMARGO CAMPANELLA3; MEIRE CRISTINA NOVELLI CASTRO3; CLAUDIA MARIA SILVA CYRINO3;

(1) UNIVERSITÉ LAVAL - CANADA; (2) CHU DE QUÉBEC UNIVERSITÉ LAVAL - CANADA; (3) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL;

Introduction/Background: The Nursing Activities Score (NAS) instrument measures the intensity of nursing care and can be used to identify variations in nursing care at admission and discharge of postoperative vascular surgery patients. The NAS enables nurses to meet patients' specific needs and to adjust staffing levels appropriately in order to improve the quality of care. Objectives: To compare the intensity of nursing care based the mean NAS at admission and discharge of postoperative vascular surgery patients. Methods: This prospective cohort study was conducted in vascular surgery units in Brazil and Canada from October to November 2025. The NAS is one of the most comprehensive tools for measuring nursing activities, and it was applied at both admission and discharge. McNemar's and Chi-square tests were used to compare NAS items at admission and discharge. A linear regression model was applied to assess the association between NAS admission and discharge with patients' clinical variables. The significance level was $p<0.05$. Resultados e Conclusions: This study included 91 patients from Brazil and 210 patients from Canada. In Brazil: The mean NAS at admission was lower than at discharge: 41.52 (SD9.12) and 58.14 (SD10.33), respectively. The comparison of NAS items at admission and discharge in Brazil showed an important increase in nursing care related to discharge protocols and multidisciplinary consultations (item 8.b), as well as organization to transport at discharge (item 23). NAS admission showed no significant association with patients variables, whereas NAS at discharge was associated with length of stay, number of adverse events and Charlson score. In Canada, the mean NAS at admission was higher than at discharge: 70.16 (SD10.63) and 55.86 (SD10.61), respectively. The comparison showed that nursing activities were intense in the first days of postoperative vascular surgery due to monitoring, drain care, mobilization, and bladder monitoring (items 1.b-1.c, 5, 6.b, and 17). NAS at admission was associated with length of stay and the number of adverse events, whereas NAS at discharge with length of stay. Thus, the mean NAS at admission was higher in Canada than in Brazil, whereas NAS at discharge was higher in Brazil than in Canada. Although social and cultural differences between these countries may have influenced the results, both settings highlight the importance of nurses' interventions in postoperative vascular surgery and the management of nursing care at admission and discharge to improve safety and outcomes.

CALF CIRCUMFERENCE AS A PREDICTOR OF APPENDICULAR SKELETAL MUSCLE MASS ASSESSED BY DUAL-ENERGY X-RAY ABSORPTIOMETRY (DXA) IN INDIVIDUALS WITH HEART FAILURE

MARCELLA RODRIGUES GUEDES1; TALITA RODRIGUES PARAIZO1; KELLI TRINDADE DE CARVALHO1; ANNA LUIZA CORREA DIAS1; JACQUELINE DA SILVA CABRAL1; ANA LUÍZA FERREIRA SALES1; MARCELO IMBROINISE BITTENCOURT1; FELIPE NEVES DE ALBUQUERQUE1; FABIO MAIA ABRAHAO1; MÁRCIA REGINA SIMAS TORRES KLEIN1; RICARDO MOURILHE-ROCHA1;

(1) UNIVERSIDADE ESTADUAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Sarcopenia, a disease characterized by the progressive and generalized loss of muscle strength and muscle mass (MM), is highly prevalent among individuals with heart failure (HF) and is associated with adverse outcomes. The diagnosis of sarcopenia requires costly equipment to assess MM, which is often not available in clinical practice. Thus, more cost-effective methods for measuring MM may enable early detection of sarcopenia. Although some studies suggest that calf circumference (CC) is a useful tool for estimating MM, evidence in patients with HF remains scarce. Objectives: To evaluate whether CC is a predictor of MM assessed by dual-energy X-ray absorptiometry (DXA) in patients with heart failure. Methods: A cross-sectional study including outpatients with HF with reduced ejection fraction (<40%) or mildly reduced ejection fraction (40–49%), aged ≥18 years, of both genders. Anthropometric assessment included body weight, height, and right CC. Low MM according to CC was defined as <34 cm for men (M) and <33 cm for women (W). MM was assessed by DXA (gold standard) based on appendicular skeletal muscle mass (ASMM) and the ASMM index (ASMI/height²). Low MM according to DXA was defined as ASMM <20 kg (M) and <15 kg (W), and ASMI <7.0 kg/m² (M) and <5.5 kg/m² (W). Pearson correlation analysis was used to evaluate the association between CC and ASMM and ASMI, and the Kappa test assessed the agreement for the diagnosis of low MM between CC and DXA. Resultados e Conclusions: A total of 157 individuals were evaluated, 68% (n=107) men, with mean of age of 60.1 ± 12 years and body mass index of 29.2 ± 6 kg/m², and the majority were physically inactive (75%). A strong association was observed between CC and ASMM ($r = 0.72$, $p < 0.001$) and ASMI ($r = 0.77$, $p < 0.001$). The frequency of low MM was 18% (n=28) according to CC, 19% (n=30) according to ASMM, and 13% (n=20) according to ASMI. The diagnosis of low MM based on CC showed moderate agreement of 86% (kappa = 0.53) with ASMM and reasonable agreement of 82.2% (kappa = 0.31) with ASMI. In conclusion, patients with HF with reduced or mildly reduced ejection fraction, CC shows a strong association with MM assessed by DXA and identifies low MM with moderate/reasonable agreement compared to ASMM, and may be useful for the screening of low MM in this population.

CARDIOVASCULAR DISEASES ATTRIBUTABLE TO HIGH BODY MASS INDEX: A COMPARATIVE ANALYSIS OF GLOBAL, BRAZIL, AND UNITED STATES DATA IN 2013 AND 2023.

RAFAELA MARTINS NEVES1; LETICIA EUNICE LEOTTI SANTOS1; MARCOS VINICIUS SANTOS SOUZA1; GUILHERME RAMALHO DE SOUZA1; VALÉRIA DA SILVA SANTOS FRANÇA1; ERIKA DA SILVA ARANTES1; LARISSA SANTOS LOPES2; EDUARDO FERREIRA CARVALHO1; DIEGO FONSECA OLIVEIRA BISPO1; ANA BEATRIZ DANTAS LOPES DE ALBUQUERQUE1; LUIZA ALEXANDRE DAMASCENO DE JESUS1; BRUNA GARCIA MARTINS1;

(1) UNIVERSIDADE DE RIO VERDE CAMPUS FORMOSA - FORMOSA - GO - BRASIL; (2) UNIVERSIDADE DO OESTE PAULISTA - UNOESTE - JAÚ - SP - BRASIL;

Introduction/Background: The increasing prevalence of high body mass index (BMI) has contributed to the burden of cardiovascular diseases (CVD) worldwide, representing an important modifiable risk factor. Objectives: To analyze the impact of CVD attributable to high BMI in individuals aged 20 to 54 years, comparing global, Brazilian, and United States scenarios between 2013 and 2023. Methods: An ecological, descriptive, and comparative study was conducted using secondary population-based data from the Global Burden of Disease Study (GBD), developed by the Institute for Health Metrics and Evaluation. Disability-adjusted life years (DALYs) attributable to high BMI as a risk factor for CVD were analyzed using absolute numbers, percentages, and rates per 100,000 inhabitants. Analyses were stratified by sex, age group (20–54 years), location (global, Brazil, and the United States), and years (2013 and 2023). Resultados e Conclusions: An increase in the impact of high BMI on CVD was observed across all analyzed locations in 2013 and 2023. Globally, both DALY rates and the proportion of CVD attributable to high BMI increased, reaching 13.1% in males and 14.0% in females in 2023. In Brazil, values exceeded global levels, corresponding to 14.9% and 17.8%, respectively, indicating an intermediate burden compared to the United States. The United States presented the highest burden, with DALY rates exceeding 1000 per 100,000 inhabitants. Males consistently showed higher DALY rates across all regions, reflecting greater overall disease burden. However, the proportion of CVD attributable to high BMI was higher among females, highlighting the greater relative contribution of obesity in this group. These findings reinforce the importance of obesity control strategies as a key approach to reducing the global burden of CVD.

CORRELATION BETWEEN HANDGRIP STRENGTH AND RESPIRATORY MUSCLE STRENGTH IN PATIENTS WITH HEART FAILURE

KELLI TRINDADE DE CARVALHO1; TALITA RODRIGUES PARAIZO1; MARCELLA RODRIGUES GUEDES1; ANA CAROLINA DE LACERDA FERREIRA CAPUCHO1; JACQUELINE DA SILVA CABRAL1; FABIO MAIA ABRAHÃO1; SIMONE OFFREDE REGO1; ANA LUÍZA FERREIRA SALES1; MARCELO IMBROINISE BITTENCOURT1; FELIPE NEVES DE ALBUQUERQUE1; MÁRCIA REGINA SIMAS TORRES KLEIN1; RICARDO MOURILHE-ROCHA1;

(1) HOSPITAL UNIVERSITARIO PEDRO ERNESTO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Respiratory muscle strength is frequently reduced in individuals with heart failure (HF) due to disease-related pathophysiological changes. This decline is associated with reduced functional capacity and worse clinical outcomes. Despite its prognostic relevance, the assessment of respiratory muscle strength is not routinely available in clinical practice. In this context, handgrip strength (HGS) emerges as a simple and accessible measure of peripheral muscle strength, also associated with clinical outcomes. Nevertheless, evidence evaluating the association between these measures in individuals with HF remains scarce. Objectives: To evaluate the association between HGS and respiratory muscle strength in patients with HF. Methods: A cross-sectional study including outpatients with HF with reduced ejection fraction (HFrEF) or mildly reduced ejection fraction (HFmrEF), aged ≥18 years, of both genders. Exclusion criteria were individuals with body mass index (BMI) ≤18.5 kg/m², pregnant or lactating women and those with other chronic inflammatory diseases. Peripheral muscle strength was assessed using HGS with a dynamometer, and low muscle strength was defined as HGS <27 kg in men and <16 kg in women. Respiratory muscle strength was measured by manovacuometry (analog manovacuometer with a measurement range of −150 to +150 cmH□O), obtaining maximal inspiratory pressure (MIP) and maximal expiratory pressure (MEP). Three maneuvers were performed for both MIP and MEP, with a 15-second interval between measurements, and were considered valid if sustained for at least two seconds and performed without air leaks. Resultados e Conclusions: A total of 158 patients were evaluated: 68% (n=107) men, 58.2% (n=92) non-smokers and 39.2% (n=62) former smokers, with mean of age of 60 ± 13 years and BMI of 29.2 ± 6 kg/m². The majority had HFrEF (84%) and were classified as New York Heart Association functional class I (45%) or II (40%), and 75% were physically inactive. HGS showed a moderate positive correlation with MEP (r = 0.62; p < 0.001) and a weak negative correlation with MIP (r = −0.33; p < 0.001). Patients with low HGS had lower MEP values (65 ± 19 vs. 82 ± 29 cmH□O; p = 0.01). Conclusion: In outpatients with HFrEF or HFmrEF, HGS shows a moderate association with expiratory muscle strength. This finding suggests that low HGS may indicate impaired respiratory muscle strength.

FOOD AND NUTRITION EDUCATION PROGRAM TO COMBAT CARDIOVASCULAR RISK FACTORS IN PUBLIC SCHOOLS IN THE STATE OF SÃO PAULO, BRAZIL

ANA PAULA QUEIROZ MELLO1; DANIELE SOUZA PAULA1; PRISCILLA PANDOLFO OLIVEIRA1; BIANCA BATISTA BARBOSA2; TAIS RIBEIRO SILVA PINTO2; PALOMA ALMEIDA OLIVEIRA1; LUIS ALBERTO MORENO AZNAR3; NAGILA RAQUEL TEIXEIRA DAMASCENO4;

(1) CENTRO UNIVERSITARIO SAO CAMILO - SÃO PAULO - SP - BRASIL; (2) CENTRO UNIVERSITARIO SAO CAMILO - SAO PAULO - SP - BRASIL; (3) UNIVERSIDADE DE ZARAGOZA - SPAIN; (4) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction/Background: Inadequate nutrition is a major risk factor for obesity and cardiovascular diseases. Therefore, promoting healthy eating habits from childhood is essential. Schools and educators play a central role in individual development, acting as key allies in building knowledge, autonomy in food choices, and healthier food systems. Thus, the school environment stands out as a fundamental tool to encourage healthier choices aimed at preventing obesity and cardiovascular diseases. Objectives: To characterize participants of the "Food and Nutrition Education Program – Integrating Science, School, and Health" (PEDUCA) and its territorial coverage in order to strengthen cardiovascular disease prevention strategies in public schools in the State of São Paulo, Brazil. Methods: Through a Brazilian partnership among universities, a Cardiology Society, and the State Department of Education — responsible for more than 5,000 schools and 3 million students — a 100% online, 110-hour distance-learning course was developed to train public school educators, called PEDUCA. PEDUCA is a strategic tool designed to prepare educators to become multipliers of food and nutrition education aimed at reducing cardiovascular risk factors from childhood. The program covered topics related to nutrition and healthy eating. The study was approved by the Research Ethics Committee. Resultados e Conclusions: A total of 6,656 individuals enrolled in PEDUCA, including 5,310 (80%) women and 4,047 (61%) self-reported White participants. Approximately one quarter of participants were from schools located in the city of São Paulo (10%), while the remainder were from coastal and inland regions of the state (90%). See Figure 1. The median age of participants was 43.0 (37.0–49.8) years, and the median body mass index was 27.1 (24.1–30.9) kg/m². At the end of the program, all participants developed a healthy eating activity to be implemented in their schools, and the best activities were published in an e-book and widely disseminated through mass communication channels.It is expected that educator training will stimulate more effective pedagogical actions promoting healthy eating habits in schools, contributing to the prevention of obesity and cardiovascular diseases.

VASCULAR HEALTH, NUTRITION, AND BODY COMPOSITION IN WOMEN ACROSS AGES

THIAGO DIPP1; GABRIELLY KENNE1; HELENA ROSETTI1; JÚLIA PEREIRA AVILA1; BETINA FOSSATI CHISTÉ FLORIAN1; ISABELLA RONCHETTI MARTINS XAVIER1; DIEGO LUAN DA CRUZ ARAÚJO1; ANDREI SILVA RECKZIEGEL1; SOFIA ZONTA BISCHOFF1; PEDRO CAMPANEL BERTOLETTI1; BRUNA EIBEL1; CLAUDIA FETTER1;

(1) UNISINOS - SÃO LEOPOLDO - RS - BRASIL;

Introduction/Background: Arterial stiffness is an important marker of vascular aging, associated with an increased risk of cardiovascular disease. In addition to age, anthropometric and dietary factors (especially sodium intake) are related to vascular dysfunction and cardiovascular risk. Objectives: To evaluate arterial stiffness and its association with anthropometric profile and dietary intake in women of different age groups. Methods: Cross-sectional analytical study (CAAE: 85730024.9.0000.5333) including women aged 18 to 59 years. Sociodemographic, clinical, and anthropometric data (body mass index [BMI], abdominal circumference [AC]) were collected. A 24-hour dietary recall (R24h) was used to assess dietary intake. Arterial stiffness was evaluated by pulse wave velocity (PWV; Arteris AOP device). Data normality was assessed, and descriptive analyses were performed using mean ± (SD) and absolute and relative frequencies. Independent samples t-tests and Pearson correlation were applied, with statistical significance set at $p \leq 0.05$ (JASP v0.96). Resultados e Conclusions: The sample consisted of 59 women divided into young (YG; n=31) and adults (AD; n=28). There was a difference in age (YG: 20.9 ± 2.2 vs AD: 38.3 ± 11.1 years; p=0.001). Most participants were white (88.1%) and had completed or incomplete higher education (83.1%). Regarding cardiovascular risk factors, 46% (n=23) were overweight/obese, 25.4% (n=15) were physically inactive, 11.9% (n=7) reported smoking, 25.6% (n=15) reported irregular menstrual cycles, and 59.3% (n=35) reported a family history of cardiovascular disease. No differences were observed in AC (p=0.275), total caloric intake (p=0.547), carbohydrate (p=0.350), protein (p=0.831), lipids (p=0.107), sodium (p=0.610), calcium (p=0.860), iron (p=0.150), vitamin C (p=0.299), vitamin B12 (p=0.686), unsaturated fatty acids (p=0.906), saturated fatty acids (p=0.828), fiber (p=0.122), and total cholesterol (p=0.140) between age groups. Similarly, no associations were identified between PWV and dietary parameters. There was a difference in PWV between groups (YG: 4.60 ± 0.45 vs AD: 5.84 ± 1.15 m/s; p=0.001). In adult women, there was an increase in arterial stiffness, indicating that changes in vascular function may occur early. However, there were no significant differences in dietary intake, anthropometric data, or the relationship between these factors and vascular function.

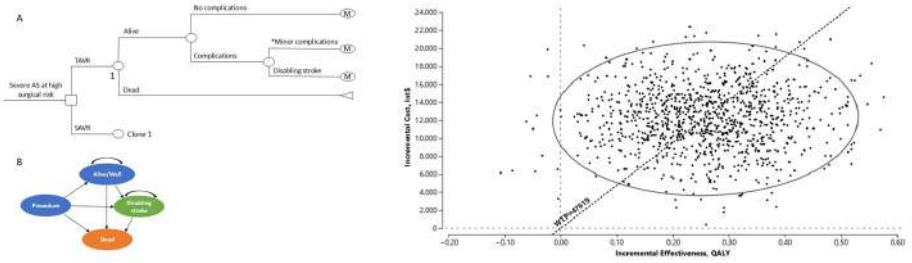
CLINICAL AND ECHOCARDIOGRAPHIC OUTCOMES AFTER TRANSCATHETER EDGE-TO-EDGE REPAIR IN ATRIAL SECONDARY MITRAL REGURGITATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

CAIO RODRIGUES ROSA1; MARIA CELESTE ROCHA1; BEATRIZ MIGUEL VENTURA1; PEDRO CHARBEL MARTINS EL TAOUIL1; FLAVIO DE ALMEIDA ROSA2;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (2) ANGIOCARDIO LINHARES - LINHARES - ES - BRASIL;

Introduction/Background: Atrial secondary mitral regurgitation (aSMR) is a distinct phenotype of functional mitral regurgitation characterized by left atrial enlargement and mitral annular dilatation in the setting of structurally normal leaflets and preserved left ventricular function. Transcatheter edge-to-edge repair (TEER) may provide therapeutic benefit in this population, although high-quality evidence remains limited. Objectives: To evaluate clinical outcomes following TEER in adults with moderate-to-severe or severe aSMR through a systematic review and single-arm meta-analysis. Methods: PubMed, Embase, LILACS, Scopus, Cochrane Central, and ClinicalTrials.gov were systematically searched according to PRISMA guidelines, identifying observational studies, multicenter registries, and sub-analyses of randomized controlled trials reporting outcomes of TEER in adult patients with moderate-to-severe or severe aSMR. Studies using equivalent definitions, such as atrial functional mitral regurgitation, were also eligible when the atrial-driven mechanism was preserved. The primary outcome was all-cause mortality, mitral regurgitation (MR) reduction (≤2+ or ≤1+), and improvement in New York Heart Association (NYHA) functional class (≤II). Resultados e Conclusions: After screening 297 records, sixteen studies comprising 2,872 patients with aSMR undergoing TEER were included. All-cause mortality showed a pooled prevalence of 10.96 events per 100 patients (95% CI 6.21–18.64; I²=87.9%). Mitral regurgitation reduction to ≤2+ after intervention was achieved in 96.48% of patients at follow-up (95% CI 93.54–98.11%; I²=60.7%). For MR reduction to ≤1+, subgroup analyses demonstrated a pooled prevalence of 78.91% at 30-day follow-up (95% CI 72.22–84.34%; I²=81.4%) and 75.19% at longer-term follow-up (≥1 year) (95% CI 67.31–81.69%; I²=89.0%). Improvement to NYHA functional class ≤II at follow-up was achieved in 72.42% of patients (95% CI 61.63–81.04%; I²=86.3%). Considerable between-study heterogeneity was observed, likely related to differences in follow-up duration, variability in patient characteristics, and devices used. Transcatheter edge-to-edge repair in patients with ASMR demonstrates high procedural success, with sustained reduction in mitral regurgitation and functional improvement in the majority of patients. Although all-cause mortality remains notable, TEER appears to be a viable therapeutic option. Further randomized controlled trials are needed to confirm long-term efficacy and identify optimal patient selection criteria.



16301

COST-EFFECTIVENESS OF TRANSCATHETER AORTIC VALVE REPLACEMENT IN HIGH-SURGICAL-RISK PATIENTS WITH SEVERE AORTIC STENOSIS IN BRAZIL

GUILHERME AUGUSTO REISSIG PEREIRA1; CARISI ANNE POLANCZYK2; ANA PAULA BECK DA SILVA ETGES3; RODRIGO PETERSEN SAADI4; EDUARDO GEHLING BERTOLDI1;

(1) PPG CARDIOLOGIA - UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL; (2) FACULDADE DE MEDICINA - UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL; (3) INSTITUTO DE AVALIACAO DE TECNOLOGIA EM SAÚDE - PORTO ALEGRE - RS - BRASIL; (4) HOSPITAL MAE DE DEUS - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: In patients with severe aortic stenosis at high surgical risk, randomized trials have demonstrated noninferiority of transcatheter aortic valve replacement (TAVR) compared with surgical aortic valve replacement (SAVR) for all-cause mortality at 5-year follow-up. However, TAVR continues to be a high-cost intervention, and its wider adoption may considerably increase the healthcare budget burden in middle-income countries such as Brazil Objectives: To conduct a cost-utility analysis comparing TAVR and SAVR in patients with severe aortic stenosis at high surgical risk, from the perspective of the Brazilian Unified Health System (Sistema Único de Saúde – SUS). Methods: A Markov model was developed to simulate a hypothetical cohort of patients with severe aortic stenosis over a lifetime horizon. A systematic review was performed to inform efficacy and effectiveness inputs. Cost data were derived from Brazilian patient cohorts who underwent TAVR or SAVR and were expressed in international dollars (Int$). A willingness-to-pay (WTP) threshold of three times Brazil's Gross Domestic Product per capita (Int$ 47,619) was adopted. Incremental-cost effectiveness ratios (ICERs) were calculated, and sensitivity analyses were performed. Resultados e Conclusions: The estimated lifetime cost was Int$ 29,897 for TAVR and Int$ 17,666 for SAVR. Lifetime quality-adjusted life-years (QALYs) were 4.70 and 4.44, respectively. The ICER for TAVR was Int$ 46,532 per QALY. The model results were most sensitive to variations in TAVR costs, followed by annual probability of disabling stroke after SAVR and TAVR, and SAVR costs. In probabilistic sensitivity analysis with 10,000 iterations, TAVR was associated with higher costs and greater QALY gains compared with SAVR. The ICER was below the WTP threshold in 52.2% of iterations and exceeded this threshold in 46.9%. In patients with severe aortic stenosis at high surgical risk, TAVR was cost-effective from the perspective of the Brazilian Unified Health System. However, probabilistic sensitivity analysis indicated that TAVR was cost-effective in 52.2% of simulations at Brazilian WTP threshold, reflecting substantial uncertainty in the base-case analysis. These results were mainly influenced by cost differentials between strategies, largely driven by device acquisition costs. Accordingly, reductions in prosthesis prices or alternative procurement strategies could substantially affect the economic value of TAVR.

COST-EFFECTIVENESS OF TRANSCATHETER AORTIC VALVE REPLACEMENT IN PATIENTS WITH SEVERE AORTIC STENOSIS AND LOW SURGICAL RISK: PERSPECTIVE OF THE BRAZILIAN PUBLIC HEALTH SYSTEM

GUILHERME AUGUSTO REISSIG PEREIRA1; CARISI ANNE POLANCZYK2; ANA PAULA BECK DA SILVA ETGES3; RODRIGO PETERSEN SAADI4; EDUARDO GEHLING BERTOLDI1;

(1) PPG CARDIOLOGIA - UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL; (2) FACULDADE DE MEDICINA - UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL; (3) INSTITUTO DE AVALIAÇÃO DE TECNOLOGIA EM SAÚDE - PORTO ALEGRE - RS - BRASIL; (4) HOSPITAL MAE DE DEUS - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Randomized controlled trials comparing transcatheter aortic valve replacement (TAVR) with surgical aortic valve replacement (SAVR) in patients with severe aortic stenosis and low surgical risk have demonstrated noninferiority of TAVR regarding all-cause mortality and stroke outcomes in 6-, 7-, and 10-year follow-up. Nevertheless, TAVR remains a costly intervention, and its widescale adoption may affect healthcare expenditure in middle-income countries such as Brazil. Objectives: This study aimed to conduct a cost-utility analysis comparing TAVR and SAVR in patients with severe aortic stenosis at low surgical risk, from the perspective of the Brazilian Unified Health System (Sistema Único de Saúde – SUS). Methods: A Markov model was developed to simulate a hypothetical cohort of patients with severe aortic stenosis over a lifetime horizon. A systematic review was performed to inform efficacy and effectiveness inputs. Cost data were derived from Brazilian patient cohorts who underwent TAVR or SAVR and were expressed in international dollars (Int$). Incremental-cost effectiveness ratios (ICERs) were calculated and sensitivity analyses were performed. Resultados e Conclusions: The estimated lifetime cost was Int$ 32,189 for TAVR and Int$ 19,717 for SAVR. Lifetime quality-adjusted life-years (QALYs) were 10.03 and 9.81, respectively. The ICER for TAVR was Int$ 55,878 per QALY gained, exceeding the Brazilian willingness-to-pay threshold of Int$ 47,619 per QALY. In the one-way sensitivity analysis, model results were most sensitive to variations in costs of TAVR, followed by annual probability of disabling stroke after TAVR and SAVR, and by SAVR costs. In the threshold analysis of TAVR costs, TAVR became cost-effective when its cost decreased below Int$ 24,171, at which point the ICER crossed the predefined willingness-to-pay threshold. In probabilistic sensitivity analysis with 1,000 iterations, TAVR was cost-effective in 37% of simulations. In patients with severe aortic stenosis at low surgical risk, TAVR was not a cost-effective strategy compared with SAVR from the perspective of the Brazilian Unified Health System. Nevertheless, probabilistic sensitivity analysis showed that TAVR was cost-effective in 37% of simulations, indicating residual uncertainty around the base-case estimate. These findings were primarily driven by cost differences between strategies, largely attributable to device acquisition costs.

RAFAEL LAURIA OLIVEIRA1; LUIZ ANTONIO FERREIRA CARVALHO1; ALEXANDRE SICILIANO COLAFRANCESCHI2; ANDRE LUIZ SILVEIRA SOUSA3; FABIULA SCHWARTZ AZEVEDO2;

(1) HOSPITAL PRO CARDIACO - RIO DE JANEIRO - RJ - BRASIL; (2) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL; (3) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL;

Introduction/Background: Accurate risk stratification remains a key component of clinical decision-making in patients undergoing transcatheter aortic valve replacement (TAVR), supporting patient selection, procedural planning, and Heart Team discussions. Several TAVR-specific risk models have been developed to estimate early mortality risk, including STS/ACC TVT, FRANCE-2, OBSERVANT, IRRMA, UNN OUS, and GAVS. However, model performance may vary when applied to populations different from those in which they were originally derived, reinforcing the importance of external validation in contemporary real-world cohorts. Objectives: To evaluate the discriminatory performance of established TAVR-specific risk scores for predicting in-hospital mortality in a Brazilian cohort. Methods: Cross-sectional analysis of a longitudinal cohort including consecutive patients with severe symptomatic native fibrocalcific aortic stenosis undergoing TAVR between 2009 and 2023 at a tertiary referral center. Clinical and procedural data were prospectively collected in an institutional registry. The primary outcome was in-hospital mortality according to VARC definitions. Discriminatory performance of STS/ACC TVT, FRANCE-2, OBSERVANT, IRRMA, UNN OUS, and GAVS scores was assessed using the area under the receiver-operating characteristic curve (AUC). Resultados e Conclusions: A total of 270 patients were included, with an observed in-hospital mortality rate of 4.4%. Discriminatory performance varied across models (Figure 1). GAVS showed the highest discrimination (AUC 0.843), followed by IRRMA (0.775), STS/ACC TVT (0.737), OBSERVANT (0.728), UNN OUS (0.692), and FRANCE-2 (0.652). In this cohort, GAVS demonstrated the greatest ability to discriminate in-hospital mortality after TAVR, supporting its potential clinical usefulness for risk stratification and contributing to more informed decision-making in contemporary practice.

Figure 1. Receiver-operating characteristic curves of TAVR-specific risk scores for in-hospital mortality.

Model	c-statistic	confidence interval	p
GAVS	0.843	[0.720 - 0.966]	<0.001
IRRMA	0.775	[0.617 - 0.933]	<0.001
STS/ACC TVT	0.737	[0.551 - 0.923]	0.012
OBSERVANT	0.728	[0.530 - 0.927]	0.024
UNN OUS	0.692	[0.528 - 0.855]	0.022
FRANCE 2	0.652	[0.493 - 0.812]	0.061

EPIDEMIOLOGY OF VALVE DISEASE IN BRAZIL FROM 1990 TO 2023: OPPOSITE TRENDS FOR RHEUMATIC AND DEGENERATIVE VALVE DISEASE.

BRUNO RAMOS NASCIMENTO1; RONEY ORISMAR SAMPAIO2; CRAIG SABLE3; GABRIEL RODRIGUES DE ANGELO4; BRENNO AUGUSTUS ALVES DOS SANTOS4; KLICIA JARDIM PEREIRA4; MARIA LUIZA BOZZI SOARES SANTIAGO4; PEDRO PAULO CUIM BERNARDO4; BRUNA CANGUSSU FREITAS5; GLAUCIA MARIA MORAES DE OLIVEIRA6; LUISA CAMPOS CALDEIRA BRANT1; ANTONIO LUIZ PINHO RIBEIRO1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (2) DEPARTAMENTO DE CARDIOLOGIA, UNIVERSIDADE DE SÃO PAULO - SÃO PAULO - SP - BRASIL; (3) OCHSNER HEALTH - UNITED STATES; (4) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (5) FACULDADE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (6) DEPARTAMENTO DE CARDIOLOGIA, UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Valvular heart disease (VHD) in Brazil reflects an ongoing epidemiologic transition, with persistent rheumatic heart disease (RHD) coexisting with increasing non-rheumatic valvular disease (NRVD), particularly degenerative etiologies, in the context of population aging and regional socioeconomic disparities. Objectives: To evaluate temporal trends in the burden of RHD and NRVD in Brazil from 1990 to 2023. Methods: We conducted an ecological analysis using estimates from the Global Burden of Disease (GBD) 2023 study, which applies standardized modeling frameworks integrating multiple data sources, Bayesian meta-regression (DisMod-MR), and cause-of-death ensemble models to estimate prevalence and mortality with 95% uncertainty intervals (UI) across time. Analyses included age-standardized and all-age metrics. Resultados e Conclusions: From 1990 to 2023, RHD prevalence increased in absolute numbers from 928,994.8 (95% UI 759,829.0–1,091,063.6) to 1,425,985.8 (1,158,391.9–1,729,730.5), but the age-standardized prevalence rate remained stable (638.7 to 628.9 per 100,000; −1.5% [−4.1 to 1.0]). In contrast, NRVD prevalence rose markedly from 131,838.4 (114,152.5–152,244.1) to 492,109.7 (416,005.0–576,511.6), with an increase in age-standardized rates from 151.4 to 186.3 per 100,000 (+23.0% [18.5–27.6]) and consistent increases across age groups and sexes. This increase was driven primarily by degenerative aortic valve disease, which reached 378,347.6 cases (302,669.2–463,214.0) in 2023 (+34.7% [27.9–41.5]), while degenerative mitral valve disease showed relative stability (−4.4% [−6.0 to −2.7]). Mortality trends also diverged. RHD deaths increased slightly in absolute numbers (2,775.5 to 3,017.9), but age-standardized mortality rates declined substantially from 2.6 to 1.2 per 100,000 (−54.2% [−58.2 to −49.6]). NRVD deaths more than doubled (2,416.5 to 5,640.9), yet age-standardized mortality decreased modestly from 2.8 to 2.2 per 100,000 (−22.1% [−27.7 to −14.7]), largely driven by degenerative aortic valve disease and aging-related risk profiles. In conclusion, Brazil exhibits clear opposite trends in VHD epidemiology: declining age-standardized burden of RHD alongside rising prevalence of degenerative NRVD, particularly aortic stenosis, reflecting demographic transition. These findings reinforce the need for integrated strategies addressing both prevention of RHD and management of age-related valve disease.

INFECTIVE ENDOCARDITIS: THE GREAT IMITATOR

NATÁLIA RODRIGUES QUERIDO FORTES1; BRENO FERREIRA TERRA MASSIÈRE2; BERNARDO VIEIRA RAMOS DE ALBUQUERQUE E SILVA2; BERNARDO DE MOURA JAPIASSÚ GONÇALVES2; BEATRIZ MACIAS KIRK2; CLAUDIO QUERIDO FORTES1;

(1) INSTITUTO DO CORACAO EDSON SAAD/UFRJ - RIO DE JANEIRO - RJ - BRASIL; (2) IDOMED/ESTACIO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Infective endocarditis (IE) is a devastating disease that, if not properly treated, progresses inexorably to a fatal outcome. Even with appropriate therapy, its lethality remains high, with in-hospital mortality around 20%, reaching up to 41.3% in some centers in Brazil. In recent decades, there has been a significant increase not only in its incidence but also in its mortality. Its clinical relevance is further emphasized by its ability to present in highly variable ways, making it essential that physicians across multiple specialties are familiar with the disease. This variability has led IE to be compared to syphilis as a "great imitator." Nevertheless, this characteristic remains underexplored in the medical literature. Objectives: To describe the initial diagnostic hypotheses at hospital admission among patients with infective endocarditis in a university hospital, and to evaluate whether there are differences in mortality between patients diagnosed with IE at admission and those diagnosed later during hospitalization. Methods: This is a retrospective cohort study including episodes of infective endocarditis classified as definite according to the modified Duke criteria (2023), in patients treated at a public university hospital in Brazil between 2001 and 2024. Data were extracted from patient records included in the Infective Endocarditis Collaborative Study database, approved by the institutional Ethics Committee (CONEP No. 986/2001). A structured data collection form was used to obtain demographic data, clinical manifestations at admission and during hospitalization, laboratory results, microbiological cultures, imaging findings, clinical and surgical treatments, and outcomes. Data were entered into Microsoft Access, exported to Excel, and analyzed using SPSS. Resultados e Conclusions: Results: From 2004 to 2024, 176 episodes of definite infective endocarditis (IE) were identified in 165 adults admitted to a university hospital. IE was suspected at admission in 71 episodes, while 105 initially received alternative diagnoses. The most frequent were fever of unknown origin, bloodstream infection, respiratory infection, heart failure, tuberculosis, urinary tract infection, and anemia of unknown etiology. Conclusion: IE can mimic multiple diseases, reinforcing the need for a high index of clinical suspicion across diverse clinical presentations. Although no statistically significant mortality difference was demonstrated, delayed suspicion of IE was associated with a trend toward worse outcomes.

Table 1 – Main Initial Diagnostic Hypotheses at Admission in Patients with Infective Endocarditis Not Initially Suspected (n = 105)

Initial Diagnostic Hypothesis	Patients, n (%)
Fever of unknown origin	22 (21.0)
Bloodstream infection	15 (14.3)
Respiratory infection	14 (13.3)
Heart failure	13 (12.4)
Tuberculosis	13 (12.4)
Urinary tract infection	10 (9.5)
Anemia of unknown etiology	9 (8.6)
Other diagnoses	9 (8.6)
Total	**105 (100)**

LEFT VENTRICULAR DIASTOLIC DYSFUNCTION IN RHEUMATIC MITRAL STENOSIS: THE ROLE OF LEFT VENTRICULAR COMPLIANCE

NAYANA FLAMINI ARANTES GOMES1; SARA REGINA SILVA CUPERTINO1; ANA BEATRIZ DA CRUZ PESSOA1; KLICIA JARDIM PEREIRA1; DANIELLY RAMOS PEREIRA1; ISABELLA DE OLIVEIRA DUARTE1; SILVIO MENDES DE MAGALHÃES1; VICENTE REZENDE SILVA1; IGOR FERREIRA DE SALES1; GUILHERME RAFAEL SANT ANNA ATHAYDE1; MARIA DO CARMO PEREIRA NUNES1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Assessment of left ventricular (LV) diastolic function in patients with rheumatic mitral stenosis (MS) remains challenging due to the limited applicability of conventional echocardiographic parameters in this population. With advances in MS management, patients are living longer, accumulating comorbidities, and frequently presenting with symptoms disproportionate to mitral valve area (MVA), raising suspicion of concomitant heart failure with preserved ejection fraction (HFpEF). Objectives: To identify clinical, echocardiographic, and laboratory determinants of LV diastolic dysfunction and evaluate its prognostic significance in patients with rheumatic MS. Methods: In this prospective study, consecutive patients with rheumatic MS referred for percutaneous balloon mitral valvuloplasty (PBMV) underwent comprehensive clinical, echocardiographic, and laboratory evaluation, including B-type natriuretic peptide (BNP). LV diastolic function was assessed invasively using LV compliance, calculated as stroke volume divided by LV diastolic pressure rise. Reduced LV compliance (lowest quartile) defined diastolic dysfunction. Determinants were assessed using logistic regression, and the association with outcomes, composite of atrial fibrillation, embolic events, need for mitral valve reintervention, and death, was evaluated using Cox models. Resultados e Conclusions: Results: Among 323 patients (age 46 ± 12 years; 86% women), median LV compliance was 5.7 mL/mmHg (IQR: 3.7–7.8), with 83 patients (21%) exhibiting reduced compliance. Reduced LV compliance was independently associated with hypertension (OR 1.99; 95% CI 1.01–3.92; p=0.047), atrial fibrillation (OR 2.09; 95% CI 1.06–4.13; p=0.034), higher BNP levels (OR 1.002 per unit; 95% CI 1.001–1.003; p=0.035), and increased mean pulmonary artery pressure (OR 1.04; 95% CI 1.01–1.07; p=0.004). The model demonstrated good discrimination (C-statistic 0.72). Over a mean follow-up of 3.6 years, 136 events occurred. Reduced LV compliance was associated with lower event-free survival (Figure 1), although this association was attenuated after adjustment for post-procedural variables. Conclusions: Reduced LV compliance identifies a distinct phenotype of diastolic dysfunction in rheumatic MS, associated with comorbidities, hemodynamic burden, and adverse clinical outcomes. However, its prognostic impact appears to be modulated by post-interventional hemodynamic status, underscoring the central role of mitral obstruction relief in determining long-term outcomes.

MYOCARDIAL WORK AS AN EARLY MARKER OF CARDIAC ATTR AMYLOIDOSIS

VIVIANE TIEMI HOTTA1; NATHALIA CONCI SANTORIO1; NATALIA MELO PEREIRA1; GARDENIA DA SILVA LOBO OISHI1; BRUNO VAZ KERGES BUENO1; FABIO FERNANDES1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction/Background: Background: Cardiac involvement by transthyretin amyloidosis (ATTR-CA) has been recognized as an important but under diagnosed cause of heart failure (HF). Myocardial work (MW) analysis by echocardiography incorporates load conditions data with advantages over solely strain curves and has been recognized as a promising variable for the analysis of myocardial dysfunction. Objectives: The aim of this study was to characterize parameters of cardiac mechanics and MW in patients with ATTR with without cardiac involvement. Methods: Methods: Single-center, prospective study of 42 patients with ATTR amyloidosis with (N = 22) and without cardiac involvement (N = 20). All patients were submitted to a clinical evaluation and transthoracic echocardiogram (TTE). Patients underwent conventional TTE, analysis of myocardial deformation and MW using the speckle tracking technique. The exams were performed on the Vivid E95 GE Vingmed, Norway and later evaluated offline using Echopac v203, GE Healthcare. Resultados e Conclusions: Results: Most patients in both groups were male. Patients ATTR without CA were younger (p < 0.001). In the ATTR-CA patients, most patients had atrial fibrillation and were on optimized medical therapy. Most patients had hereditary ATTR (ATTRh), with the majority (50%) carrying the Val142Ile variant. There were no differences between blood pressure, heart rate and body mass index between the groups. Patients with ATTR-CA presented greater values of interventricular septum (p=0.024) and posterior wall thickness (p=0.01), as well as left ventricular mass index (p<0.0001), relative wall thickness (p<0.0001) and lower values of LVEF. Indexed biatrial volumes and RA pressure (p=0.03) were greater in the ATTR-CA group (LA, p=0.03; RA, p=0.043). RV thickness was increased and RV systolic function were impaired in the ATTR-CA. Despite normal conventional TTE parameters values, patients in the group ATTR without CA had slightly reduced values of LV global longitudinal strain (GLS). Interestingly, global MW index, global constructive work and myocardial efficiency were reduced in these patients while global myocardial wasted work were increased. Conclusions: Despite normal clinical and conventional echocardiography parameters, patients with ATTR without CA present a slight reduction in LV GLS and significant abnormalities in myocardial work parameters suggesting a potential role of this tool in identifying ¬¬¬¬¬¬¬¬incipient myocardial dysfunction in these patients.

PATTERNS OF VALVULAR INVOLVEMENT IN RHEUMATIC HEART DISEASE: INSIGHTS FROM A LARGE CONTEMPORARY COHORT

ADSON PATRIK VIEIRA CARVALHO1; MARIA CLARA DE MORAES VERAS PEREIRA1; NICOLE VALENTINO FERREIRA1; HELENA DELORT1; JOANA CASTRO SILVA DA GAMA1; JUAN GABRIEL SOUSA SOARES1; NATALIA SANTOS KLEIN1; ANA BEATRIZ PESSOA1; MARIA DO CARMO PEREIRA NUNES1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Rheumatic heart disease (RHD) remains a leading cause of valvular morbidity worldwide, yet contemporary data on patterns of valve involvement in adults are limited. Objectives: To describe the spectrum and distribution of valvular involvement in a large cohort of patients with RHD. Methods: We analysed consecutive patients with echocardiographically confirmed RHD referred to our institution for valvular disease management between February 2011 and January 2026. Rheumatic involvement was defined by classical echocardiographic features, including leaflet tip thickening, commissural fusion, subvalvular thickening and fusion, restricted leaflet mobility, and the presence of valvular disfunction either regurgitation or stenosis. Resultados e Conclusions: A total of 903 patients were included (mean age 48.5 ± 12.4 years; 84% women). Most patients were symptomatic, with 38% in NYHA class II and 37% in class III–IV. The cohort was predominantly White (53%), followed by Black (28%) and other ethnic groups. Isolated mitral valve involvement was the most common pattern (469 patients, 52%), followed by combined mitral and aortic valve disease (379, 42%). Multivalvular involvement including mitral, aortic, and tricuspid valves was observed in 36 patients (4.1%), while mitral and tricuspid involvement occurred in 13 patients (1.4%). Pulmonary valve involvement was rare, identified in a single case associated with mitral stenosis (Figure 1). In this large contemporary RHD cohort, mitral valve involvement predominates, either in isolation or in combination with aortic disease, whereas right-sided and pulmonary valve involvement are uncommon. These findings reinforce the central role of mitral pathology in RHD and highlight the relative rarity of isolated right-sided disease, with potential implications for diagnostic strategies and management planning.

PREDICTORS OF MITRAL RESTENOSIS FOLLOWING PERCUTANEOUS MITRAL COMISSUROTOMY IN PATIENTS WITH RHEUMATIC MITRAL STENOSIS

VICENTE REZENDE SILVA1; LAURA MUSTAFÁ UMBELINO VIEIRA1; DANIELLY RAMOS PEREIRA1; CAROLINA MADSEN DOS SANTOS1; ISABELLA DE OLIVEIRA DUARTE1; EDUARDO ENRIQUE CARVALHO GRADE VALLEJO1; JOÃO GABRIEL FRANCISCO RODA1; NAYANA FLAMINI ARANTES GOMES1; ADSON PATRIK VIEIRA CARVALHO1; MARILDES LUIZA DE CASTRO1; WILLIAM ANTÔNIO DE MAGALHÃES ESTEVES1; MARIA DO CARMO PEREIRA NUNES1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Percutaneous mitral commissurotomy (PMC) is the primary choice of therapy for patients with rheumatic mitral stenosis (MS). However, restenosis can develop over time, becoming the main cause of functional deterioration after successful PMC. Objectives: This study aims to assess the incidence of mitral restenosis and identify the primary factors associated with its occurrence after a successful PMC in patients with rheumatic MS. Methods: This is a cohort of patients with rheumatic MS who have undergone PMC between January 1995 and May 2023, followed at the hospital. The primary outcome was the development of clinically significant mitral restenosis, defined as a reduction in mitral valve area (MVA) to less than 1.5 cm², resulting in cardiovascular death, the need for repeat PMC, or the indication for mitral valve replacement. Cox proportional hazards regression model was performed to identify pre and post procedural variables predictors of mitral restenosis. Resultados e Conclusions: A total of 379 patients were included in the study, with a mean age of 41.8 ± 12.1 years, and 321 patients were women (84.7%). The median follow-up time was 6.18 years (IQR 2.93-10.43). Restenosis occurred in 129 patients (34.3%). The 5- and 10-years rate of restenosis-free survival were 86.8 ± 1.9%, and 64.8 ± 3.3%, respectively. Variables independently associated with restenosis included age, right side heart failure, post-PMC MVA and mean mitral gradient (MMG), and brain natriuretic peptide (BNP) variation. Restenosis remains prevalent despite a successful PMC and can be predicted by age, valve morphology, post-procedural valve area, commissural opening, and the degree of BNP reduction.

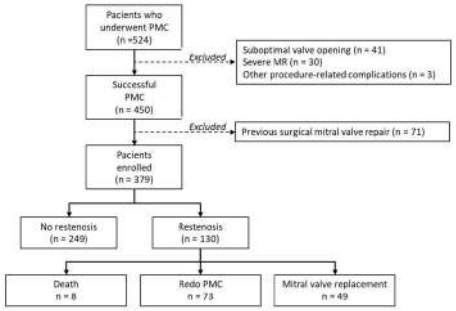

Figure 1: Flow chart of the studied population.
PMC = percutaneous mitral commissurotomy; MR = mitral regurgitation

Table 3: Independent predictors of restenosis after percutaneous mitral commissurotomy (multivariable Cox regression analysis)

Variable	Hazard ratio	95% CI	P-Value
Age	1.047	1.018-1.077	0.002
Right side HF	2.125	1.119-4.034	0.021
BNP variation*	0.631	0.436-0.912	0,014
MVA post-PMC	0.019	0.003-0.115	< 0.001
MMG post-PMC (mmHg)	1.132	1.043-1.228	0.003

BNP = brain natriuretic peptide; MMG = mean mitral gradient; MVA = mitral valve area; PMC = percutaneous mitral commissurotomy.
*BNP variation was calculated using this formula: (Pre-Post)/Pre

REMODELING OVER SYMPTOMS: A STRONGER PREDICTOR OF MORTALITY AFTER VALVE REPLACEMENT AND TAVI

RAFAELLA AVAKIAN MANSUR1; SOLANGE DESIREE AVAKIAN1; FLAVIO TARASOUTCHI1; ANTONIO PADUA MANSUR1;

(1) INSTITUTO DO CORACAO (INCOR) - HOSPITAL DAS CLINICAS DA FACULDADE DE MEDICINA DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction/Background: In patients with severe aortic valve disease (AVD) undergoing surgical valve replacement (SVR) or transcatheter aortic valve implantation (TAVI), optimal pre-procedural risk stratification remains challenging. Although symptom status guides the timing of intervention, it may not accurately reflect the degree of underlying cardiac remodeling. Echocardiographic markers may therefore provide additional prognostic information beyond symptom burden. Objectives: To evaluate the impact of symptom burden on mortality among patients undergoing aortic valve interventions. Methods: This observational cohort included patients with severe AVD who underwent aortic valve intervention, either surgical valve replacement (SVR, n=209) or transcatheter aortic valve implantation (TAVI, n=131). Symptom burden was assessed pre-procedurally based on the number of reported symptoms. Baseline clinical and echocardiographic variables were collected, including left ventricular ejection fraction (LVEF), left atrial volume (LAV), left ventricular mass (LVM), and aortic valve area (AVA). Coronary artery disease (CAD) was defined as ≥50% luminal stenosis in at least one coronary artery. The primary outcome was all-cause mortality during follow-up. Independent predictors of mortality were assessed using the Cox proportional hazards model. Resultados e Conclusions: A total of 339 patients were included (mean age 73.5 ± 6.9 years; 48.7% women). During a mean follow-up of 3.43 ± 3.65 years, 76 deaths (22.4%) occurred: 42 (55.3%) in men and 34 (44.7%) in women. Symptom burden was not associated with mortality, and mortality rates did not differ across symptom categories ($\chi^2 = 4.07$, $p = 0.25$). Sex and the presence of CAD were not associated with mortality. In the Cox model, LVEF was an independent protective factor (HR 0.977, 95% CI 0.963–0.990, $p = 0.0009$), corresponding to a 2.3% reduction in mortality risk per 1% increase in LVEF. LAV was independently associated with higher mortality (HR 1.011, 95% CI 1.003–1.020, $p = 0.0069$), representing a 1.1% increase in risk per unit increase. Age and LVM were not significant in the multivariable model. The Cox model showed overall statistical significance (score and Wald tests, $p = 0.0006$). Conclusion: In patients undergoing SVR or TAVI, mortality was driven by cardiac structure and function rather than symptom burden. Lower LVEF and increased LAV independently predicted death, highlighting cardiac remodeling markers as key tools for risk stratification.

PERIOPERATIVE IVABRADINE FOR PREVENTION OF MYOCARDIAL INJURY AFTER NON-CARDIAC SURGERY (MINS): A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

AMANDA ALVES RABELO1; ANNA LUÍSA BIZOTTO1; ISABELLA OLIVEIRA DO LAGO1; PRISCILA BORGHETTI MELIM1; MAURICIO FARIA CORVISIER2; ISABEL DE CASTRO NUNES SENFFT3; JULIA FRAGA CASTRO E OLIVEIRA4;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL; (3) HOSPITAL UNIVERSITARIO GAFFREE E GUINLE - RIO DE JANEIRO - RJ - BRASIL; (4) PONTIFICIA UNIVERSIDADE CATOLICA DE MINAS GERAIS - CAMPUS BETIM - BETIM - MG - BRASIL;

Introduction/Background: Myocardial Injury after Non-cardiac Surgery (MINS) is a major contributor to perioperative morbidity and mortality and is frequently associated with tachycardia-induced myocardial oxygen supply-demand imbalance. Although beta-blockers reduce heart rate (HR), their use may be limited by hemodynamic instability. Ivabradine, a selective If current inhibitor, has emerged as a potential alternative for perioperative HR control with a theoretically safer hemodynamic profile. Objectives: To evaluate the efficacy and safety of perioperative ivabradine in preventing MINS in adult patients undergoing non-cardiac surgery. Methods: A systematic review and meta-analysis of randomized controlled trials was conducted according to PRISMA recommendations (PROSPERO CRD420261343663). PubMed, Embase, and Cochrane CENTRAL were searched for studies comparing perioperative oral ivabradine versus placebo in adults undergoing non-cardiac surgery. The primary outcome was the incidence of MINS. Secondary outcomes included heart rate, mean arterial pressure (MAP), mortality, stroke, bradycardia, and visual symptoms. Pooled estimates were calculated using DerSimonian–Laird random-effects models. Risk of bias and certainty of evidence were assessed using RoB 2 and GRADE, respectively. Resultados e Conclusions: Eight randomized controlled trials involving 2,804 patients were included. Ivabradine significantly reduced HR compared with placebo (MD = –18.85 bpm; 95% CI –22.67 to –15.03; p < 0.0001), but did not reduce the incidence of MINS (RR = 1.05; 95% CI 0.69–1.62; p = 0.645). Ivabradine was associated with a significant reduction in MAP (MD = –15.05 mmHg; p < 0.0001). No significant differences were observed in mortality, stroke, or bradycardia risk, although a non-significant increase in visual symptoms was noted. Despite effectively controlling HR, perioperative ivabradine did not prevent MINS in non-cardiac surgery. The observed reduction in MAP suggests that impaired systemic hemodynamic stability may offset the potential benefits of HR reduction, reinforcing the importance of maintaining adequate perfusion pressure in high-risk surgical patients.

Figure 1: Forest plot of the effect of ivabradine versus placebo on heart rate (bpm) at different perioperative time points.

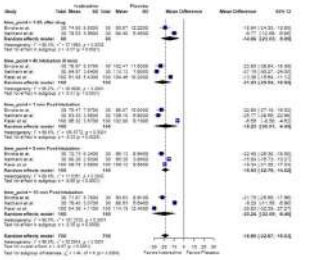

Figure 2: Forest plots of the effect of ivabradine on mean arterial pressure (MAP) across different perioperative time points

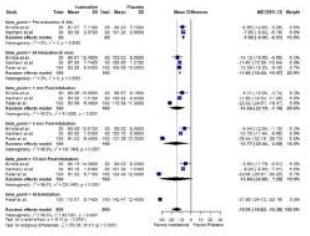

Figure 3: Forest plot of the safety and efficacy of ivabradine on Myocardial Injury after Non-cardiac Surgery (MINS)

PREOPERATIVE OBSTRUCTIVE SLEEP APNEA PREDICTS PERIOPERATIVE CARDIOVASCULAR COMPLICATIONS IN ARTERIAL VASCULAR SURGERY

CATHERINE MACHADO KATEKARU1; ADRIANA FEIO PASTANA1; LUIS AFONSO FERNANDES GONÇALVES1; NICOLLAS VICTORINO SANTOS DE CASTRO1; FRANCISCO AKIRA MALTA CARDOZO1; PEDRO AUGUSTO BENTO DE SOUSA1; LEONARDO DEIXHEIMER DA SILVA1; GERALDO LORENZI FILHO1; LUCIANA DORNFELD BICHUETTE1; MARCOS PITA LOTTENBERG1; DANIELA CALDERARO2; BRUNO CARAMELLI1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) INSTITUTO DO CORACAO (INCOR) - HOSPITAL DAS CLINICAS DA FACULDADE DE MEDICINA DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction/Background: Obstructive sleep apnea (OSA) is highly prevalent in cardiovascular populations and frequently remains undiagnosed. Whether detection of OSA in the preoperative setting improves risk stratification in arterial vascular surgery is still insufficiently defined. Objectives: The main purpose of the present study was to investigate the association between preoperatively diagnosed OSA using portable monitoring and in hospital perioperative cardiovascular and cerebrovascular events, and to evaluate its incremental prognostic value beyond clinical variables. Methods: This prospective observational study included 119 consecutive patients older than 45 years undergoing arterial vascular surgery at a tertiary academic center. All participants should have underwent overnight preoperative evaluation with a portable oximetry-based monitoring device (Biologix). Patients with moderate to severe OSA defined by an oxygen desaturation index (ODI) ≥15 events/hour were identified. The primary endpoint was a blinded adjudicated hierarchical composite event (perioperative myocardial injury, myocardial infarction, stroke, transient ischemic attack, delirium, heart failure decompensation, cardiac or non-cardiac death, and clinically significant arrhythmia. Resultados e Conclusions: Ten patients did not ultimately undergo surgery and were excluded from the primary postoperative outcome analysis that involved 109 patients. Moderate to severe OSA was present in 54 of 119 patients (49.5%). The composite endpoint occurred in 39 patients (35.8%). Event rates were substantially higher in patients with moderate to severe OSA than is patients with no or mild OSA (51.9%, versus 20.0%; relative risk 2.59, 95% CI 1.44–4.67; p=0.0006). Moderate to severe OSA remained independently associated with perioperative events after multivariable adjustment (adjusted OR 5.29, 95% confidence interval 1.78-15.74, p = 0.002). The apparent AUC was 0.741 for the clinical model and 0.806 after addition of OSA (0.74, 95% CI 0.63-0.84 and 0.806, 95% CI 0.71-0.89, respectively showing moderate discrimination (AUC 0.65, 95% CI 0.54–0.77). OSA is common in arterial vascular surgery patients and was associated with a higher rate of perioperative cardiovascular complications. These findings support the clinical relevance of systematic OSA diagnosis in high-risk vascular surgical populations and suggest that portable monitoring may be a practical perioperative strategy.

EFFECTS OF HIGH-INTENSITY INTERVAL TRAINING (HIIT) ON DIASTOLIC FUNCTION IN WOMEN WITH OBESITY

WENDELL WENDELL LOPES1; CAROLINE FERRAZ SIMÕES2; JOÃO CARLOS LOCATELLI1; ROGÉRIO TOSHIRO PASSOS OKAWA1;

(1) UNIVERSIDADE ESTADUAL DE MARINGA - MARINGÁ - PR - BRASIL; (2) CENTRO UNIVERSITARIO UNICESUMAR - MARINGA - PR - BRASIL;

Introduction/Background: Obesity is a major global contributor to heart failure and has been linked to diastolic disfunction. High-intensity interval training (HIIT) has been shown to improve body composition, inflammatory responses, and vascular function in individuals with obesity. However, the effects of HIIT on cardiac parameters, particularly diastolic function, remain unclear. Objectives: The objetive of this study was to investigate the effects of HIIT on diastolic function in women with obesity. Methods: Twenty-five young women with grade I and II obesity were randomized to perform eight weeks of HIIT (4 × 4 minutes of walking/running at an intensity between 85 and 95% of HRmax, interspersed with 3 minutes of active recovery at 65 to 75% of HRmax) or moderate-intensity continuous training (MICT) (41 minutes of walking/running at 65 to 75% of HRmax). Body composition, cardiorespiratory fitness, and diastolic function were assessed. Resultados e Conclusions: Eight weeks of HIIT or MICT were not able to significantly alter the early diastolic inflow velocity (E) to atrial diastolic inflow velocity (A) (E/A) (HIIT: 1.50 ± 0.45 vs 1.54 ± 0.43 and MICT: 1.56 ± 0.21 vs 1.62 ± 0.33, p = 0.409) or the ratio of early diastolic transmitral velocity (E) to early diastolic tissue velocity (E') (E/e') (HIIT: 6.19 ± 1.17 vs 5.79 ± 1.02 and MICT: 4.94 ± 0.85 vs 5.57 ± 1.89, p = 0.676) in women with obesity. Additionally, there was no significant change in left atrial volume index (LAVI) (19.09 ± 3.36 vs 18.74 ± 2.64 and 19.18 ± 3.74 vs 19.07 ± 2.70 mL/m², p = 0.604). Only HIIT reduced body fat and increased cardiorespiratory fitness in this population. Eight weeks of HIIT and MICT did not promote significant changes in diastolic function in young women with obesity. However, HIIT demonstrated additional benefits in reducing body fat and increasing cardiorespiratory fitness, without superiority over MICT regarding diastolic function parameters.

ANALYSIS OF HEART RATE VARIABILITY DURING HOSPITALIZATION IN PATIENTS WITH SPINAL CORD INJURY

GIULLIANO GARDENGHI1; NATHÁLIA MOURA GONÇALVES2; GRAZIELLA FRANÇA BERNARDELLI CIPRIANO3; FRANCISCO TIAGO OLIVEIRA DE OLIVEIRA4; ERIKA LETICIA GOMES NUNES5;

(1) HOSPITAL ENCORE - APARECIDA DE GOIÂNIA - GO - BRASIL; (2) HOSPITAL DE URGÊNCIAS DE GOIÁS - GOIÂNIA - GO - BRASIL; (3) UNIVERSIDADE DE BRASILIA - BRASÍLIA - DF - BRASIL; (4) ESCOLA BAHIANA DE MEDICINA E SAUDE PUBLICA (EBMSP) - SALVADOR - BA - BRASIL; (5) HOSPITAL E MATERNIDADE MUNICIPAL SANTA ANA - SANTANA DO PARNAÍBA - SP - BRASIL;

Introduction/Background: Spinal cord injury (SCI), especially at cervical and upper thoracic levels, impairs cardiovascular autonomic regulation, resulting in changes in heart rate (HR) and responses to postural stimuli. Heart rate variability (HRV) is a noninvasive method used to assess this modulation. Objectives: To analyze HRV in adult patients with spinal cord injury during hospital length of stay (LOS), comparing individuals with injuries above and below the T5 level in different body positions. Methods: This was a cross-sectional observational study conducted in the wards of an emergency hospital, including individuals aged ≥18 years of both sexes diagnosed with spinal cord injury. HRV was recorded using a Polar H10 heart rate monitor in the supine position at 0° and with head-of-bed elevation to 60°, for 5 minutes in each position. Data were analyzed using Kubios HRV software. The following parameters were assessed: mean RR interval, mean HR, RMSSD, SDNN, LF/HF ratio, and the non-linear index DFA α1. Participants were stratified according to the level of injury (above and below T5). Statistical analysis was performed using IBM SPSS Statistics 26, applying the Wilcoxon and Mann–Whitney U tests, with $p < 0.05$ considered statistically significant. Resultados e Conclusions: A total of 33 individuals participated in the study, predominantly male, with a mean age of 35 ± 14 years. In the supine position (0°), patients with injuries above T5 showed significantly reduced mean RR intervals ($p = 0.025$), higher mean HR ($p = 0.026$), and lower autonomic complexity assessed by DFA α1 ($p = 0.041$) compared with those injured below T5. During head-of-bed elevation to 60°, these differences persisted for mean RR ($p = 0.013$) and mean HR ($p = 0.014$), and were associated with a significant change in the LF/HF ratio ($p = 0.030$) and a more pronounced reduction in DFA α1 ($p = 0.005$), indicating lower autonomic adaptability in individuals with higher-level injuries. As conclusion, patients with spinal cord injury above T5 exhibit greater cardiac autonomic dysfunction and reduced adaptive capacity in response to postural changes during hospital LOS.

ANALYSIS OF THE FUNCTIONAL PROFILE OF DIFFERENT HEART FAILURE PHENOTYPES IN PATIENTS TREATED AT A HEART FAILURE CLINIC

LUANA DE DECCO MARCHESE1; DEBORAH CRISTINY OLIVEIRA MELLO1; JAQUELINE PEIXOTO LOPES2; DANIELLE WAROL DIAS SANTOS1; MARLI GOMES DE OLIVEIRA1; ROSIANE FATIMA SILVEIRA DE ABREU1; LUCIANA DA SILVA NOGUEIRA DE BARROS1; SERGIO FERREIRA SGARAGLIA1; JOSÉ EDUARDO DA COSTA GIRCYS1; MARIA APARECIDA ROSA MANHAES1; GELSOMINA ANGELINA MARTINS COSTA PEREIRA1; LÚCIA BRANDÃO DE OLIVEIRA1;

(1) CENTRO UNIVERSITÁRIO SERRA DOS ÓRGÃOS - TERESÓPOLIS - RJ - BRASIL; (2) CENTRO UNIVERSTIÁRIO SERRA DOS ÓRGÃOS - TERESÓPOLIS - RJ - BRASIL;

Introduction/Background: Heart failure (HF) is a clinical syndrome characterized by the heart's inability to meet the body's metabolic demands, leading to symptoms such as dyspnea, fatigue, and exercise intolerance, which compromise quality of life. In Brazil, it is a major public health issue associated with high hospitalization rates, cardiovascular mortality, and elevated healthcare costs. It is classified into three main phenotypes according to the left ventricular ejection fraction (LVEF): reduced (HFrEF), preserved (HFpEF), and mildly reduced (HFmrEF); this differentiation guides therapeutic and prognostic approaches. In this context, functional assessment through cardiovascular tests such as the six-minute walk test (6MWT) and manovacuometry are simple, accessible, and effective tools to quantify physical capacity, stratify risks, and assist in the clinical management of these patients. Objectives: To evaluate and compare the functional capacity, measured by the distance walked in the six-minute walk test (6MWD), and respiratory muscle strength across the different HF phenotypes. Methods: A retrospective analysis of medical records was performed for HF patients who underwent the six-minute walk test and manovacuometry during the years 2023, 2024, and 2025. Statistical Analysis: Data were recorded in a systematic spreadsheet and then entered into the BioEstat 5.3 software. The Student's t-test was used to compare variables. Data were presented as mean and standard deviation, and a p-value ≤ 0.05 was considered significant. The research was submitted to and approved by the Research Ethics Committee. Resultados e Conclusions: The sample (n=136) revealed that HFpEF presented a distinct gender profile, with a female predominance (33F/24M), contrasting with the male predominance in the other phenotypes. In the functional assessments, there were no significant differences between the groups ($p>0.05$). However, all groups demonstrated functional impairment, with mean 6MWD values (405.6 to 444.8 m) and MIP values (−70.3 to −75.4 cm/H2O) lower than the predicted values. HFmrEF achieved the highest 6MWD (444.8 m), and HFpEF recorded the lowest mean MIP values (−75.4 cm/H2O). No significant differences were found when evaluating the functional profile of different heart failure phenotypes in patients treated at a specialized clinic.

17349

ASSOCIATION BETWEEN ACUTE MYOCARDIAL INFARCTION AND FUNCTIONAL DISABILITY IN INDIVIDUALS WITH CANCER

LEONARDO BARBOSA ALMEIDA1;

(1) UFJF - JUIZ DE FORA - MG - BRASIL;

Introduction/Background: Acute myocardial infarction (AMI) and cancer share common risk factors and a strong involvement of inflammatory processes. However, the impact of the coexistence of these conditions on functional mobility remains poorly investigated. Objectives: To evaluate the association between AMI and functional disability in Brazilian individuals with cancer. Methods: A cross-sectional study was conducted including 503 participants. This study was approved by the Ethics Committee (XXX.754). AMI and cancer diagnoses were self-reported through a chronic disease questionnaire. Participants were categorized into two groups: AMI and cancer (AMI+CAN; n=45) and cancer only (CAN; n=458). Functional disability was assessed for the following activities: running 1 km, walking 1 km, walking 100 m, climbing stairs, sitting, squatting, raising the arms, pushing or pulling objects, carrying 5 kg, and picking up a coin. Outcomes were dichotomized as “absence” or “presence of disability.” Group comparisons were performed using chi-square or Fisher’s exact tests, followed by binary logistic regression and odds ratio (OR) analysis, with a significance level set at 5%. Resultados e Conclusions: The groups were similar regarding age, sex, geographic region of Brazil, skin color, and marital status (p>0.05). The absence of AMI (CAN group) was associated with higher odds of preserved function across multiple domains. Statistically significant associations were observed for lower wheelchair use (OR=2.00; 95%CI: 1.01–3.96), reduced need for orthoses (OR=1.59; 95%CI: 1.02–2.48), greater ability to walk 1 km (OR=1.38; 95%CI: 1.01–1.89), walk 100 m (OR=1.47; 95%CI: 1.07–2.02), climb a flight of stairs (OR=1.64; 95%CI: 1.20–2.23), push or pull objects (OR=1.51; 95%CI: 1.10–2.06), and carry a 5 kg load (OR=1.49; 95%CI: 1.07–2.06). Thus, AMI is associated with greater functional disability in individuals with cancer, particularly in mobility-related activities, highlighting the importance of assessing comorbidities and implementing cardio-oncology rehabilitation strategies.

15809

CLINICAL FACTORS AND FUNCTIONAL CAPACITY AS PREDICTORS OF HOSPITAL LENGTH OF STAY AFTER CORONARY ARTERY BYPASS GRAFTING

RAFAEL M IANOTTI1; GABRIELA HARADA1; GEISA N. ANDRADE1; ANGELA S. INOUE1; AMANDA A. C. COELHO1; ANA CAROLINA A. MARTINS1; LUCIANA M. D. MATA1; GABRIELLA M. M. BRAVO1; IANA V. S. ALBUQUERQUE1; SILVIA GASPAR1; KELLY C. O. ABUD.1;

(1) INSTITUTO DO CORACAO (INCOR) - HOSPITAL DAS CLINICAS DA FACULDADE DE MEDICINA DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction/Background: Background: Functional decline, assessed by the Short Physical Performance Battery (SPPB) and six-minute walk distance (6MWD), has been associated with worse outcomes after coronary artery bypass grafting (CABG). These measures are commonly analyzed in isolation, with limited integration into multivariable models that estimate their independent contribution. The one-minute sit-to-stand test (1MSTS) remains underexplored in this setting. Objectives: Objective: To evaluate the prognostic value of SPPB, 6MWD, and 1MSTS assessed preoperatively for predicting hospital length of stay (LOS) after CABG using clinical-functional models. Methods: Methods: Prospective cohort including 76 patients. A clinical model was constructed using variables previously associated with hospital LOS. Each functional test was then individually added as a dichotomized variable (SPPB ≤9 points; 1MSTS ≤17 repetitions; 6MWD ≤350 meters). NYHA class II–III was excluded due to potential collinearity and conceptual overlap. Negative binomial regression was applied, with results expressed as incidence rate ratios (IRR). Cutoffs for 1MSTS and 6MWD were defined based on the 25th percentile. Resultados e Conclusions: Results: Median hospital LOS was 9 (8–12) days. No variable from the clinical model showed an independent association. In adjusted models, only SPPB ≤9 (IRR 1.58; 95% CI 1.15–2.19) and 1MSTS ≤17 (IRR 1.76; 95% CI 1.27–2.45) were associated with higher LOS rates. 6MWD was not significant. Conclusion: In patients undergoing CABG, poorer performance in SPPB and 1MSTS was associated with 58% and 76% increases in hospital LOS rate, respectively. The 1MSTS emerges as a simple and sensitive functional marker for risk stratification.

Table 1. Predictive models of hospital length of stay.

Variables	Clinical Model	Clinical + SPPB	Clinical + 1MSTS	Clinical + 6MWD
	IRR (95% CI)	IRR (95% CI)	IRR (95% CI)	IRR (95% CI)
Age (years)	1.01 (0.98-1.03)	1.01 (0.99-1.04)	1.01 (0.99-1.04)	1.01 (0.99-1.04)
Sex (female)	0.91 (0.64-1.29)	0.79 (0.55-1.15)	0.78 (0.55-1.12)	0.79 (0.54-1.18)
BMI (kg/m²)	1.03 (1.00-1.07)	1.02 (0.99-1.06)	1.02 (0.99-1.06)	1.02 (0.98-1.06)

EVALUATION OF SARCOPENIA IN HOSPITALIZED PATIENTS WITH HEART FAILURE WITH REDUCED EJECTION FRACTION: PARTIAL RESULTS

NATHÁLIA SOUZA DA SILVA1; DÊNIS KOMONSKI SELAU1; ANDRIELI BARBIERI GARLET1; FERNANDA CECÍLIA DOS SANTOS DE VASCONCELLOS1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Heart failure is a complex clinical syndrome associated with significant systemic changes, among which sarcopenia stands out as a condition characterized by the progressive loss of muscle mass and function, associated with poorer clinical prognosis. Objectives: To assess the occurrence of sarcopenia in hospitalized patients with heart failure with reduced ejection fraction (HFrEF). Methods: This is a cross-sectional, prospective, and inferential study with a non-probabilistic sample composed of adult patients with HFrEF (≤ 40%). The clinical profile of patients was determined using data collected from medical records. The assessment of sarcopenia was conducted based on the European Working Group on Sarcopenia in Older People through screening with the SARC-F questionnaire, measurement of muscle strength by handgrip dynamometry (HGD) and the five-times sit-to-stand test (STS), evaluation of muscle mass by quadriceps ultrasound and calf circumference (CC), as well as analysis of physical performance through standardized functional tests and clinical frailty. The study was submitted for ethical review and approved under CAAE 94960926.0.0000.5327. Resultados e Conclusions: This report presents preliminary results based on 17% of the expected sample. Twelve patients were evaluated, 83% of whom were male, with a mean age of 60 ± 11.89 years and a left ventricular ejection fraction of 26 ± 8.14%. Systemic arterial hypertension being the most prevalent comorbidity, present in 50% of patients. 33.3% of the sample screened positive for predictive signs of sarcopenia using the SARC-F. Of these, 16.6% showed loss of muscle strength by HGD and 25% by STS and were thus classified as sarcopenic. Among these, 66.6% were identified with severe sarcopenia. So far, preliminary data suggest a moderate significant positive correlation (r = 0.77; p = 0.006) between muscle mass assessed by CC and sarcopenia screening by SARC-F, that is, lower CC values tend to be correlated with the prediction of sarcopenia. Based on the partial results obtained, it is concluded that the assessment instruments appear to demonstrate methodological adequacy and feasibility for the assessment of hospitalized HFrEF patients.

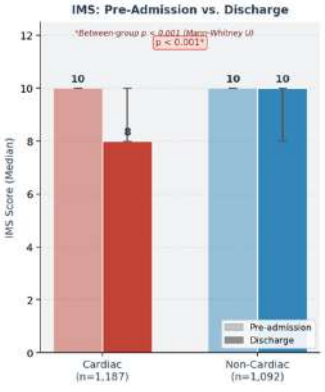
FUNCTIONAL MOBILITY AND MUSCLE STRENGTH IN HOSPITALIZED PATIENTS WITH CARDIAC COMORBIDITIES: A MULTICENTER COHORT STUDY



EZEQUIEL PIANEZZOLA1; FABIO FAJARDO1; PATRICIA FERNANDES1; CASSIO DANIEL ARAUJO DA SILVA1;

(1) REDE DOR - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Cardiac comorbidities are highly prevalent in hospitalized patients and may impair functional recovery during acute care. Functional mobility and peripheral muscle strength are critical determinants of discharge outcomes, yet their trajectories in patients with cardiac conditions remain poorly characterized in large multicenter cohorts. Objectives: To compare functional mobility (ICU Mobility Scale – IMS) and muscle strength (Medical Research Council – MRC) from pre-admission to discharge in patients with and without cardiac comorbidities. Methods: Retrospective multicenter cohort study with 2,283 patients from three hospitals, stratified by cardiac comorbidity (n=1,187; 52.0%) or absence (n=1,092; 48.0%). IMS (0–10) was assessed at pre-admission and discharge; MRC (0–60) at admission and discharge. Wilcoxon signed-rank test (paired comparisons), Mann-Whitney U test (between groups), and Spearman correlation (IMS×MRC) were applied (p<0.05). Resultados e Conclusions: Results: Mean age 54.4±20.4 years; 55.9% female. Cardiac patients were older (median 67 vs. 40 years; p<0.001) with longer stays (6 vs. 4 days; p<0.001). Overall IMS declined from pre-admission to discharge (median: 10→9; p<0.001); 41.4% worsened. Cardiac patients had lower discharge IMS (median 8 vs. 10; p<0.001) and higher deterioration rate (46.9% vs. 35.6%). MRC improved significantly in both groups (p<0.001); however, cardiac patients showed lower admission MRC (IQR: 48–60 vs. 58–60; p<0.001), lower discharge MRC (IQR: 54–60 vs. 60–60; p<0.001), and higher worsening rate (8.7% vs. 4.2%). Moderate IMS–MRC correlation at admission (ρ=0.41; p<0.001) and discharge (ρ=0.33; p<0.001). Conclusion: Cardiac comorbidities were associated with greater functional mobility decline and higher muscle strength impairment during hospitalization. These findings support the need for targeted early rehabilitation in cardiovascular patients.

Summary Statistics

Variable	Cardiac	Non-Cardiac	p-value
N	1,187	1,092	—
Age (median, years)	67	40	< 0.001
Female sex	50.5%	61.7%	< 0.001
IMS Pre-admission	10 (10–10)	10 (10–10)	< 0.001
IMS Discharge	8 (8–10)	10 (8–10)	< 0.001
IMS Worse at Discharge	46.9%	35.6%	—
MRC Admission	60 (48–60)	60 (58–60)	< 0.001
MRC Discharge	60 (54–60)	60 (60–60)	< 0.001

FUNCTIONAL PROFILE AND MUSCLE STRENGTH IN PATIENTS UNDER A CHEST PAIN PROTOCOL: IMPACT OF STRUCTURED PHYSICAL THERAPY

ANNA VICTORIA RIBEIRO PORRAS1; RAYANE CARVALHO DE ARAUJO1; ANA LUIZA FERREIRA KOGUT GELHOREN1; JOISY DOS SANTOS PERRUCHO NUNES1; DANIEL DE ALMEIDA SANTOS1; ANA PAULA PESSOA BARROS1; LEONARDO LOPES BARBOSA1; ROSANE ASSIS DO CARMO1; THIAGO MATOS BARCELLOS1; RAFAEL LESSA DA COSTA1; GUSTAVO SALGADO DUQUE1; RICARDO MOURILHE – ROCHA1;

(1) HOSPITAL SAMARITANO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Effective chest pain protocols are key to cardiovascular risk stratification in emergency and critical care setting. However, monitoring requirements and reduced mobility may contribute to functional decline and muscle weakness. Early physical therapy interventions may mitigate these effects by promoting mobility and preserving functional capacity. Objectives: To evaluate muscle strength, ambulation, and functional status at pre-discharge in patients managed under a chest pain protocol, and to identify independent predictors of functional outcomes. Methods: This retrospective observational study included patients aged ≥18 years admitted under a chest pain protocol between January 2023 and December 2025. Functional status was assessed using the ICU Mobility Scale (IMS), and muscle strength using the Medical Research Council (MRC) scale at admission and pre-discharge. ambulation was defined as the ability to walk, either independently or with assistance. Multivariable logistic regression was performed to identify independent predictors of preserved ambulation, with odds ratios (OR) and 95% confidence intervals (CI) reported. A two-sided p-value < 0.05 was considered statistically significant. Resultados e Conclusions: Among 12,863 protocol activations, 946 patients were admitted, of whom 771 met the inclusion criteria (66% male). The mean age was 63 years, and median hospital length of stay was 6 days. At pre-discharge, ambulation was preserved in 93.7% of patients, functional status in 93%, and muscle strength in 96.5%. Male sex was independently associated with preserved ambulation (OR 2.17; 95% CI 1.19–3.97; p = 0.011), whereas age (OR 1.01; 95% CI 0.98–1.03; p = 0.59) and length of stay (OR 1.05; 95% CI 0.97–1.14; p = 0.19) were not significantly associated with the outcome. Structured, protocol-driven physical therapy was associated with high rates of preserved functional status and muscle strength in patients managed under a chest pain protocol. Early mobilization may attenuate the impact of traditional risk factors for functional decline, underscoring the significant role of rehabilitation in acute cardiovascular care pathways.

FUNCTIONAL RECONCILIATION AND AMBULATION IN THE CARDIAC ICU: THE ICU MOBILITY SCALE AS AN INDICATOR OF CONTINUITY OF CARE

ANNA VICTORIA RIBEIRO PORRAS1; RAYANE CARVALHO DE ARAUJO1; ANA LUIZA FERREIRA KOGUT GELHOREN1; JOISY DOS SANTOS PERRUCHO NUNES1; DANIEL DE ALMEIDA SANTOS1; WELBER MELO MOREIRA1; ANA PAULA PESSOA BARROS1; THIAGO MATOS BARCELLOS1; RICARDO COLI DE TOLEDO1; RAFAEL LESSA DA COSTA1; GUSTAVO SALGADO DUQUE1; RICARDO MOURILHE – ROCHA1;

(1) HOSPITAL SAMARITANO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Admission to the Intensive Care Unit (ICU) is often associated with substantial functional decline. In the cardiac setting, early mobilization is a fundamental strategy to mitigate these effects; however, success depends on a systematized transition of care. Functional reconciliation, measured through the ICU Mobility Scale (IMS), emerges as an essential quality indicator to audit whether recovered functionality is preserved until discharge. Objectives: To evaluate the rate of ambulation and functional reconciliation using the IMS scale as a marker of continuity of care in a cardiac ICU. Methods: A retrospective observational study was conducted (January 2025 – March 2026) in a tertiary cardiac ICU. Patients ≥18 years were included. Functional rehabilitation (FR) and ambulation were daily monitored. Statistical analysis included descriptive statistics and 95% confidence intervals (CI) for the success rates. The association between structured physical therapy and the achievement of high mobility scores (IMS ≥ 4) was evaluated using Odds Ratio (OR). Resultados e Conclusions: A total of 1,196 patients were analyzed. Functional rehabilitation was successfully performed in 680 cases (97.3% of applicable patients). Ambulation was achieved in 730 patients, corresponding to a high success rate of 97.6% among eligible individuals (95% CI, 96.2%–98.5%) and only.18 patients failed to ambulate when clinical conditions allowed. The implementation of a protocolized physical therapy intervention was associated with an OR of 5.8 (95% CI: 3.2 – 10.4) for achieving independent functional reconciliation at discharge. These results indicate that structured monitoring significantly reduces the risk of functional stagnation during the ICU stay. Functional reconciliation through the IMS scale proved to be a sensitive and robust indicator for monitoring the transition of care. The high ambulation rate (97.6%) and the positive OR for functional gain suggest that structured physical therapy ensures that critical cardiac patients return to lower-complexity units with their motor capacity optimized, mitigating the risks associated with hospital immobility.

IMPACT OF HIGH BLOOD PRESSURE ON FUNCTIONALITY IN OLDER ADULTS RECEIVING PRIMARY HEALTH CARE

THIAGO DIPP1; JENIFER MELO BARBOSA1; MARIA CRISTINA DEMARI1; VICTOR PAGANI DE BARCELOS1; MARIANA CAMBOIM PEREIRA1; EDUARDA VITÓRIA FADINI SILVEIRA1; NATÁLIA TOEBE GIUDICE DA COSTA1; MARIANA FALHEIRO ROMANO1; MARIA EDUARDA RODRIGUES OLIVEIRA1; ANA PAULA BARCELLOS KAROLCZAK1; JULIANA NICHTERWITZ SCHERER1;

(1) UNISINOS - SÃO LEOPOLDO - RS - BRASIL;

Introduction/Background: High blood pressure (HBP) is highly prevalent in older adults and is associated with functional decline and loss of autonomy. In Primary Health Care (PHC), adequate control of HBP and monitoring of functionality are essential to promote healthy aging and reduce complications. Objectives: To compare functionality between hypertensive (HT) and normotensive (NT) older adults using PHC services. Methods: Cross-sectional study included older adults followed in PHC in a city in southern Brazil (CAAE: 37125120.0.0000.5344). Anthropometric and clinical data were obtained by self-report or electronic medical records. Functionality was assessed using the 6-Minute Walk Test (6MWT), Five Times Sit-to-Stand Test (5TSST), quadriceps isometric strength, and dominant-handgrip strength. Comparisons between groups were made using Student's t-test with bootstrapping (1,000 resamples; 95% BCa CI). Analyses were conducted in SPSS 21.0, with $p \leq 0.05$. Resultados e Conclusions: The sample consisted of 165 older adults, 72.7% HT (n=120; 70.2±6.6 years; 73.3% women) and 27.3% NT (n=45; 69.9±6.0 years; 80% women). Of these, 77% (n=127) self-identified as White, 41.2% (n=68) were married, and 57.6% (n=95) had < 9 years of schooling. There was a difference in systolic blood pressure (HT: 133.3±14.7 vs NT: 125.9±13.2 mmHg; p=0.004; Hedge's G=0.51), diastolic blood pressure (HT: 83.8±12.9 vs NT: 78.6±9.4 mmHg; p=0.004; Hedge's G=0.42), distance covered in the 6MWT (HT: 368.41±113.7 vs NT: 413.82±117.2 m; p=0.029; Hedge's G=0.39), and BMI (HT: 29.1±5.0 vs NT: 26.4±5.1 kg/m²; p=0.011; Hedge's G=0.50) between groups. No differences were identified in the 5TSST (HT: 15.5±7.1 vs NT: 15.0±6.9 repetitions; p=0.66), isometric muscle strength of the right leg (HT: 18.9±8.3 vs NT: 18.4±7.3 kgf; p=0.74) and left leg (HT: 18.4±8.0 vs NT: 17.6±6.9 kgf; p=0.55), or dominant handgrip strength (HT: 22.0±9.1 vs NT: 22.2±9.2 kg; p=0.94). Hypertensive older adults showed worse cardiorespiratory performance and higher BMI than normotensive peers, suggesting a greater impact on functional capacity than on muscle strength. Funding: FAPERGS.

INCREMENTAL SHUTTLE WALK TEST BETTER REFLECTS HEALTH-RELATED QUALITY OF LIFE THAN THE SIX-MINUTE WALK TEST IN PATIENTS WITH CHAGAS CARDIOMYOPATHY.

GUSTAVO REIS MACIEL1; MARINA SILVA REIS2; ANTONIELLY ROCHA DE SOUZA PEREIRA2; GABRIEL MELO FONSECA2; STEFÂNIA GUIMARÃES NERY2; MARTA VALQUÍRIA DA SILVA2; LUCAS FROIS FERNANDES DE OLIVEIRA3; WHESLEY TANOR SILVA4; MARCUS VINICIUS ACCETTA VIANNA2; CHEYENNE ALVES FONSECA2; SANNY CRISTINA DE CASTRO FARIA3; HENRIQUE SILVEIRA COSTA2;

(1) UN UNIVERSIDADE FEDERAL DOS VALES DO JEQUITINHONHA E MUCURI - DIAMANTINA - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DOS VALES DO JEQUITINHONHA E MUCURI - DIAMANTINA - MG - BRASIL; (3) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (4) FIOCRUZ - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Chagas disease remains a neglected condition, frequently associated with social stigma, socioeconomic vulnerability, limited access to healthcare, and impaired health-related quality of life (HRQoL). Chagas cardiomyopathy, its most severe clinical presentation, is characterized by early functional limitation and progressive reduction in exercise tolerance. Although field tests are widely used to assess submaximal functional capacity, it is still unclear to what extent their performance reflects patients' perceived health status and the daily-life impact of the disease. Objectives: To investigate the correlation of the Six-Minute Walk Test (6MWT) and the Incremental Shuttle Walk Test (ISWT) with HRQoL in patients with Chagas cardiomyopathy. Methods: Fifty patients with Chagas cardiomyopathy underwent clinical assessment, physical examination, echocardiography, 6MWT, and ISWT. HRQoL was assessed using the Short Form Health Survey (SF-36) and the Minnesota Living with Heart Failure Questionnaire (MLHFQ). Correlations were analyzed between walked distance on field tests and HRQoL domains and scores. Resultados e Conclusions: Distance walked on the 6MWT correlated only with the physical functioning domain of the SF-36 (r=0.326; p=0.021). In contrast, ISWT distance showed broader associations, correlating with physical functioning (r=0.484; p<0.001), vitality (r=0.335; p=0.029), general health perception (r=0.325; p=0.023), and the physical component summary score (r=0.373; p=0.009) of the SF-36. In addition, ISWT distance was inversely correlated with the MLHFQ score (r=-0.423; p<0.001), indicating that better functional performance was associated with better disease-specific quality of life. These findings suggest that field tests capture relevant aspects of HRQoL in patients with Chagas cardiomyopathy, with the ISWT showing stronger and more consistent associations than the 6MWT across both generic and disease-specific measures. The ISWT may therefore provide a more informative submaximal measure for functional and patient-centered assessment in this population and may be particularly useful when a broader perception of health status is clinically relevant.

NEUROMUSCULAR ELECTRICAL STIMULATION IMPROVES THE EFFECTS OF COMBINED TRAINING ON QUADRICEPS MUSCLE ARCHITECTURE IN PATIENTS AFTER CORONARY ARTERY BYPASS GRAFT SURGERY: A RANDOMIZED CLINICAL TRIAL

MAURÍCIO TATSCH XIMENES1; LETICIA CASTAGNA1; TAMIRES DAROS DOS SANTOS1; ISABELLA MARTINS DE ALBUQUERQUE1;

(1) UNIVERSIDADE FEDERAL DE SANTA MARIA - SANTA MARIA - RS - BRASIL;

Introduction/Background: Background: Coronary artery bypass graft (CABG) surgery is known to induce significant muscle wasting and structural alterations in the quadriceps, specifically on the rectus femoris. In this sense, the effects of adding neuromuscular electrical stimulation (NMES) to short-term aerobic and resistance exercise (combined training [CT]) after CABG on quadriceps muscle architecture are not established. Objectives: Objective: To determine the effects of adding NMES to combined training on quadriceps muscle architecture, muscle quality, functional capacity, and quality of life in patients after CABG participating in a phase II cardiac rehabilitation program. Methods: Methods: This was a randomized, double blind controlled trial including 24 patients (59,5±9,44 years, 17 men) who were randomly assigned to either the NMES+CT group (n=13), which received NMES with CT or the sham-NMES+CT group (n=11). Patients completed two sessions per week for 12 weeks. The primary outcome was quadriceps muscle thickness measured by ultrasound before and after the intervention. Secondary outcomes included rectus femoris cross-sectional area, peripheral muscle strength (30-seconds sit-to-stand test), functional capacity (six-minute walk test), quality of life (MacNew HRQL questionnaire), rectus femoris echogenicity and vastus intermedius echogenicity (as an indicator of skeletal muscle quality). Resultados e Conclusions: Results: Compared with the sham NMES+CT group, the NMES+CT group showed significantly greater reduction in rectus femoris echogenicity (18.2; 95% CI: 2.5 to 34.0; p<0.05). However, no significant between-group differences were observed in quadriceps muscle thickness, rectus femoris cross-sectional area, vastus intermedius echogenicity, peripheral muscle strength, functional capacity, and quality of life. Conclusions: The addition of low frequency NMES to short-term combined training provided additional benefits in rectus femoris muscle quality in patients after CABG enrolled in a phase II cardiac rehabilitation program. The potential clinical practice implications of this study suggested the importance for the addition of NMES on cardiac rehabilitation programs to enhance rectus femoris quality and becoming an effective, simple and inexpensive strategy to improve muscle strength and functional status. Large trials are needed to investigate the beneficial effectiveness of this protocol in CABG patients enrolled in a phase II CR program.

RELIABILITY AND SAFETY OF THE 2-MINUTE WALK TEST IN CARDIAC ICU PATIENTS

SHEILA DE LIMA ABDALA1; VINICIUS MARINHO COELHO1; CARLOS EDUARDO GUEDES COSTA2;

(1) INSTITUTO D'OR DE PESQUISA E ENSINO - RIO DE JANEIRO - RJ - BRASIL; (2) UNIVERSIDADE DE VASSOURAS (UNIVASSOURAS) - VASSOURAS - RJ - BRASIL;

Introduction/Background: Functional assessment in Cardiac Intensive Care Units (ICU) is clinically challenging. This study evaluated the metrological reliability, provocative capacity, and safety of the 2-Minute Stationary Walk Test (2MWT) as an alternative to the 6-Minute Walk Test (6MWT) in hospitalized cardiac patients through physiological response and vital sign recovery analysis. Objectives: To evaluate the metrological reliability, provocative nature, and safety of the 2-Minute Stationary Walk Test in patients admitted to a cardiac ICU, through a robust analysis of physiological response and vital sign recovery. Methods: An interventional, descriptive-analytical study was conducted with 218 cardiac ICU patients (55.4±14.1 years; 68.1% male). Vital signs—systolic blood pressure (SBP), diastolic blood pressure (DBP), heart rate (HR), respiratory rate (RR), and peripheral oxygen saturation (SpO□)—were monitored during pre-test (1 min rest), test (2 min stationary walk), and recovery (5 min rest) phases. Statistical analysis utilized Pearson correlation for intra-individual consistency and coefficient of variation (CV) for variability assessment. Resultados e Conclusions: The 2MWT proved to be highly provocative, with significant increases: HR +27.0 bpm (+35.2%; p<0.001), RR +9.6 breaths/min (+55.2%; p<0.001), SBP +18.6 mmHg (+15.2%; p<0.001), and DBP +5.6 mmHg (+7.2%; p<0.001). SpO□ remained stable (-0.2%; p>0.05). Reliability was confirmed by strong intra-individual correlations: SBP pre vs. recovery (r=0.672; p<0.001), HR pre vs. recovery (r=0.735; p<0.001). Variability was controlled with CV<18% for all vital signs. Safety was demonstrated by: rapid recovery of HR (85.9% in 5 minutes), RR (82.3% in 1 minute), absence of critical desaturation (SpO□<85%), absence of extreme tachycardia (HR>200 bpm), and absence of critical hypertension (SBP>220 mmHg). No adverse events were recorded during the test. The 2MWT is a reliable, provocative, and safe instrument for functional assessment in cardiac ICU patients. Its capacity to identify functional limitations, combined with a proven safety profile, establishes it as a viable alternative to the 6MWT for risk stratification and recovery monitoring in high-risk hospitalized populations.

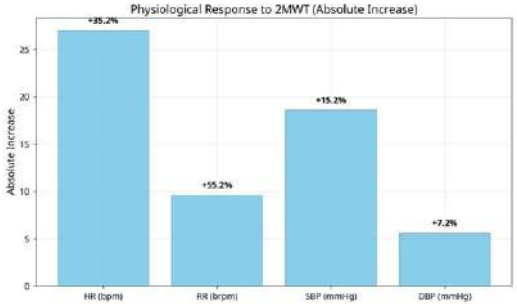

Tabela 3: Síntese dos Resultados de Confiabilidade e Caráter Provocativo do TME-2min

Aspecto	Indicador	Resultado Chave	Implicação Clínica
Confiabilidade	Correlação Intra-individual (PAS)	r=0,672 (p<0,001)	Consistência na resposta individual
	Correlação Intra-individual (FC)	r=0,735 (p<0,001)	Consistência na resposta individual
	Variabilidade (CV)	<18% para todos os SV	Baixa variabilidade, alta precisão
Caráter Provocativo	Aumento da FC	+27,0 bpm (+35,2%; p<0,001)	Induz resposta fisiológica significativa
	Aumento da FR	+9,6 irpm (+55,2%; p<0,001)	Induz resposta fisiológica significativa
	Aumento da PAS	+18,6 mmHg (+15,2%; p<0,001)	Induz resposta fisiológica significativa
	Aumento da PAD	+5,6 mmHg (+7,2%; p<0,001)	Induz resposta fisiológica significativa

RESPIRATORY MUSCLE STRENGTH AS A PREDICTOR OF EVENTS IN DILATED CHAGAS CARDIOMYOPATHY: A PRELIMINARY STUDY

STEFÂNIA GUIMARÃES NERY1; MARINA SILVA REIS1; ANTONIELLY ROCHA DE SOUZA PEREIRA1; GABRIEL MELO FONSECA1; GUSTAVO REIS MACIEL1; LUCAS FROIS FERNANDES DE OLIVEIRA2; WHESLEY TANOR SILVA3; CHEYENNE ALVES FONSECA1; MARCUS VINÍCIUS ACETTA VIANNA1; MARTA VALQUÍRIA DA SILVA1; SANNY CRISTINA DE CASTRO FARIA2; HENRIQUE SILVEIRA COSTA1;

(1) UNIVERSIDADE FEDERAL DOS VALES DO JEQUITINHONHA E MUCURI - DIAMANTINA - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) FUNDAÇÃO OSWALDO CRUZ - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: In patients with heart failure, respiratory muscle strength is associated with exercise capacity and has also been explored as a predictor of mortality. In dilated Chagas cardiomyopathy, the most severe cardiac presentation of Chagas disease, evidence on the clinical and prognostic relevance of respiratory muscle dysfunction remains limited. Although functional impairment is common in this population, few studies have investigated whether respiratory muscle strength is associated with exercise performance and whether it can help identify patients at higher risk of adverse outcomes. Objectives: To evaluate the association between respiratory muscle strength and exercise capacity, as well as its predictive value for adverse cardiovascular events, in patients with dilated Chagas cardiomyopathy. Methods: Thirty-one patients with dilated Chagas cardiomyopathy (50 ± 7 years; left ventricular ejection fraction 37 ± 7%; NYHA class I–III) underwent respiratory muscle strength assessment by manovacuometry to determine maximal inspiratory pressure (MIP) and maximal expiratory pressure (MEP). All patients also underwent treadmill exercise testing and echocardiography and were subsequently followed for 40 ± 12 months. Study outcomes included cardiac death and adverse cardiovascular events. Associations between variables were analyzed using Spearman's test. Differences between patients with and without adverse events were assessed using the Mann-Whitney test. The accuracy of respiratory muscle strength in identifying patients with adverse outcomes was evaluated using receiver operating characteristic (ROC) curves. Resultados e Conclusions: At baseline, both MIP and MEP correlated with peak oxygen uptake (VO2peak) (r=0.360, p=0.047; r=0.423, p=0.018), indicating an association between respiratory muscle performance and exercise capacity. During follow-up, 13 patients had adverse cardiovascular events (8 cardiac deaths, 5 thromboembolic events). No significant differences were observed in MIP (p=0.211) or MEP (p=0.953) between patients with and without adverse events. ROC analysis showed poor discriminatory performance for MIP (AUC=0.365) and MEP (AUC=0.506). These findings suggest respiratory muscle strength relates to functional capacity in dilated Chagas cardiomyopathy, but its isolated prognostic value is limited. It may still offer complementary functional information, though larger studies are needed to confirm added prognostic value with established markers.

SUCCESS RATE OF NON-INVASIVE VENTILATION IN A CARDIAC ICU: A CLINICAL INDICATOR OF CARE EFFECTIVENESS

ANNA VICTORIA RIBEIRO PORRAS1; RAYANE CARVALHO DE ARAUJO1; ANA LUIZA FERREIRA KOGUT GELHOREN1; JOISY DOS SANTOS PERRUCHO NUNES1; DANIEL DE ALMEIDA SANTOS1; ANA PAULA PESSOA BARROS1; EULER ROQUE OLIVEIRA1; THIAGO MATOS BARCELLOS1; RAFAEL LESSA DA COSTA1; GUSTAVO SALGADO DUQUE1; RICARDO MOURILHE – ROCHA1;

(1) HOSPITAL SAMARITANO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Acute respiratory failure (ARF) of cardiogenic etiology is a critical challenge in intensive care. Non-invasive ventilation (NIV) is a first-line intervention that optimizes lung compliance and reduces ventricular load. In high-complexity centers, the NIV success rate serves as a fundamental quality indicator, reflecting the team's ability to avoid invasive mechanical ventilation. Objectives: To evaluate the success rate and clinical profile of NIV application in patients admitted to a tertiary cardiac ICU. Methods: A retrospective observational study was conducted (from January 2025 to March 2026) via medical record analysis of patients aged ≥18 years. NIV (CPAP/Bilevel) was applied using total face masks and successful treatment was defined as the avoidance of orotracheal intubation (OTI) within 72 hours. Statistical analysis was performed using descriptive statistics, 95% confidence intervals (CI) for the success rate, and Fisher's Exact Test to compare curative versus prophylactic applications. Resultados e Conclusions: A total of 1,196 patients were analyzed, of whom 64.3% were male. Among them, 79 (6.6%) received NIV, including 44 (55.7%) for curative purposes and 35 (44.3%) for prophylaxis. A total of 1,196 patients were analyzed (64.3% male) among them, 79 (6.6%) received NIV: 44 for curative purposes (55.7%) and 35 for prophylaxis (44.3%). An overall success rate of 96.2% was achieved (95% CI: 89.3% – 99.2%), with a residual failure rate of only 3.8% (n=3). All recorded failures occurred within the curative group; however, no statistically significant difference in success was observed between the curative and prophylactic groups (p=0.25). These results reflect the precision in patient selection and the systematic choice of the total face interface, which optimizes adaptation and reduces iatrogenic risks.NIV demonstrated a high-resolution rate (96.2%), consolidating itself as a safe and effective strategy in cardiogenic ARF management. The low incidence of failure suggests that protocolized application and high-performance interfaces are determinants of therapeutic success. The results reinforce the strategic role of respiratory physical therapy in hemodynamic stabilization and the reduction of invasive support needs.

THE KANSAS CITY CARDIOMYOPATHY QUESTIONNAIRE–12 <50 PREDICTS HOSPITALIZATION AND DEATH IN 12 MONTHS

JULIANA ARAÚJO NASCIMENTO1; SARAH NAYUMI MAEDA FERREIRA DA SILVA2; MARIANE CECÍLIA REIS2; ANTÔNIO DE PÁDUA MANSUR2; JOHN SPERTUS3; NAOMI KONDO NAKAGAWA2;

(1) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (3) SAINT LUKE'S MID AMERICA HEART INSTITUTE - UNITED STATES;

Introduction/Background: Introduction: Heart failure (HF) is one of the most challenging illnesses for current world health systems. To assess quality of life of patients with HF is highly recommended for clinical evaluations, illness monitoring, and comparisons between interventions as to help setting public health policies. The Kansas City Cardiomyopathy Questionnaire (KCCQ)-12 is a specific health-related quality of life questionnaire for patients with HF, with high levels of validity and reliability properties. Objectives: Purpose: To assess whether there is an association between the KCCQ-12 with clinical outcomes (hospitalization and death) in patients with HF. Methods: Methods: This study was approved by the local Ethics Committee (CAAE: 74659717.7.0000.0065). We administered KCCQ-12 and the New York Heart Association functional classification (NYHA) by telephone to 129 patients. We included patients of both sexes with left ventricular ejection fraction (LVEF) ≤ 45 %, and aged ≥ 18 years. Demographic and clinical data were collected from electronic medical records. We followed patients monthly over one year. Resultados e Conclusions: Results: From October 2020 to December 2022, 129 patients participated in the study. Among them, 64% were male, mean age: 58 years, mean LVEF: 28%, NYHA III-IV: 55%, and mean KCCQ-12: 51. Over one year, n=16 patients were hospitalized and n=3 died from cardiovascular causes. We compared two subgroups of patients: KCCQ<50 (n=63) with worse quality of life and KCCQ ≥50 (n=66) with better quality of life, with no significant differences between age (57 vs 60 years, p=0.112), males (64 vs 65%, respectively, p=0.844), and LVEF (29 vs 32%, respectively, p=0.056). However, KCCQ<50 group showed higher proportions of patients with NYHA III-IV in comparison with KCCQ≥50 (89 vs 23%, respectively, p<0.001) and higher occurrences of hospitalizations (21 vs 5%, respectively, p=0.006). We also found a significant moderate to high correlation between KCCQ-12 and NYHA (r=0.67, p<0.001). Conclusions: Worse quality of life assessed by the KCCQ-12 predicts worse clinical outcomes (hospitalizations) over 12 months.

APOC-III INHIBITION WITH OLEZARSEN IN MODERATE AND SEVERE HYPERTRIGLYCERIDEMIA: AN INTEGRATIVE REVIEW OF RANDOMIZED CLINICAL TRIALS

LUISA GUASTI DA SILVA SANTOS1; JOÃO CARLOS ESQUINCALHA LUPARELLI2;

(1) FACULDADE MULTIVIX VITÓRIA - VITÓRIA - ES - BRASIL; (2) UNIVERSIDADE VILA VELHA - VILA VELHA - ES - BRASIL;

Introduction/Background: Moderate and severe hypertriglyceridemia are associated with increased cardiovascular risk and acute pancreatitis, particularly in patients with diabetes and obesity. Despite conventional lipid-lowering therapies, many patients continue to have elevated triglyceride levels. Apolipoprotein C-III (ApoC-III) has emerged as an important therapeutic target because it inhibits lipoprotein lipase activity and reduces clearance of triglyceride-rich lipoproteins. Olezarsen is a GalNAc-conjugated antisense oligonucleotide designed to inhibit hepatic ApoC-III messenger RNA and reduce triglyceride levels. Objectives: This integrative review evaluated the efficacy and safety of olezarsen in adults with moderate or severe hypertriglyceridemia without familial chylomicronemia syndrome, compared with placebo. Methods: The review followed the PICOTT model and included only randomized clinical trials comparing olezarsen with placebo. Searches were conducted in PubMed, Embase, and Cochrane using terms related to hypertriglyceridemia, ApoC-III inhibition, and antisense oligonucleotides. Among 401 identified records, 112 duplicates were removed. After screening and eligibility assessment, four randomized, double-blind, placebo-controlled trials published between 2022 and 2025 were included: Tardif et al. (2022), Bergmark et al. (2024; 2025), and Marston et al. (2025). Resultados e Conclusions: The studies demonstrated consistent triglyceride reductions ranging from 49% to 60%, along with ApoC-III reductions of up to 74%. Olezarsen also reduced VLDL cholesterol, non-HDL cholesterol, and apolipoprotein B levels. In patients with severe hypertriglyceridemia and high pancreatitis risk, treatment was associated with an approximately 85% reduction in acute pancreatitis incidence. The safety profile was generally favorable, with low rates of serious adverse events and good tolerability. However, hepatic enzyme elevations and thrombocytopenia were more frequent with the 80 mg dose. Overall, ApoC-III inhibition with olezarsen appears to be a promising therapeutic strategy for moderate and severe hypertriglyceridemia, particularly in patients with persistent triglyceride elevation despite conventional therapies.

STUDY	DESIGN / POPULATION	INTERVENTION	MAIN RESULTS	SAFETY
Tardif et al. (2022)	Phase 2 randomized, double-blind, placebo-controlled clinical trial. Included 114 patients with moderate hypertriglyceridemia (200–500 mg/dL) and high cardiovascular risk or established atherosclerotic cardiovascular disease.	Subcutaneous olezarsen in different dosing regimens (10 mg every 4 weeks, 15 mg every 2 weeks, 10 mg weekly, and 50 mg every 4 weeks) versus placebo for 6–12 months.	Triglyceride reduction of up to 60% compared with placebo. ApoC-III reduction of up to 74%, in addition to significant decreases in VLDL-cholesterol, non-HDL cholesterol, and apolipoprotein B. Up to 91% of patients achieved TG <150 mg/dL with the 50 mg dose.	No clinically relevant changes in hepatic function, renal function, or platelet count were observed. The most frequent adverse event was mild injection-site erythema.
Bergmark et al. (2024) – Bridge–TIMI 73a	Phase 2b randomized, double-blind, placebo-controlled clinical trial. Included 154 patients with moderate hypertriglyceridemia (150–499 mg/dL) associated with high cardiovascular risk or severe hypertriglyceridemia (≥500 mg/dL).	Olezarsen 50 mg or 80 mg monthly versus placebo for 12 months.	Triglyceride reductions of 49.3% and 53.1% were observed with the 50 mg and 80 mg doses, respectively. Significant reductions in ApoC-III, apolipoprotein B, and non-HDL cholesterol were also reported, without relevant increases in LDL-cholesterol.	Adverse events and serious adverse events occurred at similar frequencies across groups. Clinically relevant hepatic, renal, and platelet abnormalities were uncommon.
Bergmark et al. (2025) – ESSENCE–TIMI 73b	Phase 3 randomized, double-blind, placebo-controlled clinical trial. Included 1349 patients with moderate hypertriglyceridemia (150–499 mg/dL) and high cardiovascular risk or severe hypertriglyceridemia (≥500 mg/dL).	Olezarsen 50 mg or 80 mg monthly versus placebo.	Demonstrated significant and sustained triglyceride reduction compared with placebo after 6 months of treatment, in addition to ApoC-III reduction. Confirmed the efficacy of olezarsen in a large multicenter population.	Safety profile was consistent with previous studies, with good overall tolerability and low incidence of serious adverse events.
Marston et al. (2025) – CORE-TIMI 72a / CORE2-TIMI 72b	Two randomized, double-blind, placebo-controlled clinical trials. Included 1061 patients with severe hypertriglyceridemia and high risk of acute pancreatitis.	Olezarsen 50 mg or 80 mg monthly versus placebo for 12 months.	Significant reductions in triglyceride levels were observed after 6 and 12 months of treatment. Important reductions in ApoC-III, remnant cholesterol, and non-HDL cholesterol were also reported. The incidence of acute pancreatitis was approximately 85% lower with olezarsen compared with placebo.	Overall adverse events were similar across groups. Elevation of liver enzymes, thrombocytopenia, and increased hepatic fat content occurred more frequently with the 80 mg dose.

ARTIFICIAL INTELLIGENCE ENABLED RECOGNITION OF CORONARY ARTERY CALCIUM (ALERT-CAC): OPPORTUNISTIC SCREENING OF PRIOR NON-GATED CHEST CT TO INCREASE PREVENTIVE THERAPY

IBRAHIM MORTADA1; SHIVA RAJU GOLLAPALLY KRISHNA1; IZHAN HAMZA1; ABDUL QADEER1; DIANN GAALEMA1; MOHANAD ALBAYYAA1; HANI JNEID1;

(1) UNIVERSITY OF TEXAS MEDICAL BRANCH - UNITED STATES;

Introduction/Background: Coronary artery calcium (CAC) on non-gated chest computed tomography (CT) is a strong marker of cardiovascular risk but is often underrecognized in routine care. Artificial intelligence (AI) can enable opportunistic CAC detection from existing imaging and translate incidental findings into preventive action. Objectives: We evaluated whether an AI-enabled CAC identification and notification workflow was associated with downstream clinical care and treatment changes. Methods: We conducted a quality improvement evaluation of adults aged ≥18 years who underwent non-gated chest CT between May 2024 and May 2025 and had not seen a cardiologist in the prior 2 years. Patients were excluded for known CAD, prior CABG or PCI, recent cardiovascular diagnostic testing, or poor-prognosis noncardiac conditions. A validated FDA-approved deep learning algorithm with physician confirmation identified CAC. Patients with CAC scores of 100–299 (moderate) or ≥300 (severe), based on SCCT/STR guidance, triggered clinician and patient notification. Outcomes included CAC-related care-seeking, cardiology and primary care follow-up, statin and aspirin changes, cardiovascular diagnostic testing, and revascularization. Groups were compared using Wilcoxon rank-sum and chi-square/Fisher exact tests, with multivariable logistic regression adjusted for age and sex. Resultados e Conclusions: Among 4,659 screened patients, 340 (7.3%) had CAC ≥100 and received notification; 171 had CAC 100–299 and 169 had CAC ≥300. Patients with severe CAC were older (median age 71 vs 68 years, p=0.006) and had higher baseline statin use (59% vs 38%, p<0.001), hypertension (87% vs 70%, p<0.001), and hyperlipidemia (80% vs 63%, p<0.001). After notification, 19% had CAC-related care-seeking, 27% cardiology follow-up, 48% primary care follow-up, 50% a statin change, 13% statin initiation, 33% an aspirin change, 18% cardiovascular diagnostic testing, and 2.6% cardiac intervention. Compared to moderate CAC, severe CAC was associated with higher care-seeking (25% vs 12%, p=0.002), cardiology follow-up (36% vs 19%, p<0.001), aspirin change (40% vs 26%, p=0.006), and diagnostic testing (24% vs 13%, p=0.010). In adjusted analysis, severe CAC remained associated with diagnostic testing (OR 2.01, 95% CI 1.13–3.65, p=0.02). An AI-enabled opportunistic CAC detection and notification pathway was associated with meaningful downstream clinical action, especially in patients with severe CAC, and may help close a gap in cardiovascular risk recognition using existing imaging

(1) ESCOLA DE ENFERMAGEM DA UNIVERSIDADE FEDERAL DE MINAS GERAIS - BH - MG - BRASIL; (2) ESCOLA DE ENFEMAGEM DA UNIVERSIDADE FEDERAL DE MINAS GERAIS - BH - MG - BRASIL; (3) ESCOLA DE ENFERMAGEM DA UNIVERSIDADE FERDERAL DE MINAS GERIAS - BELO HORIZONTE - MG - BRASIL; (4) ESCOLA DE ENFERMAGEM DA UNIVERSIDADE FEDERAL DE MINAS GERIAS - BELO HORIZONTE - MG - BRASIL; (5) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Introduction: Anemia is a public health problem worldwide, and when related to lipid profile, it may be associated with metabolic alterations, such as reduced low-density lipoprotein (LDL). There are gaps regarding this relationship in the Brazilian adult population. Objectives: Objective: To analyze the association between anemia and lipid profile alterations in Brazilian adults. Methods: Methods: A cross-sectional study using data from the Brazilian National Health Survey (2014–2015), including 8,952 adults. Prevalence and 95% confidence intervals (95%CI) were estimated for anemia and lipid outcomes, according to sex, age, race/skin color, and region. Anemia was defined as hemoglobin < 13.0 g/dL in men and < 12.0 g/dL in women. Lipid profile cut-off points were: low HDL ≤ 40 mg/dL, high LDL ≥ 130 mg/dL, and high total cholesterol (TC) > 190 mg/dL. Differences were assessed using Pearson's chi-square test (p ≤ 0.05). Associations were examined using logistic regression models, with odds ratios (OR) and 95%CI adjusted for sex, age, and race/skin color. Resultados e Conclusions: Results: For high TC, prevalence was 43.0% (95%CI: 41.2–44.8) among adults without anemia and 34.4% (95%CI: 32.5–36.3) among those with anemia (p<0.05). For high LDL, prevalences were 19.2% (95%CI: 18.0–20.4) and 13.8% (95%CI: 12.7–15.0), respectively (p<0.05). For low HDL, prevalences were 35.1% (95%CI: 33.6–36.6) and 32.6% (95%CI: 31.1–34.1), respectively (p>0.05). Anemia was associated with lower odds of high TC (OR 0.6; 95%CI: 0.5–0.8), in men (OR 0.4; 95%CI: 0.3–0.6) and women (OR 0.8; 95%CI: 0.6–1.0), and in individuals aged ≥50 years (OR 0.5; 95%CI: 0.4–0.6). For high LDL, anemia was also associated with lower odds of the outcome (OR 0.7; 95%CI: 0.5–0.9), in women (OR 0.7; 95%CI: 0.6–1.0) and men (OR 0.5; 95%CI: 0.3–0.8), and among adults aged ≥50 years (OR 0.5; 95%CI: 0.4–0.6). A protective effect was observed in the North (OR 0.6; 95%CI: 0.3–0.9), Southeast (OR 0.5; 95%CI: 0.3–0.8), and South (OR 0.4; 95%CI: 0.2–1.0). White individuals with anemia had lower odds of high LDL (OR 0.6; 95%CI: 0.4–0.9). Conclusion: Anemia was associated with lipid profile alterations, particularly high total cholesterol and LDL, from age 50 onward, with greater magnitude in men and variation by region and race/skin color. The findings highlight the need to strengthen surveillance actions and public policies to prevent and manage anemia and cardiovascular risk factors, considering sociodemographic inequalities.

ASSOCIATION OF TILT TABLE TEST FINDINGS WITH HEMODYNAMIC AND CLINICAL VARIABLES IN DOWN SYNDROME

ANNE GERYMAIA OLIVEIRA DE MELO SILVA1; LUCINANA BARTOLOMEI ORRU D´AVILA1; NEILA ANDERS AIDAR1;

(1) MEDCOR MEDICINA - BRASÍLIA - DF - BRASIL;

Introduction/Background: Down syndrome is the most common chromosomal disorder and is associated with a wide range of cardiovascular abnormalities. While structural heart disease has been extensively studied, less is known about functional vascular and autonomic alterations. Emerging evidence suggests that individuals with Down syndrome may exhibit reduced arterial stiffness and altered autonomic regulation. However, the interaction between vascular function, aging, and metabolic factors remains unclear. Objectives: This study aimed to characterize vascular, autonomic, and metabolic parameters in 100 individuals with Down syndrome. Methods: This cross-sectional study included 100 patients. Central blood pressure, pulse wave velocity (PWV) and metabolic parameters were analyzed. Resultados e Conclusions: Results: Central systolic pressure (CSP) and cardiac output (CO) were significantly lower in the abnormal tilt table test group than in the normal group (CSP: 85.2 ± 1.1 vs. 89.8 ± 1.6 mmHg, p=0.016; CO: 3.4 ± 0.0 vs. 3.6 ± 0.0 L/min, p=0.002), with no significant differences observed in central diastolic pressure, central pulse pressure, pulse wave velocity (PWV), or total vascular resistance. PWV was below the expected range in 62.5% of patients, with no cases of elevated values and showed a strong positive correlation with age (r = 0.77, p < 0.001). CSP and diastolic blood pressure (CDP) were low across the cohort. Obese patients had significantly higher triglyceride levels (p = 0.045) and a trend toward higher PWV (p = 0.056), while no differences were observed in LDL, HDL, or fasting glucose. Tilt table test and central hemodynamic variables are summarized in Table 1, while laboratory indices are presented in Table 2. Conclusion: This study demonstrates a distinct cardiovascular phenotype in individuals with Down syndrome. Patients with Down syndrome exhibited a high prevalence of abnormal tilt table test results. . The predominance of low PWV suggests increased arterial compliance, contrasting with the pattern observed in the general population. Metabolic findings revealed a selective alteration, with increased triglycerides in obese individuals but no changes in LDL, HDL, or glucose. This suggests a dissociation between obesity and classical atherogenic profiles. Together, these findings support the concept of a unique cardiometabolic profile in Down syndrome, characterized by vascular protection and selective metabolic modulation, with no association with vasovagal syncope.

Table 1 – Tilt Table Test and Central Hemodynamic Variables in 100 Adults with Down Syndrome

	Abnormal TT (n=61)		Normal TT (n=39)		
	Mean	DP	Mean	DP	p-value
CSP (mmHg)	85.2	1.1	89.8	1.6	**0.016**
CDP (mmHg)	62.9	1.0	63.9	1.2	0.563
CPP (mmHg)	21.9	0.8	23.6	1.1	0.218
CO (L/min)	3.4	0.0	3.6	0.0	**0.002**
TVR (mmHg/ml)	1.2	0.0	1.2	0.0	0.530
PWV (m/s)	4.4	0.1	4.7	0.1	0.185

Abbreviations: CSP = central systolic pressure; CDP = central diastolic pressure; CPP = central pulse pressure; CO = cardiac output; TVR = total vascular resistance; PWV = pulse wave velocity; p-value = statistical significance level

Table 2 – Tilt Table Teste and Clinical Variables in 100 Adults with Down Syndrome

	Abnormal TT (n=61)		Normal TT (n=39)		
	Mean	SD	Mean	SD	p-value

ASSOCIATION OF VERY HIGH LIPOPROTEIN(A) LEVELS WITH SIGNIFICANT CORONARY ARTERY CALCIFICATION IN A CARDIOVASCULAR PREVENTION CLINIC IN SOUTHERN BRAZIL

PAULO EDUARDO BALLVÉ BEHR1; RAFAEL VIANNA BEHR1; RODRIGO SILVA HINTZ1; LAURA COLLET KROLIKOWSKI1; PAOLA LUCCHESE SCHÜTZ1; PAULO ERNESTO LEÃES1; FERNANDO ANTÔNIO LUCCHESE1;

(1) SANTA CASA DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Lipoprotein(a) [Lp(a)], particularly at very high levels, has emerged as an important genetic risk factor for coronary artery disease (CAD). Coronary artery calcium (CAC) score is a marker of subclinical atherosclerosis. Both are risk predictors that assist therapeutic decision-making in cardiovascular prevention. Recent studies have sought to clarify the association between these two factors. Objectives: To evaluate the association between very high Lp(a) levels and significant coronary artery calcification (CAC ≥ 100). Methods: This matched cross-sectional study included patients aged 45 to 70 years attending a cardiovascular prevention outpatient clinic, covered by private health insurance, in Southern Brazil, who had available Lp(a) and CAC measurements. To better assess the impact of Lp(a), two groups were included: very high Lp(a) (≥ 190 nmol/L or ≥ 85 mg/dL) and non-elevated Lp(a) (< 125 nmol/L or < 50 mg/dL). Groups were matched by sex and age (± 3 years). Significant coronary artery calcification was defined as CAC ≥ 100. The following baseline characteristics were evaluated: hypertension, diabetes, smoking, severe hypercholesterolemia (LDL-C ≥ 190 mg/dL), and family history of premature CAD (men < 55 years or women < 60 years). Resultados e Conclusions: A total of 160 patients were included (80 in each group); mean age was 57.9 ± 6.6 years; 65.0% were women; 46.9% had hypertension; 29.4% had severe hypercholesterolemia; 24.4% had a family history of premature CAD; 8.8% were smokers; and 4.4% had diabetes. There were no statistically significant differences in baseline characteristics between groups. Regarding coronary calcification, median CAC was 28.5 (0–134.5) in the very high Lp(a) group and 9.0 (0–77.8) in the non-elevated Lp(a) group (p = 0.013). CAC = 0 was observed in 33.8% of patients with very high Lp(a) compared with 40.0% of those with non-elevated Lp(a) (p = 0.511). Regarding the primary outcome, significant coronary artery calcification (CAC ≥ 100) was more prevalent in the very high Lp(a) group (33.8% vs. 17.5%; prevalence ratio 1.93 [1.10–3.40]; p = 0.015). In conclusion, patients with very high Lp(a) levels showed a higher prevalence of significant coronary artery calcification. These findings support the association between Lp(a) and CAD and suggest that individuals with very high Lp(a) may also be more susceptible to significant subclinical atherosclerosis.

BEYOND TRADITIONAL RISK SCORES: A NOVEL COMMUNITY CARDIOVASCULAR VULNERABILITY INDEX INTEGRATING LIFESTYLE AND ACCESS DETERMINANTS IN TRIBAL POPULATIONS OF HIMACHAL PRADESH, INDIA

AMIT SACHDEVA1;

(1) INDIRA GANDHI MEDICAL COLLEGE SHIMLA HIMACHAL PRADESH - INDIA;

Introduction/Background: Cardiovascular risk assessment in resource-limited and geographically isolated populations remains inadequate due to reliance on laboratory-based models and poor consideration of lifestyle and access-related vulnerabilities. Tribal populations represent a critical evidence gap requiring context-specific, scalable approaches. Objectives: To estimate cardiovascular risk using validated non-laboratory tools and to develop a novel Community Cardiovascular Vulnerability Index (CCVI) integrating lifestyle, dietary, and healthcare access factors in tribal regions of Himachal Pradesh, India. Methods: A community-based cross-sectional study was conducted among adults ≥18 years in tribal districts of Himachal Pradesh (Lahaul and Spiti, Kinnaur, and Chamba) using multistage sampling. Cardiovascular risk was assessed using non-laboratory WHO/ISH Risk Prediction Charts. A composite CCVI (0–100) was derived from four equally weighted domains: clinical risk, behavioral factors (physical activity via GPAQ, tobacco, alcohol), dietary exposure (salt, sugar, fat, fruit–vegetable intake), and healthcare access/awareness. Variables were assessed using structured questionnaires adapted from WHO STEPS. Internal consistency and multivariate analysis were performed. Resultados e Conclusions: A total of 452 participants (mean age 41.7 ± 15.1 years; 53% female) were included. Based on non-laboratory WHO/ISH Risk Prediction Charts, 24.1% were classified as moderate-to-high cardiovascular risk. However, the composite CCVI identified 42.3% as high vulnerability, indicating substantial underestimation by conventional risk models. Behavioral and dietary risk factors were highly prevalent: 61.2% of participants had low physical activity, 39.8% reported tobacco use, and 68.5% demonstrated high dietary risk (excess salt, sugar, and visible fat intake with inadequate fruit–vegetable consumption). Healthcare access challenges were prominent, with a significant proportion reporting seasonal inaccessibility and low awareness of cardiovascular risk. On multivariate analysis, low physical activity, high dietary exposure, and poor healthcare access were independently associated with elevated CCVI scores (p < 0.01). Notably, 31% of individuals categorized as low clinical risk were reclassified as high vulnerability after incorporating lifestyle and access factors. In Conclusion, the CCVI uncovers hidden cardiovascular risk and enables context-sensitive, scalable prevention in resource-limited settings.

BLOOD PRESSURE AND CARDIORESPIRATORY FITNESS ARE ASSOCIATED WITH ARTERIAL STIFFNESS IN MEN WITH PREVIOUS CORONARY ARTERY DISEASE

VITOR BRUNO TEIXEIRA DE HOLANDA1; TTHIAGO DIPP2; CLÁUDIA FETTER2; LUCIANNA SERFATY DE HOLANDA1; ODILON SALIM COSTA ABRAHIN3; REJANE WALESSA PEQUENO RODRIGUES ABRAHIN3; STEFANY MEL BARROS VALE1;

(1) FUNDACAO HOSPITAL DE CLINICAS GASPAR VIANNA PA - BELÉM - PA - BRASIL; (2) INSTITUTO DE CARDIOLOGIA / FUNDAÇÃO UNIVERSITARIA DE CARDIOLOGIA - PORTO ALEGRE - RS - BRASIL; (3) UNIVERSIDADE ESTADUAL DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introduction/Background: In patients with coronary artery disease (CAD), arterial stiffness may increase ventricular afterload, alter wave reflection, and contribute to a worse hemodynamic and functional profile. Pulse wave velocity (PWV) and augmentation index (AIX) are markers of arterial stiffness with potential utility in vascular risk stratification in secondary prevention patients Objectives: To evaluate, in men with previous CAD, the association between baseline arterial stiffness, blood pressure, and cardiorespiratory fitness in patients followed at a chronic coronary artery disease Methods: This was a cross-sectional baseline study including 63 men with previous CAD. The following variables were assessed: PWV, AIX, vascular age, baseline and pre-PWV blood pressure, VO□max, peak VO□, METs, and chronotropic index. Associations between continuous variables were analyzed using Spearman's correlation. A logistic regression model was used to evaluate factors associated with off-target PWV, adjusted for age Resultados e Conclusions: Mean age was 61.1±10.0 years. Mean PWV was 8.83±1.85 m/s and mean AIX was 17.42±13.95. PWV and AIX were above target values in 42.9% and 46.0% of participants, respectively. PWV was positively correlated with age (rho=0.848; p<0.001), baseline systolic blood pressure (rho=0.472; p<0.001), pre-PWV systolic blood pressure (rho=0.471; p<0.001), and pre-PWV diastolic blood pressure (rho=0.383; p=0.002). Inverse correlations were observed between PWV and VO□max (rho=-0.577; p<0.001), peak VO□ (rho=-0.454; p=0.004), and METs (rho=-0.476; p=0.002). Blood pressure above target was more frequent among patients with off-target PWV (81.5% vs. 50.0%; p=0.017). After adjustment for age, off-target blood pressure remained associated with higher odds of off-target PWV (OR 4.48; 95% CI 1.33–15.05; p=0.015). Self-reported medication adherence was 77.8%, whereas only 44.3% achieved LDL cholesterol <55 mg/dL. Altered glucose levels/prediabetes or values compatible with diabetes were observed in 49.2% of participants. Conclusions: In men with previous CAD, baseline arterial stiffness was mainly associated with age, blood pressure burden, and lower cardiorespiratory fitness. Blood pressure above target remained associated with a greater likelihood of off-target PWV even after adjustment for age. Despite good self-reported adherence, there was substantial residual blood pressure, lipid and glycemic risk, suggesting opportunities for therapeutic optimization and cardiovascular rehabilitation.

BNP AS A MARKER OF CARDIAC STRESS IN INDIVIDUALS WITHOUT HEART FAILURE: PREDICTING LONG-TERM OUTCOMES IN A POPULATION-BASED STUDY

HUMBERTO VILLACORTA1; DAVYSON GERHARDT DE SOUZA1; EVANDRO TINOCO MESQUITA1; ANTÔNIO JOSÉ LAGOEIRO JORGE1;

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL;

Introduction/Background: B-type natriuretic peptide (BNP) is a diagnostic and prognostic marker in heart failure (HF). However, its prognostic role in populations with cardiovascular risk factors but without baseline HF is not well established. Patients with risk factors, without HF may have elevated BNP, a condition named cardiac stress. Objectives: To evaluate the role of BNP in predicting long-term cardiovascular events in a population without baseline HF. Methods: Retrospective analysis of a population-based study in which 633 individuals aged >45 years were randomly selected from a primary health care program. In the present study, 527 individuals who completed at least 5 years of follow-up were included. Patients with HF or a history of heart disease, such as acute myocardial infarction (AMI), valvular heart disease, or asymptomatic left ventricular (LV) systolic dysfunction, were excluded. BNP was measured at baseline. The primary endpoint was time to cardiovascular death or hospitalization. Resultados e Conclusions: The mean age of the population was 59±9.9 years, and 191 (36.2%) were men. The mean LV ejection fraction was 62±5.7%, and the median BNP level was 15 (1st and 3rd quartiles = 10 and 28) pg/mL. Fifty-eight (11%) individuals experienced the endpoint. A BNP cutoff of 22 pg/mL showed a sensitivity of 68.4%, specificity of 68.6%, and a negative predictive value of 94.6% for the primary endpoint (area under the curve 0.70 [95% CI 0.63–0.77], p<0.0001). Event-free survival was lower among individuals with BNP >22 pg/mL (65% vs. 94%, log-rank p<0.0001). In multivariate analysis using the Cox proportional hazards model, variables independently associated with the endpoint were age (HR 1.05 [1.02–1.08], p=0.006), BNP (HR 1.01 [1.00–1.01], p=0.022), and creatinine (HR 2.61 [1.04–6.53], p=0.04) (HRs per 1-unit increase for all three continuous variables). Conclusions: BNP is an independent predictor of long-term events in individuals free of HF or other heart diseases at baseline and therefore represents a marker of cardiac stress.

BODY FAT PERCENTAGE AND TRIGLYCERIDES IN POSTMENOPAUSAL HOSPITAL WORKERS: A BIOIMPEDANCE-BASED CARDIOMETABOLIC ASSESSMENT

LEONARDO ANDRADE FERNANDES DE LUCA1; LUIS FILIPE AZEVEDO DE CARVALHO1; RODRIGO VASCONCELLOS TAVARES BRAVO1; MARIA DE FATIMA MARTINS GIL DIAS1; BRUNO DE QUEIROZ CLAUDIO1; FLAVIO ANDRADE CAMACHO2; LARISSA FRANCO DE ANDRADE1; ANA BEATRIZ DOS SANTOS RIBEIRO2; RODRIGO SILVA GAMMERDINGER2; RAYANE FARIAS AUGUSTO PENNA2; ISABELLA DE MEDEIROS MORAES2;

(1) HOSPITAL QUINTA D´OR - RIO DE JANEIRO - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL;

Introduction/Background: Postmenopausal women experience estrogen-related shifts in fat distribution and lipid metabolism, increasing atherogenic dyslipidemia risk. Body mass index (BMI) fails to capture this adiposity remodelling, as it does not distinguish fat from lean mass. Bioimpedance analysis (BIA) enables direct quantification of body fat percentage (BF%), offering a more sensitive tool for cardiometabolic risk stratification in this population. Objectives: To evaluate the association between BF% measured by BIA and serum triglyceride (TG) levels in postmenopausal female hospital workers. Methods: Cross-sectional observational study of 20 postmenopausal women (age range 58–67 years, mean 62 years) undergoing institutional cardiovascular screening. All participants completed a 12-hour fast before collection of a fasting lipid panel and BIA using a Biodynamics BIA 450 single-frequency tetrapolar analyzer, following standardized protocols. Participants were stratified by BF% (≤35% vs. >35%). Serum triglycerides, total cholesterol, HDL-C, LDL-C, non-HDL-C, and TG/HDL ratio were assessed. Associations were evaluated by Pearson correlation; group differences by Mann-Whitney U test. Resultados e Conclusions: RESULTS Mean BF% was 35.9%. A statistically significant moderate positive correlation was observed between BF% and serum TG (r = 0.46, p = 0.042). Women with BF% >35% (n=13) showed higher mean TG compared with those with BF% ≤35% (n=7) (181 vs. 114 mg/dL; p = 0.056), with the difference approaching but not reaching conventional significance. The TG/HDL ratio — a proxy for insulin resistance — was numerically higher in the higher-adiposity group (3.2 vs. 2.1). Total cholesterol (mean 205 mg/dL), LDL-C (mean 111 mg/dL), and HDL-C (mean 63 mg/dL) were similar across strata. Four participants (20%) had TG/HDL ≥3.5, indicating elevated insulin resistance risk. CONCLUSIONS In postmenopausal hospital workers, BF% assessed by single-frequency tetrapolar BIA was significantly correlated with serum triglycerides, independently of BMI-based classification. These findings support the integration of direct body composition assessment into cardiometabolic risk stratification strategies for postmenopausal women, a population where adiposity-driven dyslipidaemia may go undetected by conventional anthropometric screening. Given the limited sample size, these exploratory findings require validation in larger cohorts.

Introduction/Background: Preventing cardiovascular disease (CVD) is a strategy to alleviate the burden of mortality, morbidity and healthcare costs that CVD represents. Risk stratification is made through various calculators that estimate individual risk of developing CVD. Risk modulating and modifying factors are fundamental for accurately establishing cardiovascular risk. Subclinical atherosclerosis is a major risk modifier. Point-of-care ultrasound (POCUS) represents a growing trend, with proven effectiveness in detecting subclinical carotid atherosclerosis. Handheld ultrasound (HHU) has reduced the costs for performing POCUS and opens an opportunity to generalize this practice. Its effectiveness needs to be demonstrated in different groups of patients. Objectives: Evaluate with HHU in a primary care setting the presence of subclinical carotid atheromatosis in patients after cardiovascular risk assessment using the Pan American Health Organization's HEARTS risk calculator, when the calculated risk is low or moderate. Methods: A cross-sectional observational study was conducted. Patients over 40 years of age who attended the obesity screening sessions and consented to participate were included. Cardiovascular risk was calculated using the PAHO risk calculator. Those with low or moderate cardiovascular risk and modulating risk factors underwent carotid ultrasound with a HHU performed by trained cardiologists to determine the presence of subclinical atherosclerosis. Resultados e Conclusions: 125 patients were included with a mean age of 60 years (SD 10.8), 80% women. 3% of the patients had a history of CAD, 1.5% of stroke, 6% of peripheral vascular disease, 2% of kidney disease, and 22% of diabetes. 70% of the patients did not know their cholesterol levels. 34% had a history of smoking. 45% had high blood pressure. Based on their BMI, 21% of the patients were overweight and 76% obese. According to the risk stratification, 24% of patients were at low risk, 30% at moderate risk and 46% at high risk or very high risk of developing CVD. 68 patients with low to moderate risk underwent carotid ultrasound at the time of the consultation, revealing carotid plaques in 35% of them. After the ultrasounds were performed, the percentage of patients at high and very high risk increased to 64.8%, representing an absolute increase of 18.8%. This study demonstrates the promising utility of point-of-care ultrasound with low-cost, handheld, portable ultrasound devices for the detection of subclinical atherosclerosis improving risk stratification.

COMPARATIVE CARDIOVASCULAR EFFICACY OF SGLT2 INHIBITORS AND GLP-1 RECEPTOR AGONISTS: A BAYESIAN NETWORK META-ANALYSIS OF 22 RANDOMIZED TRIALS

MARCÍLIO DE OLIVEIRA FILHO1; SUELEN QUEIROZ2; MARINA AZEVEDO AMARAL1; ANISIO UCHOA LEITE SANTANA3; MIGUEL CHAVES LENZI4; EDUARDO BELLO MARTINS5; ANTONIO ESCAMILLA GARCIA6; LÍVIA SANTOLIA LAMOUNIER1; RENATO LABOISSIERE7;

(1) FACULDADE DE MEDICINA DE BARBACENA - BARBACENA - MG - BRASIL; (2) UNIVERSIDADE ESTADUAL DE PONTA GROSSA - PONTA GROSSA - PR - BRASIL; (3) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (4) UNIVERSIDADE ESTADUAL DO RIO GRANDE DO NORTE - MOSSORÓ - RN - BRASIL; (5) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (6) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (7) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Both SGLT2 inhibitors and GLP-1 receptor agonists reduce major adverse cardiovascular events (MACE) in patients with type 2 diabetes, yet no large-scale head-to-head trials directly compare the two classes. A network meta-analysis that jointly synthesizes evidence from both classes enables indirect comparisons and provides a probabilistic ranking of treatment efficacy. Objectives: To compare the cardiovascular efficacy of SGLT2 inhibitors and GLP-1 receptor agonists in reducing major adverse cardiovascular events (MACE) using a Bayesian network meta-analysis of randomized controlled trials, and to rank treatments according to their relative effectiveness. Methods: This Bayesian network meta-analysis included 22 two-arm randomized controlled trials (total N = 124,112 patients) derived from cardiovascular outcome trials. The network was fully connected, with no multi-arm trials. Eleven treatments were compared: three SGLT2 inhibitors (canagliflozin, dapagliflozin, empagliflozin), seven GLP-1 receptor agonists (albiglutide, dulaglutide, exenatide, liraglutide, lixisenatide, subcutaneous semaglutide, oral semaglutide), and placebo. The primary outcome was the composite of cardiovascular death, nonfatal myocardial infarction, or nonfatal stroke (MACE). A random-effects model was used to estimate odds ratios (ORs) with 95% credible intervals (CrIs). Treatment ranking was quantified using the Surface Under the Cumulative Ranking curve (SUCRA). Between-study heterogeneity was assessed by the between-study standard deviation (sd). Results: Compared with placebo, five treatments demonstrated Resultados e Conclusions: Compared with placebo, five therapies significantly reduced MACE: subcutaneous semaglutide (OR 0.773; 95% CrI 0.631–0.931), albiglutide (0.807; 0.703–0.939), canagliflozin (0.816; 0.716–0.934), liraglutide (0.822; 0.702–0.943), and empagliflozin (0.855; 0.747–0.978). Dulaglutide and exenatide showed non-significant trends, while dapagliflozin, lixisenatide, and oral semaglutide were not superior. Ranking favored subcutaneous semaglutide (SUCRA 81.4%), followed by oral semaglutide (76.1%) and albiglutide (71.9%). Although oral semaglutide had the highest probability of being best (40.7%), subcutaneous semaglutide showed the most consistent overall performance. Heterogeneity was low (sd = 0.05; 95% CrI 0.00–0.14). Overall, subcutaneous semaglutide ranked as the most effective therapy for MACE reduction.

COMPARISONS BY SEX OF METABOLIC AND ANTHROPOMETRIC INDEXES IN ASYMPTOMATIC ADULTS

FERNANDO HENRIQUE GUARNIERI1; ABEL PEREIRA2; ANITA LEME ROCHA SALDANHA2; ANA PAULA PANTOJA MARGEOTTO2; ANDRÉ LUIS VALERA GASPAROTO2; VICTORIA PANTOJA MARGEOTTO2; TANIA LEME ROCHA MARTINEZ2;

(1) UNIVERSIDADE ESTADUAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) BENEFICENCIA PORTUGUESA - SAO PAULO - SP - BRASIL;

Introduction/Background: Abdominal adiposity and the lipid and glycemic profile are important determinants of cardiometabolic risk and vary between men and women. Objectives: This study investigates whether body mass index alone is sufficient to identify these differences or whether measures of fat distribution, such as waist circumference and waist to hip ratio, are more informative. Methods: The Claude Code tool, based on Anthropic's Sonnet 4.6 model, was used as support for data analysis and table preparation. Data from men and women in the same educational environment were analyzed, including clinical and laboratory variables. After excluding extreme body mass index values, 336 women and 269 men remained. Comparisons of means and prevalences were performed, as well as regression analyses to evaluate the relationship between age, sex, adiposity, and metabolic markers. Resultados e Conclusions: Results As shown in Table 1, the mean body mass index was similar between sexes, with no significant difference. However, the distribution presented in Table 2 revealed a higher proportion of overweight among men and a higher frequency of more severe obesity among women. Central adiposity was higher in men, with greater waist circumference and waist to hip ratio, whereas women showed larger hip measurements. Men presented worse metabolic profiles, with higher levels of triglycerides, total cholesterol, uric acid, and blood glucose. Women had higher mean values of high density lipoprotein, but a greater proportion of low levels according to sex specific criteria. Age was the main predictor of blood glucose and triglycerides. Discussion Body mass index alone underestimates risk differences between sexes. Measures of fat distribution and metabolic markers are more effective for risk discrimination. Men show a pattern of higher cardiovascular risk, while women present a distinct profile with specific lipid vulnerability. Conclusion Despite similar body mass index values, men and women exhibit different metabolic profiles. The isolated use of this index is insufficient, and measures such as waist circumference, waist to hip ratio, triglycerides, and uric acid should be included for better assessment of cardiometabolic risk.

Table 1. Descriptive statistics (mean ± standard deviation; median when applicable).

Variable	Women (n=362)	Men (n=280)	p (Welch)
Age (years)	38,7 ± 7,4; 38	41,6 ± 7,9; 41	<0,001
Body mass index (kg/m²)*	26,6 ± 5,4; 26	25,9 ± 5,4; 26	0,098
Waist (cm)	86,3 ± 12,9; 84	92,0 ± 11,9; 91	<0,001
Hip (cm)	99,9 ± 10,6; 100	94,8 ± 8,0; 95	<0,001
Waist/Hip Index	0,86 ± 0,07	0,97 ± 0,07	<0,001
Systolic blood pressure (×10 mmHg)	11,9 ± 2,2	12,2 ± 1,6	0,034

CORRELATION BETWEEN CLINICAL INDICES AND CAROTID ULTRASOUND FINDINGS IN ADULTS WITH DOWN SYNDROME

ANNE ANNE GERYMAIA OLIVEIRA DE MELO SILVA1; LUCIANA BARTOLOMEI ORRU D´AVILA1; CICERO RICARDO TORRES DA COSTA2;

(1) MEDCOR MEDICINA - BRASÍLIA - DF - BRASIL; (2) HOSPITAL DE BASE DO DISTRITO FEDERAL - BRASÍLIA - DF - BRASIL;

Introduction/Background: Down syndrome (DS), caused by trisomy of chromosome 21, is the most common chromosomal disorder and is associated with increased life expectancy due to advances in medical care. Individuals with DS frequently present with metabolic abnormalities such as obesity, dyslipidemia, and insulin resistance. Despite these risk factors, several studies have reported a paradoxically low prevalence of atherosclerosis and coronary artery disease in this population. This phenomenon has been attributed to genetic and molecular mechanisms linked to chromosome 21. Carotid intima-media thickness (IMT) assessed by ultrasound is a well-established marker of subclinical atherosclerosis and cardiovascular risk. However, data on IMT and its determinants in adults with DS remain limited. Objectives: This study aimed to evaluate the association between clinical and laboratory variables and carotid ultrasound findings in adults with DS. Methods: This cross-sectional study included 110 adults with DS All participants underwent clinical evaluation, including measurement of body mass index (BMI). Laboratory tests included lipid profile (total cholesterol, LDL, HDL, triglycerides) and glycated hemoglobin (HbA1c). Carotid Doppler ultrasound was performed using a Philips Affiniti 70 system. IMT was measured according to standard protocols. Data were analyzed using the SPSS. Continuous variables are presented as mean ± standard deviation. Comparisons between groups were performed using appropriate statistical tests. Resultados e Conclusions: This study demonstrates that increased carotid IMT in adults with DS is associated with age and metabolic parameters, particularly dyslipidemia and glycemic control (Table 1) Interestingly, BMI was not associated with IMT, suggesting that obesity may not play the same role in cardiovascular risk in DS as in the general population. The absence of atherosclerotic plaques in our cohort reinforces this concept and supports the hypothesis of protective mechanisms related to trisomy 21, possibly involving differences in lipid metabolism, inflammation, and endothelial function. Conclusion: Despite the presence of cardiovascular risk factors, the absence of atherosclerotic plaques suggests a distinct vascular profile in this population. Routine vascular assessment using carotid ultrasound may be useful for early detection ofsubclinical changes and risk stratification in adults with DS.

COST-EFFECTIVENESS OF DYSLIPIDEMIA DIAGNOSIS AND TREATMENT IN THE BRAZILIAN SUS

MATHEUS MARQUES FRANCA1; SERGIO HENRIQUE RODOLPHO RAMALHO1; RAFAEL SILVA CORTES1; LUIZ SERGIO FERNANDES DE CARVALHO1;

(1) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introduction/Background: Dyslipidemia is associated with atherosclerotic cardiovascular disease (AVCD). In Brazil, events occur at least a decade earlier than in high-income countries. The LDL-C threshold and the age range above which diagnosis and treatment become cost-effective within the Brazilian Unified Health System (SUS) in unknown. Our objective was to estimate the net health benefit (NHB) of dyslipidemia diagnosis and treatment stratified by pre-treatment LDL-C, age at diagnosis, sex, and cardiovascular history. Objectives: We therefore aimed to estimate the net health benefit (NHB) of diagnosing and treating dyslipidemia from the SUS perspective, stratified by pre-treatment LDL-C level, age at diagnosis, sex, and prior cardiovascular history, against a willingness-to-pay threshold of R$55,000 per QALY Methods: A lifetime-horizon cohort Markov model was built in Open Markov (Markov Influence Diagram methodology), comprising four health states: healthy, acute cardiovascular event, stable post-event, and death. Hypothetical cohorts combined age at diagnosis (10, 30, 50, 70 years), pre-treatment LDL-C (80–320 mg/dL), sex, and prior cardiovascular history. Treatment reflected 2025 Brazilian Guidelines -recommended statin/ezetimibe regimens (mean LDL-C reduction: 33.4%, CPRD cohort). Primary outcome was NHB in QALYs against a willingness-to-pay threshold of BRL 55,000/QALY (one GDP per capita). Probabilistic sensitivity analysis used 5,000 Monte Carlo simulations. Resultados e Conclusions: NHB was positive with pre-treatment LDL-C ≥160 mg/dL, across all subpopulations regardless of age or cardiovascular history (range: 0.25–2.23 QALYs). In secondary prevention, cost-effectiveness extended to LDL-C ≥80 mg/dL (NHB: 0.19–0.26 QALYs). Diagnosis at age 10 with LDL-C = 320 mg/dL yielded 25.75 additional event-free years. Net SUS savings reached BRL 114,148/patient at LDL-C = 320 mg/dL diagnosed at age 10. In primary prevention, LDL-C ≥160 mg/dL constitutes the cost-effectiveness threshold for dyslipidemia treatment within the SUS. In secondary prevention, cost-effectiveness extends to LDL-C ≥80 mg/dL, reinforcing the economic justification for aggressive lipid control in established cardiovascular diseases. These findings support universal childhood lipid screening and family cascade testing and provide a quantitative basis for CONITEC health technology assessments.

DIAGNOSTIC PRACTICES AND EMERGING RISK BIOMARKERS IN ATHEROSCLEROTIC CARDIOVASCULAR DISEASE WITH STAGE 3-4 CHRONIC KIDNEY DISEASE: FINDINGS FROM BRAZIL, ISRAEL, AND SAUDI ARABIA

RAUL D. SANTOS1; WALEED ALHABEEB1; MOSAAD ALHUSSEIN1; YARON ARBEL1; OREN CASPI1; NANCY T. COELHO1; LUIZ CLAUDIO DANZMANN1; SHLOMI MATETZKI1; MONICA MATHIAS1; ADI M. MENAHEM1; LIDIA ANA ZYTYNSKI MOURA1; FRANCISCO FONSECA1;

(1) NOVO NORDISK - SWITZERLAND;

Introduction/Background: Introduction: Diagnostic pathways for atherosclerotic cardiovascular disease (ASCVD) with stage 3–4 chronic kidney disease (CKD) are fragmented, with inconsistent use of inflammatory and lipid biomarkers including C-reactive protein (CRP; wide-range and high-sensitivity), LDL-C, apolipopro-tein B, and lipoprotein(a) [Lp(a)]. Objectives: Objectives: This study mapped real-world diagnostic approaches and quantified use of CRP, lipid testing, repeat testing, referral times, and barriers across Saudi Arabia, Israel, and Brazil. Methods: Methods: A web-based survey of 315 clinicians in Saudi Arabia (n=110), Israel (n=95), and Brazil (n=110) was conducted. Each submitted three patient record forms (total 945) sampled by diagnosis sequence: ASCVD then CKD, CKD then ASCVD, and a recent patient from either sequence. Resultados e Conclusions: Results: CRP tests were performed in 34% of patients despite 77% of clinicians reporting access; main barriers were lack of availability (41%), lack of insurance coverage (27%), and limited awareness of clinical relevance of test (26%). Advanced lipid testing beyond LDL-C was rare (Lp(a) 16%; apolipoprotein B 10%) (Figure). LDL-C was tested in 39% of cases overall, with higher rates in Saudi Arabia (58%) than Brazil (36%) and Israel (22%) (Figure). CRP use varied by country (Saudi Arabia 46%, Brazil 30%, Israel 26%) (Figure) and specialty (heart failure cardiologists 46%, internal medicine 39%, general cardiologists 34%, nephrologists 26%, primary care physicians 20%). Repeat biomarker testing occurred in 60% of ASCVD and 69% of CKD cases; mean referral time was 1.3±3.4 months. ASCVD was most often confirmed by general cardiologists (47%); common confirmation tests were electrocardiogram (62%), echocardiogram (60%), and blood tests (51%). Conclusion: ASCVD diagnostic practice is variable, with underuse of key biomarkers and delays to diagnosis. Standardised pathways, clinician education, and improved access to CRP and lipid tests may enhance risk stratification and enable more personalised care. Underuse of CRP and Lp(a) testing in patients with ASCVD and CKD limits risk stratification and ability to tailor management. Broader adoption of these biomarkers supported by standardised diagnostic pathways, clinician education, and easier access could enable earlier identification of high-risk patients, support personalised treatment, and align practice with 2025 ESC dyslipidaemia guidelines, which recognise CRP and Lp(a) as key risk modifiers in addition to LDL-C.

DIFFERENTIATION OF THE INFLAMMATORY SUBSTRATE IN THE POST-COVID CONDITION: ENDOTHELIAL ACTIVATION (EASIX) VERSUS SYSTEMIC IMMUNE INFLAMMATION (SII) IN THE GDF-15 PHENOTYPE

MARCIO ROBERTO MORAES DE CARVALHO1; RACHEL VIANNA O'NEILL DE SOUZA1; ALICE RAMOS SILVA2; GUILHERME SCHITTINE BEZERRA LOMBA1; ANTONIO JOSÉ LAGOEIRO JORGE1; NATALIA FONSECA DO ROSÁRIO1; CLAUDIO TINOCO MESQUITA1; JOCEMIR RONALDO LUGON1;

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: EASIX and the Systemic Immune-Inflammation Index (SII) capture distinct inflammatory dimensions in post-COVID cardiovascular condition. EASIX reflects persistent endothelial dysfunction associated with late vascular biomarkers, whereas SII expresses systemic inflammation that is only weakly related to post-COVID cardiovascular manifestations. The phenotype defined by elevated GDF-15 has been widely associated in the literature with cardiovascular cellular stress, endothelial dysfunction, and myocardial involvement, indicating a predominantly inflammatory-vascular axis rather than diffuse systemic inflammation. Objectives: To compare the association of EASIX and SII with the inflammatory–myocardial phenotype defined by elevated GDF-15 in patients with post-COVID condition. Methods: Exploratory observational study derived from a cardiovascular sub-study of a cohort of individuals with post-COVID condition and GDF-15 measurement (n=77), integrated into a project approved by an institutional Research Ethics Committee. Elevated GDF-15 was defined using a cutoff derived from ROC analysis of the cohort itself (~300 pg/mL). EASIX was calculated as LDH × creatinine / platelets (elevated >1), and SII as (platelets × neutrophils) / lymphocytes. A single laboratory observation per individual was used. The indices were compared between individuals with elevated and normal GDF-15 using chi-square and Mann–Whitney tests. Resultados e Conclusions: : A higher prevalence of elevated EASIX was observed among individuals with elevated GDF-15 (57.9% vs. 36.8%), indicating a trend toward association (p=0.11). In contrast, SII showed a similar distribution between groups (medians 542 vs. 498; p=0.90), with no apparent association with the analyzed phenotype. These findings indicate dissociation between endothelial activation and systemic inflammation in post-COVID (Figure 1 **Conclusions** In the post-COVID condition, the phenotype characterized by elevated GDF-15 showed a trend toward association with endothelial activation, but not with systemic immune inflammation. These findings suggest the post-COVID cardiovascular inflammatory substrate may be predominantly endothelial–myocardial, with EASIX potentially being more sensitive in capturing late vascular involvement.

Dissociation of Inflammatory Pathways in Post-COVID Cardiovascular Condition

DISPARITIES IN SECONDARY PREVENTION ACROSS VASCULAR TERRITORIES: INSIGHTS FROM A NATIONAL REGISTRY

ALEJANDRO TOMAS YOUNG1; SEBASTIAN GARCIA ZAMORA2; FACUNDO BALSANO3; MIGUEL SEBASTIAN AYON4; GABRIEL TISSERA5; FABRICIO GASTON PROCOPIO6; PABLO SCHMIDT7; JOAQUIN PEREA7; JUAN JOSE HERRERA PAZ8; GONZALO EMANUEL PEREZ1; FERNANDO GARAGOLI9; PABLO CORRAL10;

(1) CLINICA OLIVOS - ARGENTINA; (2) SANATORIO DELTA - ARGENTINA; (3) SANATORIO ANTARTIDA - ARGENTINA; (4) SANATORIO JUNIN - ARGENTINA; (5) SANATORIO BRITÁNICO - ARGENTINA; (6) HOSPITAL UNIVERSITARIO FUNDACION FAVALORO - ARGENTINA; (7) SANATORIO GUEMES - ARGENTINA; (8) FLENI - ARGENTINA; (9) HOSPITAL ITALIANO DE BUENOS AIRES - ARGENTINA; (10) UNIVERSIDAD FASTA - ARGENTINA;

Introduction/Background: Intensive lipid-lowering and antithrombotic therapies are cornerstone, guideline-recommended strategies for secondary prevention in atherosclerotic cardiovascular disease. However, real-world differences in their implementation across vascular territories remain poorly characterized. Objectives: To evaluate differences in the use of evidence-based secondary prevention therapies between patients with coronary artery disease (CAD) and those with cerebrovascular disease. Methods: We conducted a prospective, multicenter registry including patients from 30 cardiology centers in Argentina between April 2023 and October 2024. Among 2937 patients hospitalized for cardiovascular conditions, those in secondary prevention were included. Secondary prevention was defined as prior CAD or prior cerebrovascular disease; patients with overlapping conditions were classified within the CAD group. We assessed the use of statins, high-intensity statins, ezetimibe, aspirin, and any antithrombotic therapy. Multivariable logistic regression analyses were performed adjusting for age, sex, hypertension, diabetes, smoking status, and dyslipidemia. Resultados e Conclusions: A total of 1,151 patients were classified as secondary prevention, of whom 83.3% had CAD and 16.7% cerebrovascular disease. Mean age was 70.5 ± 10.3 years and 26.2% were women. Compared with CAD, patients with cerebrovascular disease were significantly less likely to receive statins (66.1% vs 81.5%; p<0.001), high-intensity statins (31.2% vs 53.2%; p<0.001), and any antithrombotic therapy (70.3% vs 86.4%; p<0.001). Use of ezetimibe was low overall (8.0%) and similar between groups. After adjustment, CAD remained independently associated with higher use of statins (OR 1.91, 95% CI 1.33–2.75; p=0.001), high-intensity statins (OR 2.34, 95% CI 1.67–3.28; p<0.001), and any antithrombotic therapy (OR 2.60, 95% CI 1.70–3.99; p<0.001) (Table 1 and 2). Despite frequent healthcare contact, patients with cerebrovascular disease consistently received less intensive secondary prevention. These findings highlight a clinically relevant implementation gap that may contribute to residual cardiovascular risk in this population.

Table 1. Baseline characteristics by vascular territory

Variable / Intervention	Total (n=1151)	CAD (n=959)	Cerebrovasc. (n=192)	p-value
Age (years)	70.0 ± 10.5	69.7 ± 10.4	71.4 ± 10.8	0.048
Body mass index (kg/m²)	28.4 ± 4.9	28.5 ± 4.9	27.6 ± 4.7	0.014
Female sex	26.2%	22.9%	42.2%	<0.001

DYSLIPIDEMIA IN CHILDREN AND ADOLESCENTS: PREVALENCE AND ASSOCIATION WITH NUTRITIONAL STATUS IN A BRAZILIAN PEDIATRIC POPULATION

PAOLA ALMEIDAES SANTANA SOARES1; RICARDO BARRETO PITHON1; NATHALIE JEANNE MAGIOLI BRAVO-VALENZUELA1; LUCIANA CORRÊA DE SOUZA RODRIGUES1; LUIZ HENRIQUE CORRÊA PORTARI1; RENATA MAKSOUD BUSSUAN1;

(1) INSTITUTO DE CARDIOLOGIA / FUNDAÇÃO UNIVERSITARIA DE CARDIOLOGIA - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Introduction/ Background: Dyslipidemias are a primary risk factor for cardiovascular diseases, whoseatherosclerotic process begins in childhood. Childhood obesity drives atherogenic lipid profilesfrom early ages and represents a growing public health challenge. In Brazil, cardiovascular diseases account for approximately 30% of annual deaths. Objectives: Objective: To investigate the prevalence of dyslipidemias and their association with nutritional status in children and adolescents attending pediatric reference outpatient clinics. Methods: Methods: Observational, crosssectional, and descriptive-comparative study with 169 participants aged 2 to 19 years with a mean age of 11.3 years (SD = 4.6; median = 11.2; IQR: 7.8–15.1), divided into a normal weight group (n=70) and an overweight group (n=99), according to World Health Organization criteria. Anthropometric, blood pressure, and complete lipid profile data were collected and classified according to the Brazilian Society of Pediatrics guidelines. ShapiroWilk, Mann- Whitney, chi-square, Spearman correlation, logistic regression, and receiver operatingcharacteristic curve analyses were used, with a significance level of 5%. Resultados e Conclusions: Results: The overall prevalence of dyslipidemia was 59.2% (100/169), being 44.3% in the normal weight group and 69.7% in the overweight group (p=0.002). The overweight group showed significantly higher total cholesterol, low-density lipoprotein, with lower highdensity lipoprotein (all p≤0.002). Body mass index correlated with all lipid fractions (p<0.001). The receiver operating characteristic curve showed an area under the curve of 0.717 for elevated low-density lipoprotein, with an optimal cutoff body mass index of 23.3 kilograms per square meter. The number needed to screen was 3.9 and the population attributable fraction for excess weight was 36.5%. Regular physical activity was associated with higher highdensity lipoprotein levels (p=0.032). Conclusion: Dyslipidemia prevalence is high and strongly associated with excess weight in childhood. Universal lipid screening in overweight or obese children is a cost-effective strategy. Early lifestyle interventions, especially promotion of regular physical activity, are priorities for reducing future cardiovascular morbidity and mortality.

EFFECT OF GLP-1 RECEPTOR AGONISTS ON MORTALITY AND CARDIOVASCULAR OUTCOMES IN PATIENTS WITH OBESITY: A SYSTEMATIC REVIEW

JÚLIA ELIZEU OUVERNEY1; ADRIANA LIMA MAZAC DE SOUZA2;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) IDOMED/ESTACIO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Obesity is a major global public health challenge and is strongly associated with increased risk of cardiovascular diseases. Glucagon-like peptide-1 receptor agonists have emerged as a therapeutic strategy for obesity management, demonstrating weight reduction, improved glycemic control, and modulation of cardiovascular risk factors. Objectives: To analyze the effects of GLP-1 receptor agonists on mortality and cardiovascular outcomes in patients with obesity through a systematic review of the literature. Methods: This systematic review was conducted based on a PICO-structured question. The search in MEDLINE and LILACS identified 445 studies, of which 83 were screened after applying inclusion criteria. Following independent title and abstract screening, nine studies underwent full-text assessment, and four were ultimately included in the qualitative synthesis. Resultados e Conclusions: The included studies showed methodological heterogeneity, comprising three randomized clinical trials and one prospective non-randomized study, with follow-up ranging from 36 weeks to approximately four years and sample sizes from 105 to 17,604 participants. Mean age ranged from 54 to 64 years, with 27.7% to 60% female participants and body mass index between 32.6 and 37.9 kg/m². Different GLP-1 receptor agonists were evaluated, including semaglutide, dulaglutide, liraglutide, exenatide, orforglipron, and tirzepatide. Three studies compared active agents, while one used placebo. One study demonstrated a 20% reduction in the composite cardiovascular outcome, while another showed non-inferiority without superiority. The remaining studies assessed surrogate outcomes, showing reductions in blood pressure and improvements in lipid profile. Inflammatory markers were evaluated in one study, with reductions in high-sensitivity C-reactive protein and changes in interleukin-6 and NT-proBNP. One study also reported a reduction in estimated cardiovascular risk. All studies demonstrated weight reduction, with greater effects observed with subcutaneous semaglutide and tirzepatide. Additional improvements in fasting glucose, waist circumference, and lipid profile were reported. GLP-1 receptor agonists improve metabolic parameters and reduce markers associated with cardiovascular risk in individuals with obesity. Further studies assessing robust clinical outcomes are needed to clarify their impact on cardiovascular morbidity and mortality.

EFFECTIVENESS OF DATA-DRIVEN QUALITY IMPROVEMENT ON HOSPITALIZATIONS AND HEALTH OUTCOMES FOR PEOPLE WITH CORONARY HEART DISEASE IN PRIMARY CARE (QUEL): A CLUSTER RANDOMISED CONTROLLED TRIAL WITH 24-MONTH FOLLOW-UP

JULIE REDFERN1; NASHID K HAFIZ2; QIANG (TONY) TU3; ANDREW K KNIGHT4; CHARLOTTE K HESPE5; CLARA K CHOW, PHD MBBS2; ROBYN GALLAGHER2; TOM BRIFFA6; DAVID HARE7; NICK ZWAR8; KARICE HYUN2; ON BEHALF OF QUEL TRIAL INVESTIGATORS9;

(1) INSTITUTE FOR EVIDENCE-BASED HEALTHCARE, BOND UNIVERSITY - AUSTRALIA; (2) UNIVERSITY OF SYDNEY - AUSTRALIA; (3) INSTITUTE FOR EVIDENCE-BASED PRACTICE, BOND UNIVERSITY - AUSTRALIA; (4) UNIVERSITY OF NEW SOUTH WALES - AUSTRALIA; (5) UNIVERSITY OF NOTRE DAME - AUSTRALIA; (6) UNIVERSITY OF WESTERN AUSTRALIA - AUSTRALIA; (7) UNIVERSITY OF MELBOURNE - AUSTRALIA; (8) BOND UNIVERSITY - AUSTRALIA; (9) VARIOUS UNIVERSITIES - AUSTRALIA;

Introduction/Background: Cardiovascular disease (CVD), including coronary heart disease (CHD), remains the leading cause of death and hospital admissions globally. Optimising use of routinely collected data combined with collaborative quality improvement has been evaluated in variety of healthcare settings but evidence for effectiveness has focussed on surrogate endpoints with very few having robust study designs. Objectives: To test the effectiveness of a data-driven quality improvement program in primary care on cardiovascular hospitalizations, major adverse cardiovascular events (MACE), risk factor profiles and medication prescriptions at 24 months in people with CHD compared to standard care. Methods: A single-blind, cluster randomised controlled trial recruiting Australian primary care practices was conducted. Practices using compliant data extraction software and having ≥200 adult patients annually with CHD were the units of randomization and adults with CHD (visited their general practitioner in the past 12 months) were the units of analysis. Practices were randomised to intervention (12-month data-driven quality improvement including benchmarking, monthly reporting, workshops) or control (usual care). The primary outcome was proportion of participants who had unplanned CVD hospitalizations at 24-months. Secondary outcomes were MACE, medication prescriptions, risk factor targets, and primary care management planning. Outcome data were extracted from electronic records linked to administrative data. Resultados e Conclusions: 51 practices participated resulting in a patient cohort of 7,864 people with CHD. Mean age of the patient cohort was 72±12 years, 68% were male, 24% had a prior myocardial infarction. At 24-months, there was no significant difference between the groups for unplanned CVD hospitalizations (RR:0·91; 95%CI 0·75,1·10, see also Figure 1 for cumulative incidence curve); MACE (0.81; 95%CI 0·61,1·07); prescription of antiplatelet (0·94; 95% CI 0·79,1·13), stain (1·03; 95%CI 0·97,1·09), ACE/ARB (1·00; 95%CI 0·93,1·07); achieved targets for LDL-cholesterol (0·99; 95%CI 0·86,1·13), systolic blood pressure (0·97; 95%CI 0·87,1·09), smoking (0·96; 95%CI 0·57,1·59); or care planning (1·02; 95%CI:0·64,1·63). In conclusion, a primary care, data-driven quality improvement program did not reduce unplanned hospitalizations, MACE, medication prescriptions, risk factor targets or care planning. Robust evidence for a data-driven and collaborative approach to improving care for people with CHD in primary care remains elusive.

EFFECTIVENESS OF HIGH-DOSE VERSUS STANDARD-DOSE INFLUENZA VACCINE IN OLDER ADULTS WITH CARDIOVASCULAR DISEASE: A SYSTEMATIC REVIEW.

HELENA GORETTI VASCONCELOS1; MARCELA FERREIRA DA SILVA1; LUISA DE CASTRO BATISTA1; MARSELHA MARQUES BARRAL MONTESSI1;

(1) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL;

Introduction/Background: Influenza infection is a major determinant of morbidity and mortality in older adults, whose immune response is limited by immunosenescence when receiving standard-dose (SD) vaccines. In individuals with cardiovascular disease (CVD), the virus acts as an inflammatory trigger for acute cardiovascular events, including myocardial infarction and heart failure (HF) decompensation. The high-dose (HD) vaccine aims to optimize immunogenicity in this population; however, whether its superior clinical benefit is maintained in the presence of established chronic heart disease requires rigorous scientific validation. Objectives: To evaluate whether chronic CVD modifies the relative effectiveness of HD versus SD influenza vaccines in reducing hospitalizations and severe clinical outcomes in older adults. Methods: A systematic review was conducted in accordance with PRISMA guidelines. Original human clinical trials published in English within the last 5 years were analyzed using MEDLINE (PubMed) and SciELO databases. The search strategy employed Medical Subject Headings (MeSH) descriptors. Studies with insufficient methodological quality were excluded. Resultados e Conclusions: Initially, 5 studies were identified; after deduplication and eligibility screening, 3 were included, totaling 811,235 individuals aged ≥65 years. HD vaccination showed superior effectiveness over SD in reducing hospitalizations for influenza or pneumonia and cardiorespiratory complications. This benefit remained consistent regardless of baseline cardiovascular comorbidities (p > 0.05). In the HF subgroup, HD was associated with reduced hospitalizations for cardiovascular events and decompensation, with similar effectiveness to patients without HF (p > 0.05). HD also reduced all-cause mortality and severe respiratory hospitalizations. However, its effect on all-cause hospitalizations was less pronounced in individuals with established CVD. Overall, chronic CVD does not diminish the superiority of HD vaccination, supporting its use as a key strategy in secondary prevention of severe outcomes in older adults with cardiovascular disease.

EFFECTS OF VITAMIN K2 MK-7 WHEN COMBINED WITH VITAMIN D ON ENDOTHELIAL FUNCTION

ADRIANA CASTRO CARVALHO FARIA1; CLARA CASTRO FARIA2; LETICIA OLIVEIRA FARIA2; WILLE OIGMAN1; MARIO FRITSCH NEVES1;

(1) HOSPITAL UNIVERSITARIO PEDRO ERNESTO - RIO DE JANEIRO - RJ - BRASIL; (2) FUNDACAO TECNICO EDUCACIONAL SOUZA MARQUES - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Randomized trials have been inconsistent in demonstrating beneficial cardiovascular effects of vitamin D supplementation. Objectives: To evaluate the effects of vitamin K2 MK-7 supplementation combined with vitamin D on endothelial function in overweight/obese individuals. Methods: Prospective, randomized, double-blind, placebo-controlled clinical trial in adults with a body mass index between 25 and 40 kg/m² and serum vitamin D (25(OH)D)< 30ng/mL. Vascular assessment included: endothelial function by microvascular reactivity (Pericam®), arterial stiffness by oscillometry (Mobil-O-Graph®), and autonomic tone by heart rate variability (Polar® and Kubios HRV). Volunteers (n=90) were randomized into 3 groups and received daily for 16 weeks: placebo (P, n=28), vitamin-D3 7mIU (D, n=30) or vitamin D3-7mIU+vitamin-K2MK-7 180mcg (DK, n=32). Statistical significance was considered when p<0.05. Resultados e Conclusions: The groups were homogeneous according to age (51±7; 52±6; 53±7 years, p=0.739), predominantly women (75 vs 67 vs 63%, p=0.579) and presented non-normal distribution of serum 25(OH)D [22.7 (17.3-27.5) vs 22.8 (18.5-25.6) vs 22.4 (17.4-26.0), p=0.688]. After 16 weeks, there was an increase in 25(OH)D in both the D and DK groups [39.1(32.7-44.7) and 36.2(31.7-41.7), p<0.001], an increase in pulse wave velocity in the D group (7.45±0.97 vs 7.60±1.03, p=0.025), but not significant in the DK group. A significant increase in post-occlusion reactive hyperemia [44(30-69) vs 60(37-86) UAP, p=0.028] and a reduction in the instantaneous/global heart rate variability ratio (SD2/SD1) [1.92(1.40-2.48) vs 1.67(1.25-2.05), p=0.036] were observed only in the DK group. In this sample, improvements in endothelial function and greater autonomic balance were observed when vitamin K2 MK-7 was used in combination with vitamin D3, and a possible protection against increased arterial stiffness that was observed with vitamin D supplementation alone.

EFFICACY AND SAFETY OF SIRNA THERAPIES TARGETING LIPOPROTEIN(A): A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

GERMANO CARVALHO TOSCANO1; MILTON LIRA NETO2; PEDRO PIRES3; BRUNA MONTENEGRO1; DAVI CHAVES1; LUCAS BRUNET1; SAMUEL ROCHA1; WERTON ROQUE1; MARIA LUIZA MIRANDA1; YASMIN FERNANDES1; ANA GERTRUDES NEVES1; ARTHUR CICUPIRA4;

(1) FAMENE - JOÃO PESSOA - PB - BRASIL; (2) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (3) UNIPE - JOÃO PESSOA - PB - BRASIL; (4) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction/Background: Lipoprotein(a) [Lp(a)] is a genetically determined causal risk factor for atherosclerotic cardiovascular disease with no approved targeted therapies. Small interfering RNA (siRNA) agents targeting hepatic LPA mRNA have demonstrated marked reductions in circulating Lp(a) levels. Objectives: To evaluate the efficacy and safety of siRNA therapies for Lp(a) reduction versus placebo. Methods: PubMed, Clinical Trials.gov and Cochrane Library were searched through March 2026 for phase 2 randomized controlled trials evaluating siRNA therapies targeting LPA in adults with elevated Lp(a). For each trial, the prespecified regimen selected for phase 3 development and its concurrent placebo comparator were analyzed to enhance clinical relevance and avoid multiple comparisons. The primary outcome was placebo-adjusted percent change in Lp(a). A secondary pooled analysis combining phase 2 trials and phase 1 randomized dose-escalation studies was performed to evaluate the consistency of treatment effect across all available randomized evidence. Random-effects meta-analysis was performed; heterogeneity was assessed using I^2 statistics Statistical analyses were performed using R version 4.5.3. Resultados e Conclusions: Three phase 2 randomized controlled trials were included: OCEAN(a)-DOSE (olpasiran; n=56 vs placebo n=54), ALPACA (lepodisiran; n=142 vs placebo n=36), and ALPACAR-360 (zerlasiran; n=40 vs placebo n=40), totaling 238 siRNA-treated and 130 placebo participants. Pooled analysis demonstrated a marked reduction in Lp(a) levels (−92.5%; 95% CI −107.1% to −78.0%; p<0.001). Statistical heterogeneity was high (I^2=82.7%), likely reflecting differences in molecular agents and dosing regimens, although all trials showed consistent directional benefit. Pooled phase 1–2 analysis (n=436) showed consistent Lp(a) reduction: −92.3% (95% CI −97.8 to −86.8; p<0.001). No major safety signals were identified; injection-site reactions were the most common adverse events (2–17%), predominantly mild and transient. The siRNA therapies were associated with substantial reductions in Lp(a) levels and a favorable short-term safety profile in phase 2 trials. These findings suggest a potential role as targeted therapies for elevated Lp(a), although results should be interpreted in the context of between-study heterogeneity and selection of specific dosing regimens. Ongoing phase 3 trials will determine their impact on cardiovascular outcomes and long-term safety.

ENDOTHELIAL DYSFUNCTION AND INCIDENT CHRONIC KIDNEY DISEASE IN BRAZILIAN ADULTS: THE ELSA-BRASIL COHORT STUDY (ELSA-BRASIL)

KARINA PAULA MEDEIROS PRADO MARTINS1; SANDHI MARIA BARRETO1; SARA TELES MENEZES1; LIDIYANE VALLE CAMELO1; ANTONIO LUIZ PINHO RIBEIRO1; LUISA CAMPOS CALDEIRA BRANT1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Cardiovascular–metabolic–renal syndrome is characterized by interactions among metabolic risk factors, chronic kidney disease (CKD), and cardiovascular dysfunction, leading to high rates of adverse outcomes. The endothelium plays a key role in renal physiology, including podocyte support, tubular reabsorption, and antithrombotic and anti-inflammatory regulation. Endothelial dysfunction may therefore contribute to CKD development. Objectives: Evaluate the association between endothelial function and incident CKD in Brazilian adults. Methods: Participants from the ELSA-Brasil cohort free of CKD at baseline were followed for a mean of 8.0 years (SD=0.3). Endothelial function was assessed by peripheral arterial tonometry (PAT), using mean basal pulse amplitude (BPA), reflecting basal vascular tone, and PAT ratio, reflecting vasodilatory capacity. Higher BPA and lower PAT ratio indicate worse endothelial function. Sex-adjusted quartiles were analyzed. Incident CKD was defined as estimated glomerular filtration rate <60 ml/min/1.73 m^2 and/or albumin-to-creatinine ratio ≥30 mg/g. Multivariable models were adjusted for sociodemographic factors, lifestyle, cardiometabolic risk factors, and lipid profile. Resultados e Conclusions: Among 1,336 participants (mean age 51±8 years; 44% women; mean BMI 26.6±4.5 kg/m^2), 297 developed CKD. Neither the quartile representing worse endothelial function—defined as the fourth quartile for BPA (OR 0.82, 95% CI 0.52–1.30) and the first quartile for PAT ratio (OR 1.09, 95% CI 0.71–1.67)—was significantly associated with incident CKD after multivariable adjustment. We concluded that baseline endothelial dysfunction was not associated with incident CKD over 8 years in Brazilian adults. These findings contribute to a better understanding of the role of endothelial dysfunction in CKD pathophysiology.

20525

FAMILIAL CHYLOMICRONEMIA SYNDROME IS NOT ASSOCIATED WITH SUBCLINICAL CORONARY ATHEROSCLEROSIS

ANTONIO FERNANDES OLIVEIRA FILHO1; MARCIO HIROSHI SANTOS1; ANA CLAUDIA CAVALCANTE NOGUEIRA2; ADRIANA BEZERRA NUNES3; PAULA FRASSINETTE VASCONCELOS MEDEIROS4; RAUL DIAS SANTOS1;

(1) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE CATOLICA DE BRASILIA - BRASÍLIA - DF - BRASIL; (3) UNIVERSIDADE FEDERAL DO RIO GRANDE DO NORTE - NATAL - RN - BRASIL; (4) UFCG - CAMPINA GRANDE - PB - BRASIL;

Introduction/Background: Familial chylomicronemia syndrome (FCS) is a rare autosomal recessive disorder caused by pathogenic variants in genes of the lipoprotein lipase pathway. These defects lead to disorder of chylomicron metabolism, causing severe hypertriglyceridemia and increased risk of pancreatitis. However, the association between FCS and atherosclerotic cardiovascular disease remains uncertain. Objectives: To evaluate subclinical atherosclerosis in a Brazilian cohort with FCS. Methods: This Cross-sectional study included 81 individuals (12 homozygous for GPIHBP1 variants, 33 heterozygous for GPIHBP1 and LPL variants, and 36 no genetic variants group) from 9 families across 7 municipalities in Northeastern Brazil. All participants underwent clinical, anthropometric, laboratory, and coronary CT angiography evaluation. Subclinical atherosclerosis was defined as CAC >0 or the presence of luminal plaques. Univariate and multivariate logistic regression analyses were performed. Resultados e Conclusions: The mean age was 42 ± 15 years, with a predominance of females. FCS homozygotes were significantly younger (38 ± 13 years) than heterozygotes (54 ± 12) and no genetic variants group (52 ± 12; p=0.0006), with similar sex distributions across groups (p=0.8686). Body mass index (kg/m²) was lower in homozygotes (24 ± 3) than in heterozygotes (28 ± 4) and no genetic variants group (30 ± 5; p<0.0001). Triglyceride levels (median [p25-p75] mg/dL) were markedly higher in homozygotes (2025 [1260-2584]) compared to heterozygotes (235 [128-448]) and no genetic variants group (312 [193-1158]); p<0.0001), HDL-C was significantly lower (22 [18-43]) vs. (42[37-48]) vs. (44 [35-53]); p=0.0034), respectively. Apo B (mg/dL) levels were substantially reduced in homozygotes (40 [30-49]) vs.heterozygotes (106 [87-118]) vs. no genetic variants group (109 [78-130]); p<0.0001 . No significant differences were observed in subclinical atherosclerosis markers, including plaque presence (8.3% vs. 30% vs. 22%; p=0.3688), CAC=0 prevalence (92% vs. 70% vs. 78%; p=0.7326), and stenosis >50% (0% vs. 10% vs. 0%; p=0.2821). In multivariate analysis, only age at diagnosis remained independently associated (OR 1.172; p=0.0017), while genotype and lipid parameters were not associated with increased atherosclerosis risk. In this study, severe hypertriglyceridemia, as seen in FCS, does not translate into increased atherosclerotic burden.

FASUS PROJECT PHASE 2: RANDOMIZED CLINICAL TRIAL FOR SCREENING OF NON-VALVULAR ATRIAL FIBRILLATION IN THE UNIFIED HEALTH SYSTEM

MARCELO LEMOS INEU1;

(1) UNIVERSIDADE DA REGIAO DE JOINVILLE - JOINVILLE - SC - BRASIL;

Introduction/Background: Atrial fibrillation (AF) and stroke are major age-related public health issues, with AF increasing stroke risk fivefold and often remaining asymptomatic until events occur. Despite effective anticoagulation, gaps in detection and treatment persist. Improving screening and prevention, as in the FASUS Project, may reduce morbidity, mortality, and costs. Objectives: The primary objective of this study is to determine the frequency of new diagnoses of asymptomatic atrial fibrillation (AF) through screening using radial pulse palpation (Arm A) or automated oscillometric devices (Arm B) among older adults in primary care units. Secondary objectives include estimating the number of individuals needed to detect one new AF case in each arm, describing the clinical and epidemiological profile of newly diagnosed patients, evaluating indications for and rates of oral anticoagulation, and estimating the number of cardioembolic ischemic strokes prevented through screening based on historical data, as well as the potential impact on morbidity, mortality, and healthcare costs. Methods: The FASUS project evaluates AF screening in primary care. After a pilot phase using pulse palpation, Phase 2 implemented a cluster-randomized study comparing pulse palpation and oscillometric devices, with telemedicine ECG, anticoagulation management, and statistical analysis to assess outcomes. Resultados e Conclusions: During Phase 2 of the FASUS study (2023), 12,055 patients were screened across 56 primary care units, with 1,761 individuals ≥60 years included after exclusions. A total of 182 AF cases were confirmed by ECG, yielding a prevalence of 10.3% among those with irregular rhythm (1.51% overall). Detection was higher with oscillometric devices (11.5%) versus pulse palpation (8.5%) (p=0.0446). Patients with AF were older and more frequently male, with high prevalence of hypertension (94%), diabetes (41.8%), and prior cardiovascular disease. Most (94.4%) had high thromboembolic risk (CHA□DS□-VASc ≥2), and 76.8% initiated anticoagulation. Among non-AF patients, 55.7% had ECG abnormalities, with ~20% showing risk markers for AF, with no difference between groups.

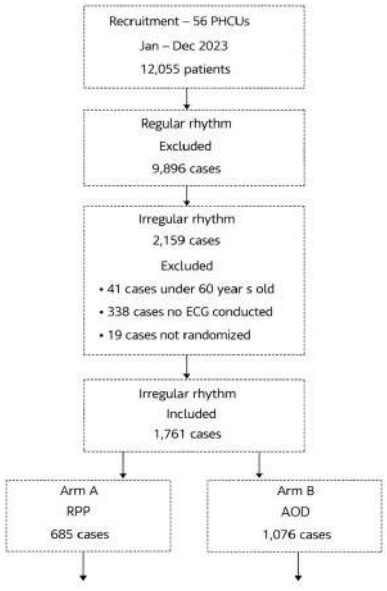

Figure 1 – Flowchart of the Final Sample Composition

HIGH BURDEN OF CARDIOMETABOLIC RISK IN YOUNG ADULTS: ASSOCIATIONS WITH ADIPOSITY, BLOOD PRESSURE AND OBSTRUCTIVE SLEEP APNEA

YASMIM CORDEIRO BRAGA1; SHARA ALVES COELHO1; ADRIELI DE SOUZA SALVADOR1; DOUGLAS RODRIGUES DE OLIVEIRA1; LORRAN MAX COSTA DE OLIVEIRA1; HUGO DE CASTRO SILVA DA CONCEICAO1; WILGOR RODRIGUES MANFREDO1;

(1) UNIVERSIDADE LA SALLE - NITEROI - RJ - BRASIL;

Introduction/Background: Cardiovascular diseases are the leading cause of mortality worldwide and are strongly associated with modifiable risk factors that may begin early in life. In young adults, the presence of adiposity, elevated blood pressure, and sleep-related disorders such as obstructive sleep apnea (OSA) may contribute to early cardiovascular alterations and increased long-term risk. Identifying the clustering of these factors in apparently healthy individuals is essential for guiding preventive strategies. Objectives: To evaluate the burden of cardiometabolic risk factors and analyze their association with anthropometric and hemodynamic variables in young adults. Methods: This cross-sectional study included 199 young adults (65.8% female; mean age 25.6 ± 10.0 years). Anthropometric measures (body mass index [BMI], waist-to-hip ratio [WHR], and neck circumference) and blood pressure were assessed using standardized procedures. Risk of OSA was evaluated using the Berlin Questionnaire. Mean BMI was 25.54 ± 4.96 kg/m². Cardiometabolic risk was defined as the presence of two or more risk factors. Descriptive statistics (mean ± standard deviation), Pearson correlation, and Fisher's exact test were performed ($p<0.05$). The study was approved by the institutional ethics committee (CAAE: 91482125.1.0000.0336). Resultados e Conclusions: A high burden of cardiometabolic risk was observed, with 41.7% of participants presenting two or more risk factors. Risk distribution showed 55.2% low risk, 30.2% moderate risk, and 14.6% high risk, indicating substantial accumulation of risk factors even in a young population. BMI demonstrated a moderate positive correlation with systolic blood pressure ($r=0.42$; $p<0.0001$), whereas WHR showed a weaker correlation ($r=0.25$; $p=0.0004$). Individuals at risk for OSA had a significantly higher prevalence of hypertension compared to those without risk (43.5% vs. 11.6%; $p=0.0005$). These findings highlight early cardiometabolic risk clustering and reinforce the importance of screening and preventive strategies in young adults to reduce future cardiovascular burden.

21729

HIGH PREVALENCE OF ELEVATED LIPOPROTEIN(A) LEVELS IN A TERTIARY CARDIOVASCULAR REFERRAL CENTER IN SOUTHERN BRAZIL

PAULO EDUARDO BALLVÉ BEHR1; DAYANA DIAS MENDONÇA1; RAFAEL VIANNA BEHR1; PAULO ERNESTO LEÃES1; FERNANDO ANTÔNIO LUCCHESE1;

(1) SANTA CASA DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Lipoprotein(a) [Lp(a)] is an independent risk factor for atherosclerotic cardiovascular disease, with predominantly genetic determination. Its measurement may improve cardiovascular risk stratification. Previous studies have reported a prevalence of elevated Lp(a) levels of approximately 18–20% in the general population. Objectives: To describe the distribution of Lp(a) levels in individuals treated at a tertiary referral cardiovascular center in Southern Brazil and to compare levels between men and women. Methods: Lp(a) levels were measured using a nephelometric assay in a private laboratory and expressed in nmol/L. Biochemical measurements were performed between October 2021 and April 2026. Lp(a) levels were categorized as normal (<75 nmol/L), intermediate (75–125 nmol/L), and elevated (>125 nmol/L), according to clinically relevant thresholds. Descriptive analyses included mean ± SD, median (25th–75th percentile), and frequencies (n, %). Comparisons between groups were performed using the chi-square test. Statistical analyses were conducted using SPSS (v21.0). Resultados e Conclusions: A total of 271 individuals were included, with a mean age of 58.65 ± 14.03 years, of whom 160 (59%) were female. In the overall sample, Lp(a) levels were 42 (12–156) nmol/L. Overall, 159 (58.7%) individuals had normal Lp(a) levels, whereas 82 (30.3%) presented elevated levels (>125 nmol/L). Among men, 63 (56.8%) had normal levels, 11 (9.9%) intermediate levels, and 37 (33.3%) elevated levels. Among women, these proportions were 96 (60.0%), 19 (11.9%), and 45 (28.1%), respectively. No significant association was observed between sex and Lp(a) categories (Pearson's chi-square test, $p = 0.627$). We highlight that a considerable prevalence of elevated Lp(a) levels was observed in this cohort, exceeding that reported in previous population-based studies. This finding is likely related to the study setting, a tertiary referral cardiovascular center in Southern Brazil. Another possible explanation is that individuals from this region may present higher Lp(a) concentrations; however, currently available data are insufficient to support this hypothesis. The high prevalence of elevated Lp(a) levels in this referral cardiovascular setting is consistent with the recognized association between Lp(a) and cardiovascular disease.

20561

HIGH PREVALENCE OF MARKEDLY ELEVATED LIPOPROTEIN(A) AND SEVERE HYPERCHOLESTEROLEMIA IN YOUNG PATIENTS WITH CORONARY ARTERY CALCIFICATION

PAULO EDUARDO BALLVÉ BEHR1; RAFAEL VIANNA BEHR1; RODRIGO SILVA HINTZ1; LAURA COLLET KROLIKOWSKI1; PAOLA LUCCHESE SCHÜTZ1; PAULO ERNESTO LEÃES1; FERNANDO ANTÔNIO LUCCHESE1;

(1) SANTA CASA DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Subclinical atherosclerosis is uncommon in young individuals and may indicate an increased risk of future coronary events. Data on risk factors (RFs) for coronary artery calcification in this population remain scarce. Objectives: To assess the prevalence of RFs in patients < 55 years with coronary artery calcification. Methods: Cross-sectional study including patients from a cardiovascular prevention outpatient clinic in southern Brazil, with private health insurance coverage, aged ≤55 years and with coronary artery calcification, defined as a coronary artery calcium (CAC) score >1 Agatston. Evaluated RFs included hypertension, diabetes, smoking, obesity (BMI ≥30 kg/m²), severe hypercholesterolemia (LDL-C ≥190 mg/dL), markedly elevated Lipoprotein(a) [Lp(a)] (≥190 nmol/L or ≥85 mg/dL), and family history of premature coronary artery disease (CAD) (myocardial infarction, percutaneous or surgical revascularization, or sudden death in men <55 years or women <60 years). Resultados e Conclusions: A total of 129 Caucasian patients aged 34–55 years were included (mean age 49.6 ± 4.6 years; 68% male). Regarding CAC distribution, 32.6% had CAC <10 Agatston, 41.1% had CAC 10–99 Agatston, and 26.3% had CAC ≥100 Agatston. The prevalence of RFs was as follows: hypertension 45.7%; severe hypercholesterolemia 24.0%; family history of premature CAD 20.2%; markedly elevated Lp(a) 19.4%; obesity 15.5%; smoking 8.5%; and diabetes 7.0%. Severe dyslipidemia, defined as markedly elevated LDL-C and/or Lp(a), was observed in 37.2% of patients. Regarding the number of RFs, 20.1% of patients had no RFs, 39.5% had one risk factor, 24.8% had two RFs, and 15.5% had three or more RFs. Among patients with markedly elevated Lp(a), 32.0% had Lp(a) as the only identified risk factor. In conclusion, this study provides novel insights into RFs associated with coronary artery calcification in young patients. A high prevalence of severe dyslipidemia, characterized by markedly elevated LDL-C and/or Lp(a), was observed. Notably, approximately one-fifth of patients had no traditional RFs, underscoring the importance of investigating nontraditional RFs for coronary artery disease in this population.

20324

IMPACT OF A STRUCTURED MULTIDISCIPLINARY INTERVENTION ON CARDIOMETABOLIC RISK FACTORS IN HIGH-RISK PATIENTS: A SIX-MONTH COHORT STUDY

MARCELO JOSÉ LINHARES1; CAMILA PASSOLD2; LARIANA STEFANELLO2; BIANCA FERRETTI BERTOTTI2; LAYLA BALTOR BARBOSA DOS SANTOS2; RAFAEL ZUCCO BARBIERI KAESTNER3; GIULLIANO GARDENGHI4;

(1) CARDIOPRIME CARDIOLOGY CENTER - BLUMENAU - SC - BRASIL; (2) BRAZILIAN INSTITUTE OF CARDIOMETABOLISM - BLUMENAU - SC - BRASIL; (3) UNIVERSITY OF BLUMENAU - FURB - BLUMENAU - SC - BRASIL; (4) ENCORE HOSPITAL - APARECIDA DE GOIÂNIA - GO - BRASIL;

Introduction/Background: Cardiometabolic risk is the synergistic potential for cardiovascular damage from clustered metabolic issues: visceral adiposity, dyslipidemia, hypertension, and insulin resistance. Driven by chronic inflammation, these factors cause cardiovascular disease. While drugs are standard, integrated multidisciplinary interventions are essential to optimizing clinical outcomes. Objectives: To evaluates the impact of a comprehensive multidisciplinary care program on the modulation of cardiometabolic risk factors among a cohort characterized by a high cardiovascular risk profile. Methods: This prospective cohort study was conducted at a multidisciplinary outpatient clinic involving cardiologists, endocrinologists, nutritionists, and exercise physiologists. At baseline, patients underwent comprehensive clinical phenotyping: biochemical profiling, cardiovascular imaging, and bioimpedance analysis. Dietary patterns, metabolic status, and comorbidities were assessed. The protocol integrated a calorie-restricted diet, protein supplements, resistance training, and titrated pharmacological therapy. After assessment, a personalized intervention plan was implemented. Patient engagement was maintained via structured feedback and 90-day follow-up cycles, using a dedicated app for communication with the clinical team. Reassessments and adjustments occurred over 6 months. Statistical analysis used one-way ANOVA (p≤0.05) with Post hoc Scheffé's test, when necessary. Resultados e Conclusions: 174 patients (age: 50.0±12.2 years, 54.0% male, weight: 99.2±18.3 kg) were followed. Initial risks: coronary artery disease 30.9%, diabetes 15.4%, hypertension 41.9%, dyslipidemia 85.3%, obesity 81.5%, and sedentary lifestyle 70.9%. At six months, BMI decreased (pre: 33.8±4.9 vs. post: 30.3±7.1 kg/m², p=0.00). Bioimpedance showed lower fat mass (pre: 37.3±8.5% vs. post: 33.1±8.6%) and higher lean mass (pre: 35.3±5.3% vs. post: 37.2±5.2%; p=0.00). Abdominal circumference dropped (pre: 110.1±13.3 vs. post: 103.3±11.1 cm, p=0.00). LDL (111.6±45.9 vs. 77.5±43.2 mg/dL) and triglycerides (140.6±88.1 vs. 95.3±49.0 mg/dL) decreased (p=0.00). Glycated hemoglobin fell (pre: 5.7±0.9% vs. post: 5.3±0.5%, p=0.00). HDL had no significant changes. Statins were used in 71.9%. Oral and injectable GLP-1 agonists were used by 35.6% and 36.3% of the cohort, respectively. In this subgroup, non-adherence was 20.2%. As a conclusion, the multidisciplinary care improved cardiometabolic risk. Long-term studies are needed to confirm sustainability of this approach.

14376

IMPACT OF ANABOLIC-ANDROGENIC STEROID USE ON CARDIOVASCULAR HEALTH: A SYSTEMATIC REVIEW.

LUISA DE CASTRO BATISTA1; MARCELA FERREIRA DA SILVA1; HELENA GORETTI VASCONCELOS1; LUCIANA HENRIQUE DUARTE1;

(1) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL;

Introduction/Background: Anabolic-androgenic steroids (AAS), synthetic derivatives of testosterone, are widely used to increase strength and promote muscle hypertrophy. Their use is prevalent among athletes and has been increasing in the general population. In this context, the growing use of AAS, along with their potential adverse health effects, represents a significant public health concern and an important focus for scientific investigation. Objectives: To investigate, through a systematic review, the association between AAS use and the increased incidence of cardiovascular diseases. Methods: A literature review was conducted including original clinical studies performed in humans, published within the last two years, in English, and available in full text. The search was carried out using the National Library of Medicine (MEDLINE), Scientific Electronic Library Online (SciELO), and Cochrane Library databases, employing the MeSH descriptors “Anabolic Steroids” and “Coronary Disease,” combined using Boolean operators. The included studies analyzed the association between AAS use and increased cardiovascular risk. Poorly described studies, abstract-only publications, animal studies, and literature reviews were excluded. The PRISMA guidelines were followed to systematize the review process. Resultados e Conclusions: Initially, 8 studies were identified; after deduplication and application of eligibility criteria, 4 studies were included in the final analysis. A total of 60,980 participants were evaluated, predominantly young adults with a mean age of 35.5 years, among whom cumulative AAS use varied across studies. A significant association was observed between AAS use and adverse cardiovascular outcomes, including left ventricular hypertrophy, heart failure, and acute myocardial infarction, in both current and former users compared to the control group ($p < 0.05$). Additionally, Buhl et al. demonstrated more severe cardiovascular outcomes in individuals with more than 5 years of AAS use ($p < 0.05$). Overall, the findings suggest that AAS use is a significant cardiovascular risk factor, with the potential to cause persistent damage to cardiovascular health even after discontinuation.

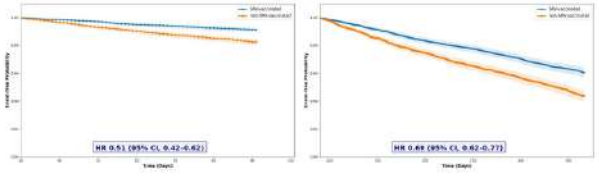
IMPACT OF RSV VACCINATION ON HOSPITALIZATION AND MORTALITY IN INFLUENZA-VACCINATED PATIENTS WITH HEART FAILURE: A MULTICENTER DATABASE ANALYSIS



GIULIANO GENEROSO1; BEATRIZ SANTANA PRADO1; ROBERTA SARETTA1; ANDRE FRANCI1; ROBERTO KALIL-FILHO1; LUCIANO FERREIRA DRAGER1;

(1) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introduction/Background: Respiratory syncytial virus (RSV) poses a significant public health burden, disproportionately affecting patients with heart failure (HF), who face an 8-fold increased risk of RSV-related hospitalization and frequent acute cardiac events during infection. Although three RSV vaccines have been approved for older adults and high-risk groups including HF, their impact on severe clinical outcomes in this population remains uncertain, with randomized trials showing no significant reduction in cardiovascular hospitalization or mortality. Objectives: To assess the impact of RSV vaccination on emergency department (ED) visits, hospitalization, acute respiratory failure, ICU admission, and mortality in HF patients already vaccinated against influenza. Methods: Retrospective observational analysis using the TriNetX Global Collaborative Network (>110 healthcare organizations, ~140 million patients). Adults (≥18 years) with HF and prior influenza vaccination, without chronic lung disease, were stratified by RSV vaccination status. After 1:1 propensity score matching for age, comorbidities, and HF medications, we analyzed risk differences (RD), risk ratios (RR) and, further, Cox proportional hazards models to estimate hazard ratios (HR) at 1-year follow-up. Resultados e Conclusions: Our analyses included a total of 17,782 patients each cohort (75± 9 years, 53% male). At 1 year, RSV vaccination was consistently associated with significant reductions in all outcomes: ED visits (RD -2.70%; RR 0.90; HR 0.81; p<0.0001), acute respiratory failure (RD -0.89%; RR 0.84; HR 0.67; p<0.0001), hospitalization (RD -2.60%; RR 0.85; HR 0.61; p<0.0001), ICU admission (RD -0.87%; RR 0.84; HR 0.57; p=0.0001), and mortality (RD -2.00%; RR 0.65; HR 0.48; p<0.0001). RSV vaccination consistently reduces, at 1 year, ED visits, hospitalization, respiratory failure, ICU admission, and mortality in influenza-vaccinated HF patients. To date, our study is the first evidence of mortality risk reduction of SRV vaccine, reinforcing its recommendation in this high-risk population.

Outcome	SRV-vaccinated events	Non-SRV events	Risk difference (95% CI)	Risk ratio (95% CI)	p-value
at 1-year					
ED visit	4652	5156	-2.70% (-3.59% to -1.81%)	0.90 (0.87–0.93)	< 0.0001
Acute respiratory failure	862	1029	-0.89% (-1.34% to -0.45%)	0.84 (0.77–0.92)	< 0.0001
Hospital admission	2760	3245	-2.60% (-3.34% to -1.85%)	0.85 (0.81–0.89)	< 0.0001
ICU admission	879	1041	-0.87% (-1.32% to -0.42%)	0.84 (0.77–0.92)	0.0001
Death	707	1081	-2.00% (-2.44% to -1.57%)	0.65 (0.60–0.72)	< 0.0001
30-90 days					
ED visit	1536	1936	-2.14% (-2.73% to -1.55%)	0.79 (0.74–0.85)	< 0.0001
Acute respiratory failure	300	374	-0.40% (-0.67% to -0.13%)	0.82 (0.69–0.93)	0.004
Hospital admission	923	1169	-1.32% (-1.78% to -0.85%)	0.79 (0.73–0.86)	< 0.0001
ICU admission	255	339	-0.45% (-0.70% to -0.20%)	0.75 (0.64–0.88)	0.0005
Death	151	306	-0.83% (-1.05% to -0.61%)	0.49 (0.41–0.60)	< 0.0001
90-360 days					
ED visit	3791	4135	-1.84% (-2.67% to -1.01%)	0.92 (0.88–0.95)	< 0.0001
Acute respiratory failure	666	757	-0.49% (-0.88% to -0.10%)	0.88 (0.79–0.97)	0.0139
Hospital admission	2156	2494	-1.81% (-2.48% to -1.14%)	0.86 (0.82–0.91)	< 0.0001
ICU admission	658	766	-0.58% (-0.97% to -0.19%)	0.86 (0.78–0.95)	0.0035
Death	557	782	-1.21% (-1.58% to -0.83%)	0.71 (0.64–0.79)	< 0.0001

Kaplan-Meier curves for all-cause mortality stratified by RSV vaccination status

Introduction/Background: Background. Lifestyle modifications are considered as a concurrent intervention among with pharmacological treatment for secondary prevention in patients with coronary heart disease (CHD). Adherence to recommended behavioral changes remains a significant clinical challenge in everyday life. Objectives: Objectives. To evaluate if ESC lifestyle recommendations in patients with CHD are reached and what risk factors associate with failure. Methods: Methods. This cross-sectional study was conducted in two-centers across the country. Patients with a history of CHD hospitalization in the last 6-24 months were randomly recruited to participate in this study. We collected age, sex, living location, income level, education level, ethnicity, anxiety, depression, cognitive function as independent variables and sleep status, alcohol consumption, smoking status, physical activity (PA) level, rehabilitation attendance, overweight/obesity status, salt and sugar in diet as dependent variables. Pittsburgh Sleep Quality Index (PSQI) was used for sleep status, International Physical Activity Questionnaire - Short Form (IPAQ-SF) was used for PA level, BMI for overweight/obesity status and Hospital Anxiety & Depression Scale (HADS) was used for anxiety and depression assessment. Handheld carbon monoxide monitor was used additionally to detect smoking. Multivariable logistic regression models were employed to estimate adjustedodds ratios (OR) to evaluate the independent associations between participant characteristics and each outcome while controlling for relevant confounders. Resultados e Conclusions: Results and conclusion. Of 402 participants the majority were male, aged ≥60 years, and of Central Asian background. Prevalence was high for obesity, cognitive impairment and rehabilitation ignorance. Male sex was strongly associated with smoking, alcohol use, and failure to reduce sugar. While females were more likely to experience poor sleep or miss rehabilitation. Older age was inversely associated with smoking and overweight/obesity. Patients missing university level education failed to achieve salt reduction. White/other ethnicities presented more chance of alcohol consumption. Depression was a strong predictor of low PA and failure to reduce salt, while anxiety predicted poor sleep and rehabilitation. These findings underscore the necessity of targeted interventions for specific subgroups of patients to improve secondary prevention in patients with CHD.

METABOLIC AND CARDIOVASCULAR OUTCOMES WITH ORAL SEMAGLUTIDE IN HIGH-RISK PATIENTS WITH TYPE 2 DIABETES MELLITUS: A SYSTEMATIC REVIEW AND META-ANALYSIS

MARIA SÍLVIA DA FONSECA E SILVA LEVY1; LARISSA ARAUJO DE LUCENA2; LETICIA DE FREITAS BARRADAS SIEBRA2; ANA KARENINA CARVALHO DE SOUZA2;

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RN - BRASIL; (2) UFRN - NATAL - RN - BRASIL;

Introduction/Background: Patients with Type 2 Diabetes at high cardiovascular risk remain susceptible to adverse metabolic and cardiovascular events despite contemporary therapies. Oral semaglutide, the first oral glucagon-like peptide-1 receptor agonist, has shown promising cardiometabolic benefits in this population. Objectives: To evaluate the metabolic and cardiovascular outcomes of oral semaglutide versus placebo in high-risk patients with type 2 diabetes mellitus (T2DM). Methods: This systematic review and meta-analysis was conducted according to Cochrane recommendations. PubMed, Embase, and Cochrane Library databases were searched from inception through May 2026. Randomized controlled trials comparing oral semaglutide with placebo in adults with high-risk T2DM were included after duplicate removal and full-text screening. Outcomes included glycated hemoglobin (HbA1c), body mass index (BMI), major adverse cardiovascular events (MACE), and all-cause mortality. Statistical analyses were performed using Review Manager version 5.4 with random-effects models, reporting mean differences (MD) and risk ratios (RR) with 95% confidence intervals (CI). Resultados e Conclusions: A total of 1,311 records were identified. Seven studies evaluating metabolic outcomes and four assessing cardiovascular outcomes were included. Oral semaglutide significantly reduced HbA1c compared with placebo (MD −1.11%; 95% CI −1.52 to −0.69; p<0.001 - FIGURE 1). BMI reduction favored oral semaglutide, although without statistical significance (MD −1.60 kg/m²; 95% CI −3.41 to 0.20; p=0.08). Cardiovascular analysis demonstrated a significant reduction in MACE (RR 0.86; 95% CI 0.78–0.95; p=0.003 - FIGURE 2), whereas no significant difference was observed in all-cause mortality (RR 0.79; 95% CI 0.48–1.29; p=0.34). Oral semaglutide was associated with significant glycemic improvement and favorable cardiovascular outcomes, supporting its role as an effective therapeutic option in high-risk T2DM patients.

MULTIDIMENSIONAL INTERVENTION FOR THE MANAGEMENT OF HYPERTENSION AND DIABETES IN LOW-INCOME MUNICIPALITIES: A QUALITATIVE RE-AIM PERSPECTIVE

THIAGO BARBABELA DE CASTRO SOARES1; MILENA SORIANO MARCOLINO1; LILIAN CRISTINA REZENDE1; DAISY MOTTA-SANTOS1; REGINA MÁRCIA FARIA DE MOURA1; SUELI FERREIRA DA FONSECA1; MARIA CECÍLIA RAMOS DE CARVALHO1; ANTÔNIO LUIZ PINHO RIBEIRO1; JAMES THIAGO BATCHELOR1; CHRISTIANE CORRÊA RODRIGUES CIMINI1; CLARA RODRIGUES ALVES DE OLIVEIRA1;

(1) TELEHEALTH CENTER, UNIVERSITY HOSPITAL, UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Control of hypertension and diabetes challenge health systems and demand continuous and longitudinal care. Primary health care centers have a central role to promote health and prevent complications of these non-communicable diseases. Strengthening primary care with hard and soft technologies can improve health outcomes. Objectives: To understand healthcare professionals' perceptions of the implementation of a multidimensional intervention for the management of hypertension and diabetes in low-income municipalities, using the RE-AIM framework. Methods: This is a substudy of a randomised clinical trial with 35 primary care centers involving a multifaceted intervention for the management of hypertension and diabetes during a year in municipalities with a low resources, including telehealth tools (web based computer decision support system [CDSS] to support patient monitoring by physicians and nurses; a CDSS installed in tablets for home visits by community health workers [CHW] to support early recognition of uncompensated disease, to prioritise for consultation ; asynchronous teleconsultations; telediagnosis with electrocardiogram; text message and educational groups to promote patient education, adherence to treatment and lifestyle modification); continuing education for health professionals. At the end, 13 focus groups were conducted with professionals from primary care centers randomized to the intervention group. Transcripts were analyzed using Bardin's content analysis with ATLAS.ti software guided by the RE-AIM (Reach, Effectiveness, Adoption, Implementation, Maintenance) framework. Resultados e Conclusions: Focus groups included 111 professionals (80% women; mean age 40·6 years; mean primary care experience 11·3 years). Reach was affected by geographic distances, access, staff shortages and duplicated data-entry systems. Group activities were a strategy for expanding reach. Effectiveness was marked by strengthened clinical decision-making and broader access to exams. Adoption varied across municipalities showing a potential relation to vulnerable settings. Implementation was threatened by high turnover of professionals and structural constraints, but was facilitated by team support and feedback. Maintenance may be supported by incorporation of multidimensional interventions into institutional workflows adapting to local realities. Success of digital health interventions in underserved settings depends on technology, but also on integration into local workflows and health system capacity.

OBESITY AS A VERTICAL RISK AMPLIFIER IN STEMI ACROSS CKM SYNDROME STAGES: ACCELERATED ONSET AND IMPAIRED MYOCARDIAL REPERFUSION DESPITE TIMELY INTERVENTION

MATHEUS MARQUES FRANCA1; LUIZ SERGIO FERNANDES DE CARVALHO1; ALEXANDRE CURVELO CALDAS1; REBECA COSTA BARBOSA1; RAFAEL SILVA CORTES1; LEONARDO SPENCER VASCONCELLOS1; SERGIO HENRIQUE RODOLPHO RAMALHO1;

(1) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introduction/Background: Obesity is intrinsically linked to the development and progression of cardiovascular disease (CVD) and metabolic dysfunction [1,2]. To address this interaction, the American Heart Association (AHA) guideline formalized the Cardiovascular-Kidney-Metabolic (CKM) syndrome in 2023, a framework that integrates cardiovascular, renal, and metabolic risk factors to stratify risk [3]. Adiposity is a central factor in the CKM spectrum, inducing chronic systemic inflammation through pro-inflammatory cytokines and atherogenesis [1,4]. However, it is unclear whether the proposed CKM stages capture the independent prognostic impact of obesity among individuals with ST-segment elevation myocardial infarction (STEMI) [5,6]. Objectives: The Cardiovascular-Kidney-Metabolic (CKM) syndrome framework provides a meaningful risk stratification strategy, yet obesity's independent prognostic role in ST-elevation myocardial infarction (STEMI) remains debated. We investigated the association of obesity with clinical outcomes across CKM syndrome stages within the Brazilian B-Care cohort. Methods: Method: This study evaluated 4,004 consecutive individuals hospitalized for STEMI in the Federal District, Brazil (2009–2019). Patients were stratified into CKM stages (0/1,2/3,and 4) and compared by the presence of obesity. Primary outcomes included all-cause mortality and major adverse cardiovascular events (MACE). Resultados e Conclusions: Results: Obesity (31% of the cohort) accelerated STEMI onset by approximately 4.2 years across all CKM stages. Despite comparable reperfusion process times (p>0.05), obese patients achieved significantly poorer myocardial reperfusion quality, with lower rates of TIMI3 flow and myocardial blush grade3 (TIMI3 in CKM4: 74.5%vs.82.1%;p<0.05). Obesity consistently amplified mortality risk, ranging from aHR2.7 (CKM1) to 6.14 (CKM4). Notably, obese patients in intermediate CKM stages (2/3) faced mortality risks comparable to non-obese patients with overt disease (CKM4). Conclusion: Obesity functions as a vertical risk amplifier across the CKM spectrum, accelerating disease onset and significantly worsening long-term prognosis. The dissociation between adequate procedural timing and inferior tissue-level reperfusion highlights a heightened ischemic vulnerability in obese patients. Therefore, obesity must be prioritized as a primary, independent driver of cardiovascular risk that necessitates targeted microvascular protection strategies beyond conventional risk scores

PREVALENCE AND ASSOCIATED FACTORS WITH ARTERIAL STIFFNESS IN FAMILIAL HYPERCHOLESTEROLEMIA

BRUNO AUGUSTO ALCOVA NOGUEIRA1; MARIA CRISTINA OLIVEIRA IZAR1; FRANCISCO ANTONIO HELFENSTEIN FONSECA1; RUI POVOA1; MARIA TEREZA NOGUEIRA BOMBIG1; SIMONE PINTO MOREIRA FISCHER1; CLAUDIA DE SOUZA OLIVEIRA1; HENRIQUE TRIA BIANCO1;

(1) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction/Background: Familial hypercholesterolemia (FH) is associated with severe and premature atherosclerosis, and pulse wave velocity (PWV) is considered a marker of arterial stiffness. Identifying variables associated with increased PWV can guide cardiovascular prevention strategies in this high-risk population. Objectives: To evaluate variables independently associated with arterial stiffness in patients with FH. Methods: Cross-sectional study with a priori sample size calculation of 110 FH patients on lipid-lowering therapy, attending a university service. Arterial stiffness was assessed by oscillometric method measuring PWV. Statistical analysis: The outcome variable was PWV and its correlation with clinical and laboratory determinants, including age, sex, systemic arterial hypertension (HTN), diabetes mellitus (DM), peripheral and central systolic blood pressure (SBP), and baseline and treated YEARS scores (LDL-c × age). Multiple linear regression, regularization with cross-validation, mixed linear models with random effects by age group, and non-parametric bootstrap (10,000 replications) were performed. The adopted significance level was 5% in two-tailed analysis. Resultados e Conclusions: Mean age was 59.9±13.0 years; 74.5% were women, 76.5% had hypertension, and 44.8% had diabetes. Mean PWV was 8.59±1.95 m/s. Age showed the strongest correlation with PWV (r=0.929, p<0.001), followed by baseline YEARS score (r=0.630, p<0.001), whereas LDL-c at diagnosis and at enrollment were not associated with PWV. In the adjusted linear regression model, PWV was independently associated with age (B=0.122, 95% BCa CI 0.112-0.137; β=0.819; p<0.001), peripheral SBP (B=0.026, 95% BCa CI 0.021-0.031; β=0.255; p<0.001), and central pulse pressure (B=0.023, 95% BCa CI 0.013-0.033; β=0.112; p<0.001). Bootstrap validation did not confirm YEARS score as independently associated with PWV. PWV tertile stratification identified a high-risk phenotype with PWV >9.30 m/s, older age (72±6 years), 100% hypertension prevalence, and 37% higher cumulative LDL burden versus the low tertile (all p<0.001). Conclusion: Age, peripheral SBP, and central pulse pressure were independently associated with PWV, highlighting the combined contribution of aging and hemodynamic load to arterial stiffness in FH.

PREVALENCE OF ELEVATED LIPOPROTEIN(A) LEVELS IN CHILDREN AND ADOLESCENTS: IMPACT ON EARLY IDENTIFICATION OF CARDIOVASCULAR RISK FACTORS

RICARDO BARRETTO PITHON1; PAOLA ALMEIDA SANTANA SOARES1; NATHALIE JEANNE MAGIOLI BRAVO-VALENZUELA1; LUCIANA CORRÊA DE SOUZA RODRIGUES1; LUIZ HENRIQUE CORRÊA PORTARI1; RENATA MAKSOUD BUSSUAN1;

(1) INSTITUTO DE CARDIOLOGIA / FUNDAÇÃO UNIVERSITARIA DE CARDIOLOGIA - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: Introduction/Background: Cardiovascular diseases are the leading cause of global mortality, with evidence that the atherosclerotic process begins in childhood and adolescence. Lipoprotein(a) is a cardiovascular risk biomarker with predominantly genetic determination, whose levels remain stable from birth regardless of environmental factors and nutritional status. Data on its prevalence in Brazilian pediatric populations are scarce. Objectives: Objective: To determine the prevalence of elevated lipoprotein(a) levels and their association with conventional cardiovascular risk factors in children and adolescents attending a reference center. Methods: Methods: Observational, cross-sectional, and descriptive study involving 94 patients aged 2 to 19 yearswith a mean age of 11.7 years (SD = 5,08; median = 11.5), stratified into an overweight group (n=56; 59.6%) and a normal weight group (n=38; 40.4%). Anthropometric data, blood pressure, complete lipid profile, and plasma lipoprotein(a) by turbidimetric immunoassay were collected. Statistical analysis used parametric and nonparametric tests according to data distribution, with a significance level of 5%. Resultados e Conclusions: Results: The prevalence of elevated lipoprotein(a) was 45.7% at the 30 milligrams per deciliter threshold and 25.5% at the 50 milligrams per deciliter threshold, the high-risk cutoff of the European Atherosclerosis Society. No significant difference in lipoprotein(a) levels was found between groups by nutritional status (p=0.911), sex (p=0.551), or age group (p=0.964), confirming its genetic independence. The overweight group showed significantly higher systolic blood pressure (p<0.001), diastolic blood pressure (p<0.001), low-density lipoprotein (p=0.002), and total cholesterol (p=0.006). Combined cardiovascular risk, defined as coexistence of dyslipidemia and lipoprotein(a) at or above 30 milligrams per deciliter, was identified in 31.9% of the sample. Conclusion: Approximately one quarter of the evaluated children and adolescents present lipoprotein(a) levels compatible with high cardiovascular risk, independently of nutritional status, sex, and age group. These findings reinforce the need to include lipoprotein(a) measurement in routine pediatric cardiovascular assessment as an early screening and prevention strategy.

REDEFINING LDL-C REDUCTION STRATEGIES IN STATIN-INTOLERANT PATIENTS: A CONTEMPORARY NETWORK META-ANALYSIS OF NON-STATIN THERAPIES

MARCÍLIO MARCÍLIO DE OLIVEIRA FILHO1; SUELEN QUEIROZ2; MARINA AZEVEDO AMARAL1; ANISIO UCHOA LEITE SANTANA3; MIGUEL CHAVES LENZI4; EDUARDO BELLO MARTINS5; ANTONIO ESCAMILLA GARCIA6;

(1) FACULDADE DE MEDICINA DE BARBACENA - BARBACENA - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE PONTA GROSSA - PONTA GROSSA - PR - BRASIL; (3) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (4) UNIVERSIDADE ESTADUAL DO RIO GRANDE DO NORTE - MOSSORÓ - RN - BRASIL; (5) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (6) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL;

Introduction/Background: Statin intolerance remains a major challenge in lipid management. Alternative therapies such as bempedoic acid, ezetimibe, PCSK9 inhibitors, and combination regimens are increasingly used, yet their relative efficacy has not been fully clarified. This study aimed to assess the comparative efficacy of non-statin lipid-lowering therapies in statin-intolerant patients through a frequentist network meta-analysis Objectives: To compare the efficacy of non-statin lipid-lowering therapies—including Evolocumab, Alirocumab, Ezetimibe, and Bempedoic acid (alone or in combination)—versus placebo or standard of care in reducing LDL-C levels among statin-intolerant patients, and to assess the consistency and comparative performance of these strategies within a network meta-analysis framework. Methods: We systematically identified 12 randomized trials (n=21,115) including 7 interventions: bempedoic acid, ezetimibe, evolocumab, alirocumab, bempedoic acid– ezetimibe, standard of care (SOC), and placebo. Direct and indirect evidence were synthesized using randomeffects models. Mean difference (MD) in LDL-C reduction was the primary outcome. Inconsistency was evaluated by node-splitting and global tests. Resultados e Conclusions: Compared with placebo, Evolocumab (MD –10.20 mg/dL; 95% CI –27.6 to 7.2), Ezetimibe (–8.34; –23.5 to 6.9), and standard of care (–9.66; –27.9 to 8.6) achieved the greatest LDL-C reductions, whereas Bempedoic acid alone showed a modest effect (–0.10; –1.1 to 0.9). The fixed-dose bempedoic acid–ezetimibe combination demonstrated improved efficacy (–1.54; –14.9 to 11.8), and Alirocumab also reduced LDL-C, although with imprecise estimates (0.00; –7.6 to 7.6). Inconsistency testing showed no significant disagreement between direct and indirect evidence, and the network was well connected (21 possible comparisons, 6 with direct data). Overall, in statin-intolerant patients, PCSK9 inhibitors and ezetimibe-based strategies provide the most consistent LDL-C reductions, while bempedoic acid has modest efficacy that may be enhanced when combined with ezetimibe, supporting a tailored approach to lipid-lowering therapy when statins are not tolerated.

REDUCED PHYSICAL PERFORMANCE DESPITE LOW OR INTERMEDIATE WHO CARDIOVASCULAR RISK IN A BRAZILIAN COHORT

ALINE CRISTINA D'ÁVILA SOUZA1; LIDIANE APARECIDA PEREIRA SOUSA2; ROSA WEISS TELLES1; RICARDO PAROLI FERREIRA SANTOS3; DÉBORA VITÓRIA SILVA MOREIRA3; BRENO FERRARI MACIEL3; SANDHI MARIA BARRETO1; ANTÔNIO LUIZ PINHO RIBEIRO1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (3) FACULDADE DE MEDICINA UNIVERSIDADE PROFESSOR EDSON ANTONIO VELANO - UNIFENAS - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: Traditional cardiovascular risk scores can underestimate clinically relevant vulnerabilities, particularly functional impairment. The Short Physical Performance Battery (SPPB) might help identify frailty even among individuals without a formal high cardiovascular risk classification. Objectives: To investigate the frequency of reduced physical performance, measured by the SPPB, across WHO cardiovascular risk strata and to identify, among individuals at low or intermediate risk, the profiles with the highest probability of functional impairment. Methods: We did a cross-sectional study nested within a large Brazilian population-based cohort. Reduced physical performance was defined as an SPPB score of 9 points or lower. In the main analytic sample (n=6235), participants were classified as low/intermediate or high/very high cardiovascular risk according to WHO criteria. We did descriptive analyses, constructed risk-performance phenotypes, and fitted logistic regression models. In analyses restricted to the low/intermediate-risk stratum, models were adjusted for sex, age, smoking, excessive alcohol use, and abdominal obesity (n=4344). Resultados e Conclusions: In the analytic sample, 55.3% of participants at low or intermediate cardiovascular risk already had an SPPB score of 9 or lower, and this proportion reached 76.0% among those at high or very high risk. The phenotype of low/intermediate risk plus reduced SPPB was the most frequent (38.9%) and was more common in women. Among low/intermediate-risk individuals, the odds of reduced physical performance were higher in women (OR=1.47, 95% CI 1.28-1.69), participants older than 74 years (OR=2.23, 1.46-3.42), and those with abdominal obesity (OR=2.01, 1.76-2.29). Smoking was also associated with the outcome (OR=1.15, 1.01-1.32). Adjusted probabilities of an SPPB score of 9 or lower increased progressively with age and reached 87.1% in women older than 74 years with abdominal obesity. The SPPB identified functional vulnerability not fully captured by formal cardiovascular risk classification, particularly in women, older adults, and individuals with abdominal obesity.

(1) NOVO NORDISK - SÃO PAULO - SP - BRASIL; (2) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL; (3) FACULDADE DE MEDICINA DA UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL; (4) INSTITUTO MEDICO DAMIC - ARGENTINA; (5) INSTITUTO DE INVESTIGACIONES CLINICAS QUILMES - ARGENTINA; (6) FUNDACION FAVALORO - ARGENTINA; (7) NOVO NORDISK - PANAMA; (8) NOVO NORDISK - SAO PAULO - SP - BRASIL;

Introduction/Background: Inflammatory risk is an independent and key risk factor to recurrent cardiovascular events in patients with atherosclerotic cardiovascular disease (ASCVD). Its prevalence and clinical correlates in Latin American populations remains poorly characterized. Chronic kidney disease (CKD) brings cardiovascular risk through both traditional and inflammation-mediated pathways, creating a high-risk cardiorenal phenotype that warrants dedicated investigation. This inflammatory burden persists despite contemporary standard-of-care therapies. Objectives: Real world study with the main objective of investigating the prevalence of inflammation, defined by hsCRP>=2. Methods: Cross-sectional, global, real-world study adults with ASCVD during a single study visit over a 17-month enrollment period. Latin America Cluster data (Brazil and Argentina). Resultados e Conclusions: A total of 1,214 patients were included in the LATAM Cluster: 456 with ASCVD+CKD and 758 with ASCVD without CKD. Overall prevalence of hsCRP≥2 in patients with ASCVD and CKD was 50.2% compared with 39.5% in patients without CKD. Of the 1214 included patients, 72% were from the Brazilian population and 28% from Argentina. The median age was 70.0 years (63.0–77.0) in the ASCVD+CKD cohort and 64.0 years (58.0–71.0) in the ASCVD without CKD cohort (p<0.001). Median hsCRP was significantly higher in the ASCVD+CKD cohort (2.02 mg/L [0.86–5.09]) versus ASCVD without CKD (1.29 mg/L [0.70–3.37]; p<0.001), as was IL-6 (3.86 vs. 2.99 pg/mL; p<0.001). Residual inflammation persisted even under statin therapy: 49.1% and 38.5% of statin-treated patients in the ASCVD+CKD and ASCVD without CKD cohorts, respectively, had hsCRP ≥2 mg/L. Systemic inflammation is highly prevalent in Latin American patients with established ASCVD, affecting one in two patients with concomitant CKD despite guideline-directed therapy. . Nearly half of statin-treated patients exhibited residual inflammatory risk. Inflammation is central and underrecognized component of residual cardiovascular risk in Latin America and underscore the need for improved strategies to identify and address inflammatory risk in this population. The high overall prevalence of cardiovascular inflammation in this population should encourage clinicians to a wide screening of hsCRP levels. Moreover, the present study gives us more insights on which patient profiles should be prioritized.

21924

RNA-TARGETING THERAPIES FOR ELEVATED LIPOPROTEIN(A) IN PATIENTS WITH ESTABLISHED ATHEROSCLEROTIC CARDIOVASCULAR DISEASE: A SYSTEMATIC REVIEW OF CLINICAL EVIDENCE AND IMPLICATIONS FOR PRACTICE

ARTHUR CHEDE CHAVES REIS1; FELLIPE DEBACKER LADEIRA1; IVENS MURAD GARCIA MAGALHÃES1;

(1) UFJF - JUIZ DE FORA - MG - BRASIL;

Introduction/Background: Lipoprotein(a) [Lp(a)] is a genetically determined cardiovascular risk factor strongly associated with atherosclerotic cardiovascular disease (ASCVD), yet no approved therapy currently exists. RNA-targeting therapies, including small interfering RNA (siRNA) and antisense oligonucleotide (ASO) agents, have demonstrated substantial Lp(a) reductions in early-phase trials. However, their impact on cardiovascular outcomes remains unclear. Objectives: To systematically review the evidence on RNA-targeting therapies for elevated Lp(a) in patients with established ASCVD, focusing on efficacy, durability, safety, and the relationship between biomarker reduction and cardiovascular outcomes. Methods: A systematic search of PubMed/MEDLINE, Embase, Cochrane CENTRAL, Web of Science, Scopus, and LILACS was conducted. Eligible studies included phase I–III clinical trials evaluating RNA-targeting anti-LPA therapies in adults with elevated Lp(a). PRISMA 2020 guidelines and the Cochrane Handbook were followed. Risk of bias was assessed using the Cochrane RoB 2 framework adapted for dose-escalation studies. Resultados e Conclusions: Among 765 identified records, 427 remained after deduplication. Eighteen full-text studies were assessed, and 15 were included in the final qualitative synthesis. Six siRNA agents were evaluated: olpasiran (4 studies + 2 sub-analyses), zerlasiran (2 studies), and lepodisiran (2 studies); and two ASO agents: pelacarsen (2 studies + 1 sub-analysis) and IONIS-APO(a)Rx/LRx (1 study reporting two trials). Placebo-adjusted Lp(a) reductions ranged from 35% with pelacarsen 20 mg Q4W to 101% with olpasiran 225 mg Q12W. siRNA therapies demonstrated superior pharmacodynamic durability compared with ASOs. Olpasiran maintained ~28–36% suppression nearly two years after treatment discontinuation, while a single 608 mg dose of lepodisiran sustained >90% suppression for 337 days. Safety profiles were generally favorable, with injection-site reactions being the most common adverse event and no serious drug-related adverse events identified. None of the included studies evaluated major adverse cardiovascular events (MACE) as primary endpoints. Heterogeneity precluded meta-analysis. RNA-targeting therapies achieve profound and durable reductions in Lp(a), particularly siRNA agents. Whether these reductions translate into lower cardiovascular event rates remains uncertain and depends on ongoing outcome trials, including OCEAN(a)-OUTCOMES, Lp(a)HORIZON, and the lepodisiran phase 3 program.

Table 2. Comparative Pharmacodynamic Profile of RNA-Targeting Lp(a)-Lowering Agents

Drug	Class	Peak Lp(a) Reduction	Time to Max Effect	Duration >50% Suppression After Last Dose	Dose for Near-Maximal Effect	Proposed Dosing Interval
Olpasiran	siRNA (GalNAc)	97–103% (in placebo)	Day 29–57 (single dose)	~48–50 wk at 225 mg (Q12W); ~18–24 wk at 75 mg (Q12W)	75–225 mg Q12W	Every 12 weeks (Q12W)
Zerlasiran (SLN360)	siRNA (GalNAc)	97–99%	Day 30–90 (multiple dose)	~28–30 wk after 2nd dose (300–450 mg Q8W)	300–450 mg Q8–16W	Every 28–24 weeks
Lepodisiran	Dicer-substrate siRNA (GalNAc)	93–97%	Day 29–85 (600 mg single)	>90% from day 22–337 (608 mg phase 1); >93.9% through day 180 (600 mg phase 2)	400 mg (phase 2)	Every 6–12 months (expected)
Pelacarsen (TQJ230)	ASO (GalNAc3)	72–85%	4–10 weeks	20 weeks off-Tx; returns to baseline; Half-life ~1 month	60 mg Q4W or 20 mg Q8W	Every 4 weeks (monthly)
IONIS-APO(a)-LRx (early pelacarsen)	ASO (GalNAc3)	Up to 92%	Day 29–36 (multiple doses)	~43–58% at 113 d after last dose	40 mg (MAD schedule)	Potential monthly or quarterly
IONIS-APO(a)Rx	ASO (unconjugated)	Up to ~72%	Return toward baseline by day 238	Returns toward baseline by day 238	300 mg QW×4 wk→2 (escalating)	Weekly (lower potency)

Values represent clinically observed data from included studies. *Off-treatment data from OCEAN(a)-DOSE extension (O'Donoghue 2024). ASO, antisense oligonucleotide; GalNAc, N-acetylgalactosamine; Q4W/Q8W/Q12W/Q24W, every 4/8/12/24 weeks; RISC, RNA-induced silencing complex; siRNA, small interfering RNA.

17616

ROLE OF POLYGENIC RISK SCORES (PRS) IN PREDICTING CORONARY ARTERY DISEASE (CAD)

MATHEUS FEITOSA DE AZEVEDO1; GABRIELA CRISTINA LOBATO2; RAFAELA SPARTANI DIAS PASSOS GALOTE3; NICOLE CAROLINE JUNGLOS4; ELISA MORAIS MILAGRES5; CECÍLIA VARCHAVSKY DE MORAES6; GABRIELA MACEDO OLIVEIRA6; LARISSA AVILA BRANCO3; MARIANA MOREIRA CARVALHO ALVES DA SILVA1;

(1) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (3) UNIVERSIDADE FEDERAL DO RIO GRANDE - RIO GRANDE - RS - BRASIL; (4) UNIVERSIDADE REGIONAL DE BLUMENAU - BLUMENAL - SC - BRASIL; (5) UNIVERSIDADE DO VALE DO SAPUCAÍ - POUSO ALEGRE - MG - BRASIL; (6) UNIVERSIDADE DE RIO VERDE - RIO VERDE - GO - BRASIL;

Introduction/Background: Polygenic Risk Scores (PRS) integrate multiple genetic variants to estimate individual cardiovascular risk. They enhance conventional risk assessment, particularly in younger individuals and those at intermediate risk, enabling earlier identification of high-risk patients and supporting targeted preventive strategies, including statin therapy. Objectives: To evaluate the role of PRS in predicting the development of CAD. Methods: A systematic search was conducted in PubMed, LILACS, Cochrane Library, Embase, Web of Science, and SciELO in April 2026 using ("Polygenic risk scores" OR "Genetic risk scores") AND ("Coronary artery disease" OR "CAD"). Clinical and observational studies published between 2016 and 2026 in English, Portuguese, or Spanish were included. Reviews, case reports, studies older than 10 years, and those without full-text access were excluded. Two independent reviewers screened studies using Rayyan. Of 136 records identified, 16 met inclusion criteria. Resultados e Conclusions: PRS were consistently associated with the presence and overall burden of coronary atherosclerosis. Individuals with higher genetic risk exhibited up to 78% higher coronary calcium scores and greater plaque prevalence (63% vs 36%), indicating a strong association with total disease burden. PRS were also linked to cardiovascular events, particularly myocardial infarction, with an estimated 60% increase in risk per standard deviation and stronger effects in individuals under 50–55 years, in whom genetic factors may account for up to 40% of events. When integrated with clinical scores, PRS improved risk stratification, reducing misclassification from 10.4% to 4.4% and achieving overall reclassification gains of 5.9%, reaching 13.5% in younger individuals. Predictive performance varied across populations, with improvements of 9.3% in individuals of European ancestry but minimal impact in African populations. PRS are robust markers of coronary atherosclerotic burden and provide clinically meaningful information for early identification of high-risk individuals, particularly at younger ages. Their integration with traditional risk models enhances risk prediction and may improve primary prevention strategies. However, broader clinical implementation requires more inclusive and ethnically diverse models to ensure equitable and accurate cardiovascular risk assessment.

SMALL DENSE LDL AND REDUCED LDL PARTICLE SIZE ARE ASSOCIATED WITH PRIOR MYOCARDIAL INFARCTION IN FAMILIAL HYPERCHOLESTEROLEMIA

ERLON O. DE ABREU-SILVA1; RACHEL H VIEIRA MACHADO1; FERNANDA J. EL KHOURI1; LEONARDO C. CASSARO1; LUCAS TRAMUJAS1; FLÁVIA CONTI CARTOLANO2; NÁGILA R. T. DAMASCENO2; ALINE MARCADENTI1;

(1) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL; (2) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction/Background: Introduction: In familial hypercholesterolemia (FH), the risk of myocardial infarction (MI) remains high even under intensive lipid-lowering therapy, suggesting persistent residual cardiovascular risk. Since LDL-cholesterol levels alone may not fully capture this risk, comparing individuals with and without prior MI may help identify more atherogenic lipoprotein profiles associated with clinical events. Objectives: Objective: To evaluate the association between the size and density of atherogenic lipoprotein subfractions and prior MI in individuals with probable or definite FH. Methods: Methods: Cross-sectional analysis of baseline data from a national multicenter randomized trial (DICA-FH) including individuals with probable or definite FH according to the Dutch MEDPED criteria. Sociodemographic, clinical, and lifestyle data, as well as LDL-cholesterol concentrations (mg/dL), were obtained at participating sites. LDL particle size (peak particle diameter, nm) and density were determined using the Lipoprint® System; LDL3–LDL7 were classified as small dense LDL (sdLDL). Data were log-transformed prior to analysis, and ANOVA was used for group comparisons (with vs. without MI). ANCOVA models assessed associations between atherogenic particles and MI independently of confounders. Resultados e Conclusions: Results: Among 58 participants (mean age 54.5 ± 13.7 years; 53.8% men; BMI 29.3 ± 4.3 kg/m²), the mean Dutch MEDPED score was 8.9 ± 3.6, 66.7% had prior MI, 56.9% low physical activity levels, and 79% were on high-intensity lipid-lowering therapy. LDL-cholesterol did not differ by prior MI status (no MI: 142 ± 60.4 mg/dL; MI: 135.4 ± 56.1 mg/dL; p=0.7). Individuals with prior MI had smaller LDL particle size (26.5 ± 0.6 vs. 26.9 ± 0.5 nm; p=0.03) and higher sdLDL percentage (6.3 ± 6.1% vs. 3.0 ± 4.7%; p=0.048). After adjustment for age, sex, physical activity (METs), and lipid-lowering treatment intensity, LDL particle size remained smaller (26.3 vs. 27.0 nm; p=0.004) and sdLDL percentage remained higher (8.4% vs. 2.0%; p=0.007) in those with prior MI. Additionally, LDL3 percentage was higher in individuals with MI (5.5% vs. 1.9%; p=0.01). Conclusion: Despite similar LDL-cholesterol levels, individuals with prior MI exhibited a more atherogenic LDL profile, with higher sdLDL and smaller particle size, supporting the role of lipoprotein subfractions in assessing residual cardiovascular risk in FH. TIRZEPATIDE REDUCES ALL-CAUSE MORTALITY IN TYPE 2 DIABETES MELLITUS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF 24,177 PATIENTS FROM 13 RANDOMIZED CONTROLLED TRIALS

MARCO AURELIO LUMERTZ SAFFI1; MARIANA RC CLEMENTE2; LUÍSA DOMINGOS CANCELA GONÇALVES3; LUCAS S MATZENBACHER4; GABRIELA HEIDEN TELO4;

(1) UNIVERSIDADE FEDERAL DO RIO GRANDE - RIO GRANDE - RS - BRASIL; (2) FACULDADE DE MEDICINA DE PETROPOLIS - PETRÓPOLIS - RJ - BRASIL; (3) FACULDADE EVANGELICA MACKENZIE DO PARANA - CURITIBA - PR - BRASIL; (4) PUCRS - PORTO ALEGRE - RS - BRASIL;

Introduction/Background: The efficacy tirzepatide, a dual glucose-dependent insulinotropic polypeptide (GIP) and glucagon-like peptide-1 (GLP-1) receptor agonist, has demonstrated robust improvements in glycemic control and body weight in patients with type 2 diabetes mellitus (T2DM). However, despite its rapidly growing clinical adoption, whether tirzepatide confers meaningful cardiovascular protection beyond its metabolic benefits remains to be established. Objectives: To assess the effects of tirzepatide on major adverse cardiovascular events (MACE) and all-cause mortality in adults with T2DM, compared with placebo or active glucose-lowering therapies. Methods: We performed a systematic review and meta-analysis of randomized controlled trials (RCTs) comparing tirzepatide versus placebo or active glucose-lowering agents in adults with T2DM. PubMed, Embase, and Cochrane Library were searched from inception through February 2026. Risk ratios (RRs) with 95% confidence intervals (CIs) were pooled using random-effects models. Analyses were performed using Review Manager 10.0.1. This study was registered with PROSPERO (CRD420261297683). Resultados e Conclusions: Thirteen RCTs comprising 24,177 patients were included; 13,912 participants (57.5%) received tirzepatide, while controls received placebo (3.2%), long-acting insulin (9.5%), or GLP-1 receptor agonists (29.8%). Tirzepatide was associated with a significant reduction in all-cause mortality compared with control therapies (RR 0.84; 95% CI 0.76–0.93; p=0.0007; I²=0%; Figure 1). No statistically significant difference was observed in MACE (RR 0.92; 95% CI 0.84–1.00; p=0.05; I²=0%; Figure 2), with a point estimate consistently favoring tirzepatide. In this meta-analysis of RCTs, tirzepatide was associated with a significant reduction in all-cause mortality in adults with type 2 diabetes compared with control therapies. No statistically significant difference was observed in MACE.

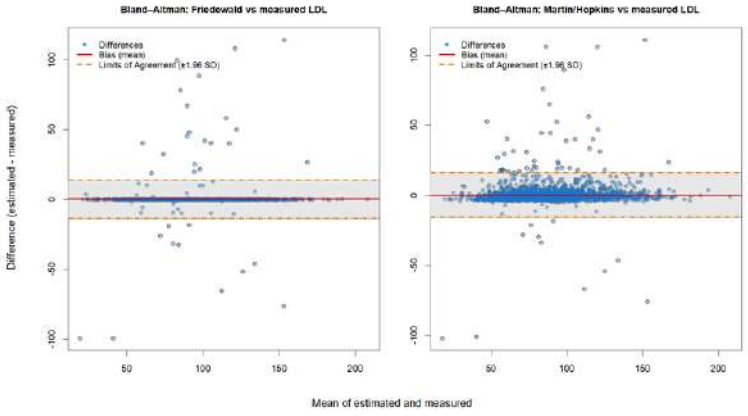
TRIGLYCERIDE-GLUCOSE INDEX AND ATHEROGENIC INDEX OF PLASMA AS PREDICTORS OF CARDIOVASCULAR RISK: A SYSTEMATIC REVIEW AND QUANTITATIVE SYNTHESIS

DAVID GARCIA DE ALCARAZ CONTI1;

(1) FACULDADE DE MEDICINA DO ABC (FMABC) - SANTO ANDRÉ - SP - BRASIL;

Introduction/Background: The triglyceride-glucose (TyG) index and the atherogenic index of plasma (AIP, log TG/HDL-C) have emerged as low-cost markers integrating insulin resistance and atherogenic dyslipidemia. Their role in cardiovascular risk stratification has gained increasing attention in large population studies. Objectives: To evaluate the association of TyG and AIP with incident and prevalent atherosclerotic cardiovascular disease. Methods: A systematic review was conducted according to PRISMA 2020 and Cochrane recommendations for prognostic factor research. PubMed/MEDLINE was searched from inception to 2025 for cohort studies and meta-analyses evaluating TyG and AIP. Eligible studies included adult populations with reported cardiovascular outcomes and adjusted effect estimates. Study selection and data extraction were performed independently by two reviewers. Pooled estimates were derived from hazard ratios (HR) and risk ratios (RR) using random-effects models. Heterogeneity was assessed using I² statistics, and certainty of evidence was evaluated using GRADE. Resultados e Conclusions: Evidence was derived from large population-based cohorts, including the Atherosclerosis Risk in Communities (ARIC) Study, UK Biobank analyses, Framingham Offspring Study, and the Kailuan cohort, encompassing over 6 million participants. The TyG index showed strong associations with incident coronary artery disease and composite cardiovascular outcomes (n=6,354,990; HR 2.01, 95% CI 1.68–2.40; I²=0%), with consistent effects across populations and follow-up durations. AIP, defined as log(TG/HDL-C), was associated with coronary artery disease (RR per SD 2.10, 95% CI 1.51–2.93; I²=90%) and major adverse cardiovascular events in established disease (RR 1.63, 95% CI 1.44–1.85). Despite heterogeneity in AIP analyses, directionality remained consistent. Certainty of evidence was moderate to high for TyG and moderate for AIP. These indices reflect underlying metabolic dysfunction and provide complementary risk stratification beyond conventional lipid parameters. Their low cost and accessibility support potential integration into clinical practice, although standardization and prospective validation remain necessary.



19554

VALIDATION OF THE FRIEDEWALD AND MARTIN-HOPKINS EQUATIONS AGAINST DIRECT LDL-C MEASUREMENT IN BRAZILIAN ADOLESCENTS

MARCOS ADRIANO GARCIA CAMPOS1; GILBERTO DE HOLANDA LOPES FILHO1; ELISA MIRANDA COSTA2; ROMULLO JOSÉ COSTA ATAIDES3; JOSENILDO COSTA DA SILVA4; ANTÔNIO AUGUSTO MOURA DA SILVA1; BRUNO FERES DE FERES DE SOUZA1; ERIKA BÁRBARA ABREU FONSECA THOMAZ1;

(1) UNIVERSIDADE FEDERAL DO MARANHAO - SÃO LUIS - MA - BRASIL; (2) UNIVERSIDADE FEDERAL DE ALAGOAS - MACEIÓ - AL - BRASIL; (3) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (4) UFMA - CAMPUS SAO LUIS - SÃO LUÍS - MA - BRASIL;

Introduction/Background: Dyslipidemia in adolescents poses significant cardiovascular risks. Direct measurement is optimal, yet cost-effective alternatives are necessary for broader application. Standard predictive formulas, such as the Friedewald formula, frequently underestimate LDL-C in patients with high triglycerides. The Martin-Hopkins equation provides greater accuracy across a range of triglyceride levels. Nonetheless, research on lipid outcomes in children and adolescents remains limited. Objectives: We aimed to validate LDL-C estimation using the Friedewald and Martin–Hopkins formulas in a large cohort of Brazilian adolescents. Methods: We used data from the São Luís birth cohort, initiated in 1997–1998, with a systematic hospital-based sample (1 in 7 births), totaling 2,493 live births across 10 maternity services. At ages 18–19 (2016–2017), 687 participants from the original cohort were evaluated, and a retrospective expansion added 1,828 adolescents born in 1997 (randomly sampled from the Brazilian National Birth Registry System and also recruited via schools/universities and social media), yielding 2,515 participants overall. Lipid profile parameters were assessed, and LDL-C was estimated using the Friedewald and Martin–Hopkins formulas. These indirect estimates were validated against direct LDL-C measurements, and incorrect and missed dyslipidemia diagnoses were quantified. Agreement between methods was evaluated using Bland–Altman analysis.

Linear association was assessed with Pearson correlation. Mean differences between directly measured and estimated LDL-C were assessed using two-sided paired Student's t-tests with a 95% confidence interval (95%CI). Diagnostic performance for high LDL-C (≥110 mg/dL) was evaluated by calculating sensitivity, specificity, and accuracy for LDL-C classification. Resultados e Conclusions: After excluding 238 adolescents with missing lipid profile data, 2,277 participants aged 18–19 years were analyzed, 51.93% male. Mean directly measured LDL-C was 89.71 ± 26.27 mg/dL, compared with 89.96 ± 26.61 mg/dL by Friedewald and 90.00 ± 26.84 mg/dL by Martin–Hopkins. Mean differences versus direct LDL-C were 0.22 mg/dL (95% CI: −0.07 to 0.51) and 0.26 mg/dL (95% CI: −0.07 to 0.59), respectively. Friedewald showed 98.77% accuracy, 96.92% sensitivity, and 99.23% specificity; Martin–Hopkins showed 96.75%, 94.50%, and 97.31%. Neither differed significantly from direct LDL-C. Both were reliable and cost-effective for adolescent screening.

BEYOND ABSTINENCE: THE ROLE OF A CLINICAL CARE PROGRAM IN SMOKING CESSATION AFTER MYOCARDIAL INFARCTION

ORNELLA ELEUTERIO OLIVEIRA1; CAROLINE RUSSO FERREIRA1;

(1) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL;

Introduction/Background: Introduction: Smoking is a modifiable risk factor for cardiovascular diseases, such as stroke and acute myocardial infarction (AMI). National data demonstrate an increase in smoking prevalence, reinforcing the need for smoking cessation and secondary prevention strategies. In this context, the role of healthcare institutions in implementing care practices aimed at promoting lifestyle changes is highlighted. This study describes the performance of a multidisciplinary program dedicated to smoking cessation in patients hospitalized after AMI. During hospitalization, patients receive educational guidance, psychological support, and joint evaluation by the medical team regarding supportive pharmacological therapy. After discharge, the program maintains structured telephone follow-up for clinical monitoring and longitudinal support. Objectives: Objective: To describe the outcomes of a multidisciplinary program focused on smoking cessation in patients after acute myocardial infarction. Methods: Methods: Retrospective cohort study conducted at a private hospital in the city of São Paulo, Brazil, between 2024 and February 2026. Data from smoking patients followed during hospitalization and after hospital discharge were analyzed. Resultados e Conclusions: Results: During the study period, 52 smoking patients were followed, corresponding to 20% of the patients monitored by the program. Seven days after discharge, 82.8% were abstinent; at 30 days, 74%; at 180 days, 80%; and after 365 days, 85.7% remained smoke-free. Overall, 79.5% achieved smoking cessation without relapse during follow-up. Among patients who continued smoking, only one did not demonstrate a reduction in tobacco consumption, while all others reduced cigarette use by at least 50%. Regarding supportive resources, 54% did not use adjunctive methods, 38% used pharmacological therapy, 6% underwent psychotherapeutic follow-up, and 1.5% accepted psychological support after discharge. Conclusion: The multidisciplinary program demonstrated favorable outcomes in smoking cessation among post-AMI patients, reinforcing the importance of longitudinal follow-up after hospital discharge. In addition to the high abstinence rate observed over one year, there was also a significant reduction in tobacco consumption among patients who continued smoking. These findings highlight how structured multidisciplinary actions focused on promoting self-care and therapeutic adherence may support sustainable lifestyle changes after myocardial infarction

Introduction/Background: Sleep quality is a key determinant of cardiovascular health. Growing evidence indicates that sleep deprivation and sleep disorders are associated with metabolic, inflammatory, and hemodynamic alterations, including elevated blood pressure, weight gain, and autonomic dysfunction. Among university students, factors such as academic stress and unhealthy lifestyle behaviors contribute to a high prevalence of poor sleep quality, thereby increasing cardiovascular risk. Objectives: To assess the association between sleep quality and cardiovascular risk in university students through a systematic review of recent evidence. Methods: A systematic review was conducted in accordance with PRISMA guidelines using PubMed, Scopus, and SciELO databases. The search strategy included the descriptors “sleep quality”, “cardiovascular risk”, and “university students”, combined using Boolean operators. Observational studies published between 2023 and 2025, in Portuguese, were included. Eligible studies assessed the association between sleep quality and cardiovascular risk factors, such as blood pressure, body mass index, and metabolic parameters. Following screening of titles, abstracts, and full texts, studies meeting the inclusion criteria were selected for qualitative synthesis. Resultados e Conclusions: The included studies consistently demonstrate a high prevalence of poor sleep quality among university students, which is associated with increased blood pressure, higher body mass index, metabolic disturbances, and elevated stress levels. Sleep deprivation was also linked to autonomic dysfunction, inflammatory processes, and unhealthy lifestyle behaviors. These findings underscore the role of sleep as a relevant modifiable factor in cardiovascular prevention and highlight the need for targeted health promotion strategies aimed at improving sleep quality in this population.

SLEEP DISORDERS IN PATIENTS WITH HEART FAILURE: HIGH FREQUENCY AND CLINICAL UNDERESTIMATION

DEBORA SILVA BIRAL1; DEBORA CONSUELO GONÇALVES PEREIRA1; KELLY REGINA NOVAES VIEIRA1; ANA CAROLINA REZENDE1; CARLOS HENRIQUE DEL CARLO1; SERGIO JALLAD1; MUCIO TAVARES OLIVEIRA JR.1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction/Background: Sleep disorders are common in patients with heart failure (HF) and are associated with persistent sympathetic nervous system activation, systemic inflammation, poor quality of life, and adverse cardiovascular outcomes. Insomnia and sleep fragmentation may contribute to relevant neurohormonal changes, impacting symptoms, functionality, and clinical prognosis. Despite their cardiovascular relevance, sleep disturbances remain poorly recognized in the routine follow-up of these patients. Objectives: To evaluate the frequency and characteristics of sleep disorders in patients with heart failure. Methods: An observational, descriptive study conducted with outpatients suffering from chronic advanced heart failure. Sleep disorders were assessed using the Insomnia Severity Index, a validated instrument for evaluating insomnia severity and its clinical impacts. The analysis included difficulty initiating and maintaining sleep, early morning awakenings, satisfaction with sleep pattern, functional interference, and concerns related to sleep disturbances. Data were subjected to descriptive analysis. Resultados e Conclusions: A total of 60 patients with HF were evaluated. It was observed that 65% of patients presented moderate or severe insomnia. Severe or very severe difficulty initiating and maintaining sleep occurred in 55% and 58.3% of the sample, respectively, while 73.3% presented moderate to very severe early morning awakenings. Furthermore, 70% reported significant dissatisfaction with their sleep pattern, 61.7% reported significant functional interference related to sleep, and 66.6% were very or extremely concerned about their sleep problems. Sleep disorders are highly prevalent in patients with heart failure, accompanied by significant functional impact and subjective distress. The findings suggest that sleep disturbances represent a frequently underestimated component in the clinical management of this population, potentially contributing to poorer quality of life and cardiovascular dysregulation.

ELEVATED SPIRITUAL WELL-BEING AND ABSENCE OF DEPRESSIVE SYMPTOMS IN PATIENTS WITH HEART FAILURE: COMPARISON BETWEEN CLINICAL GROUPS

DEBORA SILVA BIRAL1; DEBORA CONSUELO GONÇALVES PEREIRA1; KELLY REGINA NOVAES VIEIRA1; CARLOS HENRIQUE DEL CARLO1; SERGIO JALLAD1; ANA CAROLINA REZENDE1; AGATHA CAROLINE FARIA ROCHA RODRIGUES1; ELOISA SASSÁ CARVALHO NOTTOLI1; MUCIO TAVARES OLIVEIRA JR.1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction/Background: Depressive symptoms are highly prevalent among patients with heart failure and are associated with poorer quality of life, functional limitation, and unfavorable clinical outcomes. Spiritual well-being has been recognized as an important emotional coping resource, particularly in chronic disabling conditions. Dimensions related to hope, inner peace, and meaning in life have been associated with better psychological adaptation and lower emotional distress in this population. Objectives: To evaluate the association between depressive symptoms and spiritual well-being in patients with heart failure. Methods: Observational descriptive study conducted in outpatients with chronic heart failure. Depressive symptoms were assessed using the PHQ-9, and spiritual well-being was evaluated using the WHOQOL-SRPB. Spirituality levels were classified as low, moderate, moderate-high, and high/very high. Domains related to hope, inner peace, and inner spiritual strength were analyzed. Data were submitted to descriptive analysis. Resultados e Conclusions: Sixty patients with heart failure were evaluated. Mild, moderate, or severe depressive symptoms were observed in 66.7% of the sample, with predominance of moderate depression (36.7%). Patients without depressive symptoms presented higher spiritual well-being scores, particularly in domains related to hope and optimism, inner peace, and inner spiritual strength. High scores were observed for hope and optimism (100%), inner spiritual strength (100%), and inner peace (95%) among patients without depressive symptoms. In contrast, patients with depressive symptoms showed predominantly intermediate spiritual well-being scores. In conclusion, patients with heart failure without depressive symptoms presented elevated levels of spiritual well-being, especially in domains related to hope, inner peace, and inner spiritual strength. The findings reinforce the association between positive spiritual resources and better emotional adaptation, highlighting spirituality as a potentially important dimension in clinical management and quality of life in this population.

SPIRITUAL WELL-BEING AND DEPRESSION IN PATIENTS WITH DECOMPENSATED HEART FAILURE

JULIO CESAR TOLENTINO1; PEDRO BASTOS DE MEDEIROS2; ANDRE CASARSA MARQUES1; FLÁVIO ANDRADE CAMACHO3; LEONARDO ANDRADE FERNANDES DE LUCA4; THALITA VICENTE BRANDÃO3; RAÍLLA KLING DUTRA3; ANA BEATRIZ DOS SANTOS RIBEIRO5; ANDRÉ LUIZ DIAS LIMA BONFIM4; LARISSA FRANCO DE ANDRADE4; MARIA DE FATIMA MARTINS GIL DIAS1; SERGIO LUIS SCHMIDT1;

(1) UNIVERSIDADE FEDERAL DO ESTADO DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (3) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL; (4) HOSPITAL QUINTA D'OR - RIO DE JANEIRO - RJ - BRASIL; (5) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL;

Introduction/Background: Depression is highly prevalent among patients hospitalized with decompensated heart failure and is associated with worse clinical and prognostic outcomes. Although spiritual well-being has been associated with lower depression in chronic cardiovascular conditions, its independent role during acute heart failure hospitalization remains unclear. Particularly it is unknown whether specific spiritual dimensions differentially contribute to depression in this clinical context. Objectives: This study aimed to (1) evaluate whether spiritual well-being independently predicts the presence of depression in patients hospitalized with decompensated heart failure after adjustment for demographic and clinical variables; (2) examine the association between overall spiritual well-being levels and depression severity; and (3) determine the relative contribution of the spiritual well-being dimensions (peace, meaning, and faith) to depression. Methods: This cross-sectional study included 200 patients hospitalized with decompensated heart failure. Depression was assessed using the Patient Health Questionnaire-9 (PHQ-9), and SWB was measured with the Functional Assessment of Chronic Illness Therapy–Spiritual Well-Being scale (FACIT-Sp-12). Multivariable binary logistic regression identified independent predictors of depression, including age, sex, N-terminal pro B-type natriuretic peptide levels, and spiritual well-being. Linear regression examined the association between spiritual well-being and depression severity. A second logistic regression model evaluated the independent contribution of each spiritual well-being dimension. Resultados e Conclusions: The logistic model was statistically significant ($\chi^2(4)= 41.12$; $p < 0.001$), and correctly classifying 77% of cases. Higher spiritual well-being scores were independently associated with lower odds of depression (OR= 0.904; 95%CI:0.863–0.946; $p < 0.001$). Older age was protective, whereas female sex and higher log NT-proBNP levels were associated with increased odds. Spiritual well-being was inversely associated with depression severity ($F(1,198)= 63.33$; $p < 0.001$; adjusted $R^2= 0.239$). Among dimensions, peace and meaning remained significant, whereas faith was not. Conclusions: Spiritual well-being was independently associated with both the presence and severity of depression in patients hospitalized with decompensated heart failure. The dimensions of peace and meaning demonstrated the strongest associations.

SPIRITUALITY, LATENT PSYCHOSOCIAL PROFILES, AND MORBIMORTALITY AMONG HOSPITALIZED ADULTS

LAURA SIQUEIRA CASTRO1; JOHN R PETEET2; TRACY A BALBONI2; DALVA POYARES1; HAROLD G KOENIG3; ALTAY ALVES LINO DE SOUSA1; FATIMA CINTRA1;

(1) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL; (2) DANA-FARBER CANCER INSTITUTE - UNITED STATES; (3) DUKE UNIVERSITY MEDICAL CENTER - UNITED STATES;

Introduction/Background: Associations between spirituality and clinical outcomes are heterogeneous, often paradoxical, suggesting that spiritual variables may acquire distinct clinical meanings depending on broader psychosocial organization. While spirituality, personality, and mood have traditionally been investigated as isolated domains, theory-based models of subjectivity suggest these dimensions may interact as integrated configurations shaping clinical experience. Objectives: To investigate whether latent psychosocial profiles integrating spirituality, personality traits, and mood states are associated with clinically relevant outcomes in hospitalized adults. Methods: This mixed-methods study included consecutive adults admitted to internal medicine and cardiology wards of a tertiary referral center between December 2018 and August 2019. Participants completed validated measures of spirituality, mood, and personality traits. Latent class analysis was used to identify psychosocial profiles. Medical records were reviewed through July 2021 for intensive care unit (ICU) transfer, in-hospital mortality, and 30-day readmission or mortality. Multivariable models adjusted for sociodemographic variables, comorbidities, functional status, and health-related behaviors. Qualitative–quantitative triangulation explored correspondence between latent profiles and narrative-based subjective positions derived from semi-structured interviews. Resultados e Conclusions: Among 289 participants, three latent psychosocial profiles emerged: spiritualized (60%), characterized by higher spirituality, lower affective distress, and low neuroticism; skeptic (24%), characterized by lower spirituality and intermediate psychological measures; and neurotic (16%), characterized by markedly depressive mood and elevated neuroticism despite average-to-high spirituality. In fully adjusted analyses, the neurotic profile was independently associated with a three-fold increase in morbimortality (OR 2.97; 95% CI 1.0–8.3; p<0.05). Significant correspondence was observed between latent profiles and narrative-based subjective positions. Integrated psychosocial profiling combining spirituality, personality, and mood was independently associated with clinically meaningful outcomes in hospitalized patients. These findings support the relevance of multidimensional psychosocial assessment for patient-centered risk stratification and suggest that distinct subjective organizations may influence clinical trajectories.

COMBINED PHENOTYPE OF PHYSICAL INACTIVITY AND SUBCLINICAL INFLAMMATION IS ASSOCIATED WITH A HIGHER PREVALENCE OF CARDIOVASCULAR DISEASE: AN ANALYSIS OF NHANES 2015–2016

KAROLINA STEPHANY PEREIRA FERREIRA1; PALOMA RODRIGUES ROCHA2;

(1) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction/Background: Subclinical inflammation and low physical activity are both associated with a greater cardiovascular risk. However, the combination of these factors as a marker of a greater burden of cardiovascular disease (CVD) in the general population remains underexplored. Objectives: To evaluate the association between physical activity, high-sensitivity C-reactive protein (hs-CRP), and the prevalence of CVD among adults participating in National Health and Nutrition Examination Survey (NHANES) 2015–2016, with emphasis on the combined phenotype of physical inactivity and elevated hs-CRP. Methods: Cross-sectional study using data from the NHANES 2015–2016. The demographic, blood pressure, physical activity, medical conditions, and hs-CRP components were integrated. Weekly physical activity was estimated from the physical activity questionnaire, and both total moderate-to-vigorous physical activity (MVPA) volume and a binary variable for physically active ≥150 min/week were calculated. Elevated hs-CRP was defined as >3 mg/L. The primary outcome was prevalent composite CVD, defined by self-reported heart failure, coronary artery disease, angina, myocardial infarction, or stroke. Adjusted logistic regression models were used, controlling for age, sex, race, and educational level; in the models assessing CVD, additional adjustment was made for hypertension measured during the examination. Resultados e Conclusions: A total of 9,971 participants were analyzed; mean age was 33.2 years, 50.9% were women, 14.5% had hypertension (≥140/90 mmHg), 28.8% had hs-CRP >3 mg/L, and 11.1% had prevalent composite CVD. Physically active ≥150 min/week was associated with lower odds of elevated hs-CRP (OR 0.773; 95% CI 0.682–0.877; p<0.001) and prevalent CVD (OR 0.754; 95% CI 0.612–0.928; p=0.0078). Recreational physical activity was likewise associated with lower odds of elevated hs-CRP (OR 0.881 per 150 min/week; 95% CI 0.841–0.923; p<0.001) and prevalent CVD (OR 0.852; 95% CI 0.775–0.937; p<0.001). Elevated hs-CRP was independently associated with higher CVD prevalence (OR 1.561; 95% CI 1.275–1.911; p<0.001), and the inactive/elevated hs-CRP group had the highest odds of prevalent CVD compared with the active/low hs-CRP group (OR 2.057; 95% CI 1.533–2.761; p<0.001). Overall, lower physical activity and elevated hs-CRP were independently associated with higher CVD prevalence, and the combined phenotype identified the subgroup with the greatest cardiovascular burden, with potential utility for population-level risk stratification.

Deep learning-estimated electrocardiographic age in athletes: no evidence of training-related acceleration of cardiovascular aging

MILENA SORIANO MARCOLINO1; MÍRIAM RAQUEL MEIRA MAINENTI2; ANA LAURA MOREIRA GERHARDT1; ARTHUR WALACE OLIVEIRA SILVA1; BRUNO VALDIZAN PEREIRA RODRIGUES1; MANUELA LOBATO BARBOSA1; PEDRO DELALIBERA SOARES1; RAFAELA BONFIOLI COSTA1; HAROLDO CHRISTO ALEIXO1; ANGELA NOGUEIRA NEVES3; ISABELLA VIANA GOMES SCHETTINI1; ANTONIO LUIZ PINHO RIBEIRO1;

(1) TELEHEALTH CENTER, UNIVERSITY HOSPITAL, UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - Brasil; (2) ESCOLA DE EDUCAÇÃO FÍSICA DO EXÉRCITO - RIO DE JANEIRO - RJ - Brasil; (3) ESCOLA DE EDUCAÇÃO FÍSICA DO EXÉRCITO - BELO HORIZONTE - MG - Brasil;

Introduction/Background: Artificial intelligence–derived electrocardiographic age (AI-ECG age) has emerged as a biomarker of biological cardiovascular aging, with divergence from chronological age associated with morbidity and mortality. However, whether long-term high-intensity athletic training modifies this relationship remains unclear, particularly in highly trained populations representing extreme physiological adaptation. Objectives: To assess the association between AI-ECG age and chronological age in competitive athletes and to evaluate the influence of training load, cumulative exposure, sleep, and psychological distress on this relationship. Methods: This cross-sectional study included competitive athletes recruited from multiple training centers in Brazil. Participants completed standardized questionnaires assessing demographics, training history, lifestyle factors, and psychological distress (DASS-21). Resting 12-lead ECGs were recorded under standardized conditions and analyzed using a validated deep learning model to estimate biological cardiovascular age. The primary outcome was the ECG age gap (ΔECG-age: predicted minus chronological age). Linear regression models were used to assess associations, with multivariable adjustment for age, sex, weekly training volume, cumulative training years, sleep duration, and DASS-21 scores. Standardized beta coefficients were reported. Resultados e Conclusions: A total of 574 athletes were included (median age 26 years [IQR 22–31]; 62.9% male). Median ΔECG-age was 2.5 years [IQR 2.0–6.4]. In univariable analysis, cumulative years of training were associated with a lower ΔECG-age (β=–0.28, p<0.001). However, after multivariable adjustment, only chronological age remained independently associated with ΔECG-age (β=–0.59, p<0.001). Training load, cumulative exposure, sleep duration, and psychological distress were not independently associated with ECG age acceleration. These findings indicate that deep learning–estimated ECG age is primarily determined by chronological age, with no independent influence of training-related factors, psychological distress, or sleep duration. In competitive athletes, long-term high-intensity training does not appear to be associated with accelerated electrical cardiovascular aging.

ECG INTERPRETATION IN MALE BRAZILIAN FOOTBALL PLAYERS: 2017 VERSUS 2025 INTERNATIONAL CRITERIA

FILIPE FERRARI1; LUIZ GUSTAVO MARIN EMED2; GUILHERME D DALCIN DILDA3; FABRICIO BRAGA4; MARCELO RICCIO FACCIO4; HAROLDO CHRISTO ALEIXO5; THALES PESSOA CHRISTO ALEIXO6; RODRIGO OTÁVIO BOUGLEUX ALÔ7; LUIZ EDUARDO FONTELES RITT8; ARTUR HADDAD HERDY9; ANDERSON DONELLI DA SILVEIRA1; RICARDO STEIN1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL; (2) INSTITUTO DE NEUROLOGIA - CURITIBA - PR - BRASIL; (3) SOCIEDADE ESPORTIVA PALMEIRAS - SÃO PAULO - SP - BRASIL; (4) LABORATORIO DE PERFORMANCE HUMANA (LPH) - RIO DE JANEIRO - RJ - BRASIL; (5) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (6) HOSPITAL RISOLETA TOLENTINO NEVES - BELO HORIZONTE - MG - BRASIL; (7) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (8) ESCOLA BAHIANA DE MEDICINA E SAUDE PUBLICA (EBMSP) - SALVADOR - BA - BRASIL; (9) INSTITUTO DE CARDIOLOGIA DE SANTA CATARINA - FLORIANÓPOLIS - SC - BRASIL;

Introduction/Background: Accurate electrocardiogram (ECG) interpretation in athletes is essential to detect underlying cardiac disease while minimizing false-positive findings. The 2017 International Criteria (IC) improved specificity, but challenges remain, particularly in the interpretation of repolarization alterations. The 2025 IC introduce refinements aimed at further reducing false-positive rates; however, their real-world impact has not been well established. Objectives: To compare the 2017 and 2025 IC for athlete ECG interpretation in a large sample of male Brazilian football players, evaluating their impact on ECG reclassification and the subsequent false-positive rate. Methods: This multicenter, observational study analyzed ECGs from male Brazilian football players undergoing mandatory pre-participation evaluations (February 2002–February 2026). Data were collected from 86 professional clubs across 19 states. All ECGs were initially interpreted using the 2017 IC and then re-evaluated with the 2025 IC. Resultados e Conclusions: A total of 6,866 athletes were included (median [IQR] age, 19 [16–24] years); 2,680 were white, 2,216 mixed-race, and 1,970 black. The 2025 IC reduced abnormal ECG classifications from 260 (3.8%) to 176 (2.6%), representing a relative reduction of 32.3%. This was driven mainly by reclassification of isolated inferior T-wave inversion from abnormal to borderline and of anterior T-wave inversion preceded by J-point elevation and convex ST-segment elevation as normal in non-black athletes. The apparent false-positive rate decreased from 3.6% to 2.4%. No structural cardiac abnormalities were found on echocardiography in reclassified athletes. At a mean follow-up of 5.4 ± 3.3 years, no deaths were reported. The 2025 IC significantly reduce abnormal ECG classifications and false-positive rates in male Brazilian football players compared to the 2017 IC, without missing underlying structural heart disease. These findings support implementing the updated criteria to improve screening efficiency

EFFECT OF SMOKING STATUS ON IMPROVEMENT IN CARDIORESPIRATORY FITNESS DURING CARDIAC REHABILITATION

DIANN GAALEMA1; PATRICK SAVAGE2; BRIAN KATZ1; MICHAEL DESARNO2; SHERRIE KHADANGA2;

(1) UNIVERSITY OF TEXAS MEDICAL BRANCH - UNITED STATES; (2) UNIVERSITY OF VERMONT - UNITED STATES;

Introduction/Background: Patients who smoke have high-risk cardiovascular profiles. However, the influence of smoking on gains made during cardiac rehabilitation (CR), such as improvements in cardiorespiratory fitness (CRF), is less understood. Accordingly, we examined improvement in CRF by smoking status within a clinical sample, hypothesizing that current smoking impedes improvement in CRF during CR. Objectives: To examine improvements in cardiorespiratory fitness (CRF) made during cardiac rehabilitation (CR) by smoking status, hypothesizing current smoking impedes improvement in CRF during CR. Methods: Data were obtained from a prospectively collected clinical database at an academic medical center. Individuals were included if data were available on entry and exit peak oxygen uptake (VO2peak, measured during symptom-limited treadmill test) and self-reported smoking status (current, former, or never). Data were extracted on sex, age, body mass index, comorbidity score (severity of exercise-limiting comorbidities) and number of CR sessions completed. Analyses of variance and linear regressions were used to test for associations with changes in VO2peak. Variables with significant associations were entered into multivariable general linear models predicting change in VO2peak. Resultados e Conclusions: The cohort included 2390 individuals (111 currently, 1114 formerly, 1165 never smoking) enrolled January/1996 to December/2023. The current smoking group (compared to former/never) was significantly younger (58.3±10.8 vs. 65.4±10.2 and 64.2±11.2), had higher comorbidity scores (0.8±1.4 vs. 0.6±1.2 and 0.5±1.0), and attended fewer CR sessions (25.3±11.1 vs. 29.5±9.2 and 29.1±9.6). All variables examined, excepting sessions attended, were significantly associated with change in VO2peak, remaining significant in multivariable models. Estimated mean absolute improvement in VO2peak was [LSmean(SE)] 1.6(0.3), 2.8(0.1), and 3.2(0.1) mLO2*kg-1*min-1 in current, former, and never smoking, respectively. By absolute and relative measure, improvement in the current smoking group was significantly less than in former/never (ps<.05, all comparisons). In conclusion, current smoking at CR entry was significantly, independently associated with less improvement in VO2peak during CR.

EFFECTIVENESS, SAFETY, COSTS, AND DELIVERY CONSIDERATIONS OF EXERCISE-BASED CARDIAC REHABILITATION IN LOW- AND MIDDLE-INCOME COUNTRIES: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMISED CONTROLLED TRIALS

MD. JAMAL UDDIN1; ROD TAYLOR1;

(1) UNIVERSITY OF GLASGOW - SCOTLAND;

Introduction/Background: Cardiovascular disease, particularly heart disease, remains a leading cause of global mortality and disability, with low- and middle-income countries (LMICs) bearing a disproportionate burden. By 2030. Cardiac rehabilitation (CR) is a cornerstone of heart disease management; however, its availability and supporting evidence in low- and middle-income countries (LMICs) remain limited. Objectives: To conduct an contemporary systematic review and meta-analysis of randomised controlled trials (RCTs) evaluating exercise-based CR undertaken in LMICs in terms mortality, hospitalisation, exercise capacity, health-related quality of life (HRQoL), and mental health outcomes. Methods: We updated a prior systematic review by searching bibliographic databases from May 2020 to June 2025. RCTs of exercise-based CR conducted in LMICs were included. Study quality was assessed using the Cochrane risk of bias tool. Outcomes including mortality, hospitalisation, exercise capacity, HRQoL, and mental health were pooled using random-effects meta-analyses. Safety, cost, and cost-effectiveness data were narratively synthesized. Meta-regression was performed to explore potential effect modifiers, and certainty of evidence was assessed using the GRADE framework. Resultados e Conclusions: Twenty-nine RCTs involving 6,682 participants from central Asia, South Asia, Africa, and South America were included, with majority of studies judged to be at moderate-to-high risk of bias. Compared to exercise control. exercise-based CR significantly improved exercise capacity (SMD 0.71; 95% CI 0.47–0.96; I² = 72%) and was associated with better HRQoL and mental health outcomes. Despite substantial statistical heterogeneity, no evidence of effect modification was observed across trial-level factors, including CR delivery model, exercise dose, follow-up duration, or risk of bias. Only a small amount of data was available for mortality, hospitalisation cost and cost-effectiveness. Gains in exercise functional capacity and HRQoL with exercise-based CR in the LMICs setting appear similar in magnitude to those seen in high income countries. However, need for further high-quality evidence of the impact of CR on clinical events and health economic outcomes in LMICs.

ENGAGING CLINICIANS IN DATA-DRIVEN QUALITY IMPROVEMENT: QUALITATIVE INSIGHTS FROM THE QUICR TRIAL

DION CANDELARIA1; SANURI WIJESEKERA KANKANAMGE1; SHERRIE CHUNG1; ROBYN GALLAGHER1;

(1) SUSAN WAKIL SCHOOL OF NURSING AND MIDWIFERY, FACULTY OF MEDICINE AND HEALTH, THE UNIVERSITY OF SYDNEY - AUSTRALIA;

Introduction/Background: The Quality Improvement in Cardiac Rehabilitation (QUICR) trial implemented a collaborative model to strengthen data use and quality improvement across cardiac rehabilitation services. Objectives: To examine clinician engagement with and perceptions of the QUICR intervention. Methods: Five focus group discussions were conducted with clinicians (n=22) from participating intervention sites. Transcripts were transcribed verbatim and thematically analysed using the COM-B model (Capability, Opportunity, Motivation–Behaviour) to identify the mechanisms influencing engagement. The target behaviour was clinicians' ability to understand and use data to implement small, iterative changes aimed at improving service quality. Resultados e Conclusions: Clinicians reported increased capability to interpret and use data meaningfully. QUICR helped shift data entry from an administrative task to a clinical and reflective activity, with outcome measures supporting patient conversations and identifying service gaps. Many adapted local workflows including modifying forms, adjusting clinic processes, or involving administrative staff to sustain data collection. Opportunity was shaped by strong leadership support, shared workload, and facilitation that provided timely problem solving and encouragement. In-person workshops fostered connection and peer learning. Barriers included time pressure, staffing constraints, and the burden of double data entry across existing systems and REDCap, which competed with clinical priorities. Motivation was reinforced by professional pride, a belief in the value having access to their local data, and ability to collaborate and network with other sites. Motivation declined when organisational recognition was limited, or competing demands underestimated quality improvement efforts. Engagement in data-driven quality improvement was strongest when capability, opportunity, and motivation aligned. Structural barriers most often constrained participation.

HIGHER PHYSICAL ACTIVITY IS ASSOCIATED WITH LOWER MORTALITY IN HYPERTROPHIC CARDIOMYOPATHY: A META-ANALYSIS OF OBSERVATIONAL STUDIES

LEONARDO CASTRO LUNA1; FILIPE FERRRARI2; RICARDO STEIN3; LUIZ EDUARDO FONTELES RITT4; RODRIGO OTÁVIO BOUGLEUX ALÔ5; PABLO MARINO CORREA NASCIMENTO1;

(1) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL; (2) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL; (3) UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL; (4) ESCOLA BAHIANA DE MEDICINA E SAUDE PUBLICA (EBMSP) - SALVADOR - BA - BRASIL; (5) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction/Background: Hypertrophic cardiomyopathy (HCM) affects approximately 1:200–1:500 adults and historically led to exercise restriction due to fear of sudden cardiac death (SCD). Randomized controlled trials (RCTs) evaluating exercise in HCM have generally been small, heterogeneous in design and population, and focused primarily on demonstrating exercise safety—without events of mortality. Although RCTs suggest exercise safety in HCM, they were underpowered to detect mortality differences across exercise intensities. Observational studies with larger samples may better capture real-world outcomes across exercise intensity strata. Objectives: To evaluate the association between exercise intensity and mortality in adults with HCM through a systematic review and meta-analysis of observational studies. Methods: Systematic review registered in PROSPERO (CRD420251005992). PubMed/Medline, Embase, and Cochrane Library were searched from inception to December 2024. Observational studies comparing mortality across different exercise intensity levels in adults with HCM were eligible. Study selection, data extraction, and quality assessment were performed independently by two researchers, with disagreements resolved by consensus. Risk of bias was assessed using ROBINS-I; evidence certainty was graded using GRADE. Resultados e Conclusions: Two observational studies (n=9,326 participants) were included in the meta-analysis. ROBINS-I rated Kwon et al. as low and Lampert et al. as moderate risk of bias. High-intensity exercise was associated with significantly lower mortality compared to low-intensity or sedentary behavior (RR: 0.72; 95% CI: 0.60–0.85; I^2=0%; p heterogeneity=0.71). Across three physical activity strata (low/sedentary, moderate, and high/vigorous intensity), a statistically significant linear dose-response relationship was observed: greater exercise intensity was associated with progressively greater mortality reduction—a finding that, per GRADE criteria, upgraded the certainty of evidence to MODERATE. These findings suggest that, in adults with HCM without high-risk disease features, greater habitual physical activity, compared with low-intensity activity or sedentary behavior, is not associated with excess mortality and may be linked to improved survival. To our knowledge, this is the first meta-analysis on this topic, supporting individualized exercise counseling rather than routine restriction; however, further studies are needed to corroborate these findings.

Home-Based Cardiac Rehabilitation in Heart Failure with Preserved Ejection Fraction: The Rehabilitation EnAblement in CHronic HF (REACH-HFpEF) Trial

ROD S TAYLOR1; CHIM LANG2; REACH-HPEF TRIAL COLLABORATOR3;

(1) UNIVERSITY OF GLASGOW - United Kingdom; (2) UNIVERSITY OF DUNDEE - United Kingdom; (3) UNIVERSITIES OF GLASGOW & EXETER & OTHER UK UNIVERSITY & NHS INSITUTIONS - United Kingdom;

Introduction/Background: Exercise intolerance and impaired health-related quality of life (HRQoL) are defining features of heart failure with preserved ejection fraction (HFpEF), which may be improved through exercise-based cardiac rehabilitation (ExCR). REACH-HFpEF (ISRCTN47894539) is a pragmatic randomised controlled trial evaluating the clinical and cost effectiveness of ExCR in patients with HFpEF. Objectives: This late-breaking presentation seeks to provide a report of the primary and secondary outcomes of the REACH-HFpEF trial. Methods: Participants were randomised (1:1) to a home-based REACH-HF ExCR programme plus usual care or to usual care alone across 20 centres in the United Kingdom. The primary outcome is disease-specific HRQoL at 12 months, assessed using the Minnesota Living with Heart Failure Questionnaire (MLwHFQ). Key secondary outcomes include exercise capacity, generic HRQoL, hospitalisations, and mortality. Resultados e Conclusions: Recruitment and randomisation of 392 participants were completed in June 2025. The median age was 79 years, 53% were women, median body mass index was 29.7 kg/m², median left ventricular ejection fraction was 55%, and median plasma N-terminal pro–B-type natriuretic peptide (NT-proBNP) was 1,738 pg/mL. Overall, 65% of participants were in New York Heart Association class II and 35% in class III. The median baseline MLwHFQ total score was 40.0, and the EQ-5D-5L utility score was 0.65. Compared with participants in recent HFpEF trials, those enrolled in REACH-HFpEF were older, had higher NT-proBNP levels, poorer HRQoL, and lower exercise capacity. REACH-HFpEF has enrolled one of the largest and most clinically representative HFpEF populations evaluated in an ExCR trial to date. Participants demonstrate more advanced disease and greater functional impairment than those in previous HFpEF trials, enhancing the clinical relevance and external validity of the findings. This late-breaking presentation will provide the first international report of the primary and secondary outcomes of the REACH-HFpEF trial.

HORMONAL DETERMINANTS OF PHYSICAL PERFORMANCE AND CARDIAC ADAPTATION IN PROFESSIONAL ATHLETES: A CYCLE ERGOMETRY STUDY

ELENA TENYAEVA1; VICTORIA BADTIEVA1; VICTORIA KULIKOVA1;

(1) S.I. SPASOKUKOTSKY MOSCOW CENTRE FOR RESEARCH AND PRACTICE IN MEDICAL REHABILITATION, RESTORATIVE AND SPORTS MEDICINE OF MOSCOW HEALTHCARE DEPARTMENT - RUSSIA;

Introduction/Background: Hormonal status (testosterone, cortisol, prolactin) determines the metabolic response to physical stress. Objectives: The aim was to find out the relationship between hormonal status and performance allows for an objective assessment of adaptation depth and maladaptation risk in professional sports. Methods: We analyzed 174 medical records of athletes (75 females, 43%; 99 males, 57%). Statistical analysis of hormonal levels, bioimpedance, cycle ergometry, and echocardiography was performed in R (v. 4.x.x) using Spearman's correlation and regression modeling. Statistical significance was set at $p < 0.05$. Resultados e Conclusions: Mean age was 19.3±2.6 years; athletic career 9.7±3.3 years. Within physiological norms, increased cortisol significantly correlated with lower Peak HR and higher Wmax and VO2max ($p < 0.05$). In males, testosterone showed a significant positive correlation ($r=0.40$, $p < 0.05$) with Peak HR, SV, LVESD, LVEDD, LVEDV, and left ventricular mass index (MMI/BSA). Furthermore, male testosterone positively correlated with total body water and active cell mass ($r=0.41$, $p < 0.05$). In females, testosterone showed no significant correlations; however, prolactin levels were significantly positively correlated ($r=0.45$, $p < 0.05$) with Peak HR, body water, and active cell mass. The testosterone/cortisol (T/C) ratio in males revealed a significant positive correlation ($r=0.48$, $p < 0.05$) with lean body mass, total water, SV, and integral performance, while showing a negative correlation ($r=-0.39$, $p < 0.05$) with heart rate recovery post-exercise. Conclusion: Elevated cortisol within normal ranges enhances cardiac efficiency. Testosterone in males plays a key role in "athlete's heart" formation and physiological hypertrophy, increasing stroke efficiency. In female athletes, prolactin primarily performs the anabolic role. The T/C ratio serves as an integral marker of anabolic/catabolic balance and stress resistance, providing an assessment of the energy supply for athletic performance.

16055

INTRADIALYTIC RESISTANCE TRAINING IMPROVES QUADRICEPS MUSCLE STRENGTH AND FUNCTIONAL CAPACITY IN PATIENTS WITH CHRONIC KIDNEY DISEASE: A SINGLE-CENTER QUASI-EXPERIMENTAL STUDY

THIAGO DIPP1; MARIANA FLORES DE SOUZA1; MARCELLI BECK ZANOTTO1; DIEISON DE OLIVEIRA MARQUES1; KARINA LEOTÉRIO1; ESTELA DA CRUZ1;

(1) UNISINOS - SÃO LEOPOLDO - RS - BRASIL;

Introduction/Background: Patients with chronic kidney disease (CKD) undergoing hemodialysis (HD) often present musculoskeletal impairments that lead to reduced functionality. Intradialytic exercise may be a strategy to improve functional performance. Objectives: To evaluate the effect of intradialytic resistance training on the functionality of patients with CKD on HD. Methods: This quasi-experimental study (Brazilian Registry of Clinical Trials, RBR-46kd834) where patients were allocated by convenience (one shift was selected for protocol implementation) to a training group (TG) and a control group (CG). The TG completed an 8-week protocol (3 times/week) during the first hour of hemodialysis, using ankle weights, elastic bands, and a overball. The CG received no intervention. Outcomes were assessed before (pre) and after (post) the protocol using the 6-Minute Walk Test (6MWT), the 30-Second Sit-to-Stand Test (30s-STS), and dominant lower-limb isometric dynamometry. Data are presented as mean±standard deviation and absolute and relative frequencies. Generalized estimating equations (GEE) were used on analysis with $p \leq 0.05$ (SPSS v21.0). Resultados e Conclusions: Twenty-four patients participated, 12 in the TG (58.3% men; 59±13 years) and 12 in the CG (58.3% men; 52.5±15 years). Regarding medication use, all patients in both groups were using erythropoietin. Only the TG showed improvement after the protocol in 6MWT distance ($\Delta=46.8$ m; $p=0.01$), number of repetitions in the 30s-STS ($\Delta=2.8$ repetitions; $p=0.05$), and dominant quadriceps isometric strength ($\Delta=1.9$ kgf; $p=0.04$). The CG showed no post-study changes in functional capacity ($\Delta=-26.8$ m; $p=0.15$), 30s-STS ($\Delta=-0.4$ repetitions; $p=1.00$), or dominant quadriceps isometric strength ($\Delta=-2.3$ kgf; $p=0.57$). No differences were identified between groups at the end (post) of the study for the analyzed functional variables. Eight weeks of intradialytic resistance training improved lower-limb muscle strength and functional capacity in patients with CKD undergoing hemodialysis.

20238

LEFT VENTRICULAR REMODELLING IN ADOLESCENT ATHLETES OF DIFFERENT SPECIALISATIONS

IULIIA IVANOVA1; VICTORIA BADTIEVA1; VICTORIA KULIKOVA1; NATALIA TRUKHACHEVA1;

(1) S.I. SPASOKUKOTSKY MOSCOW CENTRE FOR RESEARCH AND PRACTICE IN MEDICAL REHABILITATION, RESTORATIVE AND SPORTS MEDICINE OF MOSCOW HEALTHCARE DEPARTMENT - RUSSIA;

Introduction/Background: The larger left ventricular dimensions in athletes, compared to the general population, have long been well established among sports physicians. However, the wide variety of sports with different types of physical loads makes it difficult to understand the adequacy of cardiac remodelling in each individual case — especially in adolescents actively engaged in sports. Objectives: We examined 5650 athletes aged 12–18 years (mean age 16.62 ± 1.83 years). Anthropometric data: height 172.01 ± 11.52 cm, weight 63.02 ± 14.61 kg, body surface area (BSA) 1.74 ± 0.24 m². All athletes had been training for at least 3 years, with a frequency of 4–5 times per week for 2–3 hours per session. All participants were members of national or regional teams. The cohort included 2 429 females (42.9 %) and 3 221 males (57.0 %). Methods: Echocardiography was performed using a Vivid E90 ultrasound system. Types of LV remodelling were classified according to the guidelines by Lang R.M. (2015). Resultados e Conclusions: Among the 5 650 athletes under 18 years: 96.56 % (5 456 athletes) showed no LV remodelling, and 3.43 % (194 athletes) had LV remodelling: 62 females (32.9 %) and 132 males (68.1 %). These groups did not differ significantly in age (p=0.92), height (p=0.85), or weight (p=0.86). Types of remodelling identified: Concentric remodelling group (53.1%, 103 athletes) aged 12–18. Eccentric hypertrophy (46.9 %, 91 athletes) aged 14–18. Athletes with remodelling were divided into 4 groups according to the classification by Pelliccia A. et al. (2018), which includes four main categories of sports discipline: skills, strength , mixed qualities, endurance. Concentric remodelling distribution: strength training: 32 % (33 athletes); skill training: 28 % (29 athletes); endurance training: 21 athletes (20.4 %); mixed qualities: 20 athletes (19.4 %). The distribution of concentric remodelling across groups showed no statistically significant differences (x^2=4,61). Eccentric hypertrophy distribution: endurance sports 55 % (50 athletes); mixed qualities 25 % (23 athletes); strength: 14 % (13 athletes); skills: 6 % (5 athletes). Conclusion: The overall frequency of left ventricular remodelling among adolescent athletes was 3.8 %. Concentric remodelling occurred in athletes as young as 12 years and was observed across all sports specialisations. In contrast, eccentric hypertrophy was more common in athletes older than 14 years, particularly those engaged in high intensity endurance training.

MAPPING THE ATHLETE'S HEART: A SYSTEMATIC REVIEW AND META-ANALYSIS OF ELECTROCARDIOGRAPHIC FINDINGS IN 224,606 ATHLETES

MILENA SORIANO MARCOLINO1; ARTHUR WALACE DE OLIVEIRA SILVA1; ISABELLA VIANA GOMES SCHETTINI1; ANA CAROLINA ALMEIDA BASTOS1; JOÃO GABRIEL COUTO GONTIJO1; LAURA CARRARA RIBEIRO1; ANTONIO LUIZ PINHO RIBEIRO1;

(1) TELEHEALTH CENTER, UNIVERSITY HOSPITAL, UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introduction/Background: The 12-lead electrocardiogram (ECG) is central to pre-participation cardiovascular screening in athletes. Although contemporary interpretation criteria have improved diagnostic accuracy, distinguishing physiological adaptations from pathological findings associated with sudden cardiac death (SCD) remains complex in specific scenarios. Robust, large-scale estimates of ECG findings in competitive athletes are still lacking. Objectives: To estimate the pooled prevalence of ECG findings in competitive athletes through a systematic review and meta-analysis. Methods: A systematic literature search was conducted in January/2026 across Medline, Embase, Web of Science, Cochrane, and 57 additional databases. Studies reporting 12-lead resting ECG data in competitive athletes were included. Two reviewers independently screened the records and extracted data, and a third author resolved any discrepancies. Pooled prevalence estimates were calculated using random-effects models. Statistical analysis was conducted using R software version 3.6.2 (R Foundation for Statistical Computing, Vienna, Austria) with the "metafor" package. Resultados e Conclusions: A total of 175 studies including 224,606 athletes (mean age 21.5 ± 4.3 years; 48.8% men) were analyzed. Physiological ECG patterns predominated. The most frequent findings were sinus bradycardia (37.2% [95% CI 30.9–43.9]), early repolarization abnormalities (31.6% [95% CI 24.2–40.0]), sinus arrhythmia (22.2% [95% CI 14.3–32.7]), left ventricular hypertrophy (19.9% [95% CI 15.8–24.7]), and incomplete right bundle branch block (13.1% [95% CI 10.6–16.1]). In contrast, ECG findings associated with inherited arrhythmia syndromes or cardiomyopathies were rare, including long QT interval (0.5% [95% CI 0.3-0.7]), ventricular pre-excitation (0.3% [95% CI 0.2-0.4]), Brugada type 1 pattern (0.2% [95% CI 0.1-0.4]), and pathological Q waves (0.5% [95% CI 0.3-0.7]). ECG findings in competitive athletes are predominantly physiological, with low prevalence of abnormalities associated with SCD. These results provide the most comprehensive prevalence estimates to date and reinforce the importance of athlete-specific ECG interpretation criteria to improve screening accuracy.

STRUCTURAL CARDIOTOXICITY IN ANABOLIC-ANDROGENIC STEROID USERS: A CASE SERIES FROM A TERTIARY OUTPATIENT CLINIC

RODRIGO DANTAS FERRAZ1; JOAO FELIPE TAMIOZZO REIS1; RAFAEL ENGEL DUCATTI1; MATHEUS LORENZETTI PERON1; RAFAELA ROSSINI BUSSO1; RODRIGO OTAVIO BOUGLEUX ALO1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction/Background: Indiscriminate use of anabolic-androgenic steroids (AAS) is associated with potentially irreversible deleterious effects on the cardiovascular system. Data from specialized outpatient settings in Brazil remain scarce. Objectives: : To describe the clinical profile and structural cardiac abnormalities in a cohort of AAS users followed at a specialized tertiary outpatient clinic. Methods: Descriptive case series of patients followed at a specialized tertiary outpatient clinic from 2023 to 2026. Assessments included demographic data, comorbidities, substances used, gonadal axis evaluation, transthoracic echocardiography (TTE), and cardiac magnetic resonance (CMR) when clinically indicated. Data expressed as means ± SD and proportions. Resultados e Conclusions: Fifty-one AAS users were evaluated (50 male, 1 female), mean age 42.5 ± 10.1 years (range 22–67). Active users: 36/51 (70,6%); former users: 15/51 (29.4%). Trenbolone use: 16/51 (31.4%). Gonadal axis suppression: 23/33 evaluated (69.7%). TTE was abnormal in 15/32 evaluated patients (46.9%); left ventricular ejection fraction (LVEF) below 50% in 5/33 (15.2%); mean interventricular septum 10.0 ± 1.9 mm (n=31). CMR was performed in 20 patients and was abnormal in 18 (90.0%); late gadolinium enhancement (LGE) indicating myocardial fibrosis was detected in 14/20 (70.0%) and T1 mapping abnormalities in 10/20 (50.0%). Systemic hypertension: 9/51 (17.6%); renal disease: 7/44 evaluated (15.9%). These findings demonstrate a high burden of structural cardiotoxicity in a young cohort (mean 42.5 years), with CMR detecting myocardial fibrosis in 70% of evaluated patients. AAS use is associated with significant structural cardiac damage, and systematic cardiovascular screening including CMR should be considered in this population.

THE INTERNATIONAL COUNCIL OF CARDIOVASCULAR PREVENTION AND REHABILITATION (ICCPR'S) 2025 GLOBAL CARDIAC REHABILITATION AUDIT UPDATE: SERVICE COVERAGE AND DELIVERY

DION CANDELARIA1; SHERRY L GRACE2; KARAM TURK-ADAWI3; GABRIELA LM GHISI2;

(1) SUSAN WAKIL SCHOOL OF NURSING AND MIDWIFERY, FACULTY OF MEDICINE AND HEALTH, THE UNIVERSITY OF SYDNEY - AUSTRALIA; (2) YORK UNIVERSITY - CANADA; (3) QATAR UNIVERSITY - QATAR;

Introduction/Background: Cardiac rehabilitation (CR) is a guideline-recommended model of secondary prevention, yet it remains under-used. In 2016, the International Council of Cardiovascular Prevention and Rehabilitation (ICCPR) conducted a first-of-its-kind global Audit to characterize the availability and delivery of CR worldwide. Objectives: To provide an updated assessment of global CR since ICCPR's 2016 Audit, examining service availability, coverage, and shortfalls; referral; staffing; program dose; core components; and alternative delivery models. Methods: Cross-sectional, observational Audit update. Program-level data were collected from May-September 2025 via REDCap. CR need was estimated using annual ischemic heart disease incidence (Global Burden of Disease Study; 2023), with adjustment for early morbidity. CR service coverage (capacity/need%) and shortfall (capacity-need) and were computed. Resultados e Conclusions: Of 7,025 programs in 113/195 (57%) countries with CR globally, coverage was 2.5% of need globally (lowest in Africa and Western Pacific). The annual CR service shortfall was 7,476,390 patients/year (median=4,936 patients/country), being the greatest in UMICs (India, China). CR availability increased most in Africa (17%-32% of countries) and the Western Pacific (43%-61%), but increased only 2% globally since 2016. 1,505 (62% median program response rate/country) programs initiated a survey from 90 (80%) countries with CR. Of programs with an inpatient cardiology service, 62% referred patients before discharge, with a bedside discussion. Programs were comprehensive, offering a median of 8 core components (P25-P75=6-10), with UMICs offering significantly more (p<.001). CR continued to be delivered by a multidisciplinary team of 7 (median, P25-P75=5-8; cardiology, nursing, physiotherapy, dietetics most common); physician specialty varied. Centre-based programs prescribed a median of 20 hours/patient/program (IQR 12-30; mean=2 sessions/week over 8 weeks). Globally, in 65 (72%) countries with CR, programs prescribed a median ≥12 sessions/program. 285 (31.1%) programs in 57 countries reported alternative/hybrid models were available. Major gaps in CR availability and access persist globally. Coordinated strategies to scale and resource delivery are needed.

THE REGULAR PRACTICE OF PHYSICAL EXERCISE AS AN INFLUENCING FACTOR ON SERUM CONCENTRATIONS OF OXIDATIVE STRESS AND ANTIOXIDANT MARKERS: A SYSTEMATIC REVIEW WITH META-ANALYSIS OF RANDOMIZED CLINICAL TRIALS

ISABELA MARTINS MÜLLER1; LETÍCIA BASTOS PONTIERI AUGUSTO1; LUANE DO AMOR DIVINO MATTOS1; LAURA MARIA TOMAZI NEVES1; SAUL RASSY CARNEIRO1; TATIANE CARINTA DE SOUZA1; ANA LUISA VICENTE MENDES1; PAULO MATNI DOS SANTOS1; ALINE PASQUINI DOS SANTOS1;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introduction/Background: Heart failure (HF) is a major public health issue in Brazil, marked by high prevalence, incidence, and mortality. Regular physical exercise (RPE), a key non-pharmacological therapy, improves clinical outcomes. Because oxidative stress contributes to cardiac remodeling and exercise enhances antioxidant defenses, this meta-analysis examined the association between RPE and oxidative/antioxidant markers in HF. Objectives: To evaluate whether regular physical exercise (RPE) demonstrates positive functional and structural effects in the management of heart failure (HF), as well as in the modulation of free radicals and antioxidants, given that tissue injury is an important factor in the pathophysiology of HF and oxidative stress (OS) is a key component. This study aims to assess whether RPE in HF conditions is associated with changes in oxidative and antioxidant markers. Methods: A systematic review with meta-analysis of randomized clinical trials was conducted, including an intervention group of adults with HF who practiced RPE (n = 225), compared with a control group of sedentary patients with HF (n = 166). Six databases were searched: Excerpta Medica Database (Embase), US National Library of Medicine (PubMed), Virtual Health Library (VHL), Register of Controlled Trials (Cochrane), Scientific Electronic Library Online (SciELO), and Latin American and Caribbean Health Sciences Literature (LILACS), up to January 31 of 2026, totaling 1,321 records. Resultados e Conclusions: This review included randomized trials comprising a total of 391 patients from 10 randomized controlled clinical trials. The meta-analysis demonstrated that RPE potentially reduces oxidative markers such as IL-6, MPO, TNF-α, LPO, TBARS, ICAM-1, VCAM-1, MDA-LDL, and ROS, with a weighted mean difference (WMD) of -1.73 (-2.9; -0.56), as well as increases antioxidant markers such as SOD, CAT, CcO, COX, GPX, Pon1, and MAPR, with a WMD of 1.99 (1.11; 2.88). However, most studies included in the meta-analysis had a high risk of bias, mainly due to unreported randomization methods, resulting in a “very low” certainty of evidence according to the GRADEPro system. This suggests the need for further studies with clearly explained randomization criteria and better-established intention-to-treat analyses. Patients with HF who participated in RPE programs may potentially show a reduction in oxidative markers and an increase in antioxidant markers, although the certainty of the evidence remains “very low.”

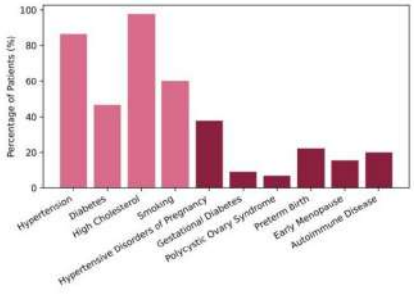
ACLS COURSE AS AN UNUSUAL TRIGGER FOR TAKOTSUBO SYNDROME – A CASE REPORT

JOSE ANTONIO CALDAS TEIXEIRA1; SONIA VELIHOVETCHI LAREDO1; MAURO ALVES1; MATEUS FREITAS TEIXEIRA1; DIVA MARINA BASTOS SILVA1;

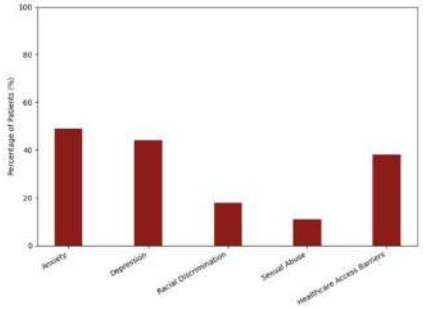
(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL;

Introduction/Background: Takotsubo cardiomyopathy is an acute cardiac syndrome characterized by transient left ventricular (LV) dysfunction. It occurs in the absence of obstructive coronary artery disease, and predominantly affects postmenopausal women. It is mostly precipitated by emotional or physical stress. Its occurrence in the context of medical stress related simulation, like the ACLS course, remains underreported. Objectives: The aim of this case report is to highlight the potential of ACLS training as a trigger for Takotsubo Syndrome. Methods: CASE REPORT A 68-year-old asymptomatic female physician, with no prior cardiovascular history, presented with chest pain and presyncope during ACLS session. Hemodynamically stable, baseline EKG showing ST segment elevation in the anterior leads. A coronary angiography showed normal epicardial coronary arteries, however ventriculography changes raised suspicion of Takotsubo Syndrome. High levels of Troponin (6.191 ng/ml) and NT Pro BNP (1.750 pg/ml); hypokinesis of the mid-apical region of the LV, moderate global LV dysfunction, EF of 44%, and reduced LGS, at -12 in the echocardiogram. Cardiac magnetic resonance revealed moderate global systolic dysfunction and segmental contractile deficit. Myocardial edema and late gadolinium enhancement of a non-ischemic pattern were observed in the anterior, anteroseptal, anterolateral segments and at the apex of the LV, consistent with the suspected diagnosis. Resultados e Conclusions: Inpatient treatment for acute heart failure was instituted. She remained asymptomatic after discharge, continuing with Dapagliflozin 10 mg, Enalapril Maleate 5 mg, and Bisoprolol 2,5 mg, under outpatient follow-up, with improvement and regression to normal clinical, laboratory, and functional parameters after 6 month Heart dysfunction in this syndrome causes the affected LV to take on a shape similar to a “Takotsubo - octopus fishing pot”. The pathophysiology comprises the excess of catecholamines released in stressful situations, triggering coronary vasospasm, direct myocardial toxicity, and temporary reversible myocardial dysfunction. Clinical presentation includes chest pain, acute heart failure, electrocardiographic changes, elevated enzymes, and abnormalities in imaging studies.



15956

ASSOCIATION OF NON-CLASSICAL AND PSYCHOSOCIAL RISK FACTORS IN WOMEN WITH CORONARY ARTERY DISEASE: DESCRIPTIVE ANALYSIS



JACKELLINE CAMARGO PRETO1; MARIA JULIA DIAS BATISTA DESTRO1; GUILHERME SILVA MENDES GAIA1; ADRIANO HENRIQUE PEREIRA BARBOSA1; MARIA TERESA NOGUEIRA BOMBIG1; MARIA CRISTINA DE OLIVEIRA IZAR1;

(1) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL;

Introduction/Background: Coronary artery disease (CAD) remains one of the leading causes of cardiovascular morbidity and mortality in women. While classical risk factors like hypertension, hyperlipidemia, and smoking are well-documented, emerging evidence highlights the significant role of non-classical risk factors, especially those unique to women, in elevating lifetime cardiovascular risk. Notably, hypertensive disorders of pregnancy (HDP), gestational diabetes mellitus (GDM), and autoimmune diseases are key contributors to the increased risk of CAD in women. Additionally, mental health disorders, particularly anxiety and depression, have been closely linked to a higher risk of cardiovascular events, underscoring the role of psychosocial factors in heart disease not included in traditional scores. Objectives: To determine the prevalence of non-classical cardiovascular risk factors, female-specific conditions, and psychosocial determinants in women with a prior diagnosis of CAD. Methods: Observational, cross-sectional study with descriptive analysis including 45 women aged over 18 years with a prior diagnosis of CAD, defined as ≥50% atherosclerotic coronary stenosis confirmed by invasive coronary angiography or coronary computed tomography angiography in the evaluation of stable angina. Data were collected through structured questionnaires assessing non-classical cardiovascular risk factors, female-specific conditions, and under-recognized psychosocial determinants. Resultados e Conclusions: Among the 45 women with a prior diagnosis of CAD, psychosocial risk factors were highly prevalent, including anxiety (48.9%), depression (44.4%), and barriers to healthcare access (37.8%). Racial discrimination and sexual abuse were reported by 17.8% and 11.1%, respectively. Among female-specific factors, hypertensive disorders of pregnancy were the most common (37.8%), followed by preterm birth (22.2%) and autoimmune diseases (20.0%). Other conditions included early menopause (15.6%), gestational diabetes mellitus (8.9%), and polycystic ovary syndrome (6.7%). Moreover, traditional cardiovascular risk factors were also highly prevalent, particularly high cholesterol (97.8%), hypertension (86.7%), smoking (64.4%), and diabetes (46.7%). In conclusion, these findings suggest that cardiovascular risk assessment in women should be broadened beyond traditional factors, supporting a more comprehensive and sex-specific approach to risk stratification and prevention.

ATRIAL FIBRILLATION ABOLISHES THE FEMALE SURVIVAL ADVANTAGE IN HEART FAILURE

ERNESTO AMARAL BRAGA1; ANTONIO PADUA MANSUR1;

(1) INSTITUTO DO CORACAO (INCOR) - HOSPITAL DAS CLINICAS DA FACULDADE DE MEDICINA DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction/Background: Heart failure (HF) is associated with high morbidity and mortality. Persistent atrial fibrillation (AF) adds further risk in these patients. However, sex differences in prognosis remain limited. Objectives: To analyze sex differences in the prognosis of HF with and without AF. Methods: We analyzed, from February 2017 to January 2024, mortality and predictors of all-cause death in 2,817 patients with HF, 61% men, and 38% had AF. Baseline data included clinical features and echocardiographic findings, which included left ventricular ejection fraction (LVEF) change. We used the Kaplan-Meier (K-M) and Cox proportional hazards models to analyze mortality rates. The model's validity was verified using the Schoenfeld residual test (Supremum Test). Resultados e Conclusions: Mortality was higher in presence of AF (53% vs. 47%; p < 0.001). The K-M curve showed a significant difference in 6-year survival by AF status and sex (p < 0.0001). Among patients without AF, survival was higher in women (61% vs. 53%; p = 0.032), but the presence of AF equalized mortality between sexes (women: 48% vs. men: 44%; p = 0.272) (Figure A). In men, multivariate Cox analysis revealed that kidney disease (KD), age, AF, and worsening LVEF were associated with worse prognosis. In women, predictors of mortality were age, KD, and AF. LVEF exhibited a time-dependent effect; although initially protective (HR: 0.78 at baseline), temporal interaction (p = 0.005) indicates that this benefit progressively attenuates over the follow-up period (Figure B1, men; B2, women). Conclusion: Atrial fibrillation markedly worsens prognosis in patients with heart failure and appears to abolish the survival advantage observed in women without AF. These findings highlight AF as a key modifier of sex-related HF prognosis.

CANNABIS USE DURING PREGNANCY AND RISK OF HYPERTENSIVE DISORDERS: ASSOCIATION WITH GESTATIONAL HYPERTENSION AND PRE-ECLAMPSIA

JOÃO PEDRO ALVES DE BARROS1; ANA LAURA GOMES DA SILVA1; ALAN CARLOS BATISTA CASCALHO JUNIOR2; ELIAS ZOGBI DONHA1; THAYLLA BIANCA DE ALMEIDA VILELA1; LARISSA SOBRINHO ANICETO1; IGOR DE ALMEIDA BALDUINO LEITE1; MARCUS VINÍCIUS SENS BORGES1; THIAGO PAULUZI JUSTINO1;

(1) UNIVERSIDADE FEDERAL DA GRANDE DOURADOS - DOURADOS - MS - BRASIL; (2) UNIVERSIDADE FEDERAL DE MATO GROSSO DO SUL - CAMPO GRANDE - MS - BRASIL;

Introduction/Background: Cannabis use during pregnancy is increasingly common and represents the most frequently used psychoactive substance during gestation, with an estimated prevalence of 6.8% (95% CI 4.9–9.3) among pregnant women in the United States. Delta-9-tetrahydrocannabinol (THC) crosses the placental barrier and may impair maternal–fetal vascular homeostasis through mechanisms including endothelial dysfunction, impaired placental angiogenesis, and fetal vascular malperfusion. These alterations may contribute to hypertensive disorders of pregnancy. Objectives: To systematically evaluate the association between cannabis exposure during pregnancy and hypertensive disorders of pregnancy, particularly gestational hypertension and pre-eclampsia, emphasizing placental vascular dysfunction and maternal–fetal cardiovascular outcomes. Methods: This systematic review was conducted according to PRISMA Statement 2020 guidelines and guided by a PECO framework. A systematic search of the PubMed/MEDLINE database was performed using the descriptors "Cannabis," "Marijuana Use," "Pregnancy," "Gestational Hypertension," and "Pre-eclampsia," combined with Boolean operators AND/OR. Observational studies evaluating cannabis exposure during pregnancy and hypertensive disorders of pregnancy were considered eligible. Two independent reviewers performed study screening and data extraction, with disagreements resolved by consensus. Methodological quality was assessed using the Newcastle–Ottawa Scale. A total of 204 studies were initially identified; after screening and eligibility assessment, 20 studies were included, comprising cohort studies, meta-analyses, and placental histopathological investigations. Resultados e Conclusions: The reviewed evidence demonstrated an association between cannabis exposure during pregnancy and increased risk of gestational hypertension and pre-eclampsia. Frequent exposure was associated with greater maternal vascular risk. Placental abnormalities, fetal vascular malperfusion, prematurity, fetal growth restriction, and low birth weight were also observed. Conclusions: Cannabis exposure during pregnancy may represent a maternal cardiovascular risk factor associated with hypertensive disorders and adverse maternal–fetal outcomes. Prenatal screening, counseling, and cessation interventions should be incorporated into prenatal care.

CENTRAL HEMODYNAMICS, ARTERIAL STIFFNESS AND CARDIORESPIRATORY FITNESS IN WOMEN WITH ISCHEMIC HEART DISEASE: A BASELINE CROSS-SECTIONAL ANALYSIS

LUCIANNA SERFATY DE HOLANDA1; CLAUDIA FETTER2; VITOR BRUNO TEIXEIRA DE HOLANDA1; THIAGO DIPP2; MARIA CLAUDIA IRIGOYEN2; ROSANE MARIA NERY2; ODILON SALIM COSTA ABRAHIM3; REJANE WALESSA PEQUENO RODRIGUES3;

(1) FUNDACAO HOSPITAL DE CLINICAS GASPAR VIANNA PA - BELÉM - PA - BRASIL; (2) INSTITUTO DE CARDIOLOGIA / FUNDAÇÃO UNIVERSITARIA DE CARDIOLOGIA - PORTO ALEGRE - RS - BRASIL; (3) UNIVERSIDADE ESTADUAL DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introduction/Background: Central blood pressure, pulse wave velocity (PWV) and augmentation index (AIx) may provide additional information beyond peripheral blood pressure in women with ischemic heart disease. However, the relationship between these vascular markers and cardiorespiratory fitness remains to be better defined Objectives: To evaluate the baseline association between central hemodynamic parameters, arterial stiffness and cardiorespiratory fitness in women with ischemic heart disease enrolled in a cardiac rehabilitation study Methods: This was a baseline cross-sectional analysis including 50 women with ischemic heart disease. Central systolic blood pressure, central diastolic blood pressure, central pulse pressure, PWV and AIx were obtained by oscillometric pulse wave analysis. Cardiorespiratory fitness was assessed by peak oxygen uptake (VO_2 peak) and metabolic equivalents (METs) during exercise testing. PWV, AIx and central blood pressure were classified according to age- and sex-specific reference values, using the 90th percentile as the upper limit of normality. Associations were assessed using Spearman correlation Resultados e Conclusions: Mean age was 60.9 ± 8.4 years and mean body mass index was 27.3 ± 4.6 kg/m². At baseline, 30.0% of participants had abnormal PWV, 38.0% had elevated central systolic blood pressure, 30.0% had elevated central pulse pressure and 56.0% had at least one abnormal central hemodynamic or arterial stiffness marker. PWV was positively correlated with age (ρ = 0.689; p < 0.001), central systolic blood pressure (ρ = 0.449; p = 0.001) and central pulse pressure (ρ = 0.529; p < 0.001). Conversely, PWV was inversely correlated with VO_2 peak (ρ = -0.360; p = 0.024) and METs (ρ = -0.394; p = 0.013). AIx showed weak and non-significant inverse correlations with VO_2 peak (ρ = -0.131; p = 0.583) and METs (ρ = -0.180; p = 0.447). Conclusions: In women with ischemic heart disease, greater arterial stiffness, expressed by PWV, was associated with higher central hemodynamic load and lower cardiorespiratory fitness. Although AIx showed a numerical trend toward lower VO_2 peak and METs, this association was not statistically significant. These findings suggest that PWV may be a more robust marker than AIx for integrating vascular aging, central hemodynamic burden and functional limitation in this population.

CLINICAL AND EPIDEMIOLOGICAL PROFILE OF PATIENTS WITH PREGNANCY HYPERTENSIVE EMERGENCIES AT A MATERNITY HOSPITAL IN LUANDA, ANGOLA.

JOÃO HOUARI AFONSO ADELAIDE1; SILKE WEZA JOSÉ ANTÓNIO2; ROSÁRIA EPANDI LUCANDA CAIANGULA2; ISAURA CONCEIÇÃO ALMEIDA LOPES2; HENRIQUE COTCHI SIMBO MUELA3;

(1) FACULTY OF MEDICINE, AGOSTINHO, LUANDA NETO UNIVERSITY - ANGOLA; (2) FACULTY OF MEDICINE, AGOSTINHO NETO UNIVERSITY, LUANDA - ANGOLA; (3) 1FACULTY OF MEDICINE, AGOSTINHO NETO UNIVERSITY, LUANDA - ANGOLA;

Introduction/Background: Hypertensive disorders of pregnancy remain one of the leading causes of maternal morbidity and mortality worldwide, particularly in Sub-Saharan Africa, where prevalence rates exceed global averages and are frequently associated with severe maternal complications. Objectives: To study the clinical and epidemiological profile of pregnant women presenting with hypertensive emergencies admitted to a tertiary maternal hospital in Luanda, Angola. Methods: An observational study was carried out, including 116 pregnant women diagnosed with hypertensive emergencies admitted to a tertiary maternal hospital in Luanda, Angola, during the second semester of 2025. Continuous variables were tested for normality using the Kolmogorov–Smirnov test. Normally distributed variables were expressed as mean ± standard deviation, whereas non-normally distributed variables were presented as median and range. Categorical variables were summarized using absolute and relative frequencies. Resultados e Conclusions: The mean age of patients was 31 ± 6 years, and most were married (73.3%). The mean educational level was 11 ± 4 years, and 43.1% were employed. A personal history of chronic hypertension was reported in 13.8% of patients, while 32.8% reported previous pre-eclampsia or eclampsia in prior pregnancies. Family history of hypertension was present in 61.2% of cases, and family history of pre-eclampsia in 18.9%. The most frequent symptoms were headache (56.9%), dizziness (30.2%), and blurred vision (30.2%). At hospital admission, 67.2% of patients presented systolic blood pressure ≥160 mmHg and 46.6% diastolic blood pressure ≥110 mmHg. The most common complications were HELLP syndrome, followed by acute kidney injury and placental abruption. Hypertensive emergencies in pregnancy predominantly affected young adult women and were characterized by markedly elevated blood pressure and neurological symptoms. HELLP syndrome, acute kidney injury, and placental abruption were the most frequent maternal complications, highlighting the need for early detection and timely management to reduce adverse maternal outcomes.

COMPARATIVE ANALYSIS OF RISK FACTORS AND SHORT-TERM OUTCOMES AFTER PRIMARY PCI IN PRE- AND POST-MENOPAUSAL WOMEN WITH STEMI.

SHUMAILA FURNAZ1;

(1) NATIONAL INSTITUTE OF CARDIO VASCULAR DISEASES - PAKISTAN;

Introduction/Background: Coronary artery disease (CAD) is a leading global cause of mortality and a major burden in Pakistan, increasingly affecting premenopausal women, suggesting limited estrogen protection. We conducted a cross-sectional study among women with STEMI at a tertiary cardiac center in Karachi.Pakistan Objectives: comparing the prevalence of conventional and non-conventional risk factors of atherosclerotic cardiovascular disease (ASCVD) between pre- and post-menopausal women. Methods: This cohort study was conducted at the National Institute of Cardiovascular Disease (NICVD), Karachi, Pakistan, between May and October 2025. We have recruited two independent cohorts of women diagnosed with STEMI. The first cohort consisted of consequently selected pre-menopausal women, while, second cohort consisted of consequently selected post-menopausal women. The two cohorts were compared in terms of clinical and demographic characteristics (e.g., age), clinical presentation (e.g., presenting symptoms), medical history (e.g., co-morbid conditions), triggering factors, angiographic characteristics (e.g., involved vessels), and in-hospital outcomes using appropriate independent sample t-test or chi-squared test at 5% level of significance. Resultados e Conclusions: Among 210 female STEMI patients, 27.6% were premenopausal and 72.4% postmenopausal. Premenopausal women were younger (41 vs. 55.8 years), with similar baseline characteristics. Diabetes was higher in postmenopausal women, while preeclampsia and gestational diabetes were more common in premenopausal women. Premenopausal patients more often had shortness of breath and higher smoking/substance use, whereas a sedentary lifestyle was more common post menopause. Single-vessel disease predominated in premenopausal women, and three-vessel disease in postmenopausal. RCA was most commonly involved. TIMI III flow and in-hospital outcomes were similar, with no complications or mortality. Conclusion Premenopausal women showed unique pregnancy-related and behavioral risk factors, while metabolic risks, especially diabetes, were more prominent postmenopause. Despite differing profiles, procedural and in-hospital outcomes were comparable. Preventive strategies should include screening for pregnancy-related cardiovascular risks, promoting lifestyle modification in younger women, and strict metabolic control in postmenopausal women. Further research on early-onset CAD in South Asian women is recommended

COMPARATIVE EFFECTS OF VASOPRESSORS ON MATERNAL CARDIOVASCULAR STABILITY DURING NEURAXIAL ANESTHESIA FOR CESAREAN DELIVERY: A SYSTEMATIC REVIEW

MARIANA DE PAULA PESSOA BEZERRA1; ENZO ZONARY ALENCAR DE OLIVEIRA1; FELIPE PIRES DE CARVALHO OLIVEIRA1; MATHEUS DE PAULA PESSOA BEZERRA1; GUSTAVO LOPES TEIXEIRA1; JÚLIA CAMBRAIA DANTAS1; LARISSA TORRES PLUTARCO1; MARIA EDUARDA TELMOS DE LIMA1; MARINA CALADO LIMA1; MARINA CARVALHO LIMA MENDONÇA1; REBECA CAVALCANTE MENDES SOEIRO1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introduction/Background: Hypotension following neuraxial anesthesia during cesarean delivery is a frequent and clinically relevant complication caused by sympathetic blockade, leading to impaired uteroplacental perfusion and adverse maternal and fetal outcomes. Vasopressors are essential to maintain hemodynamic stability; however, different agents have distinct effects on vascular resistance and heart rate, directly influencing cardiovascular stability. Despite widespread use of phenylephrine and norepinephrine, uncertainties remain regarding the optimal choice. Objectives: To compare the impact of vasopressors on maternal hemodynamic stability during neuraxial anesthesia, focusing on their effectiveness in preventing and treating hypotension and on maternal outcomes. Methods: A comprehensive literature search was conducted in PubMed, SciELO, Cochrane Library, and LILACS to identify randomized and comparative studies addressing vasopressor use during cesarean delivery under neuraxial anesthesia. Studies published from database inception to 2025 were included. Selection followed PRISMA guidelines and PICO strategy. Outcomes included incidence of post-spinal hypotension, systolic and mean arterial pressure, heart rate, and overall hemodynamic stability. Resultados e Conclusions: Five randomized trials (n=546) showed similar efficacy among norepinephrine, phenylephrine, and metaraminol in preventing hypotension and maintaining systolic blood pressure. Norepinephrine demonstrated a more favorable hemodynamic profile, with higher heart rate, better preservation of cardiac output, and lower incidence of bradycardia compared to phenylephrine. Neonatal outcomes were comparable across groups. The small number of included studies and potential heterogeneity should be considered when interpreting the results. Overall, although vasopressors provide similar blood pressure control, their cardiovascular effects differ. Norepinephrine may be considered a preferred option for maintaining maternal hemodynamic stability during neuraxial anesthesia for cesarean delivery.

EARLY MENOPAUSE AS A CARDIOVASCULAR RISK FACTOR: A SYSTEMATIC REVIEW.

MARCELA FERREIRA DA SILVA1; LUISA DE CASTRO BATISTA1; HELENA GORETTI VASCONCELOS1; LETÍCIA VIEIRA GUIMARÃES1; MARSELHA MARQUES BARRAL MONTESSI1;

(1) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL;

Introduction/Background: Cardiovascular diseases (CVD) represent the leading cause of death among women, accounting for approximately 50% of all fatalities. Although the incidence of acute myocardial infarction typically occurs 7–10 years later in women compared to men, there is a gradual increase in cardiovascular risk following menopause. In this context, early menopause is associated with a profile of higher cardiovascular vulnerability, as the premature reduction of estrogen—which exerts a cardioprotective effect—promotes metabolic and vascular alterations that favor the development of coronary diseases. Objectives: To investigate, through a systematic review, the association between early menopause and a higher incidence of cardiovascular diseases. Methods: A literature review was conducted including original human clinical studies published within the last four years, originally in English, and available in full text. The search referenced the National Library of Medicine (MedLine), Scientific Electronic Library Online (SciELO), and Cochrane Library databases, using the MeSH descriptors “Premature Menopause” and “Coronary Diseases”, combined by Boolean operators. Studies analyzed the association between early menopause and increased cardiovascular risk. Poorly described studies, abstract-only publications, animal models, and literature reviews were excluded. The PRISMA statement was used for the systematization of the review process. Resultados e Conclusions: Initially, 8 studies were identified; after deduplication and application of eligibility criteria, 4 were included in the final analysis. A total of 13,366 participants were evaluated, among whom the prevalence of early menopause varied across studies. The selected publications demonstrated a significant increase in cardiovascular outcomes in women with early menopause compared to those with normal menopause timing ($p < 0.05$). Furthermore, Yamanouchi et al. observed a higher frequency of cardiovascular diseases in women with premature menopause associated with low BMI and high parity ($p < 0.05$). Overall, the evidence supports early menopause as a relevant cardiovascular risk factor, highlighting the importance of targeted preventive strategies in this population.

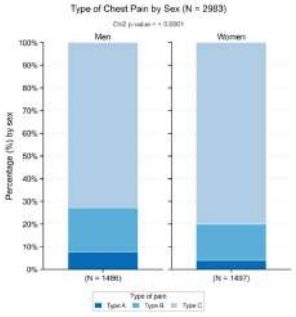
HIDDEN ADIPOSITY IN NORMAL-BMI POSTMENOPAUSAL WOMEN: LIPID RISK MISCLASSIFICATION REVEALED BY BIOIMPEDANCE

LEONARDO ANDRADE FERNANDES DE LUCA1; LUIS FILIPE AZEVEDO DE CARVALHO1; RODRIGO VASCONCELLOS TAVARES BRAVO1; FLAVIO ANDRADE CAMACHO2;

(1) HOSPITAL QUINTA D´OR - RIO DE JANEIRO - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL;

Introduction/Background: Postmenopausal estrogen deficiency promotes visceral fat redistribution, potentially creating a phenotype of normal BMI coexisting with excess adiposity — termed hidden adiposity or normal-weight obesity. This phenotype may carry cardiometabolic risk comparable to overt obesity while evading standard BMI-based screening, representing a diagnostic gap of particular clinical relevance in postmenopausal women. Objectives: To determine the prevalence of hidden adiposity and characterize its lipid profile among postmenopausal hospital workers. Methods: Cross-sectional study of 20 postmenopausal women (58–67 years) assessed by anthropometry and BIA (Biodynamics BIA 450 single-frequency tetrapolar analyzer) following a 12-hour fast. Hidden adiposity was operationally defined as BMI 18.5–24.9 kg/m² combined with body fat ≥30% by BIA. Fasting lipid profiles were obtained for all participants. Descriptive comparisons were performed across groups; formal statistical testing was not applied given the small subgroup size. Resultados e Conclusions: RESULTS Four women (20%) had normal BMI; among them, three (15% of the total sample) met criteria for hidden adiposity. Despite a mean BMI of 23.3 kg/m², this subgroup exhibited markedly elevated total cholesterol (individual values: 159, 264, and 314 mg/dL; mean 246 vs. 198 mg/dL in those without hidden adiposity) and LDL-C (individual values: 78, 177, and 202 mg/dL; mean 152 vs. 103 mg/dL). None of the three women were receiving lipid-lowering therapy, suggesting that their lipid risk was undetected by BMI-based screening. Mean triglycerides were 129 mg/dL in this subgroup, consistent with a predominantly hypercholesterolaemic rather than hypertriglyceridaemic pattern. CONCLUSIONS Hidden adiposity was identified in 15% of postmenopausal workers with normal BMI and was associated with substantially elevated total cholesterol and LDL-C in the absence of treatment. Reliance on BMI alone may systematically underestimate lipid-related cardiometabolic risk in postmenopausal women. Given the small subgroup size (n=3), these findings are hypothesis-generating and require confirmation in larger prospective cohorts, but the clinical signal warrants early attention in occupational cardiovascular prevention programmes.

15791



HIGHER PREVALENCE OF NON-ANGINAL CHEST PAIN IN WOMEN PRESENTING TO THE EMERGENCY DEPARTMENT

LARISSA FRANCO DE ANDRADE1; EDUARDO PIETRE1; BERNARDO BARCELOS FERNANDES FUMAGALLI SILVA2; BIANCA FERREIRA BRITO3; FABIOLA LUCIO CARDAO1; ISABELA DA COSTA FURTADO3; JEORGIANE DE ASSUMPÇÃO COSTA3; MARIANA CRISTINA MAYWORN3; MARIA DE FATIMA MARTINS GIL DIAS3; VAGNER DA SILVA MEIRA3; LUIS FILIPE AZEVEDO DE CARVALHO4; LEONARDO ANDRADE FERNANDES DE LUCA3;

(1) HOSPITAL QUINTA D' OR - RIO DE JANEIRO - RJ - BRASIL; (2) HOSPITAL QUINTA D'OR - RIO DE JANEIRO - RJ - BRASIL; (3) HOSPITAL QUINTA D'OR - RIO DE JANEIRO - RJ - BRASIL; (4) HOSOITAL QUINTA D'OR - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Acute chest pain is one of the most common reasons for presentation to the emergency department (ED) and requires rapid risk stratification to identify patients with suspected ischemic heart disease. Although sex-based differences in symptom presentation have been described, contemporary data from the Brazilian population remain limited. Objectives: To evaluate sex-based differences in chest pain presentation and clinical characteristics among patients presenting to a tertiary care ED. Methods: This retrospective observational study included patients presenting with acute chest pain to the ED to a tertiary hospital. Clinical data, cardiovascular risk factors, and prior cardiovascular history were collected. Chest pain was categorized as Type A (definitively anginal), Type B (probably anginal), or Type C (probably non-anginal). Continuous variables are presented as mean ± standard deviation and compared using Welch's t-test, while categorical variables were compared using the chi-square test. A p-value < 0,05 was considered statistically significant. Resultados e Conclusions: A total of 2,983 patients were included, of whom 1,497 were women. Women were older than men (53 ± 17 vs. 50 ± 16, p < 0.001). Men had a higher prevalence of hypertension (46.9% vs. 41.0%, p = 0.001), dyslipidemia (23.1% vs 17.9%, p<0.001), prior myocardial infarction and previous percutaneous coronary intervention (p < 0.001). Significant differences were observed in symptom presentation. Women were more likely to present with probably non-anginal chest pain (Type C: 80.1% vs 72.8%), whereas men more frequently presented with definitively anginal (Type A: 7.7% vs 4.0%) and probably anginal chest pain (Type B: 19.4 vs 15.9), overall p < 0.001. These findings raise concern that the clinical presentation of women may be less readily recognized as cardiac in origin, potentially leading to underestimation of cardiovascular risk, delays in diagnosis, and lower likelihood of appropriate investigation or treatment. They highlight the limitations of relying on symptom typicality alone and reinforce the need for a more sex-specific approach to the evaluation of chest pain in the ED.

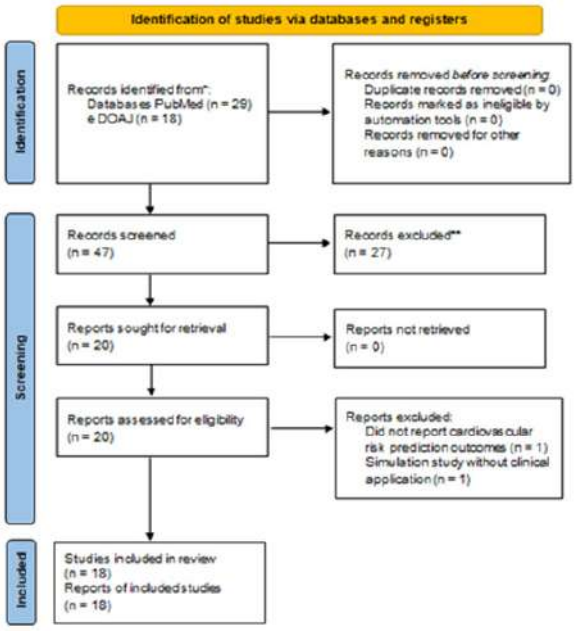
ORAL HORMONAL CONTRACEPTION AND FEMALE CARDIOVASCULAR RISK: EVIDENCE AND CLINICAL IMPLICATIONS

ANA BEATRIZ SCHIAVON MOREIRA1; ANA LUIZA GUSMÃO DE CASTRO1; JULIA CAPUTO AMORIM1; LARISSA BEVILAQUA SAMPAIO CONTREIRAS1; VICTOR HUGO DE OLIVEIRA CARDOSO1; CRISTIANA DA SILVA CAMPOS1;

(1) UNIVERSIDADE CATOLICA DE BRASILIA - BRASÍLIA - DF - BRASIL;

Introduction/Background: Female cardiovascular health is influenced throughout the reproductive lifespan, with hormones playing a significant role in the development of cardiovascular disease (CVD). The use of oral contraceptives (OCs) containing estrogen may exert procoagulant effects, increase blood pressure, and elevate the risk of thrombosis, predisposing to acute myocardial infarction (AMI) and stroke. Objectives: To analyze the association between combined oral contraceptives and cardiovascular events in women of reproductive age. Methods: This systematic review followed PRISMA guidelines. The descriptors "Oral Contraceptives," "Hormonal Contraception," "Cardiovascular Risk," "Stroke," "Myocardial Infarction," and "Women of Reproductive Age" were used in Portuguese and English. PICO criteria included: women of reproductive age (P), combined OCs use (I), non-use or progestin-only methods (C), and cardiovascular risk (O). PubMed and SciELO searches yielded 214 studies (2020–2026). After independent screening, Newcastle-Ottawa quality assessment, and removal of duplicates, 6 studies were included. Resultados e Conclusions: Ethinyl estradiol (EE) increases procoagulant factors, reduces natural anticoagulants, and activates the renin-angiotensin-aldosterone system, thereby elevating blood pressure and thrombotic risk. Cameron et al. (2023) reported that combined OCs increased blood pressure (0.7 mmHg systolic and 0.4 mmHg diastolic) with hypertension risk ranging from 1% to 8.5%. Regarding lipid profile, Fabunmi et al. (2023) found higher total cholesterol among OC users (Standardized Mean Difference – SMD = 0.94) and increased LDL levels (SMD = 0.79). In terms of cardiovascular outcomes, Yonis et al. (2025) demonstrated a twofold increased in the risk of ischemic stroke and AMI compared to non-use, with approximately 21 additional stroke cases and 10 AMI cases per 100,000 women per year. Higher EE doses (30–40 µg) were associated with a twofold increase in stroke and AMI compared to formulations containing 20 µg. In contrast, progestin-only contraceptives showed a lower impact on blood pressure and a weaker association with thrombotic risk (Relative Risk – RR of 1.6 for stroke and 1.5 for AMI). Combined OCs are associated with increased cardiovascular risk in reproductive-age women (RR ≈ 2.0 for stroke and AMI) and elevated blood pressure. This effect appears to be dose-dependent, with higher risk in formulations containing 30–40 µg EE. Contraceptive choice should be individualized based on clinical history and risk profile.



18086

PERFORMANCE OF ARTIFICIAL INTELLIGENCE IN PREDICTING CARDIOVASCULAR RISK IN WOMEN: A SYSTEMATIC REVIEW

JÚLIA GALVÃO MARTINS1; LAURA HENRIQUES GUIMARÃES1; CALEBE GARCIA FONSECA SALLES2; RALDNER BORGES E RÉGES3;

(1) UNIVERSIDADE FEDERAL DE SÃO JOÃO DEL-REI - DIVINÓPOLIS - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE SÃO JOÃO DEL-REI - SÃO JOÃO DEL-REI - MG - BRASIL; (3) COMPLEXO DE SAÚDE SÃO JOÃO DE DEUS - DIVINÓPOLIS - MG - BRASIL;

Introduction/Background: Cardiovascular diseases (CVD) are the leading cause of death worldwide, with greater impact on women. Factors such as menopause and hormonal changes increase cardiovascular risk (CVR) in this population. Although essential, current risk tools generally still do not consider these particularities, and studies rarely perform sex-stratified analysis. In this context, AI emerges as a promising strategy for more personalized assessment. This study, therefore, synthesizes evidence on its use in predicting CVR in women. Objectives: Synthesize evidence on the accuracy of AI models in predicting cardiovascular risk in women, evaluating their performance metrics. Methods: Systematic review following PRISMA, with searches in PubMed and DOAJ (2021–2026, no language restriction) and descriptors on AI and prediction of CVR in women. Selection was performed by two independent reviewers, in two stages (titles/abstracts and full text), with consensus. Of 47 studies, 18 met the criteria (quantitative data, sex-based analysis, and full text), with studies outside the topic, reviews, and unavailable ones excluded. Data were extracted on AI type, number of women, outcomes, and metrics (AUC, sensitivity, and specificity), with quality assessed by PROBAST and descriptive analysis. Resultados e Conclusions: Eighteen studies were included, mostly using machine learning models to predict CVR, assessing cardiovascular events, mortality, and risk stratification. Only one study analyzed women exclusively (n=458, postmenopausal), using Random Forest, XGBoost, Gradient Boosting, SVM, Neural Network, Logistic Regression, and Gaussian Naive Bayes models, with high performance (AUC ~1.00; sensitivity 0.92; no specificity data), with Random Forest, XGBoost, and Ensemble standing out. In studies with mixed populations, results were aggregated without sex-based analysis, with predominance of algorithms such as Random Forest, XGBoost, Naive Bayes, logistic regression, and neural networks, showing AUC from 0.61 to 1.00, sensitivity from 0.47 to 1, and specificity from 0.51 to 0.99 (rarely reported), with overall better performance for XGBoost. Despite the high performance, the scarcity of women-specific analyses limits the assessment of applicability. Thus, although AI shows great potential in CVR prediction, its implementation depends on validation in female cohorts and the development of more inclusive models, aiming at greater accuracy and equity in cardiovascular care.

18780

PREECLAMPSIA: A RISK FACTOR FOR HEART FAILURE DECADES AFTER DELIVERY

GABRIELLI BACCHI COLOMBO1; MARIA GABRIELA PANIZ BACEDO1; EDUARDA SONDA DE GODOY1;

(1) UNIVERSIDADE DE CAXIAS DO SUL - CAXIAS DO SUL - RS - BRASIL;

Introduction/Background: Preeclampsia (PE) is a multisystemic gestational syndrome characterized by hypertension and endothelial dysfunction. Although considered transient, evidence demonstrates persistent cardiovascular risk, including increased incidence of heart failure (HF) decades after delivery. Objectives: To evaluate the association between a history of PE and the incidence of HF in the decades following delivery. Methods: Systematic review according to PRISMA guidelines. Search conducted in March 2026 in PubMed and LILACS databases (2017-2026) using MeSH/DeCS descriptors: “Pre-Eclampsia” AND “Heart Failure” AND (“Incidence” OR “Long-term”). Meta-analyses and observational studies with follow-up ≥1 year postpartum comparing women with PE to normotensive controls were included. Independent selection by two reviewers. Quality assessed using the Newcastle-Ottawa Scale (NOS). Certainty of evidence classified by the GRADE system. Of 18 articles identified, 4 studies were included after applying eligibility criteria. Resultados e Conclusions: Women with a history of PE have a relative risk (RR) of future HF of 4.19 (95% CI: 2.09–8.38), in addition to higher relative risk of coronary artery disease (RR 2.5) and cardiovascular death (RR 2.2). These associations are independent of age, BMI, smoking, or diabetes. A dose-response effect was observed: mild PE is associated with RR ~2.0, while severe PE elevates the risk to levels >5.0. Recurrence of the syndrome potentiates the outcome, with HF risk 2.9 times higher than with a single episode. Magnetic resonance imaging and stress testing reveal persistent subclinical alterations, such as diastolic dysfunction, concentric left ventricular hypertrophy, and reduced chronotropic reserve. The association is more robust for HF with preserved ejection fraction, suggesting a phenotype of chronic endothelial dysfunction and myocardial remodeling. The certainty of evidence was moderate (GRADE), with upgrade for magnitude of effect and biological plausibility. The LILACS search did not return long-term cohorts, highlighting a gap in Latin American populations. Women with a history of PE have a significantly higher incidence of postpartum HF (MODERATE evidence). PE is a chronic sex-specific cardiovascular risk factor. Integration of gestational history into routine risk stratification is recommended to implement early prevention strategies.

REDUCED LEAN MASS PHENOTYPE DETECTED BY BIOIMPEDANCE SCREENING IN POSTMENOPAUSAL HOSPITAL WORKERS: CARDIOMETABOLIC IMPLICATIONS

LEONARDO ANDRADE FERNANDES DE LUCA1; LUIS FILIPE AZEVEDO DE CARVALHO1; RODRIGO VASCONCELLOS TAVARES BRAVO1; BRUNO DE QUEIROZ CLAUDIO1; MARIA DE FATIMA MARTINS GIL DIAS1; FLAVIO ANDRADE CAMACHO2;

(1) HOSPITAL QUINTA D´OR - RIO DE JANEIRO - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL;

Introduction/Background: Postmenopausal estrogen deficiency accelerates lean mass loss and promotes fat redistribution, creating a relative fat-to-muscle imbalance that may precede clinical sarcopenia. Detectable by bioimpedance as a reduced lean mass percentage, this phenotype has been associated with adverse cardiometabolic profiles and may be identifiable in occupational screening settings before functional impairment develops. Objectives: To characterize lean mass phenotypes using BIA-derived lean mass percentage and explore their association with cardiometabolic risk markers in postmenopausal hospital workers. Methods: Cross-sectional study of 20 postmenopausal women (58–67 years) undergoing BIA (Biodynamics BIA 450 single-frequency tetrapolar analyzer) and fasting lipid assessment after a 12-hour fast. Lean mass percentage (lean%) was the primary classification criterion: reduced lean mass (lean% <65%, n=13) vs. preserved lean mass (lean% ≥65%, n=7). Lean mass index (LMI = lean kg/m²) was calculated as a complementary descriptive metric only; its strong collinearity with BMI (r=0.93) precluded its use as primary classifier. ASMI was not calculable, as the BIA 450 does not yield segmental limb measurements. Lipid markers were compared descriptively. Resultados e Conclusions: RESULTS Mean lean mass percentage was 64.1% (range 56.5–72.1%); mean LMI was 17.7 kg/m² (descriptive). Thirteen women (65%) met criteria for reduced lean mass (lean% <65%). This group showed higher mean triglycerides (181 vs. 114 mg/dL) and TG/HDL ratio (3.2 vs. 2.1) compared with the preserved lean mass group, suggesting clustering of relative muscle deficit with atherogenic dyslipidaemia. Four participants (20%) had TG/HDL ≥3.5, a proxy threshold for elevated insulin resistance risk. No participant met criteria for clinical sarcopenia, as muscle strength and functional performance data were not collected. CONCLUSIONS Reduced lean mass percentage was present in 65% of postmenopausal workers and associated with higher triglycerides and TG/HDL ratio. These are screening-level findings; definitive sarcopenia classification requires strength and functional testing. The collinearity between LMI and BMI (r=0.93) confirms lean mass percentage as a more appropriate classifier than absolute lean mass indices in total-body BIA studies. Integrating lean mass phenotyping into occupational prevention programmes may enhance early cardiometabolic risk identification in postmenopausal women.

RETROSPECTIVE ANALYSIS OF THE EPIDEMIOLOGICAL AND CLINICAL CHARACTERISTICS OF ACUTE CORONARY SYNDROME IN A TERTIARY HOSPITAL IN CURITIBA IN 2024.

KARINA MIDORI NAZIMA1; FRANCISCO MAIA DA SILVA2; BETINA PERIN REZENDE3;

(1) SANTA CASA DE MISERICÓRDIA DE CURITIBA - CURITIBA - PR - BRASIL; (2) SANTA CASA DE MISERICÓRIDA DE CURITIBA - CURITIBA - PR - BRASIL; (3) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL;

Introduction/Background: Coronary artery disease represents the leading cause of death among postmenopausal women, surpassing breast cancer and other gynecological malignancies. Globally, acute coronary syndrome is responsible for 7.4 million deaths annually. The incidence of acute myocardial infarction increases substantially in the postmenopausal period supported by the hypothesis of estrogen's protective. Objectives: In light of the increasing recognition of the distinct characteristics of acute coronary syndrome (ACS) in women, particularly in the postmenopausal period, together with the persistent undertreatment and under-recognition of female-specific risk factors, the present study proposes to undertake a retrospective epidemiological analysis of ACS cases in women aged 55 years or older admited at a public hospital in Curitiba during the year of 2024, with the aim of further elucidating disease patterns and improving the clinical management of ACS in this population. Methods: A retrospective observational study analyzed anonymized medical records of female patients admitted to the hemodinamics unit over 2024, aged ≥55 years, yielding a final sample of 532 patients, treated at a tertiary public hospital in Curitiba, Paraná, Brazil. Data were anonymized; variables were summarized descriptively, and significant associations assessed using chi-square (p<0.05). Resultados e Conclusions: Mean age was 70.9 years. Hypertension (77.6%) and type 2 diabetes (43.6%) were the most prevalent risk factors. Chest pain predominated, with dyspnea (43.2%) as the main associated symptom. Unstable angina was most frequent (25.3%), followed by NSTEMI (23%) and STEMI (13%). Non-obstructive coronary findings occurred in 38.7%, mainly ANOCA (57.7%), MINOCA (27.1%), and INOCA (15%). PCI was the most common treatment (31.8%). Mortality was 9.4%, associated with advanced age and diabetes (60% of deaths). LAD involvement (42.7%) and multivessel disease (26.7%) were frequent; LAD lesions were present in 72% of deaths. NSTEMI showed greater metabolic and anatomical complexity, STEMI was linked to severe acute complications, and unstable angina had lower obstructive burden. Findings support complete revascularization and highlight the impact of postmenopausal status on atherosclerotic progression.

SAFETY OF STATIN EXPOSURE DURING PREGNANCY: AN INTEGRATIVE REVIEW OF CONGENITAL MALFORMATIONS AND PERINATAL OUTCOMES

JOÃO CARLOS ESQUINCALHA LUPARELLI1; LUISA GUASTI DA SILVA SANTOS2;

(1) UNIVERSIDADE VILA VELHA - VILA VELHA - ES - BRASIL; (2) FACULDADE MULTIVIX VITÓRIA - VITÓRIA - ES - BRASIL;

Introduction/Background: Statins are widely used for primary and secondary prevention of atherosclerotic cardiovascular disease. However, their use during pregnancy remains controversial because of historical concerns regarding teratogenicity and the increasing number of women of reproductive age receiving lipid-lowering therapy. Rising rates of obesity, diabetes mellitus, metabolic syndrome, and familial hypercholesterolemia have increased the likelihood of inadvertent first-trimester exposure, a critical period for fetal organogenesis. Although early studies suggested possible associations between statin exposure and congenital anomalies, recent observational studies have shown conflicting results. Objectives: To evaluate the safety of statin exposure during pregnancy, particularly during the first trimester, focusing on congenital malformations, spontaneous abortion, preterm birth, and low birth weight. Methods: This integrative review was structured according to the PICOTT model. Pregnant women exposed to statins during pregnancy were compared with non-exposed pregnant women. Searches were conducted in PubMed, Embase, and Cochrane using terms related to pregnancy, statins, and drug exposure. A total of 149 records were identified. After duplicate removal and screening, eight observational cohort studies based on national population registries from the United States, Norway, Taiwan, Japan, South Korea, and the United Kingdom were included. Resultados e Conclusions: Overall, the studies demonstrated that first-trimester statin exposure was not significantly associated with an increased overall risk of major congenital malformations after adjustment for confounding factors, especially pre-existing diabetes and maternal comorbidities. Large nationwide cohorts consistently showed no robust teratogenic effect associated with statin use during pregnancy. However, some studies identified possible associations with adverse perinatal outcomes, including preterm birth, low birth weight, spontaneous pregnancy loss, and ventricular septal defect. High-intensity statins also demonstrated possible increased risk in subgroup analyses. Current evidence does not support a strong independent association between first-trimester statin exposure and major congenital malformations, although caution remains necessary regarding specific adverse perinatal outcomes, reinforcing the need for individualized therapeutic decisions during pregnancy.

STUDY	COUNTRY / DATABASE	DESIGN	POPULATION	MAIN OUTCOMES EVALUATED	MAIN FINDINGS
Bateman et al. (2015)	USA / Medicaid Analytic eXtract	Observational cohort	886,996 pregnancies	Major congenital malformations	The crude increase in malformations lost significance after adjustment for confounders, especially pre-existing diabetes. No significant teratogenic effect associated with statins was observed.
Chang et al. (2021)	Taiwan / NHIRD	Nationwide retrospective cohort	1,443,657 pregnant women	Congenital malformations, prematurity, low birth weight, Apgar score	No increase in congenital malformations was observed. Higher risks of prematurity, low birth weight, and lower Apgar scores were identified.
McGrogan et al. (2017)	United Kingdom / GPRD	Retrospective cohort	281 exposed vs 2,643 unexposed	Spontaneous pregnancy loss	Statin exposure was associated with increased risk of spontaneous abortion/pregnancy loss (adjusted HR 1.64).
Lee et al. (2018)	USA / Kaiser Permanente	Retrospective cohort	379,238 pregnancies	Fetal cardiac malformations	First-trimester statin exposure was associated with increased risk of fetal ventricular septal defect (adjusted OR 3.3).
Christensen et al. (2026)	Norway / National registries	Nationwide cohort	805,368 pregnancies	Major and minor congenital malformations	No significant association between statin exposure and congenital malformations after adjustment. Updated meta-analysis also showed no significant increase in risk.
Fujioka et al. (2026)	Japan / JDIIP	Nationwide cohort	968 pregnant women	Congenital malformations, prematurity, low birth weight	No increase in congenital malformations was observed. Weighted analyses suggested higher risks of prematurity and low birth weight.
Kay et al. (2025)	South Korea / NHIS	Nationwide cohort	218,296 pregnant women with dyslipidemia	Congenital malformations and neurodevelopmental outcomes	No overall increase in malformations after adjustment. High-intensity statins were associated with increased risk of congenital malformations in subgroup analyses.
Svendsen et al. (2025)	Norway / National registry	Observational cohort	3,869 pregnancies in women with FH	Preeclampsia, low birth weight, prematurity	No overall increase in adverse neonatal outcomes. Possible association between statin use and low birth weight in some subgroups.

SEX DIFFERENCES IN LEFT VENTRICULAR EJECTION FRACTION PHENOTYPE AND CLINICAL PROFILE IN PATIENTS HOSPITALIZED WITH DECOMPENSATED HEART FAILURE

LARISSA FRANCO ANDRADE1; LEONARDO ANDRADE FERNANDES DE LUCA ANDRADE LUCA1; LUIS FILIPE AZEVEDO DE CARVALHO AZEVEDO CARVALHO1; JEORGIANE DE ASSUMPCAO COSTA ASSUMPCAO COSTA2; MARIANA CRISTINA MAYWORN CRISTINA MAYWORN1; MARCOS MORAIS DE MEIS3; VAGNER DA SILVA MEIRA SILVA MEIRA1; BARBARA ELAINE DE JESUS ABUFAIA1; FABÍOLA LUCIO CARDÃO1; EDUARDO PIETRE PIETRE1; PAULO MACHADO PONTES MACHADO PONTES4; MARIA DE FATIMA MARTINS GIL DIAS1;

(1) HOSPITAL QUINTA DOR - RIO DE JANEIRO - RJ - BRASIL; (2) HOSPITAL QUIANTA DOR - RIO DE JANEIRO - RJ - BRASIL; (3) HOSPITAL QUINAT DOR - RIO DE JANEIRO - RJ - BRASIL; (4) HOSPITAL QUINTA DOR - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Heart failure (HF) is highly prevalent, with significant morbidity and mortality. Sex-related differences in clinical presentation, comorbidities, and outcomes are increasingly recognized, yet women remain underrepresented in landmark HF trials, limiting evidence-based recommendations. Objectives: To evaluate sex differences in clinical characteristics, laboratory findings, and LVEF phenotype in patients hospitalized with decompensated HF. Methods: This cross-sectional study included 369 patients hospitalized with decompensated HF at a tertiary care center. Comorbidities, laboratory markers, and LVEF phenotype were assessed. Continuous variables were compared using Mann–Whitney U test and categorical variables using Chi-square or Fisher's exact test, with $p < 0.05$ considered significant. Resultados e Conclusions: A total of 369 patients included, of whom 187 (50.7%) men and 182 (49.3%) women. Women were significantly older than men (80.38 ± 12.95 vs. 73.20 ± 14.38 years, p<0.001), whereas body mass index was similar between groups. Hypertension and dyslipidemia were highly prevalent, with no significant differences between sexes. Diabetes mellitus was more frequent in men (61.0% vs. 47.3%, p=0.011), while atrial fibrillation showed a non-significant trend in women. Women presented higher LVEF than men (50.65 ± 17.80% vs. 44.12 ± 16.81%, p<0.001). Accordingly, LVEF phenotypes differed significantly: preserved ejection fraction (HFpEF) was predominant in women (54.9%), whereas reduced ejection fraction was more frequent in men (46.0%), p<0.001. At admission, women had significantly lower hemoglobin (11.50 ± 2.09 vs. 12.58 ± 2.35 g/dL) and ferritin levels (170.56 ± 250.59 vs. 220.60 ± 191.60 ng/mL) than men (p<0.001). NT-proBNP levels did not differ significantly between groups. Men had higher creatinine levels; however, creatinine clearance did not differ significantly across groups. In conclusion, women hospitalized with decompensated HF present a distinct clinical profile compared to men. They were older, more frequently exhibited preserved ejection fraction, and had lower hemoglobin and ferritin levels, suggesting a higher burden of anemia. In contrast, diabetes mellitus was more prevalent in men. These findings highlight clinically relevant sex-specific differences and support the need for gender-sensitive approaches in HF management, particularly in patients with HFpEF, a phenotype with limited therapeutic options

Variable	Overall	Men	Women	p-value
Count	369	187	182	
Age (mean ± SD)	76.75 ± 14.14	73.20 ± 14.38	80.38 ± 12.95	<0.001

SEX-BASED DIFFERENCES IN CLINICAL MANAGEMENT ACCORDING TO HEART SCORE IN PATIENTS PRESENTING WITH CHEST PAIN TO THE EMERGENCY DEPARTMENT OF A TERTIARY CENTER

LARISSA FRANCO DE ANDRADE1; EDUARDO PIETRE2; BERNARDO BARCELOS FERNANDES FUMAGALLI SILVA2; BIANCA FERREIRA BRITO3; FABÍOLA LUCIO CARDÃO3; ISABELA DA COSTA FURTADO2; JEORGIANE DE ASSUMPÇÃO COSTA2; MARIANA CRISTINA MAYWORN2; MARIA DE FATIMA MARTINS GIL DIAS3; VAGNER DA SILVA MEIRA2; LUIS FILIPE AZEVEDO DE CARVALHO3; LEONARDO ANDRADE FERNANDES DE LUCA3;

(1) HOSPITAL QUINTA D' OR - RIO DE JANEIRO - RJ - BRASIL; (2) HOSPITAL QUINTA D'OR - RIO DE JANEIRO - RJ - BRASIL; (3) HOSPITAL QUINTA D' OR - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: The HEART Score is widely used for risk stratification in patients presenting with chest pain to the emergency department (ED), guiding decisions regarding early discharge and diagnostic strategies. However, potential sex-based differences in management across categories remain insufficiently explored. Objectives: To evaluate the association between HEART Score risk categories and management strategies, stratified by sex. Methods: This retrospective observational study included patients presenting with chest pain, categorized into low (1-3), intermediate (4-6), and high (7-10) risk groups according to the HEART Score. Management strategies were classified as non-invasive testing, cardiac catheterization, percutaneous coronary intervention (PCI), and combined strategies. Associations were assessed using the Fisher–Freeman–Halton exact test. Resultados e Conclusions: A total of 352 patients were included (204 men and 148 women). Management differed across HEART risk categories ($p < 0.001$). In the low-risk group, most patients were managed non-invasively, with a higher proportion among women compared to men (64.8% vs. 57.4%). Fewer underwent cardiac catheterization or revascularization. In the intermediate-risk group, marked sex-based differences were observed. Women were more often managed non-invasively than men (55.9% vs. 29.5%), whereas men more frequently underwent invasive evaluation, with higher rates of catheterization (30.8% vs. 17.6%) and PCI (34.6% vs. 17.6%), indicating a more aggressive approach despite similar risk classification. In the high-risk group, all patients underwent invasive evaluation. However, although women underwent catheterization at rates comparable to men, they were less likely to proceed to PCI. Approximately, 45% of women were managed with catheterization alone, while a similar proportion underwent PCI. In contrast, among men, PCI following catheterization predominated (54.5%), indicating a higher likelihood to revascularization after invasive assessment. Management was consistent with HEART Score categories but differed by sex. Differences were most evident in intermediate-risk patients, where women were more often managed conservatively and men more invasively. In high-risk patients, women were less likely to undergo PCI despite undergoing catheterization. These findings suggest potential disparities in clinical decision-making and warrant further investigation into sex-specific management of acute chest pain.

TRENDS IN MORTALITY FROM ISCHEMIC HEART DISEASE AND CEREBROVASCULAR DISEASE IN BRAZILIAN WOMEN: A TIME-SERIES STUDY, 1990–2023

LARISSA LARISSA DE ANDRADE1; MARIA CRISTINA MEIRA FERREIRA1; PAOLO BLANCO VILLELA1; GLAUCIA MARIA MORAES OLIVEIRA1;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introduction/Background: Cardiovascular disease remains the leading cause of death among women in Brazil. Although overall declines in cardiovascular mortality have been observed, recent patterns indicate uneven progress across causes and age groups. Objectives: To characterize temporal patterns in cardiovascular mortality among Brazilian women, examining age-related differences and geographic variation between IHD and cerebrovascular diseases (CBVD). Methods: An ecological time-series analysis was conducted using national mortality data from DATASUS (1990–2023). Age-standardized mortality rates were calculated using 2022 Brazilian population as reference. Temporal patterns were assessed using moving averages and regression models. Analyses focused on premature mortality (<50 years), including proportional contribution and regional variation across federative units. Resultados e Conclusions: Between 1990 and 2023, mortality rates declined for both causes, with greater reduction observed for CBVD than for IHD. CBVD mortality decreased from 106.9 to 47.3 per 100,000 (−56%), whereas IHD declined from 81.9 to 44.3 per 100,000 (−46%). Among women under 50 years, CBVD mortality showed a marked decline of approximately 65% (APC −3.58%), whereas IHD decreased 38% (APC −1.53%). This divergence was accompanied by an increase in the proportional contribution of IHD (from 11.3% to 15.0%) and a reduction in CBVD (from 26.1% to 18.1%). Despite declining rates, absolute IHD deaths in this group increased by 33%, while CBVD deaths decreased by 31%. Nearly half of premature cardiovascular deaths occurred in women aged 40–49 years. In contrast, among women aged 50 years or older, both causes exhibited substantial and more parallel declines, with reductions of approximately 58% for CBVD and 49% for IHD. Regional analyses showed heterogeneous patterns for IHD, with reductions of 57% in the South and 41% in the Southeast, contrasted by stable or increasing trends in parts of the North and Northeast. In contrast, CBVD mortality declined more uniformly across the country. Despite overall declines in cardiovascular mortality among Brazilian women the persistence of slower declines in IHD, together with its increasing relative contribution among younger women, suggests a shift in the cardiovascular mortality profile. These findings highlight the need to reassess current prevention strategies, with greater attention to early detection and management of IHD n women, particularly in regions with less favorable trends.

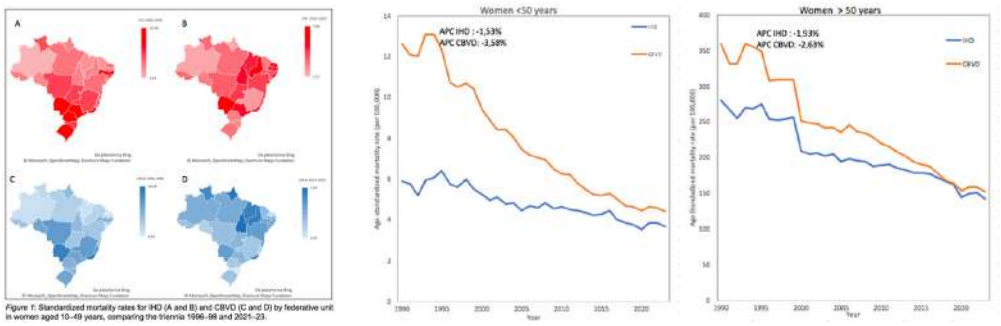

Figure 1: Standardized mortality rates for IHD (A and B) and CBVD (C and D) by federative unit in women aged 10–49 years, comparing the triennia 1990–98 and 2021–23.

ACUTE MYOCARDIAL INFARCTION AND ISCHEMIC STROKE IN A PATIENT WITH HYPERHOMOCYSTEINEMIA

JOSÉ EDUARDO RICETO LOYOLA JÚNIOR1; THIAGO ARTIOLI1; HENRIQUE TROMBINI PINESI1; ANDRÉ COSTA FERNEDA1; MICHELLY RODRIGUES CAVALCANTE1; EDUARDO FERREIRA AMORIM1; ISABELLA DE LUNA KALIL1; THIAGO VICENTE LIPARI PEREIRA1; FABIO GRUNSPUN PITTA1; FABIANA HANNA RACHED1; CARLOS VICENTE SERRANO JR.1; EDUARDO GOMES LIMA1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction: Atherosclerotic cardiovascular disease is a chronic multifactorial inflammatory disease, with endothelial dysfunction being one of its components. Mutations in the methylenetetrahydrofolate reductase (MTHFR) gene and the resulting hyperhomocysteinemia are risk factors for thromboembolic phenomena. Elevated homocysteine levels promote endothelial injury, smooth muscle cell proliferation, and activation of the coagulation cascade, increasing the risk of recurrent arterial and venous events. Case Description: A 44-year-old male with hypertension presented with typical exertional chest pain. Initial ECG revealed an extensive anterior STEMI. After dual antiplatelet therapy (DAPT) and tenecteplase fibrinolysis, he met reperfusion criteria with resolution of pain and ST-segment improvement. Transferred to a tertiary center in Killip class I, angiography showed a 90% proximal LAD stenosis and 50% circumflex artery stenosis. A successful PCI was performed on the LAD. On post-procedure day 2, the patient developed right hemiparesis and aphasia. Brain CTA demonstrated a subacute left parietal ischemic stroke; intra-arterial thrombolysis led to partial clinical improvement. Shortly after, he developed recurrent chest pain and new ST-segment elevation in leads V1-V6. Emergency angiography confirmed acute in-stent thrombosis, treated with aspiration thrombectomy, balloon angioplasty, new stent placement, and IABP support. Echocardiography showed an LVEF of 35% with anterior, septal, and apical akinesia, and an apical mural thrombus (7x5 mm). Thrombophilia screening revealed markedly elevated homocysteine (66.3 µmol/L; ref: 5.5–16.2) and a homozygous MTHFR C677T mutation. Protein C, S, Factor V Leiden, and antithrombin III were within normal limits. The patient was treated with tirofiban and therapeutic anticoagulation; hemodynamic support was successfully weaned. Conclusions: This case illustrates the clinical severity of severe hyperhomocysteinemia as a trigger for catastrophic thrombotic events (both coronary and cerebral). The acute in-stent thrombosis developed while the patient was on dual antiplatelet therapy and immediately following intra-arterial thrombolysis for his ischemic stroke. Homozygous MTHFR mutations should be considered in young patients presenting with multivessel or multisystemic thromboembolic events, as they may portend a significantly higher risk of recurrent, life-threatening complications.

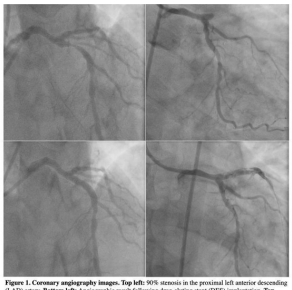

Figure 1. Coronary angiography images. Top left: 90% stenosis in the proximal left anterior descending (LAD) artery. **Bottom left:** Angiographic result following drug-eluting stent (DES) implantation. **Top right:** Acute in-stent occlusion shown in a different projection. **Bottom right:** Evidence of thrombus formation within the previously stented LAD segment.

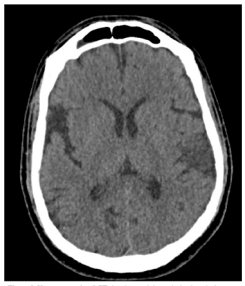

Figure 2. Non-contrast head CT showing a subtle cortical-subcortical hypoattenuating area in the left parietal lobe, representing a subacute ischemic infarct.

ACUTE MYOCARDIAL INFARCTION WITH ST-SEGMENT ELEVATION IN A PATIENT WITH BILATERAL CORONARY FISTULAS TO THE PULMONARY ARTERY TRUNK: CASE REPORT

ANA LAURA SANTOS DE ALMEIDA1; FABIO MASTROCOLA1; MARIA GABRIELA MEDEIROS CUNHA DE ARAUJO1; INGRID NÓBREGA ARAÚJO QUEIROZ1; ROBERTO MORENO MENDONÇA1; LILIAN KAROLINE DE OLIVEIRA ROCHA1; LETICIA DE FREITAS BARRADAS SIEBRA1; THALYTA DE SOUZA ALVES1;

(1) UFRN - NATAL - RN - BRASIL;

Introduction: Coronary arteriovenous fistulas (CAFs) are anomalous vascular communications that divert blood flow from the conventional myocardial capillary bed. Although rare, they represent the most frequent coronary arteriovenous malformation with the potential for hemodynamic repercussions. Although most young patients remain asymptomatic, the incidence of complications increases with age. The clinical spectrum is variable and depends on the caliber, origin, and drainage site of the fistula. For symptomatic cases, surgical ligation or percutaneous occlusion are the interventions frequently recommended. Case Description: Male patient, 50 years old, with a family history of coronary artery disease (CAD). In September 2020, the patient presented with an inferior wall STEMI (Delta-T 4h, Killip I). Coronary angiography revealed an 80% obstructive lesion in the proximal left anterior descending artery (LAD), 70% in the right coronary artery (RCA) – the culprit vessel – and 50% in the diagonal branch (Dg2). A large fistula from the RCA to the pulmonary artery trunk was also identified. Primary angioplasty with a drug-eluting stent was performed in the RCA. During hospitalization, computed tomography angiography confirmed the RCA fistula and showed thin fistulous tracts from the LAD to the pulmonary trunk as well. Eight days after the acute event, elective angioplasty of the LAD with two drug-eluting stents and a balloon pump was performed in Dg2. The initial echocardiogram demonstrated septal hypokinesis and moderate systolic dysfunction (LVEF 34%). In outpatient follow-up under optimized medical therapy, the patient progressed to NYHA functional class I, with sporadic atypical precordialgia and progressive improvement in ventricular function (LVEF 65% in February 2025). Conclusions: This report highlights the therapeutic challenge in the coexistence of bilateral coronary fistulas and severe obstructive CAD. Differentiation between atherosclerotic ischemia and the “coronary steal” phenomenon is essential for management. The favorable evolution under conservative treatment of the fistulas reinforces the safety of this strategy in asymptomatic patients, reserving invasive interventions for cases of persistent ischemia or documented hemodynamic overload.

(1) UNIVERSIDADE ESTADUAL DE LONDRINA - LONDRINA - PR - BRASIL; (2) UNIVERSIDADE ESTADUAL DE LONDRINA - LONDRINA - PR - BRASIL; (3) LONDRINA - LONDRINA - PR - BRASIL;

Introduction: Coronary artery anomalies are rare conditions and are generally asymptomatic; however, certain anatomical variations have a significant potential to cause myocardial ischemia, myocardial infarction, and sudden death. Case Description: A 77-year-old male with heart failure with improved ejection fraction (HFimpEF) secondary to tachycardia-induced cardiomyopathy, with a permanent pacemaker implanted due to atrial fibrillation (AF) refractory to rate and/or rhythm control requiring atrioventricular (AV) node ablation for symptomatic control. The patient presented with typical anginal chest pain (retrosternal, pressure-like, radiating to the left upper limb, worsened by exertion and relieved by rest). Coronary angiography was performed and showed no evidence of significant obstructive lesions. Coronary computed tomography angiography (CCTA) was subsequently performed for anatomical evaluation, revealing an anomalous right coronary artery (RCA) originating from the left coronary sinus with a malignant interarterial course between the aorta and the pulmonary artery. Due to prior AV node ablation and pacemaker dependence, the patient was unable to achieve the target heart rate during dobutamine stress echocardiography, resulting in a negative test for ischemia. Therefore, the examination was repeated with pacemaker reprogramming to increase the heart rate, allowing detection of progressive anginal pain with increasing heart rate, along with hypokinesia of the inferior wall at heart rates above 120 bpm. Based on these findings, angina secondary to the anomalous course of the right coronary artery was diagnosed. The patient was referred for surgical revascularization and underwent coronary artery bypass grafting (CABG) using the internal mammary artery to the RCA, along with ligation of the proximal segment of the RCA. After an uneventful recovery, the patient was discharged. At follow-up, he reported significantly improved symptoms and no chest pain. Conclusions: When identifying anomalous coronaries with non-significant lesions in a patient with angina, functional tests must determine the cause. However, the presence of a pacemaker may prevent the patient from achieving maximal heart rate with conventional pharmacological protocols, potentially leading to false-negative results. Increasing the heart rate through device reprogramming during functional testing is a strategy that can be used to achieve optimal conditions for the assessment of myocardial ischemia under stress.

CONGENITAL ATRESIA OF THE LEFT CORONARY ARTERY (CALM): CASE REPORT

ANA LUIZA IANNARELLA LACERDA1; ÍCARO BAZONI DA SILVA1; RAUL FERREIRA DE SOUZA MACHADO1; BRUNO DE OLIVEIRA FIGUEIREDO1; ISABELA JULIO DA SILVA1; LUIZ COELHO SOARES FIGUEIREDO1; LUCAS OSNI MARTINS ENNES DA SILVA1; LUCIANA IANNARELLA LACERDA2; GISELE MESSIAS MATTIOLI1; FELIPE JOSÉ MONASSA PITTELLA1;

(1) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL; (2) FUNDACAO TECNICO EDUCACIONAL SOUZA MARQUES - RIO DE JANEIRO - RJ - BRASIL;

Introduction: CALM is an extremely rare coronary anomaly, characterized by the absence of the ostium and/or trunk of the left coronary artery, with myocardial perfusion dependent on collateral circulation from the right coronary artery (RCA). Clinical presentation ranges from asymptomatic individuals to severe conditions including angina, heart failure, arrhythmias, and sudden death. Diagnosis is based on imaging methods, particularly coronary angiography, which demonstrates absence of the left ostium and retrograde flow through collaterals. Myocardial revascularization is usually recommended in symptomatic patients, but remains controversial in asymptomatic individuals without inducible ischemia. Case Description: A 53-year-old female with dyslipidemia and prediabetes, previously active, developed exertional chest pain over the past two months. Electrocardiography was normal. Echocardiogram (ECO) showed an ejection fraction of 65% with basal septal and inferior hypokinesia. The first exercise stress test achieved 10.34 METs and showed 0.25 mV horizontal ST depression at peak exercise. A second test, performed after four weeks of beta-blocker therapy, achieved 7.6 METs with no criteria for ischemia. Four weeks later, the patient suffered intense chest pain and was diagnosed with non-ST elevation myocardial infarction. Cardiac catheterization revealed occlusion of the left coronary artery trunk at its origin, with distal bed filling via grade 3 heterocollaterals. ECO showed no new alterations. Computed tomography coronary angiogram showed agenesis of the left coronary artery trunk, with the left anterior descending and circumflex arteries ending in a blind pouch and perfused by moderate-to-large caliber heterocollaterals from the RCA. No atherosclerotic disease was identified. Stress myocardial perfusion imaging after optimization of medical therapy showed 8.4 METs with no inducible ischemia. Conclusions: CALM is a rare anomaly with heterogeneous presentation and potentially serious outcomes, and its diagnosis can be challenging. This case highlights the importance of imaging modalities in diagnostic clarification and anatomical characterization, enabling appropriate risk stratification. In selected patients without inducible ischemia and with adequate collateral compensation, medical management may be a safe strategy. Therapeutic approach should be individualized aiming to optimize prognosis and reduce adverse events.

CORONARY ARTERY BYPASS GRAFTING IN A PATIENT WITH SEVERE MULTIVESSEL CORONARY ARTERY DISEASE AND HEMOPHILIA A: A MULTIDISCIPLINARY MANAGEMENT CASE REPORT

MARIA CLARICE AKIL1; BARBARA ELAINE DE JESUS ABUFAIAD1; GUILHERME PAULO TORRESINI1;

(1) REDE DOR - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Patients with hemophilia A undergoing cardiac surgery represent a major clinical challenge due to the high risk of perioperative bleeding and thrombotic complications. The coexistence of complex coronary artery disease (CAD) requires careful multidisciplinary planning involving cardiology, cardiac surgery, and hematology teams. Case Description: A 42 year-old male with type 2 diabetes, dyslipidemia, and hemophilia A (factor VIII deficiency) was admitted due to unstable angina. Echocardiography demonstrated preserved left ventricular ejection fraction (LVEF 68%) with mild mitral and tricuspid regurgitation. Coronary CT angiography revealed a calcium score of 67.8 (Agatston) and suggested severe triple-vessel CAD. Coronary angiography confirmed complex multivessel disease with surgical anatomy, including occluded left anterior descending artery with collateral filling, severe marginal branch lesions, and critical distal right coronary artery stenosis. Factor VIII replacement therapy was optimized under hematology supervision, including preprocedural and perioperative infusions. The patient underwent complete coronary artery bypass grafting (CABG) using left internal mammary artery and saphenous vein grafts under cardiopulmonary bypass (CPB time 145 min; aortic cross-clamp time 125 min). The postoperative period was complicated by mild bleeding requiring plasma transfusion and coagulation factor support. Electrocardiographic changes suggested postoperative pericarditis. Peak postoperative troponin I reached 4407 ng/L. Follow-up echocardiography demonstrated preserved ventricular function without significant pericardial effusion. Cardiac MRI showed minimal subepicardial late enhancement (4%) with preserved biventricular function. Factor VIII replacement was maintained for 14 days postoperatively according to hematology protocol. The patient progressed with stable hemodynamics, early mobilization, and no further complications. At discharge, he was asymptomatic and presented preserved cardiac function with mild residual pericardial effusion. Conclusions: This case highlights that CABG can be safely performed in patients with hemophilia A and complex CAD when guided by strict perioperative coagulation management and multidisciplinary collaboration. Individualized factor VIII replacement protocols are essential to balance bleeding and thrombotic risks, enabling favorable surgical outcomes.

MINOCA ASSOCIATED WITH PERIPHERAL ARTERIAL THROMBOSIS IN A YOUNG PATIENT USING ELTROMBOPAG FOR IMMUNE THROMBOCYTOPENIC PURPURA: CASE REPORT

FILIPE ALBERTO MOREIRA LIESNER1; GUSTAVO TOBIAS PIMENTA2; GUILHERME SOUZA LAMOUNIER3; FERNANDA ALVES GUIMARARAES4; ESTEVAO LANNA FIGUEIREDO5;

(1) REDE MATER DEI DE SAUDE - BELO HORIZONTE - MG - BRASIL; (2) FACULDADE DE MEDICINA UNIVERSIDADE PROFESSOR EDSON ANTONIO VELANO - UNIFENAS - BELO HORIZONTE - MG - BRASIL; (3) PONTIFICIA UNIVERSIDADE CATOLICA DE MINAS GERAIS - CAMPUS BETIM - BETIM - MG - BRASIL; (4) CENTRO UNIVERSITARIO UNIATENAS - PARACATU - MG - BRASIL; (5) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introduction: Acute coronary syndrome with non-obstructive coronary arteries (MINOCA) represents a challenging diagnosis, requiring integration of clinical, laboratory, and imaging data to define etiology. Thrombopoietin receptor agonists, such as Eltrombopag, used in the treatment of immune thrombocytopenic purpura (ITP), are associated with increased risk of arterial and venous thrombotic events, even in young patients without traditional cardiovascular risk factors. Case Description: A 34-year-old female with refractory ITP on Eltrombopag presented with sudden resting chest pain. Electrocardiogram showed T wave inversion in V1–V5, associated with elevated high-sensitivity troponin. Coronary angiography revealed epicardial coronaries without significant obstructive lesions. Twenty-four hours post-procedure, the patient developed severe pain, cyanosis, and signs of digital ischemia in the right upper limb distal to the radial puncture site. Vascular ultrasonography confirmed right radial artery thrombosis. During hospitalization, platelet counts ranged from 391,000 to 450,000/µL. Due to the pro-thrombotic state related to Eltrombopag, the drug was suspended and therapeutic anticoagulation initiated. Cardiac magnetic resonance imaging revealed transmural late gadolinium enhancement in the anterior wall, confirming ischemic myocardial injury and establishing the diagnosis of MINOCA likely of thrombotic etiology. This case illustrates the temporal association between Eltrombopag use and arterial thrombotic events in different vascular territories. Although rare, thrombopoietin receptor agonists can induce a pro-thrombotic state independent of marked thrombocytosis. The etiological investigation of MINOCA requires exclusion of obstructive coronary disease and diagnostic complement with cardiac magnetic resonance, crucial for confirmation of myocardial necrosis and definition of the underlying pathophysiological mechanism. Conclusions: MINOCA represents a complex and potentially serious clinical condition, particularly in young patients without evident obstructive coronary disease. Etiological investigation is essential for diagnostic confirmation and therapeutic guidance. Early recognition of the thrombotic mechanism allows targeted management and reinforces the importance of a multimodal approach in these patients.

MULTIMODAL APPROACH IN HIGH-RISK CTEPH AND CRITICAL LEFT MAIN CORONARY ARTERY DISEASE: A CASE REPORT

MATHEUS HENRIQUE DE JESUS LIMA1; ROBERTA ABRÃO PACHECO RODRIGUES DE QUEIROZ1; THAÍNE INÁCIO DE MENDONÇA1; MATHEUS FERREIRA GONÇALVES1; VINICIUS RODRIGUES FRANÇA1; TAÍS LORRANE MENDES SILVA CRISTOVÃO1; AGUINALDO FIGUEIREDO DE FREITAS JUNIOR1;

(1) UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL;

Introduction: Chronic thromboembolic pulmonary hypertension (CTEPH) is a potentially treatable condition, yet frequently underdiagnosed and associated with high morbidity and mortality. Its nonspecific presentation often delays early diagnosis. The coexistence of complex coronary artery disease further increases therapeutic complexity, requiring a multidisciplinary approach. We report an illustrative case of this scenario. Case Description: A 59-year-old male patient with hypertension, diabetes, and a history of smoking, had been diagnosed with Group 4 pulmonary hypertension—CTEPH—4 years earlier. He progressed with limiting angina and dyspnea (CCS/NYHA IV), as well as syncope preceded by chest pain. Hemodynamic assessment revealed a critical condition: right ventricular systolic pressure of 103 mmHg (echocardiography), mean pulmonary artery pressure of 58 mmHg, cardiac index of 1.6 L/min/m², and pulmonary vascular resistance of 15.5 Wood units (right heart catheterization). NT-proBNP was 2424 pg/mL. Coronary angiography demonstrated a 70% distal left main coronary artery (LMCA) lesion (trifurcation) and a 70% proximal left anterior descending (LAD) lesion. Discussion and Management: Due to low cardiac output and the severity of pulmonary hypertension, the risk of coronary artery bypass grafting (CABG) and pulmonary endarterectomy (PEA) was considered prohibitive. The Heart-Pulmonary Team opted for percutaneous coronary intervention (PCI) of the LMCA and LAD with drug-eluting stent implantation as a myocardial protection strategy and clinical "bridge." After stabilization, balloon pulmonary angioplasty (BPA) was scheduled, as recommended for inoperable or high-risk cases (Class I, Level B – ESC 2022). Optimized medical therapy included high-intensity statin therapy (LDL target <50 mg/dL), SGLT2 inhibitors, and transition to short-term triple antithrombotic therapy in the periprocedural period for one week, followed by dual therapy (oral anticoagulant plus clopidogrel) for 12 months. Conclusions: This case highlights the importance of percutaneous revascularization as hemodynamic support to enable subsequent pulmonary mechanical interventions in patients with extreme surgical risk, demonstrating the effectiveness of a personalized and multimodal approach in referral centers.

PURULENT PERICARDITIS AFTER ACUTE MYOCARDIAL INFARCTION: A VARIANT OF DRESSLER?

ANA ELISA DA SILVA FERNANDES1; GABRIELA MEDEIROS JUNQUEIRA DE PÁDUA1; JÉSSICA CAMPIONI NASCIMENTO1; THAÍS FERNANDES DE ARAÚJO KUNH1; TALITA TIEMI HOSHINO BUENO1; CHARLENE TROIANI DO NASCIMENTO1;

(1) UNIVERSIDADE DO OESTE PAULISTA - UNOESTE - PRESIDENTE PRUDENTE - SP - BRASIL;

Introduction: Dressler syndrome(DS), also called post-myocardial infarction syndrome, is characterized as a form of secondary pericarditis that may present with or without pericardial effusion resulting from injury to the heart or pericardium. Case Description: A 50-year-old man was referred to the emergency department of a public hospital with back pain at rest radiating to the left hemithorax for three days, associated with a measured fever of 39°C and dyspnea requiring supplemental oxygen. He had been recently hospitalized at the same institution and discharged one week earlier due to an inferior ST-segment elevation acute myocardial infarction that occurred 25 days prior, for which delayed coronary angioplasty was performed on the second left marginal branch. Cardiac catheterization revealed multivessel coronary artery disease. The patient was an active smoker with a history of previous deep vein thrombosis, diabetes mellitus, and heart failure with reduced ejection fraction of 40%, associated with moderate mitral and tricuspid regurgitation, grade II diastolic dysfunction in addition to an intracavitary thrombus in the same chamber. Stent thrombosis was ruled out, with myocardial necrosis markers showing only a mild isolated elevation of troponin and electrocardiogram demonstrating diffuse ST-segment elevation. Hematology evaluation excluded hereditary thrombophilias. Blood cultures were positive for Staphylococcus aureus, leading to initiation of antibiotic therapy and transfer to the intensive care unit. The patient subsequently developed mixed shock (distributive and cardiogenic) requiring hemodialysis. Transthoracic echocardiography showed worsening of the ejection fraction to 28%, with an image suggestive of rupture of the LV lateral wall and significant pericardial effusion with systolic collapse of the right atrium (Figure 1). These findings were confirmed by transesophageal echocardiography, and the patient was referred for exploratory mediastinotomy. Purulent secretion was drained after pericardial resection with the presence of fibrin, without evidence of ventricular wall discontinuity, thus ruling out rupture (Figure 2). In the postoperative period, the patient evolved with refractory vasoplegic shock and, on the third day, presented cardiac arrest in pulseless electrical activity without return of spontaneous circulation, progressing to death. Conclusions: Dressler syndrome remains a clinical challenge due to its variable presentation and potential for severe outcomes.

21835

SPONTANEOUS CORONARY ARTERY DISSECTION CONCOMITANT WITH NEWLY DIAGNOSED SECONDARY HYPERTENSION AS THE FIRST MANIFESTATION OF ENDOGENOUS CUSHING SYNDROME: A CASE REPORT

BRENDA BADARÓ REIS1; RICARDO PEIXOTO OLIVEIRA1; JOBERTO PINHEIRO SENA1; JOANA BARRETO BITTENCOURT1;

(1) SANTA CASA DE MISERICORDIA DA BAHIA - HOSPITAL SANTA IZABEL - SALVADOR - BA - BRASIL;

Introduction: Spontaneous coronary artery dissection is a cause of non-atherosclerotic and non-iatrogenic acute coronary syndrome and may present as myocardial infarction with non-obstructive coronary arteries. It is characterized by an intramural hematoma within the coronary artery wall, usually related to vasa vasorum disruption or underlying arterial wall abnormalities, leading to luminal compression, impaired coronary blood flow, and myocardial necrosis. Although considered an uncommon condition, it has been increasingly recognized, particularly among young women and pregnant or postpartum patients. Elevated cortisol levels may contribute to vascular fragility and arterial wall weakening, potentially predisposing to this condition. Case Description: A 40-year-old obese woman with recently diagnosed and poorly controlled hypertension presented to the emergency department complaining of severe chest pain lasting two hours, radiating to the left arm and jaw. Physical examination showed no relevant abnormalities. The electrocardiogram demonstrated anterior ST-segment elevation. Urgent coronary angiography was performed and revealed normal right coronary and circumflex arteries, while the left anterior descending coronary artery showed diffuse narrowing of the distal segment, suggestive of type 2b spontaneous coronary artery dissection (Image 1). Cardiac magnetic resonance imaging revealed subendocardial, non-transmural late gadolinium enhancement in the mid-anteroseptal and apical walls, consistent with myocardial infarction (image 1). After clinical stabilization, a comprehensive investigation was performed. Abdominal computed tomography (image 2) showed bilateral adrenal masses. The post-dexamethasone cortisol suppression test was compatible with endogenous hypercortisolism. The diagnosis of Cushing syndrome was established, and surgical resection was subsequently performed. Conclusions: Spontaneous coronary artery dissection is an important cause of MINOCA. This case suggests endogenous hypercortisolism as a potential contributor to vascular wall fragility, hypertension, and coronary vulnerability. In young patients with SCAD, especially when associated with newly diagnosed or poorly controlled hypertension, secondary causes should be investigated. Early recognition of Cushing syndrome may guide treatment, prevent recurrence, and improve prognosis.

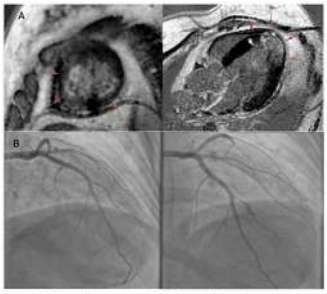

Figure 1. A. Cardiac magnetic resonance imaging showing late gadolinium enhancement consistent with acute myocardial infarction (red arrows). B. Coronary angiography of the left anterior descending artery showing diffuse narrowing of the distal segment, without other signs of coronary artery disease, consistent with type 2b spontaneous coronary artery dissection.

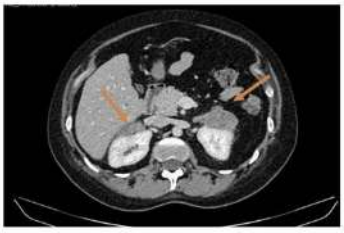

Figure 2. Computed tomography showing bilateral adrenal masses, consistent with adrenal lesions identified during the investigation of secondary hypertension and endogenous hypercortisolism.

AORTIC ARCH DISSECTION AND PSEUDOANEURYSM AFTER HIGH-IMPACT TRAUMA: MANAGEMENT CHALLENGES IN A POLYTRAUMA PATIENT

ANA LAURA SANTOS DE ALMEIDA1; FABIO MASTROCOLA1; MARIA GABRIELA MEDEIROS CUNHA DE ARAUJO1; INGRID NÓBREGA ARAÚJO QUEIROZ1; ROBERTO MORENO MENDONÇA1; LILIAN KAROLINE DE OLIVEIRA ROCHA1; LETICIA DE FREITAS BARRADAS SIEBRA1; DAVI NUNES SANTOS DE ALMEIDA2;

(1) UFRN - NATAL - RN - BRASIL; (2) UNIVERSIDADE POTIGUAR (UNP) - NATAL - RN - BRASIL;

Introduction: Traumatic aortic dissection results from high-impact deceleration forces and is the second most common cause of death in trauma patients. The aortic isthmus is the most frequent site, although the aortic arch can also be affected. Computed tomography angiography (CT angiography) is the diagnostic gold standard, with high sensitivity and specificity. Strict control of blood pressure and heart rate is essential to prevent rupture and extension of the lesion. Case Description: Male patient, 46 years old, truck driver, victim of a truck collision (motorcycle-truck). The patient initially presented with severe thoracoabdominal trauma, including aortic arch laceration, a 5.5 cm diameter pseudoaneurysm, traumatic diaphragmatic hernia on the left, bilateral hemothorax, and multiple rib fractures (3rd to 10th on the left). Initial management included laparotomy for reduction of herniated contents and herniorrhaphy, as well as bilateral thoracostomy. During stabilization, the patient developed limb pain and sweating, and a Stanford A-type aortic arch dissection was diagnosed via CT scan. The patient underwent complex surgical correction with interposition of a Dacron prosthesis between the brachiocephalic trunk and the left carotid artery (in a Y-shape), along with implantation of an endoprosthesis in the aortic arch and descending aorta. The cardiopulmonary bypass (CPB) time was 61 minutes. Postoperatively, the patient presented with post-pericardiotomy syndrome, treated with drainage of 400 mL of serosanguineous fluid and administration of colchicine. The patient was discharged from the hospital in good general condition, breathing normally and ambulating, maintaining outpatient follow-up with CT angiography, which demonstrated aortic prostheses without signs of leakage. Conclusions: The success in managing traumatic aortic dissection in polytrauma patients depends on early diagnosis and a precise surgical approach. The case highlights the complexity of hybrid treatment (open and endovascular surgery) and the need for vigilance for postoperative complications, such as post-pericardiotomy syndrome, ensuring long-term survival and stabilization.

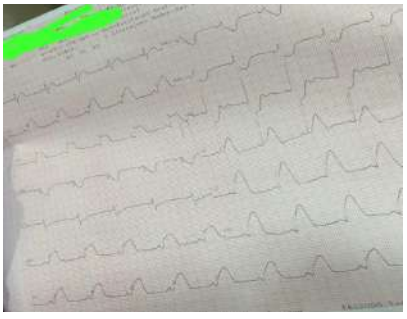
HIGH-VOLTAGE ELECTRICAL INJURY TRIGGERING ACUTE CORONARY STENT THROMBOSIS: A CASE REPORT



VINÍCIUS MENEZES ROZENWINKEL1; JULIA HELIOTERIO CAMPOS1; RUI NUNOMURA XAVIER1; MARIA ANTONIA FRIZZERA DE CARVALHO1; MURILLO JOSÉ DE ABREU ACERBI1; LEANDRO RUA RIBEIRO1;

(1) UNIVERSIDADE VILA VELHA - VILA VELHA - ES - BRASIL;

Introduction: Electrical injuries are associated with a wide spectrum of cardiac complications, including arrhythmias and myocardial damage. However, acute coronary stent thrombosis following high-voltage electrical shock is rarely described. We report a case of acute coronary stent occlusion immediately after electrical injury, highlighting a possible causal relationship. Case Description: A 64-year-old male electrician with a history of coronary artery disease treated with percutaneous coronary intervention and stent implantation in the circumflex artery eight years earlier presented with typical chest pain immediately after sustaining a high-voltage electrical injury (13,000 V) at work. The initial electrocardiogram showed ST-segment elevation in the inferior, anterior, and apical leads, with reciprocal ST-segment depression in the septal lead, consistent with acute inferoapical ST-segment elevation myocardial infarction. Emergency coronary angiography revealed acute thrombotic occlusion at the distal edge of the previously implanted circumflex stent, without significant obstructive lesions in the remaining coronary segments. During the procedure, the patient developed sustained ventricular tachycardia with hemodynamic instability, requiring immediate electrical cardioversion. Revascularization was successfully performed, restoring coronary flow and leading to clinical stabilization. The immediate onset of ischemic symptoms after the electrical accident, together with the angiographic findings and the absence of other evident triggers, supports a plausible association between the electrical injury and acute stent thrombosis. A potential mechanism may involve local electrical and thermal endothelial damage at the stent site, promoting thrombus formation and myocardial infarction. The marked temporal relationship between the accident and symptom onset, as well as the lack of significant obstructive disease elsewhere, reinforces the hypothesis that the electrical insult acted as the precipitating trigger of the coronary event. This case underscores the need for rapid recognition and immediate invasive management. Conclusions: High-voltage electrical injury may represent a rare trigger for acute coronary stent thrombosis in patients with previous coronary stenting. The marked temporal relationship, compatible electrocardiographic findings, and angiographic confirmation of stent-edge occlusion make this association clinically compelling and reinforce the importance of rapid recognition and reperfusion.

18763

LAVA-ECMO AS A RESCUE STRATEGY FOR REFRACTORY LEFT VENTRICULAR DISTENSION DURING VA-ECMO IN FULMINANT MYOPERICARDITIS: A CASE REPORT

ISADORA HAETINGER ANDRIOTTI ALVES1; CLAUDIA SEVERGNINI EUGÊNIO1; BRENDA GONÇALVES DONAY ALVES1; LETICIA PEREIRA DE SOUZA1; TANIA MARIA MASSUTI1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction: Fulminant myopericarditis is a rare and potentially fatal condition, frequently associated with rapid hemodynamic deterioration and the need for advanced mechanical circulatory support. Among the complications of venoarterial extracorporeal membrane oxygenation (VA-ECMO), left ventricular distension represents a critical event that can compromise myocardial recovery. Case Description: A 29-year-old female patient, previously healthy, was admitted after experiencing flu-like symptoms and developed acute myopericarditis. The initial echocardiogram showed a left ventricular ejection fraction (LVEF) of 57% and moderate pericardial effusion with signs of increased intrapericardial pressures. She developed cardiac tamponade and underwent subxiphoid pericardial window surgery. In less than 24 hours, she experienced abrupt hemodynamic deterioration, with severe biventricular dysfunction (LVEF 15%). During pulmonary artery catheterization, the patient developed ventricular tachycardia followed by pulseless electrical activity, which resolved after advanced resuscitation maneuvers. The patient presented refractory cardiogenic shock, classified as SCAI E, and VA-ECMO was initiated. Despite the support, persistent left ventricular distension was observed, with acute dilation and impaired emptying on echocardiography. As an initial unloading strategy, an intra-aortic balloon pump was implanted, without clinical or echocardiographic improvement, with an LVEF of 9%. Given the refractory overload, left ventricular decompression was performed via LAVA-ECMO with percutaneous atrioseptostomy, allowing for a reduction in filling pressures and resolution of ventricular distension. After the intervention, there was hemodynamic stabilization, control of arrhythmias, and progressive recovery of ventricular function, with LVEF 42% during weaning and subsequent normalization of left ventricular function (LVEF 57%), allowing for decannulation. There were 19 days of hospitalization in intensive care. Conclusions: The use of LAVA-ECMO proved decisive for hemodynamic stabilization and myocardial recovery, highlighting its potential as a rescue strategy in fulminant myopericarditis. Early recognition of this complication and timely intervention were crucial for shock reversal and improved prognosis. The study was approved by the Institutional Research Ethics Committee (CAAE: 91641525.0.0000.5327)

CARDIAC AMYLOIDOSIS DUE TO RARE ASP58ALA VARIANT WITH RECURRENT PERICARDIAL EFFUSION PROGRESSING TO CARDIAC TAMPONADE IN THE CONTEXT OF SUSPECTED PULMONARY TUBERCULOSIS

KELEN MARQUES DE SOUZA1; GUSTAVO GUARACY LOPES PEREZ2; ALINE BRASIL ARANHA3; NAYARA DO CARMO SANTOS LIMA3; MATHEUS MARTINS MONTEIRO3; MARCELA OLIVEIRA DE AZEVEDO3; DIEGO CORREA LAMBERTI3; MARINA DE CASTRO FERREIRA3; KATIA DO NASCIMENTO COUCEIRO2; ALVARO QUEIROZ MAGALHAES2; RENATA TEODORA JALES BARRETO1; JOAO MARCOS BEMFICA BARBOSA FERREIRA3;

(1) UNIVERSIDADE FEDERAL DO AMAZONAS - MANAUS - AM - BRASIL; (2) UEA - MANAUS - AM - BRASIL; (3) HOSPITAL DO CORACAO FRANCISCA MENDES - MANAUS - AM - BRASIL;

Introduction: Transthyretin cardiac amyloidosis is a progressive infiltrative disease. Pericardial effusion is common, although cardiac tamponade is a rare complication. The association with pulmonary tuberculosis may accelerate the progression of pericardial effusion and trigger hemodynamic instability. We report a case of rapid progression to cardiac tamponade in a patient with an aggressive genetic variant and suspected associated pulmonary tuberculosis. Case Description: A 66-year-old female patient with mixed transthyretin amyloidosis (neurological and cardiac involvement) carrying the rare Asp58Ala variant, on regular treatment with inotersen. In January 2026, she was hospitalized for investigation of massive hemoptysis. Chest computed tomography revealed a thick-walled cavitary lesion in the right upper lobe, suggestive of tuberculosis, and a 40-mm pericardial effusion, although without echocardiographic signs of diastolic restriction. The patient requested discharge against medical advice before completion of the investigation. In February 2026, she was readmitted with daily episodes of syncope on minimal exertion and hypotension. Echocardiography demonstrated progression of the pericardial effusion and the appearance of tamponade physiology, with respiratory variation of tricuspid inflow of 42% and mitral inflow of 22%. Emergency pericardiocentesis was performed, draining 550 mL of serosanguinous fluid with immediate clinical improvement. Acid-fast bacilli testing in the pericardial fluid was negative. Bronchoscopy with bronchoalveolar lavage was performed to investigate Mycobacterium tuberculosis. Conclusions: The Asp58Ala transthyretin amyloidosis variant may progress to cardiac tamponade, a rare complication, particularly in the presence of suspected pulmonary tuberculosis. Syncope in patients with amyloidosis requires immediate echocardiographic evaluation to rule out tamponade. This case highlights the importance of genetic characterization for prognostic definition and of comprehensive etiological investigation in patients with recurrent pericardial effusion.

16134

CARDIONEUROABLATION IN ELDERLY PATIENT - A CASE REPORT

ALBERTO PEREIRA FERRAZ1; ESTEBAN WISNIVESKY ROCCA RIVAROLA1; MAURICIO IBRAHIM SCANAVACCA1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction: Cardioneuroablation (CNA) has been presented as an alternative to pacemaker implantation for patients with refractory vasovagal syncope and demonstrated cardioinhibition. The ELEGANCE multicenter study has included elderly patients and expanded the age range for this procedure. This case reports one of the oldest patients submitted to catheter ablation of ganglionated plexi to highlight the possibility of this treatment at this age. Case Description: A 78-year-old man with a history of syncope after meal and documentation of pauses and advanced atrioventricular(AV) block came for evaluation for pacemaker implantation. He had been feeling dizzy after lunch for the past six months, but had never experienced syncope until then. He was otherwise healthy, with no other complaints and no significant medical history. Of note, he had practiced sports since childhood and played soccer as a professional for about 20years. After retirement, he kept practicing. He was used to taking large meals preceding the symptoms of dizziness. The 12-lead ECG showed sinus rhythm with first-degree AV block and narrow QRS. A 24-hour Holter monitor revealed 464 pauses greater than 2s (longest 4.3s) and episodes of advanced AV block during the night (including third-degree AV block). Atropine test resulted in an increasement in heart rate (57bpm to 78bpm) and a decrease in PR interval (280ms to 200ms). In the electrophysiology study, vagal stimulation elicited an AV block response of up to 6s. In the right atrium, a large area corresponding to the right inferior ganglionated plexus(RIGP) in the posterior aspect of the coronary sinus ostium also elicited prolonged AV block. RF ablation of this large area was performed using an irrigated ablation catheter guided by Surpoint. Following ablation, repeat high-frequency stimulation in the right internal jugular vein and at the RIGP was performed, and the AV nodal response was no longer reproduced. After the procedure, the patient had no further complaints of dizziness or syncope. An initial repeated Holter monitor revealed a PR interval < 200 ms, no further abnormal AV conduction, and no pauses. Conclusions: CNA was proposed in this case after the functional nature of AV block became unequivocal. Advanced age alone should not be an absolute exclusion criteria for CNA, provided the patient does not have specific contraindications. The main decision-making factors should rely on clinical characteristics and the assessment of frailty, rather than just chronological age.

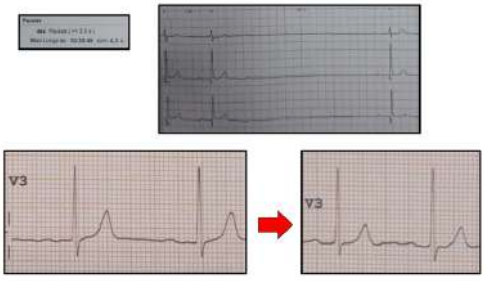

Figure 1: A -Holter monitor before Cardioneuroblation. B- Atropine test increased heart rate (57 bpm to 78 bpm) and a decreased in PR interval (280 ms to 200 ms)

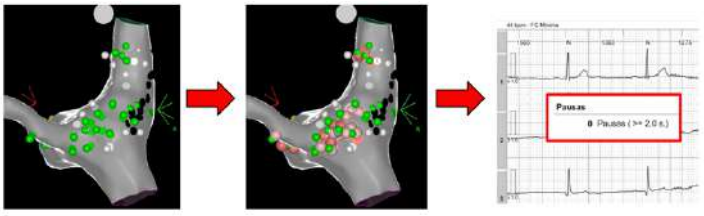

Figure 2: Electroanatomic mapping of posterior wall of RA using CARTO system. Fixed vagal stimulation parameters throughout the procedure were: pulse duration 5 seconds; frequency 30 Hz; pulse width 50 µs; amplitude 0.5–1 V/kg. A - Green points indicates the area where AV block could be elicited by vagal stimulation, while white points indicates it limits (no AV block elicited). Black dots indicates proximity to the phrenic nerve. Pink points indicates ablation lesions.

CORONARY VASOSPASM AS A CAUSE OF SYNCOPE AND POLYMORPHIC NON-SUSTAINED VENTRICULAR TACHYCARDIA IN A YOUNG PATIENT WITHOUT STRUCTURAL HEART DISEASE

RAFAEL CASTRO DIAS1; ANA CRISTINA PINOTTI PEDRO LUDOVICE1; GUILHERME FENELON1; CRISTIANO DIETRISCH1; GUY FERNANDO DE ALMEIDA PRADO1; PEDRO LEMOS1; FABIO SILVA BAPTISTA JUNIOR1;

(1) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL;

Introduction: Syncope associated with chest pain and ventricular arrhythmias in young patients without apparent structural heart disease represents a diagnostic challenge and requires careful etiological investigation. Coronary vasospasm, although frequently underdiagnosed, may present with transient ischemia, ST-segment changes, and potentially life-threatening arrhythmias, even in the absence of obstructive coronary artery disease. Acetylcholine coronary reactivity testing is a key diagnostic tool for this condition. Case Description: A 40-year-old previously healthy male patient presented to the emergency department after an episode of syncope preceded by chest pain and palpitations. Echocardiography, coronary computed tomography angiography, and cardiac magnetic resonance imaging demonstrated preserved biventricular function and no evidence of structural heart disease. Tilt-table testing was positive for a vasodepressor response. Monitoring with an implantable loop recorder revealed frequent premature ventricular contractions, episodes of polymorphic non-sustained ventricular tachycardia (NSVT), and transient ST-segment elevation during symptoms. Coronary angiography demonstrated a myocardial bridge in the mid-segment of the left anterior descending artery, with significant systolic compression. Myocardial perfusion scintigraphy and exercise stress testing were negative for ischemia. Due to persistent symptoms and dynamic electrocardiographic changes, acetylcholine coronary reactivity testing was performed, demonstrating epicardial coronary spasm with significant luminal reduction of the left coronary artery, associated with ST-segment depression and T-wave inversion, which resolved after nitrate administration. Microvascular spasm was also observed, characterized by ST-segment depression in both right and left coronary territories without angiographic luminal reduction, in addition to transient atrioventricular block during infusion. Treatment with verapamil was initiated, resulting in complete symptom resolution and no recurrence of arrhythmias. Conclusions: Coronary vasospasm, involving both epicardial and microvascular dysfunction, should be considered in the differential diagnosis of syncope associated with ventricular arrhythmias and dynamic electrocardiographic changes in young patients with non-obstructive coronary arteries. Acetylcholine testing was decisive for establishing the diagnosis and guiding specific therapy, leading to a favorable clinical outcome.

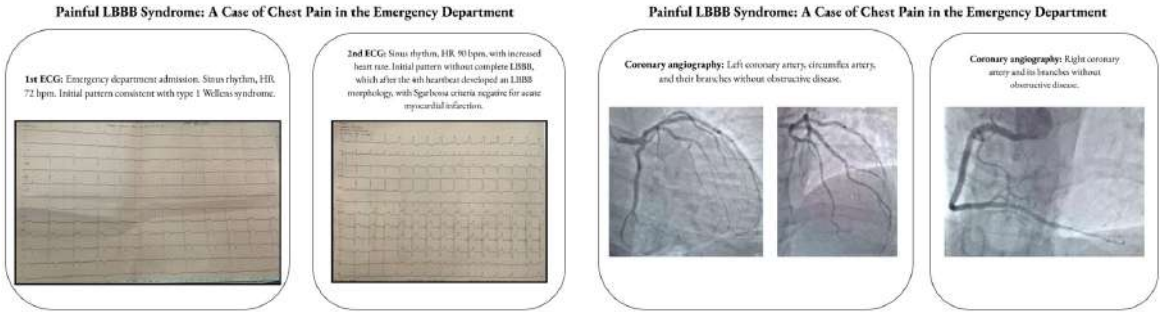
CORONARY-CAMERAL FISTULA AFTER LEFT BUNDLE BRANCH AREA PACING: A RARE CAUSE OF CHEST PAIN

FELIPE BARBOSA BOTELHO ROLIM1; VITOR DA SILVA DIAS1; BERNARDO NOYA ALVES DE ABREU1; FELIPE AUGUSTO ORTENCIO1; JUAN CARLOS ZERPA ACOSTA1; RAYZA KARLLA SALES ARAÚJO1; ELTON SIMIONATO SCURO1; MARIEL MARA PERON DE OLIVEIRA1; ANDRE KEVEN VIANA DA SILVA1; RAFAEL CRISTIANO BRANDL1; ANA CAROLINE PARAGUAY MARTINS2; BRUNA ORBITE GARCIA1;

(1) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL; (2) INSTITUTO DE MEDICINA INTEGRAL PROFESSOR FERNANDO FIGUEIRA - IMIP - RECIFE - PE - BRASIL;

Introduction: Conduction system pacing, specifically left bundle branch area pacing (LBBAP), is a physiological method to maintain ventricular synchrony. However, the deep septal lead penetration required poses risks of vascular trauma. Coronary-cameral fistula (CCF) is an exceptionally rare iatrogenic complication of this technique. As physiological pacing becomes more prevalent, identifying such adverse events is essential for postoperative management and patient safety. Case Description: A 58-year-old male with coronary artery disease (four previous infarctions and recent multivessel percutaneous intervention) and heart failure with reduced ejection fraction underwent a dual-chamber implantable cardioverter-defibrillator (ICD) placement with LBBAP. On the second postoperative (PO) day, an atrial lead displacement required repositioning. The following day, he developed severe retrosternal chest pain, refractory to intravenous nitroglycerin. Troponin levels rose significantly (peak 312 ng/L; reference 19.8 ng/L). Urgent angiography showed no new obstructive lesions but revealed a CCF exactly at the LBBAP lead fixation site. ICD interrogation showed optimal parameters. Due to hemodynamic stability, the patient was managed conservatively with high-dose opioids and intravenous nitroglycerin in the intensive care unit. Following gradual clinical improvement and analgesic titration, he was discharged on the 10th PO day. Conclusions: CCF can mimic acute coronary syndrome through refractory pain and troponin elevation, even with optimal pacing parameters. Multimodality imaging is crucial for diagnosis. In stable patients, a conservative approach focusing on symptom control may be a safe alternative to invasive interventions like embolization or lead extraction, avoiding the risks of removing a deep septal lead.



18742

PAINFUL LEFT BUNDLE BRANCH BLOCK (LBBB) SYNDROME: A CASE OF CHEST PAIN IN THE EMERGENCY DEPARTMENT

ANDRE ASSIS RODRIGUES1;

(1) UNIMED SERRANA - NOVA FRIBURGO - RJ - BRASIL;

Introduction: Painful LBBB syndrome is a rare condition characterized by the presence of intermittent LBBB during episodes of chest pain, without evidence of myocardial ischemia. Painful left bundle branch block syndrome was first described by William V. Vieweg et al. in 1976 in the article “Rate-dependent left bundle branch block...” published in Chest. The main differential diagnosis is acute coronary syndrome (ACS), particularly in the setting of dynamic electrocardiographic changes during chest pain. A systematic review identified only 50 published cases worldwide, highlighting the rarity of this condition. Case Description: We report the case of a 51-year-old woman with a history of obesity and systemic arterial hypertension. The patient had been evaluated at another hospital the day before admission due to exertional oppressive chest pain for three days, relieved by rest (typical angina). She was admitted following the chest pain protocol, and the admission ECG demonstrated sinus rhythm (72 bpm) with a pattern compatible with type 1 Wellens syndrome. On admission, vital signs and physical examination were normal, with a HEART score of 6. During episodes of chest pain, dynamic ECG changes occurred, with the appearance of new-onset LBBB, initially interpreted as high-risk ACS. The patient underwent urgent coronary angiography, which demonstrated no significant coronary artery obstruction. Laboratory tests, including high-sensitivity troponin, as well as chest radiography and echocardiography, were normal. After clinical assessment and review of complementary tests, the diagnosis of painful LBBB syndrome was established. Following 48 hours of monitoring, symptoms improved and the ECG normalized. The patient was discharged with treatment directed toward cardiovascular risk factors, including beta-blocker therapy, in addition to recommendations for supervised physical activity. She was referred for outpatient cardiology follow-up. Conclusions: This case highlights the importance of broadening the diagnostic approach in patients presenting to the emergency department with chest pain and dynamic ECG changes. Given the rarity of this clinical condition, it is essential that patients are informed about the diagnosis in order to avoid repeated invasive investigations during future episodes of chest pain. Furthermore, adherence to medical therapy and supervised exercise should be encouraged, with appropriate cardiology follow-up for symptom control and management of comorbidities.

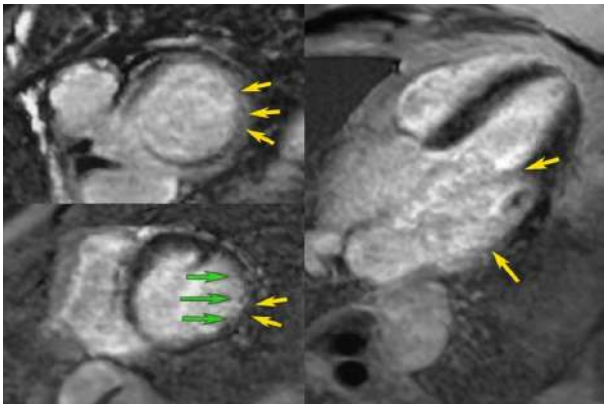
SIMPLIFIED LEFT BUNDLE BRANCH AREA PACING GUIDANCE USING A MANUFACTURER PACING SYSTEM ANALYZER: COMPARISON WITH AN ELECTROPHYSIOLOGY RECORDING SYSTEM, A CASE SERIES

ANDRES DI LEONI FERRARI1; BERNARDO NEUHAUS LIGNATI1; GUSTAVO RAMIRES1; GUSTAVO CHIARI CABRAL2; JESSICA CAROLINE FELTRIN WILLES1; THIAGO CAMARGO MOREIRA1; LUISA RODRIGUES NUNES DE MARAES1; DANIEL NUNES DA ROSA1;

(1) PUCRS - PORTO ALEGRE - RS - BRASIL; (2) UNIVATES - UNIVERSIDADE DO VALE DO TAQUARI - LAJEADO - RS - BRASIL;

Introduction: Left bundle branch area pacing (LBBAP) requires confirmation of conduction system capture using intracardiac electrograms and ECG criteria. However, dependence on an electrophysiology recording system (EP-RS) may limit broader adoption. We evaluated whether a conventional manufacturer pacing system analyzer (PSA) could reliably reproduce EP-RS measurements during LBBAP implantation, aiming to simplify and expand access to conduction system pacing procedures. Case Description: We prospectively analyzed five consecutive patients undergoing LBBAP implantation at a tertiary university hospital in Porto Alegre, Brazil. We compared one brand PSA measurements against EP-RS from two different manufacturers. Surface lead positioning was modified to obtain PSA-derived V1 and V6 signals analogous to those displayed by the EP-RS, combined with intracardiac electrogram assessment. Measurements obtained from PSA and EP-RS during implantation were compared, including baseline QRS duration, paced QRS duration, V6 R-wave peak time (V6-RWPT), V6–V1 interpeak time (IPT), and morphology-based criteria for LBBAP, including the presence of r′/R′ in V1. PSA and EP-RS measurements were closely aligned.Initial W morphology in V1 was observed in both cases. Final paced QRS duration was 103.75 ± 13.38 ms with EP-RS versus 103.75 ± 13.38 ms with PSA. V6-RWPT 67.25 ± 5.62 ms versus 70.50 ± 3.32 ms, and V6–V1 IPT 47.50 ± 5.97 ms versus 44.50 ± 9.43 ms. According to current criteria, successful LBBAP was identified in all patients with EP-RS, and all these met criteria using PSA measurements. No PSA system in unipolar/bipolar configuration showed superiority over another. Conclusions: This is one of the first prospective demonstrations that a standard manufacturer PSA may reliably substitute for EP-RS guidance during LBBAP implantation. A simplified PSA-based approach centered on V1/V6 surface leads and intracardiac electrograms accurately reproduced key EP-RS implantation criteria for LBBAP. This strategy may facilitate conduction system pacing in centers without dedicated EP-RS infrastructure, including urgent pacemaker implantations, potentially broadening access to physiologic pacing techniques. Early experience also suggests a relatively short learning curve for reproducible measurements. Further studies comparing feasibility with all the PSAs in the market and different EP-RS systems are needed.



19704

SUSTAINED VENTRICULAR TACHYCARDIA IN ARRHYTHMOGENIC MITRAL VALVE PROLAPSE TWO YEARS AFTER MITRAL VALVE SURGERY

NÁGELA S V NUNES1; PAULA GONZALEZ1; ALFREDO S BOMFIM1;

(1) COMPLEXO HOSPITALAR DE NITEROI - NITERÓI - RJ - BRASIL;

Introduction: Arrhythmogenic mitral valve prolapse (MVP) has been increasingly recognized as a substrate for malignant ventricular arrhythmias and sudden cardiac death. The persistence of arrhythmic events after surgical correction of mitral regurgitation highlights the role of the underlying myocardial substrate rather than the valvular abnormality alone. Case Description: A 74-year-old man with hypertension, diabetes mellitus, atrial fibrillation (previously ablated), and severe mitral regurgitation due to mitral valve prolapse underwent mitral valve replacement with a bioprosthesis and coronary artery bypass grafting (left internal mammary artery to left anterior descending artery). Two years after surgery, he was admitted with malaise and dizziness, progressing to syncope. On presentation, he was hemodynamically stable but had a regular wide-complex tachycardia (heart rate 171 bpm), which was terminated with intravenous amiodarone. Electrocardiographic analysis demonstrated sustained monomorphic ventricular tachycardia with morphology suggestive of an inferior left ventricular origin. Transthoracic echocardiography showed a normally functioning mitral bioprosthesis and no evidence of mitral annular disjunction. Cardiac magnetic resonance revealed mildly reduced left ventricular systolic function and non-ischemic late gadolinium enhancement in basal inferolateral segments, consistent with a typical arrhythmogenic substrate in MVP. Importantly, this fibrotic pattern did not correlate with the anatomical distribution of coronary artery disease. Ambulatory monitoring demonstrated a high burden of ventricular ectopy and episodes of nonsustained ventricular tachycardia. Given the documented sustained ventricular tachycardia, an implantable cardioverter-defibrillator was indicated and successfully implanted. The clinical presentation was interpreted as sustained ventricular tachycardia in the context of arrhythmogenic MVP, highlighting the persistence of arrhythmic risk despite prior surgical correction of mitral regurgitation. Conclusions: Arrhythmogenic MVP is a cause of malignant ventricular arrhythmias. Sustained ventricular tachycardia years after mitral valve surgery suggests that risk is driven by the underlying myocardial substrate rather than the valve lesion. Absence of mitral annular disjunction does not exclude fibrosis or arrhythmic risk, and when cardiac magnetic resonance identifies the inferolateral substrate, ICD implantation is warranted.

WHEN THROMBOSIS MEETS DEVICE LEADS: NAVIGATING THROMBOLYSIS IN PAGET-SCHROETTER SYNDROME WITH A TRANSVENOUS ICD

ANDREA OLIVIA CIOBANU1; IOANA PATRICIA ISFAN1; SIMONA IONELA VISOIU1; ALINA IOANA NICULA2; DRAGOS VINEREANU1;

(1) UNIVERSITY OF MEDICINE AND PHARMACY CAROL DAVILA, BUCHAREST, ROMANIA; UNIVERSITY AND EMERGENCY HOSPITAL OF BUCHAREST (DEPARTMENT OF CARDIOLOGY AND CARDIOVASCULAR SURGERY), BUCHAREST, ROMANIA - ROMANIA; (2) UNIVERSITY AND EMERGENCY HOSPITAL OF BUCHAREST (DEPARTMENT OF RADIOLOGY), BUCHAREST, ROMANIA - ROMANIA;

Introduction: Upper-extremity venous thrombosis is uncommon and should be suspected in patients presenting with acute arm swelling, particularly in the presence of transvenous cardiac device leads or thoracic outlet compression. Case Description: A 42-year-old woman presented with acute left upper limb swelling and erythema, after starting a new upper-body exercise program with repetitive overhead arm movements with forced abduction. She had a transvenous implantable cardioverter-defibrillator (ICD) implanted in primary prevention of sudden cardiac death for a spontaneous type I Brugada ECG pattern and a positive electrophysiological study, with a variant of uncertain significance in the SCN5A gene (p.Met881Ile). Lab tests showed elevated D-dimers, and transthoracic echocardiography was unremarkable. Since Doppler ultrasound was inconclusive due to device-related artifacts, contrast-enhanced CT was performed and showed extensive thrombosis of the left subclavian vein extending to the distal left internal jugular vein at the confluence with the brachiocephalic vein (Fig. 1). Despite therapeutic anticoagulation with UFH and the LMWH, no clinical improvement was observed. Given the extensive thrombosis, severe symptoms, young age, and the risk of post-thrombotic syndrome, early thrombus-removal strategy was considered. However, catheter-directed thrombolysis was considered high risk due to the presence of ICD lead within the thrombosed vein, with a risk of lead displacement or entanglement during endovascular manipulation. After Heart Team multidisciplinary discussion, systemic thrombolysis with alteplase was performed, followed by oral anticoagulation. This approach resulted in rapid clinical improvement of the upper limb. Follow-up imaging confirmed near-complete venous recanalization (Fig. 2). After thoroughly ruling out malignancy and thrombophilia as causes, we diagnosed the case as effort thrombosis consistent with Paget–Schroetter syndrome, linked to the dynamic compression of the subclavian vein at the thoracic outlet during the patient's recent physical activities. The transvenous ICD lead may have further contributed to local venous flow disturbance and promoted subsequent thrombosis. Conclusions: This case illustrates the complex interplay between effort thrombosis, namely Paget-Schroetter syndrome, and transvenous cardiac device lead, highlighting how device-related anatomical constraints may influence thrombolytic strategy in symptomatic upper-extremity deep vein thrombosis.

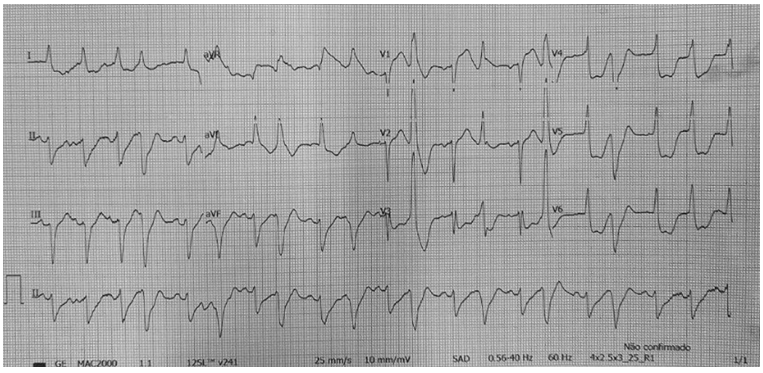
ACUTE MYOCARDIAL INFARCTION IN A YOUNG ADULT SECONDARY TO CARDIAC MYXOMA: CASE REPORT

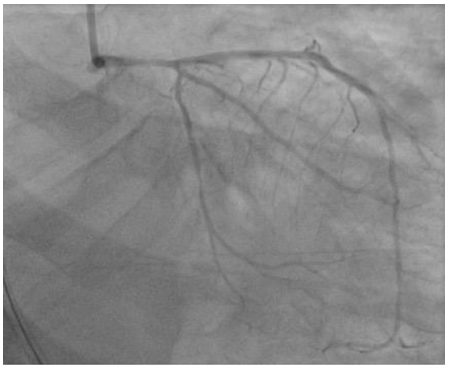
LANA ALVES DE LIMA1; CAROLINE ALMEIDA PINTO2; LORENA BATISTA VALENCIANO1; NIVALDO CORTELA3; ANA BEATRIZ BOAMORTE CORTELA4; GIBRAN RODER FEGURI5;

(1) UNIVERSIDADE DO ESTADO DE MATO GROSSO - CÁCERES - MT - BRASIL; (2) UNVERSIDADE DO ESTADO DE MATO GROSSO - CÁCERES - MT - BRASIL; (3) FACULDADE DE MEDICINA DE MARILIA - MARÍLIA - SP - BRASIL; (4) CENTRO UNIVERSITARIO DE VARZEA GRANDE - UNIVAG - CUIABÁ - MT - BRASIL; (5) CENTRO UNIVERSITÁRIO SERRA DOS ÓRGÃOS - TERESÓPOLIS - RJ - BRASIL;

Introduction: Cardiac myxomas are the most frequent primary benign neoplasms of the heart, although their presentation as acute myocardial infarction is rare. Case Description: Male patient, 31 years old, previously healthy, admitted with sudden chest pain and electrocardiogram compatible with acute myocardial infarction with ST-segment elevation of the inferior wall. Due to the unavailability of primary angioplasty, thrombolysis was performed successfully. The etiological investigation evidenced, on transthoracic echocardiogram, an intracavitary mass in the left atrium compatible with myxoma. Coronary angiography demonstrated distal occlusions in multiple coronary territories, without significant atherosclerotic disease, suggesting tumor embolic phenomenon. The patient was submitted to complete surgical resection of the tumor, with favorable clinical evolution Conclusions: Atrial myxoma should be considered as a rare cause of myocardial infarction in young patients, especially in the context of non-obstructive coronaries, being fundamental the etiological investigation for adequate diagnosis and treatment.



18576



CARDIAC ARREST DUE TO CRITICAL LEFT CORONARY ARTERY VASOSPASM ASSOCIATED WITH CISPLATIN: A RARE AND POTENTIALLY FATAL CAUSE OF CARDIOTOXICITY

PEDRO RODRIGUES DE CARVALHO1; BEATRIZ LOPES FIGUEIREDO1; ANA CAROLINA LOAYZA BENCHIMOL BARBOSA1; JOÃO LUÍS GOMES DA SILVA1; ALICE FARIA SANTOS FERNANDES1; VICTOR ALMEIDA PONTES1; JULIA CALDAS BEDIN1; FELIPE GALLEGO LIMA1; ENZO MAY DE MIO1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction: Coronary vasospasm is a recognized cause of acute coronary syndrome, often associated with vasoactive substances and fluoropyrimidines. Its occurrence with platinum-based agents, such as cisplatin, is less frequently described. We report a case of severe left coronary artery vasospasm associated with chemotherapy, progressing to cardiac arrest. Case Description: A 47-year-old man with lung cancer undergoing treatment with cisplatin and pemetrexed, with a history of HIV infection and extrapulmonary tuberculosis, was admitted after out-of-hospital cardiac arrest in a shockable rhythm (ventricular tachycardia), successfully reversed with defibrillation. On admission, he was intubated, hemodynamically stable, with a tendency toward hypertension. Electrocardiography showed ST-segment elevation in aVR and diffuse ST depression. There was a marked increase in troponin levels (peak >70,000; normal ≤14 ng/L), with no electrolyte disturbances or renal dysfunction. Coronary angiography revealed severe vasospasm of the left coronary artery, reversed with intracoronary nitroglycerin, without significant obstructive lesions. Echocardiography showed a left ventricular ejection fraction of 50% with anterior wall hypokinesia. A similar prior episode had occurred, presenting as angina (hospitalization at an external service less than one week earlier), with resolution after nitrate administration. After discontinuation of cisplatin, the patient had no recurrence and remained on diltiazem and nitrate therapy. Conclusions: Cisplatin-induced vasospasm, although rare, may present with severe events, including cardiac arrest. Early recognition and discontinuation of the offending agent are essential to prevent recurrence and reduce mortality.

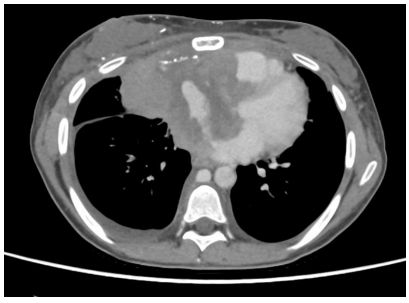
DIAGNOSIS OF A POORLY DIFFERENTIATED CARDIAC SARCOMA IN A YOUNG PATIENT: A RARE CASE REPORT FROM A HOSPITAL IN NORTHWESTERN ESPÍRITO SANTO

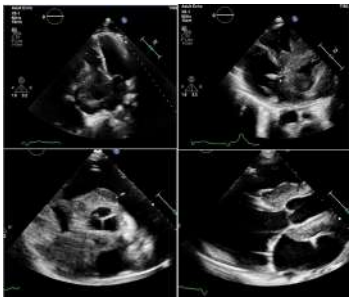
JULIA TORRES MOULIN MARRÉ1; CAROLINA GUIDONE COUTINHO2; BÁRBARA TONINI RIBEIRO1; LARA ARAÚJO DIAS1; INGRID GILES RAMOS1; ALEXANDRA BONELLA CAPRIOLI1; MARIA EDUARDA SIQUEIRA1; ADRIENE DE FREITAS MORENO RODRIGUES1; LUCIANO ANTONIO RODRIGUES1; LORENZO CESANA VANZO3; SANDRO ADAUTO MARTINS4; LEONARDO CRISTIANO FRIGINI4;

(1) CENTRO UNIVERSITÁRIO DO ESPÍRITO SANTO (UNESC) - COLATINA - ES - BRASIL; (2) HOSPITAL UNIVERSITÁRIO CASSIANO ANTONIO MORAES - HUCAM - VITÓRIA - ES - BRASIL; (3) MULTIVIX - VITÓRIA - ES - BRASIL; (4) HOSPITAL SÃO JOSÉ - COLATINA - ES - BRASIL;

Introduction: Primary malignant cardiac neoplasms are extremely rare, with cardiac sarcomas accounting for most cases. Patients typically present with nonspecific symptoms, hindering early diagnosis. The condition carries a poor prognosis, and surgical resection remains the mainstay of treatment. Case Description: Patient, a 44-year-old female, presented with a syncopal episode 4 days prior following physical exertion. She also reported dyspnea on moderate and mild exertion, progressive lower limb edema for 1 month, pallor, and unmeasured febrile episodes. On physical examination: pale (+/4+), afebrile, normotensive, tachycardic, with irregular rhythm, no murmurs, and bilateral edema. Electrocardiography revealed sinus tachycardia, diffuse low voltage, and isolated ventricular extrasystoles. Transthoracic echocardiography demonstrated an ejection fraction of 56%, a thickened mitral valve, and a mass in the left atrium extending into the left ventricle (LV), causing mechanical obstruction (7 × 2 mm). Significant tricuspid regurgitation (PSAP of 81 mmHg), right ventricular (RV) dilation, and moderate pericardial effusion were observed. Anticoagulation, empirical antibiotic therapy, and transesophageal echocardiography were performed, revealing a mobile (7.2 × 2.5 cm), heterogeneous mass attached to the interatrial septum, prolapsing into the LV with significant obstruction. Extension into the right superior pulmonary vein reaching the mitral valve was noted. The patient was admitted to the ICU, and CT angiography demonstrated bilateral pulmonary thromboembolism. She developed worsening dyspnea, and milrinone was initiated. She progressed to acute respiratory failure, requiring orotracheal intubation, and developed cardiogenic shock. She underwent emergency cardiac surgery, which revealed infiltrative tumors in the myocardium and an extensive mass occupying the atrial cavity, protruding through the mitral valve, hardened with multiple nodules. Mitral valve replacement was performed; however, she developed severe RV dysfunction, refractory shock, and died intraoperatively. Histopathological analysis of intracardiac, myocardial, and epicardial lesions revealed a poorly differentiated malignant neoplasm with spindle epithelioid morphology, confirmed by immunohistochemistry as a high-grade poorly differentiated sarcoma. Conclusions: Cardiac sarcomas are rare and highly aggressive. Diagnosis relies on histopathology confirmation, and even with surgical intervention, prognosis is generally poor.



17838



RARE CASE OF SEVERE CARDIAC INFILTRATION IN PRIMARY MEDIASTINAL B-CELL LYMPHOMA: MANAGEMENT AND THERAPEUTIC CHALLENGES

MARIA LUIZA ARANEGA DE ASSIS FIGUEIREDO1; HERBERT IAGO FEITOSA DA FONSECA1; TIAGO MANSUR KOBBAZ1; JESSICA LOUISE DE GODOI PIERINI1; IASMIN HASEGAWA1; DICKSON VENEGAS JUSTINIANO1; NATALIA SAVASTANO JORGE1; MARCELLA LUISA EIRAS AMARAL HOSSRI NOGUEIRA BRAGA1; DOUGLAS RIBEIRO TRISTAO DE OLIVEIRA1; JOÃO PAULO BRANDÃO DE MEDEIROS1; RAFISAH SEKEFF SIMÃO ALENCAR1;

(1) UNICAMP - CAMPINAS - MT - BRASIL;

Introduction: Primary mediastinal B-cell lymphoma (PMBCL) is an uncommon aggressive subset of diffuse large B-cell lymphomas. It frequently spreads locally from the thymus into the pleura or pericardium. The myocardial infiltration in this type of tumor is rare, and it may occur due to direct invasion, hematogenous spread, transvenous invasion or lymphangitic spreading. The clinical presentation varies and may include conduction disturbances, Superior Vena Cava Syndrom, and symtoms of cardiac insuficiency. Case Description: The case reports a 22-year-old female patient with a history of diffuse large B-cell non-Hodgkin lymphoma, treated since 2022. In 2024, patient presented clinical symptoms and PET-CT scan revealed a hypermetabolic area suggesting relapse. She remained under outpatient follow-up but started with dyspnea, abdominal distension, anorexia, facial edema, in addition to daily fever and diarrhea which lead her to hospital in May 2025. A chest CT scan demonstrated a large, moderately hypervascular, expansile mass with a primitive/infiltrative appearance, centered in the anterior mediastinum, with myocardial invasion, involving the right heart chambers (RA/RV). There was also obliteration of the superior vena cava with no clear plane separating it from other mediastinal vessels, causing compressive effects on the inferior vena cava and the right pulmonary artery. Transthoracic echocardiography showed a LVEF: 51% and revealed an infiltrative mass with an interatrial communication - shunt from the RA to the RV resulting in hemodynamic repercussions; and left atrium, encasing the proximal aorta and pulmonary artery. The patient developed arrhythmias- junctional rhythm and complete atrioventricular block. An epicardial pacemaker was considered, as the presence of an intracavitary tumor mass precluded transvenous pacemaker implantation. Hematology team indicated chemotherapy. A cardiac MRI was performed for surgical planning, which determined that epicardial pacemaker implantation was not feasible due to tumor location in the anterior mediastinum. The patient's clinical condition deteriorated, progressing to respiratory failure requiring intubation. She died due to the severity of her condition. Conclusions: Although rare, this case is an example of the repercussions from the extensive mediastinal and cardiac involvement by a PMBCL, complicated by severe conduction disturbances and rapid clinical deterioration, illustrating the diagnostic and therapeutic challenges of this pathology.

18921

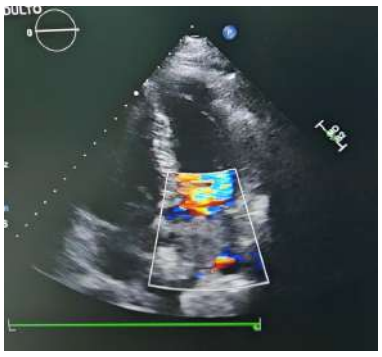
RECURRENT PERICARDIAL TAMPONADE AND MEDIASTINAL MASS IN A YOUNG ADULT: THE CHALLENGE OF DIFFERENTIAL DIAGNOSIS BETWEEN LYMPHOMA RELAPSE AND INFLAMMATORY PERICARDITIS

ISABELA GONÇALVES RIBEIRO1;

(1) SANTA CASA DE MISERICORDIA DE BELO HORIZONTE - BELO HORIZONTE - MG - BRASIL;

Introduction: Lymphomas involving the mediastinum represent a significant proportion of mediastinal masses. Due to their anatomical proximity to cardiovascular structures, these neoplasms may be associated with cardiac complications, among which pericardial effusion stands out because of its potential severity. Pericardial effusion in patients with lymphoma may result from direct pericardial infiltration, lymphatic obstruction, or an inflammatory response associated with the disease. Although often asymptomatic, it may progress to cardiac tamponade, constituting a clinical emergency. Our objective is to report a case of recurrent pericardial effusion in a patient with a prior history of lymphoma. Case Description: A 27-year-old patient with a prior diagnosis of lymphoblastic lymphoma at age 17, previously treated and under outpatient follow-up. In May 2025, the patient presented with chest pain, and a large pericardial effusion was identified. Mediastinal and pericardial biopsies were performed, both showing no evidence of malignancy. Given the clinical severity, requiring intensive care and with a risk of death, empirical chemotherapy was initiated, considering the possibility of lymphoma relapse. In August 2025, a repeat biopsy of the mediastinal mass was performed, and histopathological analysis revealed lymphoid hyperplasia without evidence of neoplasia. In September 2025, the patient developed a new episode of chest pain associated with fever, again with a large pericardial effusion identified. Pericardial drainage with biopsy was performed. Immunophenotyping analysis of the pericardial fluid showed T lymphocytes without atypia, and the pericardial biopsy demonstrated mild lymphocytic infiltration, with no evidence of malignancy. Treatment for pericarditis was initiated with colchicine, nonsteroidal anti-inflammatory drugs, and corticosteroide. The patient showed an excellent response. During long-term follow-up, corticosteroids were tapered and subsequently discontinued; however, the patient developed recurrent chest pain secondary to a large pericardial effusion. Conclusions: Recurrent pericardial effusion in patients with a prior history of lymphoma represents a diagnostic challenge. The absence of malignancy in multiple biopsies and immunohistochemical analyses does not completely exclude relapse but reduces its likelihood. A favorable response to pericarditis treatment supports the hypothesis of an inflammatory mechanism, although it does not allow definitive exclusion of neoplastic disease.

20004



SURGICAL RESECTION OF A LEFT ATRIAL MASS WITH SEVERE MITRAL OBSTRUCTION: A MYXOMA-MIMICKING CASE

LEVI LOPES CAVALCANTE1; ELAINE CHAVES GADELHA1;

(1) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introduction: Left atrial masses are classically attributed to myxoma, especially when attached to the interatrial septum and associated with mitral inflow obstruction. However, malignant cardiac tumours may present with overlapping imaging features, creating a critical diagnostic pitfall with major therapeutic and prognostic implications. Case Description: A 34-year-old male patient was admitted with progressive dyspnoea and dizziness. Initial evaluation raised suspicion of intracardiac pathology. Transthoracic echocardiography demonstrated preserved biventricular function and a large left atrial mass attached to the interatrial septum, occupying nearly the entire atrial cavity. The mass prolapsed through the mitral valve, causing severe functional obstruction, with a mean transmitral gradient of 10 mmHg and an estimated mitral valve area of 0.85 cm², mimicking severe mitral stenosis. Thoracic computed tomography revealed a hypodense expansile lesion with focal calcifications, reinforcing the initial suspicion of atrial myxoma. The patient underwent surgical resection. In the postoperative period, superior vena cava thrombosis was identified and anticoagulation was initiated. Episodes of atrial fibrillation and atrial flutter were documented. Histopathological analysis revealed a high-grade undifferentiated pleomorphic sarcoma, with a high proliferative index (Ki-67 approximately 70%) and immunohistochemical positivity for MDM2, p16, and CDK4. During follow-up, early intracardiac tumour recurrence was observed, accompanied by pulmonary hypertension, pleural effusion, and progressive respiratory deterioration. Conclusions: This case highlights a critical diagnostic pitfall: malignant cardiac tumours may closely mimic myxoma both anatomically and functionally, including classic features such as septal attachment and mitral obstruction. In this scenario, imaging alone was insufficient to differentiate benign from malignant disease. The aggressive postoperative course, with early recurrence and rapid clinical deterioration, contrasts with the expected benign evolution of myxoma and reinforces the importance of maintaining diagnostic suspicion. The presence of calcifications and large tumour burden did not allow reliable preoperative distinction. This case underscores the limitation of conventional imaging in characterizing atrial masses and the central role of histopathological diagnosis.

HEREDITARY PULMONARY ARTERIAL HYPERTENSION ASSOCIATED WITH SUDDEN DEATH: THE ROLE OF GENETIC INVESTIGATION IN A PEDIATRIC CASE REPORT

ARTHUR CHEDE CHAVES REIS1; LOURENÇO SALVADOR CÔRTES1; LUÍS FELIPE PARREIRA PELUSO1;

(1) UFJF - JUIZ DE FORA - MG - BRASIL;

Introduction: Pulmonary Arterial Hypertension (PAH) is a progressive and potentially fatal condition characterized by elevated pulmonary vascular resistance, leading to right ventricular dysfunction and heart failure. Heritable forms of PAH are strongly associated with pathogenic variants in the BMPR2 gene and are frequently linked to severe clinical presentation, early disease onset, and increased risk of sudden death. In this context, detailed family history and genetic investigation play a fundamental role in early diagnosis, therapeutic decision-making, and risk stratification of affected families. Case Description: A 3-year-old male patient presented with a significant family history suggestive of severe hereditary cardiovascular disease. His sister died suddenly at 2 years of age, while his maternal grandmother and maternal aunt died before the age of 30 due to acute respiratory failure and pulmonary embolism, respectively. In addition, his mother had been diagnosed with severe Pulmonary Arterial Hypertension four years earlier. At the initial evaluation, physical examination revealed a systolic murmur at the left sternal border. Echocardiography demonstrated findings compatible with primary PAH, including enlargement of the right heart chambers, right ventricular systolic dysfunction, moderate tricuspid regurgitation, and an estimated pulmonary artery systolic pressure (PASP) of 65 mmHg. During follow-up, the patient showed progressive worsening of right ventricular contractility, increased ventricular wall thickness, dilation of the pulmonary trunk, and elevation of PASP to 72 mmHg. Genetic testing identified a pathogenic variant in the BMPR2 gene, confirming the hereditary form of PAH. Treatment with Tadalafil and Bosentan was initiated, resulting in significant improvement in cardiac parameters during follow-up. Conclusions: Genetic screening in families with PAH and a history of sudden death is essential for early diagnosis, prompt therapeutic intervention, and improved prognosis. This case highlights the importance of combining family history assessment with molecular investigation to identify hereditary PAH and guide long-term surveillance strategies. However, clearer guidelines are still needed to better define indications and protocols for genetic testing among at-risk relatives.

HYPERTROPHIC CARDIOMYOPATHY IN A PATIENT WITH RAF1, LINKED TO NOONAN SYNDROME, AND MYBPC3 MUTATIONS: A CASE REPORT

ANGÉLICA PIOVESANA1; HELENA PIOVESANA1; GABRIEL SIGNORI1; PATRICIA ABISAMBRA1; FABIANO DE OLIVEIRA POSWAR1; LIVIA ADAMS GOLDRAICH1; FERNANDO LUIS SCOLARI1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction: Noonan Syndrome is characterized by dysmorphic facial features, short stature and congenital heart defects. The most common cardiovascular defects found are pulmonary valve stenosis with dysplastic leaflets and hypertrophic obstructive cardiomyopathy with asymmetric septal hypertrophy. Hypertrophic cardiomyopathy in Noonan Syndrome is more frequently related to pathogenic variants in the genes MRAS and RAF1. In adults, establishing a clinical diagnosis can be very difficult, since their expression of facial dysmorphic features tends to be more subtle. Case Description: Male patient, 40 years old, born with congenital heart disease. On physical examination presents ocular hypertelorism, downward slanting palpebral fissures and short neck. In the family, his sister had a sudden death at age 12 and the mother has hypertrophic cardiomyopathy with a similar phenotype. Started outpatient follow-up in 2000 and had a diagnosis of hypertrophic cardiomyopathy, progressing with an ICD implanted in 2002. In his youth, he presented with persistent atrial fibrillation needing multiple ICD discharges. In 2019, at the age of 33, he received the diagnosis of Noonan Syndrome and genetics was consulted for evaluation and etiological investigation of hypertrophic cardiomyopathy with asymmetric septum and burnout phenotype – already with ventricular dilation and advanced heart failure with reduced ejection fraction. A genetic panel was performed, identifying pathogenic variants on RAF1 and on MYBPC3 c.1828G>A (p.Asp610Asn). Due to the progression of the disease, cardiac transplantation was performed in 2025. Conclusions: The case highlights a unique combination of Noonan syndrome in a patient with sarcomeric mutations leading to hypertrophic cardiomyopathy. The delayed diagnosis of both conditions may have an impact in clinical outcomes, evidencing the importance of early triage for Noonan Syndrome – especially since its more prominent features are present in children. This presentation, with dominance of asymmetrical septum hypertrophy, is more common in MYBPC3 mutations – although it can also be related to RAF1. Therefore, this case calls attention to the importance of expanded panels in detecting causes for ventricular hypertrophy that can coexist in a patient – valuing other variants of uncertain significance identified.

VIRTUAL AND PHYSICAL THREE-DIMENSIONAL RECONSTRUCTION OF A FETAL HEART WITH A LEFT VENTRICULAR DIVERTICULUM

JULIANA DUTRA SILVESTRE MENDES1; HERON WERNER2; GERSON RIBEIRO2; NATHALIE JEANNE MAGIOLI BRAVO-VALENZUELA3; EDWARD ARAUJO JÚNIOR4;

(1) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - RJ - BRASIL; (2) PONTIFICIA UNIVERSIDADE CATOLICA - RIO DE JANEIRO - RJ - BRASIL; (3) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (4) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction: Congenital ventricular diverticulum is a rare cardiac malformation, accounting for 0.05% of congenital heart diseases, and is associated with other cardiac and extracardiac malformations, such as midline thoracoabdominal defects. A left ventricular (LV) diverticulum is defined as a pulsatile protrusion in the LV wall containing the endocardium, myocardium, and pericardium. It is generally benign but may be associated with complications such as embolism, arrhythmia, heart failure, and even ventricular rupture leading to the patient's death. Thus, the importance of early diagnosis via fetal echocardiography is emphasized in order to guide appropriate and timely treatment. 3D ultrasound with STIC software allows for the acquisition of these cardiac volumes, which can be reconstructed into virtual and physical three-dimensional models and used for anatomical understanding by the multidisciplinary team, in therapeutic planning, in medical education, and in parental counseling. Case Description: Cardiac volume measurements of the fetus with LV diverticulum were obtained via 3D ultrasound using STIC (Spatio-temporal image correlation) software on a Voluson E8 (GE Healthcare, Zipf, Austria) with a volumetric transducer (MB 4-8L) and sent to the post-processing stage, where virtual and physical 3D reconstruction was performed. 3D Slicer software (Bristol, UK) was used for segmentation, and a Stratasys 15 printer with Polyjet technology was used to print the 3D model in photosensitive resin. The print was life-size and allowed for clear visualization of the LV diverticulum with its posterior course until it adjoined the right ventricle. Conclusions: In conclusion, a 3D reconstruction of a fetal heart with a LV diverticulum was performed, resulting in both a virtual model and a printed model. 3D reconstruction proves to be a promising tool for the management of rare congenital heart diseases (illustrated by the LV diverticulum in this case). The printed model allows for anatomical detail that facilitates understanding of the heart disease in the neonatal period by both family members and cardiac surgeons and other professionals on the multidisciplinary team. The virtual model enables specialized teams worldwide to visualize the structures of the fetal heart realistically, including through 3D navigation, contributing to diagnostic accuracy in rare cases and therapeutic decision-making.

CARDIAC SARCOIDOSIS PRESENTING AS AN ACUTE ARTERIAL EMBOLIC EVENT: DIAGNOSIS GUIDED BY CARDIAC MAGNETIC RESONANCE IMAGING

CAMILLA FIDENCIO REIMBERG1; TIAGO SENRA GARCIA DOS SANTOS1; ARTHUR FELIPE GIAMBONA RENTE2; GUSTAVO REBEQUE MODOLO1; ANTONIO TITO PALADINO FILHO1; PEDRO CASAGRANDE2;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (2) REDE DOR - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Cardiac sarcoidosis is an inflammatory granulomatous disease with heterogeneous presentation and is frequently underdiagnosed, being associated with potentially severe outcomes such as heart failure, malignant arrhythmias, and sudden cardiac death. Case Description: We report the case of a previously healthy 51-year-old woman admitted with sudden pain and cyanosis of the left upper limb at rest. Electrocardiography showed no ischemic changes, and arterial Doppler ultrasonography demonstrated occlusion of the left subclavian artery, for which successful thromboembolectomy was performed. During etiological investigation, transthoracic echocardiography revealed left ventricular apical akinesia and apical septal hypokinesia associated with the presence of an apical thrombus and reduced ejection fraction (Left Ventricular Ejection Fraction: 42%). Based on these data, Coronary angiography was indicated, and demonstrates no obstructive coronary artery disease. Cardiac magnetic resonance was an option for complementary research, and revealed multiple foci of late gadolinium enhancement with a non-ischemic pattern, predominantly involving septal and apical segments, associated with myocardial thickening, characterizing infiltrative involvement suggestive of cardiac sarcoidosis. Chest computed tomography demonstrated multiple pulmonary nodules and mediastinal lymphadenopathy, and lung biopsy confirmed noncaseating granulomatous disease. After initiation of specific therapy, ventricular function recovered, and the patient remained in New York Heart Association functional class I during outpatient follow-up. This case illustrates a rare presentation of cardiac sarcoidosis as a peripheral arterial embolic event, emphasizing the importance of etiological investigation in patients with intracardiac thrombus and non-obstructive coronary arteries. Conclusions: The case highlights the decisive role of cardiac magnetic resonance imaging in the early detection of myocardial involvement, with direct impact on risk stratification, therapeutic decision-making, and prognostic modification. It represents an emblematic example of how multimodality imaging integration can be crucial in contemporary clinical practice.

MULTIMODALITY IMAGING REVEALING BIVENTRICULAR ARRHYTHMOGENIC CARDIOMYOPATHY INITIALLY SUSPECTED AS PULMONARY HYPERTENSION

MARIANA ARAGAO PASSOS1; LAÍS ANTONIETO PEDROTTI1; MARIA EDUARDA MENEZES DE SIQUEIRA1; POLIANA FONSECA DUTRA FRANCO1; JORGE DANIEL ORUE BENITEZ1; AYMÉE CHYARA CASTELLANO VERZEMIAZZI1; JOÃO VICTOR MACEDO SILVA1; ANTÔNIO DOS SANTOS PAES JÚNIOR1;

Introduction: Arrhythmogenic cardiomyopathy (ACM) is a hereditary and progressive disease associated with an increased risk of sudden cardiac death. It is characterized by fibro-fatty replacement of the ventricular myocardium resulting from mutations in desmosomal proteins, leading to structural remodeling. Cardiac involvement may occur in isolation in the right ventricle (RV) or left ventricle (LV), although the classic phenotype predominantly affects the RV, with possible progression to biventricular disease. Clinical presentation ranges from asymptomatic individuals to malignant ventricular arrhythmias and heart failure. Transthoracic echocardiography (TTE) is the initial imaging modality and may demonstrate right chamber dilation, tricuspid regurgitation (TR), and estimated elevation of pulmonary artery systolic pressure (PASP). Cardiac magnetic resonance imaging (CMR) provides greater sensitivity for early detection of structural abnormalities and tissue characterization. Case Description: A 67-year-old female patient, former smoker, NYHA functional class I, with a history of arrhythmia and aborted sudden cardiac death during pregnancy in 2004. She remained asymptomatic thereafter, with no recurrence of arrhythmias. TTE demonstrated an estimated PASP of 50 mmHg, right chamber dilation, moderate TR, and grade I LV diastolic dysfunction, prompting investigation for possible pulmonary hypertension. Right heart catheterization revealed normal mean pulmonary artery pressure and pulmonary capillary wedge pressure; however, reduced cardiac output, elevated pulmonary vascular resistance, and hemodynamic signs of RV dysfunction were observed. CMR demonstrated marked right chamber dilation, severe RV systolic dysfunction (ejection fraction 14%), dyskinesia of the RV outflow tract, mid-apical akinesia, and non-ischemic mesocardial and epi-mesocardial late gadolinium enhancement, findings consistent with biventricular ACM. Conclusions: This case illustrates an atypical presentation of biventricular ACM and highlights the importance of multimodality imaging in diagnosis. TTE played a key role in the initial identification of structural and functional abnormalities, while CMR provided tissue characterization and precise definition of the disease phenotype. These imaging modalities therefore play complementary roles in the diagnosis and prognostic stratification of ACM.

INCLISIRAN AND LIPOPROTEIN(A) REDUCTION IN END-STAGE RENAL DISEASE: A CASE REPORT

GABRIEL MANDARINI DOHO1; FRANCISCO HELFENSTEIN FONSECA1; CLÁUDIA SOUZA OLIVEIRA1; SIMONE MATHEUS FISCHER1; DANIEL BORTOLLI VALLE1; GUILHERME MENDES GAIA1; MARIA CRISTINA IZAR1;

(1) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction: Lipoprotein(a) [Lp(a)] is a particle primarily determined by genetics, with limited influence from lifestyle factors, playing a significant role in the development of atherosclerotic disease². Mendelian randomization studies and meta-analyses have linked elevated Lp(a) levels to an increased risk of coronary artery disease, suggesting a causal role in the progression of atherosclerosis. In patients with end-stage renal disease (ESRD), Lp(a) levels are elevated compared to those with preserved renal function, not due to increased production but rather a reduction in particle catabolism. Despite reductions in LDL cholesterol, studies evaluating statin therapy in ESRD patients have failed to demonstrate a significant reduction in cardiovascular events. It is well established that statins do not significantly lower Lp(a). Inclisiran, a small interfering RNA targeting PCSK9, has shown promise in reducing both LDL cholesterol and Lp(a) (by around 20%). Although the clinical benefit of lowering Lp(a) remains uncertain, this effect may have relevance in patients with ESRD. Case Description: A 48-year-old woman with dyslipidemia, anxiety disorder, and a history of total thyroidectomy at 16 years of age, with chronic kidney disease on dialysis since 2006 secondary to hypertension. She presented with an acute myocardial infarction in September 2025, undergoing percutaneous coronary intervention of the right coronary artery. The patient was started on diltiazem 120 mg twice daily, atorvastatin 40 mg, ezetimibe 10 mg, acetylsalicylic acid 100 mg, and prasugrel 10 mg. In addition, she was taking cinacalcet 60 mg/day, levothyroxine 150 mcg/day, erythropoietin 4000 IU twice weekly, and vortioxetine 10 mg/day. In 2025, Lpa(a) was measured for the first time and was found to be 419 nmol/L. Despite initial reductions in TC, LDL, and non-HDL-C, levels remained well above recommended targets. Inclisiran was initiated on December 12, 2025. After 5 months, a follow-up lipid profile demonstrated reductions in LDL cholesterol and non-HDL cholesterol, achieving targets for very high cardiovascular risk. Additionally, Lp(a) decreased to 195 nmol/L. Conclusions: In this patient, treatment with inclisiran led to a 51% reduction in LDL and a 53% reduction in Lp(a). Given the limited effect of statins on Lp(a) and their modest impact on cardiovascular outcomes in renal replacement therapy, Lp(a) reduction emerges as a potentially important therapeutic target; however, it may not translate into fewer CV events.

ANALYTES	07/04/2026	14/11/2025	07/10/2025	23/12/2021

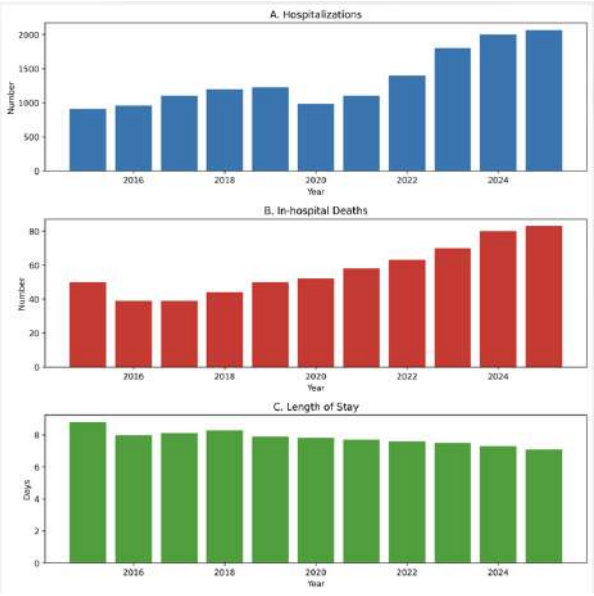
SITOSTEROLEMIA PRESENTING AS PREMATURE ATHEROSCLEROTIC CARDIOVASCULAR DISEASE IN ADULTHOOD: A CASE REPORT

PAMELA CAVALCANTE1; GIULLIA SARABANDO CURY CORDEIRO PEREZ1; FERNANDA ANICETO PEREIRA RABELO1; GUSTAVO FREITAS CARDOSO FAGUNDES1; DANIEL BRANCO ARAUJO1; DANIEL MANGNONI1; HENRI PAULO ZATZ1; CRISTIANE KOVACS AMARAL1; KLEBER G FRANCHINI1; RAFAELA ANDRADE PENALVA FREITAS1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction: Sitosterolemia is a rare autosomal recessive lipid disorder caused by pathogenic variants in the ABCG5 or ABCG8 genes, which encode sterol transporters responsible for limiting intestinal absorption and promoting biliary excretion of plant sterols. Defective function of these transporters leads to systemic accumulation of phytosterols, resulting in hypercholesterolemia. Due to phenotypic overlap with familial hypercholesterolemia, sitosterolemia is frequently underdiagnosed, particularly in adults presenting with premature coronary artery disease (CAD) and suboptimal response to statin therapy. We report a case of genetically confirmed sitosterolemia in an adult patient with premature coronary artery disease, highlighting the importance of etiological diagnosis and the favorable response to targeted therapy. Case Description: A 42-year-old man was referred due to persistently elevated low-density lipoprotein cholesterol (LDL-C), with a peak value of 199 mg/dL documented in 2021. His medical history was notable for elective coronary angioplasty at age 34 years old and a positive family history of premature CAD, with his father having died of an acute myocardial infarction at age 54 years old. Medications included atorvastatin 80 mg/day, atenolol 50 mg/day, enalapril 20 mg twice daily, and aspirin 100 mg/day. Laboratory tests showed total cholesterol 162 mg/dL, LDL-C 88 mg/dL on high-intensity statin therapy, HDL-C 36 mg/dL and triglycerides 188 mg/dL. Given the combination of premature coronary artery disease, family history and partial response to statins, genetic testing for monogenic dyslipidemias was performed, revealing a homozygous pathogenic variant in the ABCG8 gene, confirming sitosterolemia. Ezetimibe 10 mg/day was initiated along with dietary counseling. After continued adherence to combined therapy with atorvastatin and ezetimibe, repeat laboratory testing demonstrated a marked further reduction in LDL-C to 7 mg/dL. Conclusions: In conclusion, sitosterolemia, although rare, should be included in the differential diagnosis of premature coronary artery disease. Early recognition and targeted therapy with ezetimibe and dietary intervention can optimize lipid control and may improve cardiovascular outcomes. Failure to recognize this condition may delay appropriate treatment and contribute to disease progression.



18457

TEMPORAL TRENDS AND HEALTHCARE BURDEN OF PERICARDITIS IN THE BRAZILIAN PUBLIC HEALTH SYSTEM (SUS): A NATIONWIDE ANALYSIS FROM 2015 TO 2025

LEONARDO CASTRO NUNES1; BERNARDO DINOA NUNES2; ISABELA LIRA VIERA1; GUILHERME CESAR FERNANDES DE OLIVEIRA DA COSTA1; JOSE GREGORIO VALERO RODRIGUEZ1; EVANDRO TINOCO MESQUITA1;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL; (2) FACULDADE ESTACIO IDOMED - ALAGOINHAS - BA - BRASIL;

Introduction: Myopericardial inflammatory syndromes comprise a spectrum of diseases characterized by inflammation of the pericardium, with or without myocardial involvement. Pericarditis, the most common clinical presentation, is traditionally considered a benign condition with low mortality. In developed countries, viral etiologies predominate, whereas in low- and middle-income settings, infectious causes such as tuberculosis remain relevant. However, nationwide data on hospital burden and outcomes remain limited in Brazil. The objective of this study was to evaluate temporal trends and healthcare burden of pericarditis-related hospitalizations in the Brazilian Public Health System (SUS) over the past decade, including in-hospital mortality, length of stay, and associated costs. This retrospective observational study used publicly available data from the Brazilian Unified Health System database (DATASUS/TABNET). Hospitalizations for pericarditis from January 2015 to December 2025 were analyzed using the search term “treatment of pericarditis,” according to DATASUS procedural coding. Case Description: A total of 14,345 hospitalizations for pericarditis were recorded during the study period. The Southeast region accounted for approximately half of all cases (49.2%). A total of 628 in-hospital deaths were observed, corresponding to an overall in-hospital mortality rate of 4.38%. The Southeast region had the highest absolute number of deaths (245), followed by the Northeast (181). However, significant regional disparities were identified, with higher mortality rates in the North (7.26%), Northeast (5.82%), and Center-West (5.69%), compared to the Southeast (3.47%) and South (3.62%).A clear regional gradient was observed in length of hospital stay, with longer durations in the North (9.7 days) and Northeast (9.8 days), compared to shorter stays in the Southeast (7.4 days) and South (6.1 days).Over time, hospitalizations increased progressively, accompanied by a marked rise in healthcare costs. In contrast, the mean length of hospital stay decreased over the study period. Conclusions: In conclusion, pericarditis represents an increasing healthcare burden in the Brazilian public health system, with rising hospitalizations and costs despite shorter hospital stays. Regional disparities in mortality and length of stay reflect socioeconomic inequalities. Early diagnosis and optimized management are essential to improve outcomes and reduce disparities across regions.

UNUSUALLY LARGE TENDON XANTHOMAS AS A PRESENTATION OF FAMILIAL HYPERCHOLESTEROLEMIA

PEDRO HENRIQUE DE ANGELO PEREIRA1; LETICIA CAROLLYNE GALVÃO1; TALITA BEITHUM RIBEIRO MIALSKI1; ROBSON FERNANDO GARCIA DE LIMA1; RAMON EDUARDO SZYMCZAK CONDE1; JULIA BERTOL1; MATEUS FRANZONI BOCHNIA1;

(1) CHC-UFPR - CURITIBA - PR - BRASIL;

Introduction: Tendon xanthomas are nodular lesions resulting from the deposition of cholesterol and other lipids within tendinous tissue. They most commonly involve the Achilles tendon, although other tendons may also be affected. Tendon xanthomas are typically associated with familial hypercholesterolemia but may also occur in the context of other lipid metabolism disorders. The present case report describes a patient presenting with unusually large tendon xanthomas. Case Description: A 59-year-old woman sought medical attention for painless nodules affecting both ankles, which had shown progressive enlargement since the age of 16 years. During the preoperative evaluation for surgical excision of the lesions, severe dyslipidemia was identified, with an LDL-cholesterol level of 318 mg/dL, prompting referral for cardiologic assessment. At presentation, the patient reported episodes of mild chest tightness occurring at rest and unrelated to physical exertion. These symptoms led to coronary computed tomography angiography, which demonstrated a coronary artery calcium score of 753 and evidence of three-vessel coronary artery disease. Subsequent invasive coronary angiography revealed subtotal occlusive lesions in the right coronary artery and left anterior descending artery, as well as severe stenoses involving the first diagonal branch and the circumflex artery. The patient was therefore admitted for planned surgical myocardial revascularization. During hospitalization, family history assessment revealed two offspring with LDL-cholesterol levels ranging from 390 to 500 mg/dL. Physical examination demonstrated unusually large tendon xanthomas involving both Achilles tendons (Figures 1 and 2). Bilateral patellar tendon xanthomas were also observed. According to the Dutch Lipid Clinic Network criteria, the patient scored 15 points, consistent with a definitive diagnosis of familial hypercholesterolemia. Coronary artery bypass graft surgery was successfully performed, and the patient was discharged without postoperative complications. Conclusions: This case highlights the importance of physical examination and recognition of findings such as tendon xanthomas and corneal arcus in patients with dyslipidemia. Early recognition should prompt appropriate diagnostic evaluation, initiation of intensive lipid-lowering therapy, and cascade family screening, thereby reducing cardiovascular morbidity and mortality in affected patients and their relatives.

CONTAINED RUPTURE OF A GIANT ASCENDING AORTIC PSEUDOANEURYSM PRESENTING AS ST-SEGMENT ELEVATION AFTER FAILED RIGHT CORONARY CATHETERIZATION: A CASE REPORT.

RICARDO CHMIELEWSKI DE CARVALHO1; ANDRE LUIZ XAVIER CANEVAROLI2; LUCAS HENRIQUE PRADO SOUSA2; RICARDO BARROS CORSO2; ABRAAO KESSLER SANTANA SILVA METELLO2;

(1) CENTRO UNIVERSITARIO UNIEURO - BRASÍLIA - DF - BRASIL; (2) HOSPITAL DE BASE DO DISTRITO FEDERAL - BRASÍLIA - DF - BRASIL;

Introduction: Ascending aortic pseudoaneurysm is a rare but life-threatening complication following cardiac surgery, with reported high morbidity and mortality rates, particularly in cases of rupture or delayed diagnosis. It typically arises from suture lines or sites of previous aortic manipulation and is strongly associated with infection, reoperation, and prosthetic valve endocarditis. Its clinical presentation is highly variable and may mimic acute coronary syndromes, leading to diagnostic challenges and potential delays in management. In more severe cases, contained rupture may occur, resulting in compression of adjacent mediastinal structures, embolic phenomena, and hemodynamic instability. Case Description: A 26-year-old male with rheumatic heart disease underwent mitral/aortic repair (2017) and double bioprosthetic valve replacement (2025). He presented with acute chest pain, ST-segment elevation (inferior/lateral leads), and elevated troponin. Coronary angiography showed no left coronary lesions and difficulty catheterizing the right coronary artery, suggesting anatomical distortion. CT angiography revealed a giant ascending aortic pseudoaneurysm (7.0×8.9×7.7 cm) with contained rupture, mediastinal compression, and systemic embolization. Emergency surgery was performed using a transsternal bithoracotomy (clamshell incision) to minimize the risk of intraoperative rupture, combined with bicarotid cannulation to maintain adequate cerebral perfusion during surgical exposure and control of the ascending aortic rupture.. Conclusions: Reoperative aortic surgery in this context is highly complex and carries significant risk. Strategies such as peripheral cannulation, cerebral perfusion through carotid access, and hypothermic management are critical to minimize intraoperative complications,. CT angiography illustrates the extent of mediastinal involvement and justifies the need for a clamshell approach. The suspected association with prosthetic valve endocarditis further reinforces infection as an important etiological factor in pseudoaneurysm formation, particularly in patients undergoing multiple cardiac procedures Ascending aortic pseudoaneurysm with contained rupture may mimic STEMI, creating diagnostic challenges. Failure to catheterize the right coronary artery may indicate aortic pathology. Early CT diagnosis and surgical intervention are crucial for improved outcomes.

16889

LATE RECURRENCE OF CARDIAC FIBROMA AFTER RESECTION: A CASE REPORT

EDUARDO MENDONCA SOARES1; LUCAS DO VALLE CICCOZZI1; MICHAEL HIKARU MIKAMI1; THIAGO PICUSSA DE CAMPOS MELLO1; DIANA ZOLET BERGONZINI1; CLARA MAYUMI MIKAMI2; CLAUDINEI COLLATUSSO1; FRANCISCO DINIZ AFFONSO DA COSTA1;

(1) SANTA CASA DE MISERICORDIA DE CURITIBA - CURITIBA - PR - BRASIL; (2) FACULDADE EVANGELICA MACKENZIE DO PARANA - CURITIBA - PR - BRASIL;

Introduction: Primary cardiac tumors are rare, and cardiac fibroma is among the most clinically significant benign neoplasms due to its association with arrhythmias, intracardiac obstruction, and ventricular dysfunction. Surgical resection remains the treatment of choice in symptomatic patients or in those with significant anatomical and functional impairment. Recurrence after surgical treatment is uncommon, and reports of late reoperation remain scarce. Case Description: A 26-year-old woman with a history of cardiac fibroma resection at age 14 presented with tumor recurrence 12 years after the initial procedure, associated with exertional dyspnea. Preoperative cardiac magnetic resonance imaging revealed an oval lesion measuring 36 × 33 × 22 mm, located adjacent to the interventricular septum, with intense contrast enhancement. Because of the reoperation, cardiopulmonary bypass was established via femoral arterial and venous cannulation. The tumor was approached through a right ventriculotomy and identified in the upper portion of the interventricular septum. To enable resection, detachment of the septal papillary muscle of the tricuspid valve was required, followed by enucleation of the tumor, which had a firm consistency and was friable on manipulation. During reconstruction, a bovine pericardial patch was used to repair the septal area, followed by reimplantation of the papillary muscle and implantation of a Gore-Tex® artificial chord. Histopathological examination confirmed the diagnosis of cardiac fibroma. Postoperative transthoracic echocardiography showed normal ventricular function, moderate tricuspid regurgitation, and a pulmonary artery systolic pressure of 20 mmHg. Conclusions: Late recurrence of cardiac fibroma after surgical resection is rare. This case highlights the possibility of recurrence even after a long disease-free interval and emphasizes the importance of long-term follow-up and individualized surgical planning in reoperations for intracardiac tumors.

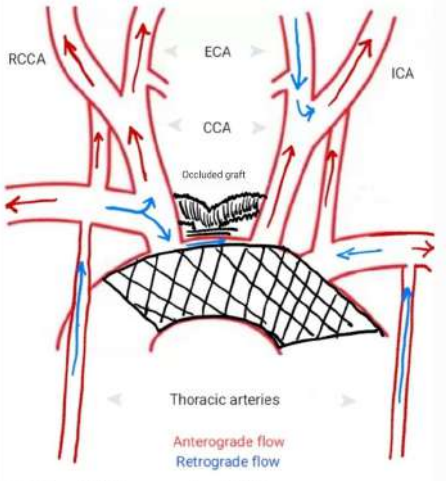
20490

RENAL ARTERY STENOSIS IN A SOLITARY KIDNEY IN POTTER SYNDROME: CARDIOVASCULAR IMPACT AND ENDOVASCULAR APPROACH

CARLOS ALBERTO BAVARESCO BRANCHIER1; RODRIGO OLIVEIRA VENDRAMIN1; GUILHERME JOSÉ CABRAL DE MELO AZEVEDO1; MATEUS CORREIA DA SILVA1; JOÃO PEDRO VALLE MARIANO1; AMÉRICO ÁLVARO FARINHA MARTINS2;

(1) UNIVERSIDADE FEDERAL DO PARANÁ - CURITIBA - PR - BRASIL; (2) HOSPITAL ANGELINA CARON - CAMPINA GRANDE DO SUL - PR - BRASIL;

Introduction: Potter syndrome is a malformative sequence arising from severe and persistent oligohydramnios, most commonly associated with bilateral renal agenesis or major fetal urinary tract anomalies. The reduction in amniotic fluid impairs fetal lung expansion and diminishes intrauterine mechanical protection, predisposing to pulmonary hypoplasia, characteristic facies, and limb deformities. Although the renal-pulmonary axis remains the defining hallmark of the syndrome, cardiovascular malformations may also integrate this developmental spectrum, underscoring its relevance in comprehensive perinatal assessment. We report a 55-year-old male with Potter syndrome and partial renal agenesis who developed renal artery stenosis of the remaining kidney, culminating in renovascular hypertension with significant cardiovascular structural impact. Case Description: A 55-year-old male with an established diagnosis of Potter syndrome, based on unilateral renal agenesis with a right kidney present but structurally defective at the superior pole, alongside characteristic syndromic facies including flattened nose, low-set protruding ears, receding chin, and epicanthal folds. He presented with refractory arterial hypertension, and investigation revealed significant stenosis of the right renal artery, corresponding to his sole functional kidney. He underwent percutaneous transluminal angioplasty with stent implantation, with successful restoration of renal perfusion. Transthoracic echocardiography demonstrated concentric left ventricular hypertrophy, with preserved ejection fraction and no evidence of systolic dysfunction or heart failure. Conclusions: This case illustrates the cardiovascular complexity that Potter syndrome may carry into adulthood, an aspect that remains underrecognized in the literature. The coexistence of a solitary functional kidney and hemodynamically significant renal artery stenosis resulted in structural cardiovascular remodeling, evidenced by concentric left ventricular hypertrophy. This presentation reinforces the importance of systematic screening for target-organ damage in patients with congenital renal anomalies. Early diagnosis, timely endovascular intervention, and multidisciplinary follow-up are paramount to mitigating cardiovascular morbidity and ensuring long-term renal functional preservation.



17463

RETROGRADE FLOW THROUGH THE INTERNAL THORACIC ARTERIES SUPPLYING SUPRA-AORTIC VESSELS AFTER DACRON GRAFT OCCLUSION: A CASE REPORT

FABRÍCIO DA SILVA CONCEIÇÃO1; LUCAS BARBOSA DE OLIVEIRA1; MARIA LUÍSA SOUZA BARBOSA1; ANTONIO DE JESUS CHAVES JUNIOR1; JÚLIA OLIVEIRA MEDRADO DE ALMEIDA2; JOSÉ AUGUSTO BAUCIA3; JACKSON BRANDÃO LOPES3; RILSON FRAGA MOITINHO1;

(1) HOSPITAL UNIVERSITÁRIO PROFESSOR EDGARD SANTOS (HUPES) - SALVADOR - BA - BRASIL; (2) UNIME - LAURO DE FREITAS - BA - BRASIL; (3) HOSPITAL UNIVERSITÁRIO PROFESSOR EDGARD SANTOS - SALVADOR - BA - BRASIL;

Introduction: Long-term patency remains a major challenge in the use of prosthetic vascular grafts due to complications such as thrombosis and intimal hyperplasia. Endothelial injury triggers thrombosis followed by smooth muscle cell proliferation, with intimal hyperplasia being the leading cause of late obstructive complications. We report the case of a patient with a thoracic aortic aneurysm secondary to Takayasu arteritis who developed occlusion of a Dacron graft to the supra-aortic vessels and a complex collateral circulation pattern. Case Description: A 34-year-old female with a diagnosis of Takayasu arteritis presented with aneurysms of the thoracic aorta and brachiocephalic trunk and underwent hybrid surgical treatment in 2014. The first stage consisted of revascularization of the supra-aortic vessels through interposition of a Y-shaped Dacron graft between the ascending aorta, the brachiocephalic trunk, and the left common carotid artery, along with proximal ligation of these vessels. The second stage involved implantation of an endograft extending from the proximal aortic arch to the distal descending thoracic aorta. The patient developed an ischemic stroke in 2025. Computed tomography angiography of the chest demonstrated occlusion of the prosthetic graft between the ascending aorta and the brachiocephalic trunk, as well as in the proximal segment of the left common carotid artery, with preserved patency of the thoracic endograft. Arterial Doppler ultrasound revealed bilateral flow reversal in the internal thoracic arteries, with retrograde supply originating from the superior epigastric arteries, resulting in reconstitution of the subclavian arteries. Additionally, reconstitution of the right common carotid artery from the right subclavian artery was observed, along with flow reversal in the left external carotid artery. The left common carotid artery demonstrated antegrade flow, likely maintained by collateral circulation. This hemodynamic pattern is consistent with complex collateral circulation characterized by retrograde filling of the supra-aortic vessels through the internal thoracic arteries. The patient is currently scheduled for corrective surgical reintervention. Conclusions: This case illustrates late failure of vascular reconstruction associated with the development of complex collateral circulation. The role of the internal thoracic arteries as an alternative pathway for cerebral perfusion is highlighted, demonstrating a rare and underreported hemodynamic adaptation.

CRITICAL LEFT MAIN CORONARY ARTERY COMPRESSION BY LEFT ATRIUM IN A PATIENT WITH MARFAN SYNDROME: DEFINING ROLE OF CARDIAC COMPUTED TOMOGRAPHY ANGIOGRAPHY (CTA)

RENATA BERLINGER SARAIVA1; LARA LORRAYNE FREITAS GOMES1; LUCAS MATOS FERNANDES1; ADRIANO CAMARGO DE CASTRO1; TAMARA CORTEZ MARTINS1; MARCELO BISCEGLI JATENE1; IEDA BISCEGLI JATEBE1; PATRICIA FIGUEIREDO ELIAS1;

(1) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL;

Introduction: Marfan Syndrome has major cardiovascular involvement, as evidenced by aortic root dilation and mitral valve disease. Less common complications, like extrinsic coronary compression from chamber enlargement, are rare but can be fatal. These abnormalities are detected through advanced imaging, particularly Cardiac CTA. Case Description: A 16-year-old male with Marfan syndrome and severe mitral regurgitation from mitral valve prolapse presented in our service with progressive chest pain. Imaging showed a large left spontaneous pneumothorax requiring drainage, as well as a persistent air leak suggestive of an air fistula. Holter monitoring revealed frequent supraventricular ectopy without malignant arrhythmias. Echocardiography revealed moderate left chamber dilatation, markedly enlarged left atrium (57,8 ml/m²), significant mitral regurgitation with myxomatous degeneration, and aortic root dilatation (Z score +3.0). Cardiac CTA was performed due to a discrepancy between clinical and echocardiographic findings, which identified marked left chamber enlargement (left atrium 136 ml/m²; left ventricle 167 ml/m²), mitral valve prolapse with flail P2 segment, and significant ostial narrowing (0,6 cm²) of the left main coronary artery due to extrinsic compression from the enlarged left atrium. This finding changed the management, which caused the planned thoracic surgery (air fistula closure) to be cancelled, and the patient was referred to cardiac intervention due to the high risk of myocardial ischemia and sudden death. The patient had mitral valve repair with Carpentier ring, left atrial plication, coronary exploration, pulmonary segmentectomy and pleurodesis with mild residual mitral regurgitation. Conclusions: In Marfan syndrome, severe mitral regurgitation leads to progressive left atrial enlargement, which can compress adjacent structures. It is a high-risk condition difficult to diagnose with echocardiography. In this instance, Cardiac CTA was required for correct anatomical assessment to the detection of coronary compression and redefinition of the surgical approach. Therefore, it is highly recommended in patients with severe heart disease in Marfan where the clinical and echocardiographic findings are not in accordance, affecting management and changing prognosis.

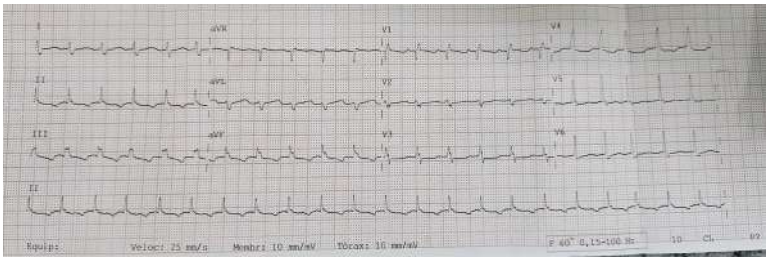
EARLY NEONATAL DIAGNOSIS AND LONG-TERM SURVIVAL IN GENERALIZED ARTERIAL CALCIFICATION OF INFANCY

ANDRESSA MUSSI SOARES1; BERNARDO MUSSI SOARES1; LEONARDO MUSSI SOARES1; RESI APOLINARIO1; RENATA MOREIRA DE BACKER PACIFICO1; ARIANE BINOTI PACHECO1; RICARDO ABREU VENTURY1; LIVIA ALBINO ALBINO1; HOSANA FERNANDES MAZZOCCO1; PAULO JOSE FERREIRA SOARES1; FABIO RABBI BORTOLINI1; VERA DEMARCHI AIELLO2;

(1) HOSPITAL EVANGELICO (HECI) - CACHOEIRO DE ITAPEMIRIM - ES - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction: Generalized arterial calcification of infancy (GACI) is a rare, frequently underdiagnosed and often fatal disorder, commonly associated with hydrops fetalis and high neonatal mortality, with up to 85% of affected infants dying within the first six months of life. Due to its rapid and severe course, long-term survival is rarely reported, highlighting the importance of early diagnosis and intervention.. Case Description: We report an 11-year-old male who presented at birth with hydrops fetalis, severe cardiovascular compromise, and significant pericardial effusion requiring pericardiocentesis. Early echocardiography raised suspicion of GACI by demonstrating diffuse arterial hyperechogenicity involving the aorta, pulmonary arteries, coronary arteries, and great vessels. Computed tomography angiography confirmed extensive arterial calcification. Treatment with sodium pamidronate was initiated in the neonatal period and maintained in repeated cycles over long-term follow-up, along with optimized medical therapy for systemic hypertension and myocardial dysfunction. Serial imaging demonstrated marked regression of previously diffuse vascular calcifications, particularly in the pulmonary arteries and large vessels. Clinically, the patient evolved with progressive improvement, maintaining good functional status, appropriate growth and development, preserved renal function, stable metabolic profile, and controlled systemic hypertension. In the late phase, imaging revealed residual arteriopathy with segmental vascular narrowing and renovascular involvement, including right renal hypoplasia and compensatory left kidney hypertrophy. Cardiac function remained preserved, although mildly reduced global longitudinal strain suggested subclinical myocardial dysfunction. Conclusions: This case highlights the critical role of early diagnosis in GACI, a life-threatening condition with traditionally poor prognosis. Long-term follow-up demonstrates that continuous pamidronate therapy, combined with optimized clinical management, may be associated with prolonged survival and significant regression of vascular calcifications. The transition to residual arteriopathy reinforces the need for lifelong surveillance.

17850



LATE DIAGNOSIS OF EBSTEIN ANOMALY PRESENTING AS UNSTABLE ATRIAL TACHYARRHYTHMIA: SURGICAL MANAGEMENT WITH CONE REPAIR IN AN ELDERLY PATIENT

LEVI ALBUQUERQUE LOPES CAVALCANTE1; ELAINE CHAVES GADELHA1; RODOLFO BASILIO MADEIRA NETO2;

(1) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

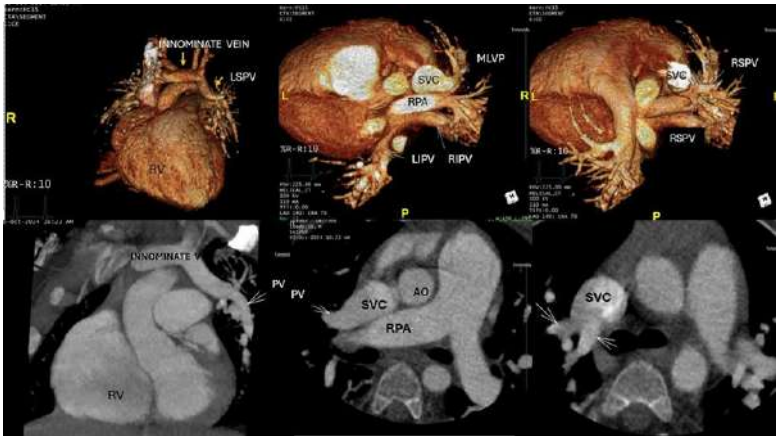
Introduction: Ebstein anomaly is a rare congenital heart disease that may remain undiagnosed until adulthood, especially in patients with less severe anatomical forms. Supraventricular arrhythmias are a common initial manifestation in adult patients and may lead to late diagnosis. Case Description: A 63-year-old female patient was admitted to the emergency department with supraventricular tachycardia (heart rate 150 bpm, narrow QRS), associated with chest discomfort. She had a prior history of presumed mitral valve disease and heart failure, with loss of outpatient follow-up. Initial management with adenosine showed no response but revealed atrial activity suggestive of atrial flutter. Amiodarone was initiated, resulting in adequate rhythm control. Transthoracic echocardiography demonstrated marked right atrial enlargement, mild right ventricular dilation, and severe tricuspid regurgitation, in addition to moderate left ventricular systolic dysfunction. Multimodality imaging confirmed the diagnosis of Ebstein anomaly. The patient underwent tricuspid valve repair using the cone technique, associated with right atrial reduction and reconstruction of the right ventricular outflow tract. In the early postoperative period, echocardiography showed reduction of tricuspid regurgitation to mild degree, recovery of left ventricular function, and persistence of right ventricular dysfunction. During follow-up, she developed recurrent atrial tachyarrhythmias, requiring antiarrhythmic therapy and electrical cardioversion. At late evaluation, persistent atrial tachyarrhythmia and ongoing right ventricular dysfunction were observed, without hemodynamic compromise. She was discharged on beta-blocker, digoxin, amiodarone, and oral anticoagulation, with planned outpatient follow-up and consideration of catheter ablation. Conclusions: Ebstein anomaly may present in adulthood, including in advanced age groups, with atrial arrhythmias as the initial manifestation. Surgical correction using the cone technique improves valvular function; however, residual right ventricular dysfunction and recurrence of arrhythmias are common, requiring long-term follow-up and individualized management.

21660

PATENT FORAMEN OVALE AS A CAUSE OF CHRONIC HYPOXEMIA: A CASE REPOR

DJALMA MARIANO VILELA1; HENRIQUE PATRUS MUNDIM PENA1; GIOVANINE PIRES DE CAMARGOS1; DANILO CASTRO PIRES DE ALMEIDA1; MARINA PINHEIRO ROCHA FANTINI1; GABRIEL SEIXAS CARVALHO1; LUCAS LODI JUNQUEIRA1; MARCO ANTONIO MOURA1; ÉRICA SILVA1; CAMILA SOUZA GODINHO1; ANA LUIZA VALLE MARTINS1; FERNANDA DEL CASTANHEL1;

(1) REDE MATER DEI DE SAUDE - BELO HORIZONTE - MG - BRASIL;



Introduction: Patent foramen ovale (PFO) is the most common congenital cardiac abnormality of fetal origin[1], which typically closes after birth but may persist in up to 25% of adults[2], remaining asymptomatic in most cases[3]. PFO is classically associated with cryptogenic stroke resulting from paradoxical embolism. However, in some patients, a right-to-left shunt with clinical repercussions may occur; resting hypoxia is a rare manifestation, generally related to the presence of predisposing variants such as atrial septal aneurysm[4]. Case Description: A 21-year-old female patient with a diagnosis of congenital total atrioventricular block, having used a pacemaker since the age of two, with no other known structural cardiac abnormalities. She presented with chronic hypoxemia (baseline oxygen saturation of 87% on room air), associated with peripheral cyanosis and digital clubbing, previously investigated for pulmonary etiologies without a definitive diagnosis. She progressed with worsening dyspnea, hypoxemia, and syncopal episodes, leading to hospital admission for further investigation. During the diagnostic workup, she underwent a transthoracic echocardiogram with microbubbles, which suggested a right-to-left shunt, later confirmed by transesophageal echocardiogram, revealing an atrial septal aneurysm with immediate passage of microbubbles from the right atrium to the left atrium. Right heart catheterization confirmed a patent foramen ovale with a significant right-to-left shunt (right atrial pressure: 8 mmHg; left atrial pressure: 6 mmHg; mean pulmonary artery pressure: 11 mmHg), without right ventricular dysfunction or tricuspid regurgitation. An occlusion test resulted in an immediate increase in arterial saturation (from 90% to 98%) without an increase in right atrial pressures, followed by a drop after balloon deflation, confirming the functional repercussion of the shunt. Percutaneous PFO closure was performed, resulting in improvement of hypoxemia and regression of peripheral cyanosis. Conclusions: Patent foramen ovale is a frequent condition and, in most cases, carries no clinical repercussion. However, it should be considered in the investigation of intracardiac shunts and may be the cause of unexplained chronic hypoxemia, as in the present case, with the possibility of resolution following appropriate treatment.

RIGHT HEART DILATION IN A CASE OF DUCHENNE MUSCULAR DYSTROPHY: UNRAVELING A DIAGNOSTIC CHALLENGE THROUGH MULTIMODALITY IMAGING

ANDRESSA MUSSI SOARES1; LEONARDO MUSSI SOARES1; BERNARDO MUSSI SOARES1; RENATA MOREIRA DE BACKER PACIFICO1; SUSI LEAL ARANHA1; IZABEL CRISTINA TEIXEIRA PAULA1; LUIZ FERNANDO LUNZ1; AMANDA SAID BRITTO1; FATIMA FERNANDA D LESSA1; SAULO AYUB FERNANDES1; PAULO JOSE FERREIRA SOARES1; ARIANE BINOTI PACHECO1;

(1) HOSPITAL EVANGELICO (HECI) - CACHOEIRO DE ITAPEMIRIM - ES - BRASIL;

Introduction: Duchenne muscular dystrophy (DMD) is characterized by progressive cardiomyopathy, predominantly affecting the left ventricle. Although right ventricular involvement may occur, significant right heart dilation is uncommon in early stages and should prompt investigation for alternative etiologies. In this context, multimodality imaging plays a pivotal role in clarifying complex and potentially misleading clinical scenarios. Case Description: A 10-year-old male with genetically confirmed Duchene muscular dystrophy (deletion of exons 45–50), weighing 28 kg and measuring 124 cm in height, under long-term cardiologic follow-up, presented with borderline left ventricular ejection fraction and reduced global longitudinal strain, under optimized medical therapy. During follow-up, he developed marked right atrial and right ventricular dilation, disproportionate to the expected pattern of DMD. Transthoracic echocardiography was limited by suboptimal acoustic windows, related to the patient's body habitus in the context of DMD. Cardiac magnetic resonance revealed significant right heart enlargement with preserved right ventricular function and raised suspicion of partial anomalous pulmonary venous connection (PAPVC). Cardiac computed tomography confirmed a complex PAPVC, with three right pulmonary veins draining into the superior vena cava and the left upper pulmonary vein draining into the innominate vein, while inferior pulmonary veins drained normally into the left atrium, resulting in a significant left-to-right shunt. The patient underwent successful surgical correction, with favorable clinical outcome and evidence of reverse remodeling of the right-sided chambers on follow-up imaging. Conclusions: This case highlights that right heart dilation in DMD should not be solely attributed to myocardial involvement. Multimodality imaging was essential in unraveling a diagnostic challenge, allowing identification of a coexisting and surgically treatable congenital anomaly. An integrated imaging approach is crucial in complex patients, as it may significantly alter management and improve clinical outcomes.

RUPTURED SINUS OF VALSALVA ANEURYSM INTO RIGHT ATRIUM IN A CHILD WITH BICUSPID AORTIC VALVE: TEN-YEAR EVOLUTION

GABRIEL AMARAL1; MARCELO BRANCHI2; RAFAEL KOCINAS3; JUSSARA CALDAS4; GEISE COTRIM4;

(1) AFYA FACULDADES DE CIENCIAS MEDICAS GUANAMBI - GUANAMBI - BA - BRASIL; (2) UNIVERSIDADE FEDERAL DA FRONTEIRA SUL - PASSO FUNDO - RS - BRASIL; (3) UNOESTE CAMPOS GUARUJÁ - GUARUJÁ - SP - BRASIL; (4) AFYA FACULDADE DE CIENCIAS MEDICAS GUANAMBI - GUANAMBI - BA - BRASIL;

Introduction: Sinus of Valsalva aneurysm is a rare cardiovascular condition, representing approximately 0.09% of congenital heart diseases. Rupture constitutes the main clinical severity determinant, potentially causing acute heart failure and hemodynamic instability. Echocardiography plays a central role in diagnosis and hemodynamic assessment. Most evidence derives from retrospective series and case reports, particularly in pediatric populations, making new case descriptions valuable for understanding natural history and management strategies. Case Description: A male patient was followed since six months of age for mild aortic stenosis secondary to bicuspid aortic valve, diagnosed due to characteristic murmur. Serial transthoracic echocardiograms demonstrated stable valve dysfunction. At age 10, echocardiography revealed aneurysmal dilation of the right sinus of Valsalva with increased mobility but no color Doppler flow, measuring over 50% of unaffected sinuses diameter. Elective surgical correction was indicated. Six months later, while awaiting referral appointment, he presented to emergency department with acute chest pain, dyspnea, and presyncope during physical exertion. Examination revealed blood pressure 90/50 mmHg, heart rate 110 bpm, and grade 6/6 continuous murmur with thrill at all auscultatory areas. Urgent echocardiography confirmed rupture into the right atrium with torrential left-to-right shunt and reversed diastolic flow in abdominal aorta. Emergency cardiac surgery confirmed fistulous communication between right sinus of Valsalva and right atrium. Surgical repair included aortic annular enlargement with synthetic patch, aortic valve repair, fistula closure, and patent foramen ovale closure. At two-year follow-up, patient remains asymptomatic with unrestricted physical activity and no residual shunt on control echocardiography. Conclusions: This case documents rare ten-year longitudinal follow-up from bicuspid aortic valve diagnosis to sinus of Valsalva aneurysm rupture, potentially representing the first such documented evolution in pediatric literature. It reinforces unpredictable natural history of unruptured aneurysms even in asymptomatic patients and supports early surgical intervention when size exceeds 50% of contralateral sinus, shows progressive growth, or presents increased mobility. Echocardiography proved essential throughout clinical course. Surgical repair demonstrated excellent medium-term outcomes with no residual shunt or valvular dysfunction.

THROMBOSIS IN THE INTERATRIAL SEPTUM IN THE LATE POSTOPERATIVE PERIOD FOLLOWING REPAIR OF AN ATRIAL SEPTAL DEFECT WITH MULTIPLE SYSTEMIC EMBOLISMS.

FILIPE MENEZES FIRMINO1; MATHEUS DINIZ ARAÚJO TEIXEIRA1; MATHEUS MARTINS MONTEIRO1; DENIS CLARK CORRÊA MIRANDA1; FERNANDO ALMEIDA BEZERRA1; MOISÉS ABTIBOL MACHADO1; ANA CAROLINA MOTA DE SOUSA1; ALUISIO JULIANO BAUMGARTNER1; LUCAS DOS SANTOS VALENTE1; MARIA LUIZA GAZZANA1; JOÃO MARCOS BEMFICA BARBOSA FERREIRA1; KÁTIA DO NASCIMENTO COUCEIRO1;

(1) HOSPITAL DO CORACAO FRANCISCA MENDES - MANAUS - AM - BRASIL;

Introduction: Atrial septal thrombosis can occur in cases of septal aneurysm or postoperative percutaneous Amplatzer prosthesis implantation, and is rare after surgery to correct an atrial septal defect (ASD). Case Description: A 41-year-old female patient from Manaus- AM, with systemic arterial hypertension and surgical correction of an ostium secundum ASD in July 2024. She has been using combined oral contraceptives for 22 years, in addition to angiotensin receptor blockers and calcium channel blockers. Ten months after the surgical correction of the ASD, she began experiencing claudication in her lower limbs and dyspnea on exertion. Physical examination showed no abnormalities. The resting electrocardiogram showed altered ventricular repolarization of the anteroseptal wall. Transthoracic echocardiography revealed a heterogeneous, pedunculated, and mobile mass adhered to the left atrial face of the interatrial septum, measuring 11 × 17 mm, suggesting a differential diagnosis between atrial myxoma and thrombus. In contrast, cardiac magnetic resonance imaging described the lesion as homogeneous, isointense on T1, without late enhancement, an appearance more compatible with thrombus. Transesophageal echocardiography confirmed a homogeneous echogenic mass covering the interatrial septum and projecting into the left atrium via a pedicle (approximately 1.1 × 0.9 cm), suggestive of thrombus. Doppler ultrasound revealed extensive arterial thrombosis in multiple segments of both lower limbs, with significant occlusions and stenoses, suggestive of multiple systemic embolization. Without deep vein thrombosis. Antiphospholipid antibody testing and screening for hereditary thrombophilias were negative. Fifteen months after the ASD repair, the patient underwent a new surgical intervention. During the intraoperative period, a closed atrial septal defect with a bovine pericardial patch was observed, presenting a pedunculated thrombus adhered to the left atrial surface. Excision of the patch with thrombectomy, plication of the left atrium, and atrial septoplasty with a new bovine pericardial patch were performed, with good postoperative evolution. Conclusions: This is a rare report of postoperative thrombosis following ASD repair with multiple peripheral embolisms, whose thrombophilia tests were normal. It is speculated that prolonged use of contraceptives may have been the cause of the event.

FROM INTRA-AORTIC BALLOON PUMP TO ECMO AS A BRIDGE TO HEART TRANSPLANTATION: NURSING CARE IN LATE CHEMOTHERAPY-INDUCED CARDIOTOXICITY

LETICIA RODRIGUES LEITE1; REBECA EVANGELISTA FOLHADELA1; VANESSA ROSSATO GOMES1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction: Nursing care for patients with heart failure secondary to late chemotherapy-induced cardiotoxicity requiring mechanical circulatory support includes hemodynamic monitoring, infection prevention, anticoagulation management and surveillance for device complications. Case Description: 51-year-old female with breast cancer cT4aN1M0 follow-up that received neoadjuvant chemotherapy and radiotherapy. In 2018, she underwent right mastectomy and axillary node dissection, followed by adjuvant hormone therapy with Tamoxifen. In 2025, was treated for pulmonary tuberculosis and bacterial spondylodiscitis plus palliative radiotherapy at T12-L1 for four months due to suspected bone tuberculosis. The patient had dilated cardiomyopathy secondary to late chemotherapy-induced cardiotoxicity, biventricular dysfunction and LVEF of 20%. She was admitted to the intensive care unit with cardiorenal syndrome and decompensated heart failure requiring optimization of inotropic support, mechanical circulatory support with an intra-aortic balloon pump and continuous renal replacement therapy for systemic congestion. Besides, vertebral biopsy demonstrated no evidence of neoplasia, inflammatory process, or granulomatous disease. Subsequently, developed signs of low cardiac output, leading to the indication for venoarterial extracorporeal membrane oxygenation (VA-ECMO) as a bridge to heart transplantation. As a result, highly specialized nursing care was required due to hemodynamic instability and the concomitant use of multiple advanced support devices, including intra-aortic balloon pump, continuous renal replacement therapy, and VA-ECMO. Nursing care included hemodynamic monitoring, vasoactive drug management, fluid balance control, peripheral perfusion assessment and early identification of complications associated with the devices. The nursing team also played a central role to ensure patient safety during intra-hospital transport and prone positioning for vertebral biopsy, considering the limitations imposed by the intra-aortic balloon pump and the high risk of clinical instability. Emotional support for the patient and family also was essential throughout the prolonged hospitalization and the anticipation of heart transplantation. Conclusions: Systematized and specialized nursing care was essential for maintaining advanced circulatory support, ensuring patient safety, and enabling heart transplantation in a highly complex clinical context.

VEXUS AS A DECISION-MAKING TOOL IN THE MANAGEMENT OF DIURETIC THERAPY IN PATIENTS POST-CARDIAC SURGERY: A CASE REPORT

MARCOS JOSÉ VILCHEZ DAVID1; GABRIEL SANTANA DA SILVA2; ANTONIO ALVES DE FONTES JUNIOR3; NATALIA DE MOURA MARMELEIRO4; ELIDIANE SOUZA MAIA LEITE1; MARCELLE GONÇALVES ZUCHELLI1;

(1) UNIVERSIDADE ESTADUAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (3) UNIVERSIDADE CRUZEIRO DO SUL - SP - SP - BRASIL; (4) HOSPITAL UNIVERSITARIO PEDRO ERNESTO - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Point-of-care ultrasound (POCUS) is a tool for assessing venous congestion, with the Venous Excess Ultrasound (VExUS) technique gaining prominence. VExUS facilitates noninvasive quantification of venous congestion based on measurements of inferior vena cava (IVC) size and Doppler assessments of the hepatic vein (HV), portal vein (PV), and intrarenal vein, providing real-time information on hemodynamic status and guiding therapeutic interventions. The VExUS classification system aids in stratifying the severity of congestion. Case Description: Patient J.G.M., male, born in Rio de Janeiro, 79 years old, widower, with hypertension, type 2 diabetes, dyslipidemia, and a history of smoking for 18 years. Admitted in the late postoperative period following coronary artery bypass grafting (CABG) with 3 bypasses, 48 hours prior, requiring ventilation via nasal cannula at 2 L/min, tachycardic, tachypneic, hyperthermic, with a urine output of 0.40 mL/kg/h over the past 6 hours. On physical examination, he presents with cold skin, capillary refill time >3s, clammy skin, and bilaterally edematous lower extremities. Laboratory results show Cr 2.1 mg/dL, lactate 3.2 mmol/L, elevated BNP, and Hb 9.8 g/dL. When performing a POCUS was performed, revealing diffuse hypokinesis in the cardiac window and an enlarged (2.5 cm) left ventricle with collapse. Bilateral B-lines were present, suggestive of pulmonary congestion. Low cardiac output and systemic congestion were noted, and VExUS the IVC was performed. It revealed slight collapse of the IVC, with reverse flow during systole, increased pulsatile right ventricle (>50%), and a discontinuous pattern in the renal vein, concluding a grade 3 classification of severe venous congestion. Based on the nursing diagnoses of decreased cardiac output, ineffective renal perfusion, impaired gas exchange, and fluid volume excess. The medical team was called, and diuretics and inotropes were initiated, in addition to maintaining strict fluid balance. Conclusions: VExUS has proven to be a decisive tool in guiding diuretic therapy and the initiation of inotropic therapy in the postoperative period following cardiac surgery, as it allows for an objective assessment of venous congestion and greater precision in volume management. The use of this technology strengthens the nurse's role in advanced hemodynamic assessment, expands professional autonomy, and contributes to safer, individualized care grounded in scientific evidence.

IMPLEMENTATION OF A CARDIAC AMYLOIDOSIS CENTER OF EXCELLENCE IN A TERTIARY PRIVATE HOSPITAL: A CASE STUDY FROM BRAZIL

LUIS FILIPE AZEVEDO DE CARVALHO1; LEONARDO ANDRADE FERNANDES DE LUCA1; LARISSA FRANCO DE ANDRADE2; MARIA DE FATIMA MARTINS GIL DIAS3; ANDRE LUIZ DIAS LIMA BONFIM3; ANE CRISTINE DE SOUZA CORREIA1; BIANCA FERREIRA BRITO1; BERNARDO BARCELOS FERNANDES FUNAGALLI SILVA3; ISABELA DA COSTA FURTADO1; FABIOLA LUCIO CARDÃO1; JEORGIANE DE ASSUMPÇÃO COSTA1; RODRIGO VASCONCELLOS TAVARES BRAVO3;

(1) HOSPITAL QUINTA D'OR - RIO DE JANEIRO - RJ - BRASIL; (2) HOSPITAL QUINTA D'OR - R - RJ - BRASIL; (3) HOSPITAL QUINTA D'OR - RIO - RJ - BRASIL;

Introduction: Background: Cardiac amyloidosis remains underdiagnosed due to low clinical suspicion and limited access to diagnostic tools. Centers of excellence may improve detection and management of rare diseases. Objectives: To describe the implementation of a cardiac amyloidosis center in a tertiary private hospital and evaluate its initial impact on diagnosis and treatment. Case Description: Methods: This is a case study conducted in a tertiary hospital in Rio de Janeiro, Brazil. Implementation strategies included multidisciplinary team formation, diagnostic workflow structuring, professional training, and partnerships to enable access to advanced diagnostic methods. Data were collected from institutional registries during the first year of operation. Results: Seventeen patients were referred in the first year. Five cases of transthyretin amyloidosis (ATTR) and two cases of light-chain amyloidosis (AL) were diagnosed. All patients underwent echocardiography, 82% underwent cardiac MRI, and 41% underwent scintigraphy. Targeted therapies, including Tafamidis for transthyretin amyloidosis and chemotherapy for the cases of light-chain amyloidosis, were initiated accordingly. Compared to previous institutional data, there was a significant increase in diagnostic rates. Conclusions: Conclusion: The implementation of a center of excellence significantly improved clinical suspicion, diagnostic capacity, and treatment initiation in cardiac amyloidosis. This model may be replicated for other rare cardiovascular diseases at the same institution and may be replicated for the same disease at others hospitals.

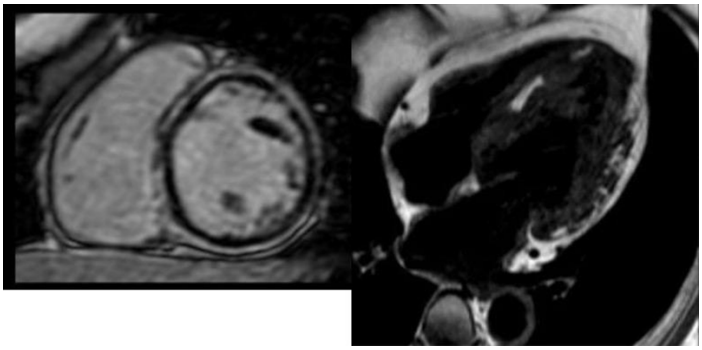
Introduction: Sudden cardiac death in young individuals, especially during physical activity, is a rare event but is often associated with genetic cardiomyopathies, such as hypertrophic cardiomyopathy. We report the case of a previously healthy male patient who presented with cardiac arrest during sports activity. Case Description: A 22-year-old previously healthy male from Tabatinga (AM), Brazil, experienced a sudden collapse during physical activity (soccer), progressing to witnessed cardiac arrest. Cardiopulmonary resuscitation was initiated on-site and maintained for approximately 40 minutes until return of spontaneous circulation. The patient developed initial respiratory and neurological complications, with progressive clinical recovery during intensive care unit hospitalization. Given the suspicion of arrhythmic etiology, an implantable cardioverter-defibrillator was indicated for secondary prevention of sudden cardiac death. Electrocardiogram showed right bundle branch conduction abnormality. Echocardiography and cardiac magnetic resonance imaging were within normal limits, with preserved cardiac dimensions and systolic function, and no evidence of structural abnormalities. Etiological investigation included genetic testing, which revealed a pathogenic variant in the MYBPC3 gene, consistent with genetically determined hypertrophic cardiomyopathy, despite the absence of overt structural changes. Conclusions: This case highlights the importance of genetic investigation in young patients with unexplained cardiac arrest, as well as the relevance of genotype–phenotype correlation in risk stratification and clinical management.

15915



CURLY HAIR AND PALMOPLANTAR KERATODERMA AS DIAGNOSTIC CLUES TO LEFT-DOMINANT ARRHYTHMOGENIC CARDIOMYOPATHY: A RARE CASE OF CARVAJAL SYNDROME

LUCAS GUIMARÃES DA ROCHA1; VILMAR DA ROCHA II1; LUIZ FELIPE FERNANDES CALDAS1; LUIZA BARRETO ARAÚJO DE OLIVERA1; LUÍSA ARAÚJO MARINHO SILVA1; MONALISA SANTOS CAVALCANTI1; MARIA LUIZA ANDRADE MENESES1; JOSÉ MANOEL FREIRE FILHO NETO1; ERIC ZEIN GAMA RODRIGUES1; CARLOS AURÉLIO SANTOS ARAGÃO1;

(1) UNIVERSIDADE TIRADENTES (UNIT) - ARACAJU - SE - BRASIL;

Introduction: Carvajal syndrome is a rare inherited cardiocutaneous disorder caused by bi-allelic pathogenic variants in desmoplakin (DSP), characterised by myocardial fibrofatty replacement, woolly hair, and palmoplantar keratoderma. Left-dominant arrhythmogenic cardiomyopathy (LDAC) represents a particularly rare and diagnostically challenging phenotype within this spectrum. Case Description: A 32-year-old male with no prior medical history presented with a two-month history of progressive dyspnoea, orthopnoea, paroxysmal nocturnal dyspnoea, and peripheral oedema. No family history of cardiomyopathy or sudden cardiac death was reported. Physical examination revealed NYHA class III heart failure, jugular venous distension, and positive hepatojugular reflux. Transthoracic echocardiography demonstrated severe left ventricular dilatation with markedly reduced ejection fraction. Cardiac magnetic resonance imaging revealed extensive circumferential subepicardial late gadolinium enhancement forming a ring-like pattern, highly suggestive of DSP-related cardiomyopathy. Dermatological assessment identified diffuse palmoplantar keratoderma and woolly hair. Genetic testing confirmed a pathogenic DSP variant. Guideline-directed medical therapy was optimised and an implantable cardioverter-defibrillator was implanted for primary prevention given the high arrhythmic risk associated with the DSP genotype. The patient remains clinically stable on outpatient follow-up. Conclusions: LDAC may manifest as new-onset heart failure in young adults without family history, underscoring the importance of systematic extracardiac examination. Woolly hair and palmoplantar keratoderma are pathognomonic clues that, when integrated with multimodality imaging and genotype-phenotype correlation, enable timely diagnosis and risk stratification in cardiocutaneous syndromes

16458

EARLY GRANULOMATOUS RECURRENCE OF CARDIAC SARCOIDOSIS IN THE ALLOGRAFT: DIAGNOSIS AND MANAGEMENT

LORENNA OLIVEIRA MENEZES1; CAROLINA CASADEI DOS SANTOS1; PLINIO JOSE WHITAKER WOLF1; RAPHAEL MACHADO ROSSI1; VICTOR BEMFICA DE MELLO MATTOS1; MARCO AURELIO FINGER1; JOAO MANOEL ROSSI NETO1; AMANDA MAGNAGO FACCINI1; ALICE MONTEIRO SOARES CAJAIBA SOARES1; ANTONIO DOSUALDO NETO1; ALEXANDRE DINIZ MENDES DA SILVA1; HAISSA ASSAD DOS SANTOS GERALDO1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction: Cardiac sarcoidosis is a rare and potentially fatal cause of dilated cardiomyopathy that may progress to refractory heart failure requiring heart transplantation. Recurrence of the disease in the allograft has been described in the literature; however, its incidence, timing, and optimal management remain poorly defined. Endomyocardial biopsy (EMB) plays a central role in surveillance and diagnosis in this setting. Case Description: A 38-year-old male, former athlete, diagnosed with dilated cardiomyopathy secondary to cardiac sarcoidosis (cardiac MRI with ring-like late gadolinium enhancement pattern; negative genetic panel for inherited cardiomyopathy). He underwent orthotopic bicaval heart transplantation due to advanced heart failure with cardiogenic shock. Native heart pathology confirmed sarcoidosis. First surveillance EMB (post-transplant week 7): ISHLT Grade 0R, no granulomas. Second EMB (post-transplant week 10): granulomatous myocarditis with lymphohistiocytic infiltrate and giant cells in 2 of 5 fragments, consistent with sarcoidosis recurrence in the allograft, associated with acute cellular rejection Grade 2R. Intravenous methylprednisolone pulse therapy was administered for 11 days, followed by transition to oral corticosteroids with a taper extended beyond the standard 6-month protocol, along with optimization of mycophenolate sodium. Third EMB (post-transplant week 12): ISHLT Grade 0R, no granulomas on serial histological sections. Conclusions: Cardiac sarcoidosis can recur in the allograft, manifesting even in early postoperative phases. Serial EMB surveillance is essential in transplant recipients with sarcoidosis as the underlying etiology. Extended corticosteroid maintenance beyond standard protocols may be warranted in this subgroup. This case highlights the importance of individualized immunosuppressive strategies in high-risk transplant populations.

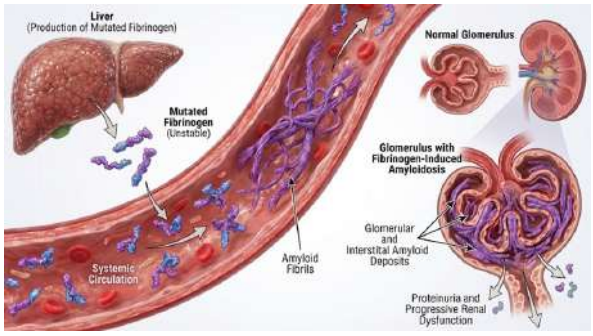
16501

GLOBALLY RARE VARIANT, PREDOMINANT IN ASIA, CAUSING HEREDITARY TRANSTHYRETIN AMYLOIDOSIS IN THE BRAZILIAN AMAZON

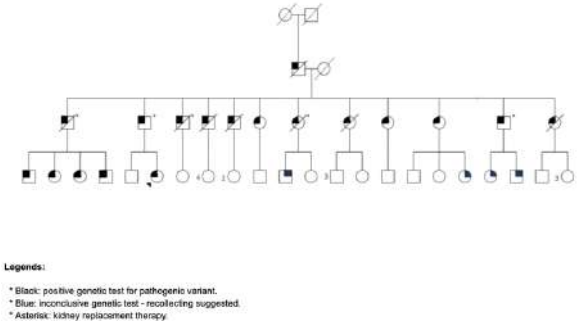
MATHEUS MARTINS MONTEIRO1; MARCELA OLIVEIRA DE AZEVEDO2; MOISES ABTIBOL MACHADO2; FERNANDO ALMEIDA BEZERRA2; NAYARA DO CARMO SANTOS LIMA2; DIOGO CORRÊA LAMBERTI2; ANDREZA ARAÚJO DE OLIVEIRA3; DÊNISON CLARK CORRÊA DE MIRANDA2; ALUÍSIO JULIANO BAUMGARTNER4; ANA CAROLINA MOTA DE SOUZA4; KÁTIA DO NASCIMENTO COUCEIRO2; JOÃO MARCOS BEMFICA BARBOSA FERREIRA2;

(1) BENEFICENCIA PORTUGUESA - SAO PAULO - AM - BRASIL; (2) UNIVERSIDADE DO ESTADO DO AMAZONAS - MANAUS - AM - BRASIL; (3) UNIVERSIDADE NILTON LINS - MANAUS - AM - BRASIL; (4) HOSPITAL DO CORACAO FRANCISCA MENDES - MANAUS - AM - BRASIL;

Introduction: Transthyretin amyloidosis may occur in either wild-type or hereditary forms. In Brazil, the most common variants are Val50Met and Val142Ile. The Asp58Ala variant is considered globally rare and has not been described in large epidemiological studies conducted in Brazil. In Asian populations, particularly in South Korea, it has been reported as the most frequent variant. This report describes the detection of this variant in the Brazilian Amazon. Case Description: This was a descriptive study conducted at a referral center in the Amazon region. Patients with hereditary transthyretin amyloidosis carrying the Asp58Ala genetic variant confirmed by genetic testing were included. Results: In recent years, ten cases of hereditary transthyretin amyloidosis associated with the Asp58Ala variant were diagnosed through genetic testing in a cardiology service in the Amazon. Among these patients, six were index cases and four were identified through family screening. In the state of Amazonas, this variant accounted for 27.3% of index cases, representing the most frequent mutation alongside Val50Met. The mean age at diagnosis was 59.7 years, with a predominance of female patients (77.8%). Most patients originated from the municipality of Maués (66.7%), followed by Manaus (22.2%) and Barcelos (11.1%), reinforcing the regional concentration of cases. Regarding clinical presentation, the mixed phenotype was the most prevalent (55.6%), followed by asymptomatic cases (22.2%), isolated cardiac involvement (11.1%), and familial amyloid polyneuropathy (11.1%), highlighting the phenotypic heterogeneity of the disease. Among index cases, the mean left ventricular ejection fraction was 53.8%, with a mean septal thickness of 16.2 mm and posterior wall thickness of 14.4 mm. During follow-up, three of the six index cases died, corresponding to 33.3% of the total sample. In addition to the index cases, four relatives carrying the same variant were identified through genetic screening and remain under specialized follow-up. Conclusions: The Asp58Ala mutation is rare and more frequently described in Asian populations. The identification of multiple cases in the Amazon highlights an unusual regional pattern with potential epidemiological relevance.



15896



HEREDITARY FIBRINOGEN DEPOSITION AMYLOIDOSIS: RARE, BUT FUNDAMENTAL FOR DIFFERENTIAL DIAGNOSIS

MARIO HENRIQUE CALIANO1; PATRICIA DE SOUZA MAGALHAES1; MATHEUS SACCO GOMES1; BRUNO LEAL MARTINS1; AMANDA RAQUEL COSTA CRUZ1; KELIN CHEN1; PLINIO JOSE WHITAKER WOLF1; EDILEIDE DE BARROS CORREIA1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction: Hereditary fibrinogen amyloidosis is a rare and frequently underdiagnosed condition. It is predominantly characterized by progressive renal involvement. The recognition of familial aggregation, associated with genetic confirmation, is fundamental for diagnosis, clinical management, and genetic counseling. Case Description: A 45-year-old white female patient, healthy, without cardiovascular manifestations at the time of evaluation, was referred due to a marked family history of chronic kidney disease and early deaths. Genetic investigation identified the pathogenic variant c.1634 A>T in the FGA gene, which is associated with hereditary fibrinogen deposition amyloidosis. In terms of family history, her paternal grandfather had advanced heart failure and her uncles and aunts (paternal side), 5 out of 12 had kidney disease requiring replacement therapy, 3 died, and another 4 died without a diagnosis of kidney disease. All of them underwent genetic testing which evidenced the presence of the same pathogenic variant. In addition to chronic kidney disease, frequently progressing to kidney replacement therapy, they also presented other heterogeneous systemic manifestations, such as amyotrophic lateral sclerosis, chronic obstructive pulmonary disease, multi-vessel coronary artery disease, and non-amyloidosis related neoplasms. In the next generation, which includes our patient, genetic screening revealed positive results in some of those investigated. The patient is asymptomatic from a cardiovascular standpoint, doesn't have structural cardiac or renal changes, and doesn't have proteinuria or renal dysfunction. Conclusions: We describe a large family with hereditary fibrinogen amyloidosis, with incomplete penetrance and variable phenotypic expressivity, predominantly featuring progressive renal involvement and high morbidity and mortality. We did not detect cardiac or renal involvement in the described patient, and the other family members were not investigated. The case reinforces the importance of clinical suspicion in the face of a suggestive family history of kidney disease, as well as genetic confirmation and cascade family screening for early diagnosis, genetic counseling, and target organ surveillance. Although this form of amyloidosis is not included among those that deposit in the heart, the presence of heart failure in the family may raise this possibility, which was not investigated.

20332

PRKAG2 CARDIOMYOPATHY AND PROGRESSION TO ADVANCED HEART FAILURE: DIAGNOSTIC AND THERAPEUTIC CHALLENGES

ANDRE LUCAS ARCOVERDE VIEIRA1; MARIA CARDOSO GUERREIRO COSTA1; BIANCA DE ALMEIDA NUNES1; CRISTIANO RICARDO BASTOS DE MACEDO1; YANDRA GORDIANO AMÂNCIO1; LORENA LIMA WEBER1; GARDENIA ELLEN ALMEIDA DE AMORIM1; JOSEYLTON GONÇALVES SANTANA1; ADIMEIA SANTOS1; ALEX TEIXEIRA GUABIRU1; JUSSARA DE OLIVEIRA PINHEIRO1; LUÍS PEREIRA DE MAGALHÃES1;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL;

Introduction: PRKAG2 cardiomyopathy is a rare autosomal dominant genetic disorder resulting from glycogen deposition, characterized by ventricular pre-excitation and myocardial hypertrophy. The phenotype mimics hypertrophic cardiomyopathy, frequently associated with arrhythmias, sudden death, and the need for cardiac device. We report a case of progression to advanced heart failure (HF), highlighting clinical and therapeutic aspects. Case Description: A 49-year-old woman with a family history of cardiomyopathy presented with electrocardiographic evidence of ventricular pre-excitation and marked concentric left ventricular hypertrophy (echocardiography: interventricular septum 22 mm; posterior wall 20 mm). Due to these findings and episodes of syncope, an implantable cardioverter-defibrillator was indicated. Family screening identified the Iç5 years with progressive HF (NYHA functional class IV). In 2022, the left ventricular ejection fraction (LVEF) on cardiac magnetic resonance imaging was 44%, in addition to ventricular dyssynchrony. Progressive deterioration of ventricular function was later documented on echocardiography, with LVEF declining to 27% in 2025. Due to the presence of ventricular dyssynchrony, advanced HF, and recurrent hospitalization for decompensation, cardiac resynchronization therapy was performed. Although symptomatic improvement was achieved, the patient remains under evaluation for heart transplantation. Conclusions: PRKAG2 cardiomyopathy is a genetic heart disease with a progressive clinical course. This case demonstrates the possibility of progression of this heart disease to advanced heart failure, reinforcing the importance of genetic investigation and family screening. Early diagnosis allows for appropriate monitoring and treatment, including the indication of implantable devices and heart transplantation, capable of reducing severe outcomes.

Introduction: Introduction: Left atrial appendage aneurysm (LAAA) is an uncommon anomaly that may be congenital, usually related to dysplasia of the pectinate musculature or pericardial defects, or acquired, secondary to mitral valve disease or chronic atrial hypertension. It can lead to serious complications, including arrhythmias and thromboembolic events, with stroke reported in up to 12% of cases. Case Description: Case: A 49-year-old previously healthy woman presented with recurrent ischemic stroke despite oral anticoagulation. On initial evaluation, atrial fibrillation was documented, and computed tomography angiography revealed an enlarged left atrial appendage measuring 7.6 × 4.7 cm. Decision making: Given the history of embolic events and persistent atrial fibrillation, the dilated appendage was considered the most likely substrate for thrombus formation and arrhythmogenesis. Medical management with anticoagulation was deemed insufficient to adequately reduce the high risk of recurrent thromboembolic events. The case was reviewed by a multidisciplinary team (cardiology, cardiac surgery, and radiology), and surgical resection of the aneurysmal appendage was recommended as definitive treatment. The patient underwent successful excision of the aneurysm, with intraoperative findings confirming a large, thin-walled saccular dilation. Postoperative recovery was uneventful, and the patient was discharged in good condition under rhythm control and anticoagulation therapy. Conclusions: Conclusion: LAAA is an exceptionally rare diagnosis. Early recognition through multimodality imaging is essential, particularly in patients with unexplained left atrial enlargement, arrhythmias, or embolic events. Timely surgical intervention may transform prognosis and prevent devastating and irreversible complications.

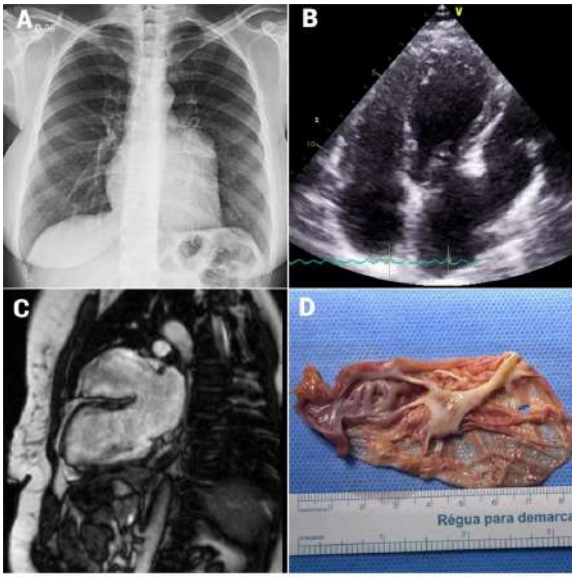

FIGURE 1: Imaging findings of a left atrial appendage aneurysm. (A) Chest X-ray showing prominence of the left atrium. (B) Transthoracic echocardiogram in a four-chamber view demonstrating the left atrial appendage aneurysm. (C) Cardiac magnetic resonance imaging showing left atrial enlargement. (D) Macroscopic view of the surgical specimen, with the left atrial appendage aneurysm measuring approximately 8 cm in diameter.

BLOOD PRESSURE INSTABILITY ASSOCIATED WITH CHRONIC CANNABIS USE IN A HYPERTENSIVE PATIENT WITH MODERATE AORTIC REGURGITATION: A 24-HOUR AMBULATORY BLOOD PRESSURE MONITORING (ABPM) CASE REPORT

MARIANA DAMIAO SEABRA ROSANAO1; AMANDA PAULA NOZELA2; LUIZ FERNANDO MARIANO REZENDE3; AMANDA TIEMI YOKOTA4; MIRIAM DAMIAO GOMES SEABRA5;

(1) UNIVERSIDADE CATOLICA DE BRASILIA - BRASÍLIA - DF - BRASIL; (2) UNIVERSIDADE DE UBERABA - UBERABA - MG - BRASIL; (3) HOSPITAL UNIVERSITARIO SAGRADA FAMILIA - ARAGUARI - MG - BRASIL; (4) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (5) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - MG - BRASIL;

Introduction: Cannabis may produce complex cardiovascular effects, including transient blood pressure elevation and clinically significant hypotension after use. These effects may be especially relevant in patients with structural heart disease. This study aimed to analyze the impact of chronic cannabis use on blood pressure control in a hypertensive patient with moderate aortic regurgitation. Case Description: A 61-year-old physically active man with hypertension and moderate aortic regurgitation, followed as an outpatient for 3 years, presented with marked blood pressure oscillation, dizziness, and anxiety. He had smoked cannabis for 20 years. Past history included diverticulitis with vesicocolic fistula and two abdominal surgeries. Medications included olmesartan 20 mg, hydrochlorothiazide 25 mg, and bupropion 300 mg. Office blood pressure was 150/70 mmHg. He had recently reduced cannabis use, although he continued nightly smoking before sleep. The most relevant pattern occurred after cannabis use, when he developed symptomatic hypotension with dizziness, weakness, and persistence of low blood pressure during sleep. Twenty-four-hour ambulatory blood pressure monitoring (ABPM) showed normal mean blood pressure (125/61 mmHg), yet documented post-cannabis hypotension, followed by awakening at around 3:00 a.m. with agitation. Management included psychological and psychiatric support, olmesartan reduction to 10 mg, and counseling for cannabis cessation. At 30-day follow-up, symptoms improved and blood pressure normalized to 120/60 mmHg. Conclusions: This case shows that normal average values on ambulatory blood pressure monitoring may conceal clinically relevant symptomatic hypotension related to cannabis use. In moderate aortic regurgitation, post-cannabis blood pressure decline may have greater impact because of the underlying valvular physiology and wide pulse pressure. Recognition of this pattern may support careful antihypertensive adjustment, gradual cannabis cessation, mental health support, and close hemodynamic follow-up.

HYPERTENSIVE EMERGENCY AS THE INITIAL MANIFESTATION OF POLYCYTHEMIA VERA IN A YOUNG PATIENT: A CASE REPORT

JOAO DA SILVA FERREIRA MARINHO1; LUCAS MACEDO AURÉLIO PAIVA1; FRANCISCO THIAGO SANTOS SALMITO2; GABRIEL TEIXEIRA MONTEZUMA SALES3; LETÍCIA TIMBÓ MARTINS FERREIRA1; CECÍLIA GABRIELA DANTAS DE SOUZA1; LUANA VELOSO MAGALHÃES1; MARINA CARVALHO LIMA MENDONÇA1; LUANA RODRIGUES DAROWISH1; BRUNO SANTOS CHAVES1; RAFAELA RIOS SABINO1; RENAN GOMES MENDES DINIZ1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (2) UFC - FORTALEZA - CE - BRASIL; (3) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Introduction: Hypertensive emergency (HE) is associated with thrombotic microangiopathy (TMA), a condition with diverse etiologies. Polycythemia vera (PV) typically affects older individuals and is commonly associated with thrombotic events; however, its presentation as renal TMA in young patients is rare. This report describes a case of PV presenting as HE with renal involvement in a young patient. Case Description: A 23-year-old male was admitted with altered mental status, headache, nausea, and vomiting. Blood pressure was 212/144 mmHg. Physical examination was unremarkable. Intravenous sodium nitroprusside was initiated. Fundoscopy and brain CT were normal. Laboratory tests revealed polycythemia (hemoglobin 18.5g/dL; hematocrit 56.4%), thrombocytosis (1,200,000/mm³), and renal dysfunction (creatinine 3.54mg/dL; urea 56mg/dL), along with hyperkalemia (5.7mEq/L) and significant proteinuria (protein-to-creatinine ratio 2.2g/g). Urinalysis showed leukocyturia without hematuria. Renal ultrasound revealed normal kidney size, increased echogenicity, and patent renal arteries. The etiological investigation excluded autoimmune, infectious, and endocrine causes of secondary hypertension. Evaluation of polycythemia revealed a JAK2 V617F mutation, confirming the diagnosis of PV as the underlying etiology, associated with acquired von Willebrand disease. Initial assessment showed reduced von Willebrand factor (vWF) activity, which improved after hematologic stabilization under cytoreductive therapy. Given the reduced bleeding risk, a kidney biopsy was performed 15 days after admission due to persistent renal dysfunction and proteinuria. It revealed diffuse mesangiolysis, interstitial fibrosis with lymphomononuclear infiltrate, focal hyalinosis, and onion-skin arteriolar myointimal proliferation. Immunofluorescence showed IgM and C3 mesangial deposits, consistent with thrombotic microangiopathy (TMA) After 25 days, the patient was discharged on losartan 100mg per day. Six months follow-up has shown improvement in creatinine level (2.4mg/dL), hemoglobin 16.5g/L but no thrombotic event. Conclusions: This case illustrates an atypical age presentation of PV, resulted in chronic kidney disease due to the rapid progression of TMA without systemic manifestations. Although uncommon, PV may present with small-vessel TMA leading to kidney disease in young patients. This case highlights the importance of a thorough investigation of hypertension in young individuals, considering diverse etiologies to ensure optimal care.

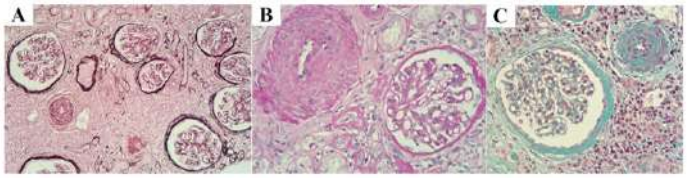

Figure 1. Histopathological findings in the patient's renal biopsy. Microscopic analysis of the kidney biopsy with hematoxylin and eosin staining revealed (**A**, 40×; **B**, 100×) diffuse mesangiolysis, focal segmental mesangial expansion, and concentric interstitial fibrosis accompanied by lymphomononuclear inflammatory infiltrate. Additionally, there was focal hyalinosis and arteriolar myointimal proliferation with an onion-skin pattern. Immunohistochemical examination targeting immunoglobulin M demonstrated (**C**, 100×) finely granular deposits in the mesangium, confirming the diagnosis of thrombotic microangiopathy in a reparative phase.

REFRACTORY HYPERTENSION RESPONSIVE TO AMILORIDE: A CASE OF LIDDLE SYNDROME

PEDRO HENRIQUE DE ANGELO PEREIRA1; LETICIA CAROLLYNE GALVÃO1; TALITA BEITHUM RIBEIRO MIALSKI1; ROBSON FERNANDO GARCIA DE LIMA1; GUSTAVO LENCI MARQUES1; EDUARDO MARTELLI MOREIRA1; JULIA BERTOL1; RAMON EDUARDO SZYMCZAK CONDE1; MATEUS FRANZONI BOCHNIA1; BETINA VILLACA MONTEIRO1; ALESSANDRA AYUMI TANAKA1; PÂMELA SANDRI1;

(1) CHC-UFPR - CURITIBA - PR - BRASIL;

Introduction: Liddle Syndrome is a disorder characterized by increased function of the epithelial sodium channel of the distal nephron, leading to excessive sodium retention and potassium excretion, metabolic alkalosis and early-onset hypertension. These features often mimic primary hyperaldosteronism, but the renin and aldosterone dosages are normal or low. It can also cause sudden death due to arrhythmias caused by hypokalemia and ventricular hypertrophy. Case Description: A 58-year old female patient was admitted to investigate secondary causes and optimize treatment of refractory hypertension. At the moment of admission, the patient was receiving olmesartan, amlodipine, hydrochlorothiazide, spironolactone, carvedilol, methyldopa, hydralazine and clonidine. Medical history includes diagnosis of hypertension at 12 years old and familiar history of two siblings with unexplained sudden death at 7 and 21 years of age. During the hospitalization, the patient maintained systolic pressure between 190 and 220mmHg at all times. The inpatient screening of secondary causes of hypertension was negative for aortic coarctation, renal artery stenosis and other renal or adrenal causes, and hypercortisolism; electrolytes were within the normal range. The serum bicarbonate was 26,5mmol/L (normal range 22-26), renin 4,3µUI/mL (normal range 2,8-39) and aldosterone 5,2ng/dL (normal range 1,76-23,3). Previous dosage of plasmatic renin activity was below the normal range. Considering hypertension diagnosed at a young age associated with metabolic alkalosis, renin and aldosterone near the lower limit of normal and unexplained sudden death in the family, the hypothesis of Liddle Syndrome was considered and amiloride and chlorthalidone were initiated in association due to the disponible formulations. In the first day of amiloride administration, the systolic pressure decreased to values between 140 and 170mmHg and in the following days it decreased to values between 100 and 130mmHg with the need to lower the dosage of other hypertension medications due to hypotension. The bicarbonate dosage was normalized and the patient was discharged after 5 days. Genetic testing has not been done yet. Conclusions: Liddle Syndrome is a rare cause of hypertension not responsive to spironolactone and needs to be considered in patients with early-onset hypertension with no apparent cause. If genetic testing is not readily available, therapeutic testing with amiloride may be considered.

GHOST THROMBUS ON LEFT ATRIAL APPENDAGE. STOP OR GO AHEAD ON CLOSURE IT?

THYAGO FURQUIM1; HERBERT IAGO FEITOSA DA FONSECA1; NATALIA SAVASTANO JORGE1; RAFISAH SEKEFF SIMÃO ALENCAR1; MARIA LUIZA ARANEGA DE ASSIS FIGUEIREDO1; SILVÉRIO ALBANO FERNANDES JÚNIOR1; LOURENÇO TEIXEIRA LIGABÓ1; DIEGO ANTONIASSI1; BENEDITO DARCI DE CAMARGO NETO1; THOMÁS BORGES CONFORTI1;

(1) UNICAMP - CAMPINAS - MT - BRASIL;

Introduction: The left atrial appendage (LAA) is a small ear-shaped structure that is attached to the left atrium of the heart. This small structure may present low to moderate blood flow, which is an important component of Virchow's triad for thrombus formation. In this context, several studies have evaluated its closure to prevent thromboembolic consequences, with varying results. This report describes a patient previously on anticoagulation, with no thrombus detected in the echocardiogram, who subsequently developed a sudden stroke and was later found to have a thrombus in the LAA during angiography closing procedure. Case Description: An 86-year-old female with a history of hypertension, dyslipidemia, diabetes, and permanent atrial fibrillation on DOACs was initially admitted with decompensated heart failure. During hospitalization, she developed melena with significant bleeding, requiring blood transfusion. Upper endoscopy and colonoscopy were performed but did not identify active bleeding. Capsule endoscopy was then performed, revealing intestinal ulcers, which were treated with argon plasma coagulation. Given the need for anticoagulation and the high bleeding risk, left atrial appendage occlusion (LAAO) was proposed. Transthoracic echocardiography showed no thrombus and preserved emptying velocity. A decision was made not to perform CT imaging due to impaired renal function. Four days after transesophageal echocardiography, the patient developed sudden left hemiplegia, and stroke was confirmed by MRI. After heart team discussion, the decision was made not to reintroduce DOACs and to maintain aspirin 100 mg daily. LAAO was performed three days after the stroke. Intra-procedural transesophageal echo showed no thrombus in the LAA. Cerebral protection was not available (healthcare insurance denied). Angiographic images during the procedure demonstrated a thrombus in the distal segment of the appendage. A "no-touch" technique was considered feasible and was performed despite the associated risks. Due to the high bleeding risk, the patient was maintained on aspirin alone after the procedure, and showed a good functional recovery. Conclusions: Thrombi can form quickly in the LAA, even with a few days without use of anticoagulants. The size, location and mobility ot the thrombi should be evaluated to help in the decision of the progression ou postergation of the procedure. Cerebral Protection should be considered in cases like this.

HETEROTOPIC CAVAL VALVE IMPLANTATION WITH TRICVALVE FOR TORRENTIAL TRICUSPID REGURGITATION IN EBSTEIN'S ANOMALY

ANDRÉS G. SÁNCHEZ1; CARLOS A. F. NOVO1; IBSEN S. TRINDADE1; WALNEY RABELO DE SOUZA1; NATHALIE ADAMOGLU DE MENDONÇA1; MARCIO JOSE MONTENEGRO2;

(1) UNIVERSIDADE FEDERAL DO TOCANTINS - PALMAS - TO - BRASIL; (2) IECAC - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Ebstein's anomaly is a rare congenital heart disease frequently associated with severe tricuspid regurgitation and progressive right heart failure. Management becomes particularly challenging in patients with prior surgical repair and high risk for reintervention. In this context, transcatheter therapies have emerged as a promising alternative. Heterotopic caval valve implantation using the TricValve system represents an innovative approach aimed at reducing systemic venous congestion by preventing backflow into the venae cavae, thereby improving symptoms and functional status in selected patients. Case Description: A 55-year-old woman with a history of Ebstein's anomaly underwent surgical tricuspid valve repair 40 years earlier. She subsequently developed Wolff–Parkinson–White syndrome, which was treated with catheter ablation, followed by permanent pacemaker implantation. Over the past few years, she experienced progressive right heart failure with severe systemic venous congestion, classified as New York Heart Association (NYHA) class IV, despite optimal medical therapy, including high-dose diuretics (furosemide 200 mg/day). Transesophageal echocardiography revealed torrential tricuspid regurgitation with preserved right and left ventricular systolic function. Additional assessment included evaluation of inferior and superior vena cava dimensions, right atrial volume, fractional area change (FAC), tricuspid annular plane systolic excursion (TAPSE), suprahepatic vein Doppler flow, and exclusion of patent foramen ovale. Pre-procedural planning with cardiac computed tomography angiography was performed, including detailed assessment of caval anatomy, landing zones, and spatial relationship with hepatic veins and azygos vein. A three-dimensional (3D) anatomical model was also used to simulate the procedure and optimize prosthesis sizing and positioning. Given the prohibitive surgical risk and persistent symptoms, a Heart Team decision was made to proceed with heterotopic caval valve implantation using the TricValve system. Conclusions: Heterotopic caval valve implantation using the TricValve system is a feasible and effective option for patients with Ebstein's anomaly and torrential tricuspid regurgitation at prohibitive surgical risk. Multimodality imaging is essential for accurate planning and device positioning. This approach can significantly reduce systemic venous congestion and improve functional status in carefully selected patients.

INTEGRATED ANATOMICAL AND FUNCTIONAL ASSESSMENT FOR SURGICAL INDICATION IN ANOMALOUS RIGHT CORONARY ARTERY: THE ROLE OF STRESS-FFR AND IVUS

FELIPE BARBOSA BOTELHO ROLIM1; GUILHERME DE JIOVANI MOYSES AUADA1; FABIO BISCEGLI JATENE1; ALEXANDRE ANTONIO CUNHA ABIZAID1; AUGUSTO SANTOS TAVARES1; ERIC MAXIMO ORRICO SIQUEIRA1; SALETE APARECIDA DA PONTE NACIF1;

(1) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL;

Introduction: The anomalous origin of the right coronary artery (RCA) from the left coronary sinus with an intramural course is a high-risk condition associated with sudden cardiac death. In middle-aged patients, surgical indication is often challenging and requires more than just anatomical identification. A multimodality approach, combining high-risk anatomical features with physiological evidence of ischemia, is essential to guide clinical decision-making. Case Description: A 59-year-old male with dyslipidemia and a significant family history of premature sudden death presented with complaints of chest discomfort and palpitations. Coronary computed tomography angiography (CCTA) was performed, identifying an anomalous origin of the RCA in the left coronary sinus with an interarterial course and suspected intramural course. For diagnostic completion, invasive coronary angiography associated with intravascular ultrasound (IVUS) was performed, confirming a high-risk intramural course in the ostial region with a change in vessel morphology from cylindrical to elliptical (slit-like ostium). Dynamic compression was observed, resulting in a significant cross-sectional area reduction, with a minimal luminal area (MLA) of 3.57 mm². Functional assessment was conducted using the Resting Full-Cycle Ratio (RFR) and Fractional Flow Reserve (FFR). While the RFR was negative at rest (0.93), pharmacological stress with dobutamine (30 mcg/kg/min) and atropine (0,5mg) reached a maximum heart rate (HR) of 162 bpm (100% of the predicted maximum HR), resulting in a positive FFR of 0.80. Based on symptoms, high-risk anatomical features on IVUS, and physiological evidence of stress-induced ischemia, surgical correction was indicated. The patient underwent surgical repair with RCA reimplantation in the left coronary sinus, presenting a good clinical evolution. Conclusions: This case illustrates that the surgical indication for anomalous RCA should be based on the integration of clinical, anatomical, and functional data. IVUS provides critical details about ostial morphology and dynamic compression, while stress-FFR is important to document ischemia when resting indices are negative. This multimodality framework ensures that surgical intervention is targeted precisely at patients with proven physiological compromise.

PACLITAXEL-COATED BALLOON ANGIOPLASTY IN AN EXTREMELY PRETERM INFANT WITH MULTIFACTORIAL PULMONARY HYPERTENSION AND SEVERE RIGHT INFERIOR PULMONARY VEIN STENOSIS

MARCO ANTONIO GONÇALVES DE MOURA1; ALEXIA DOS SANTOS RIBEIRO1; MARINA PINHEIRO ROCHA FANTINI1; LUCAS QUEIROZ FERNANDES CAMPOS1; LUCAS LODI JUNQUEIRA1; GUILHERME RAFAEL SANT'ANNA ATHAYDE1; FERNANDO GUSMÃO CAMARA1; GABRIEL SEIXAS CARVALHO1;

(1) REDE MATER DEI DE SAUDE - BELO HORIZONTE - MG - BRASIL;

Introduction: Pulmonary hypertension (PH) in extremely preterm infants with bronchopulmonary dysplasia (BPD) is frequently multifactorial and associated with high morbidity and mortality. Structural abnormalities such as pulmonary vein stenosis and intracardiac shunts may further increase pulmonary vascular burden and hinder clinical stabilization. Early recognition of these contributors is essential for individualized management. Case Description: A 6-month-old female infant (corrected age 2 months), born at 25+3 weeks of gestation with a birth weight of 834 g, remained hospitalized since birth because of complications related to extreme prematurity. She required early surfactant therapy, prolonged mechanical ventilation, and subsequently developed severe BPD, chronic ventilator dependence, and tracheostomy. Persistent PH progressed despite combination therapy with sildenafil, bosentan, iloprost, inhaled nitric oxide, diuretics, and vasoactive support. Serial echocardiograms demonstrated a large secundum atrial septal defect, right heart dilation, and suspected abnormal pulmonary venous return. Owing to refractory disease, she underwent cardiac catheterization and pulmonary angiography, which revealed mean pulmonary artery pressure of 31 mmHg, significant pulmonary overcirculation (Qp/Qs 2.3:1), and severe stenosis of the right inferior pulmonary vein associated with hypoperfusion of the right middle and lower lobes. Percutaneous intervention was therefore performed with angioplasty of the right inferior pulmonary vein using conventional balloons followed by a paclitaxel-coated balloon. The procedure achieved an immediate favorable angiographic result, reduction in pulmonary pressures, and no periprocedural complications. In the subsequent clinical course, the patient showed recovery of pulmonary function with improved respiratory status and was able to tolerate progressive reduction of ventilatory parameters. Conclusions: This case highlights the complexity of PH in former preterm infants with severe BPD and supports invasive evaluation when clinical deterioration appears disproportionate or refractory to standard therapy. Identification of pulmonary vein stenosis significantly changed therapeutic strategy. Percutaneous angioplasty with a paclitaxel-coated balloon was feasible and may represent a valuable adjunctive option in selected high-risk infants, with favorable hemodynamic and respiratory recovery.

SUCCESSFUL MANAGEMENT OF IATROGENIC LEFT MAIN CORONARY PERFORATION USING SIMULTANEOUS KISSING COVERED STENTS: A CASE REPORT.

AHMED SABRA1; REZA RASOOL1; SHOUAIB QAYYUM1; JAMES FOLEY1;

(1) MID YORKSHIRE TEACHING NHS TRUST - UNITED KINGDOM;

Introduction: Coronary perforation is a rare but life-threatening complication of percutaneous coronary intervention, frequently encountered in complex interventions particularly in elderly patients. Rapid recognition and management are essential to prevent catastrophic outcomes such as cardiac tamponade, haemodynamic collapse and death. Case Description: A woman in her late 80s was admitted with NSTEMI following a 6-month history of exertional chest pain. Her medical history included giant cell arteritis and polymyalgia rheumatic. ECG demonstrated widespread ST-segment depression. Troponin T was elevated (92 ng/L), and echocardiography showed moderately impaired left ventricular systolic function (EF 45%) with anterolateral hypokinesia. Coronary angiography via right radial access revealed moderate LMS disease and severe disease to LAD and dominant circumflex artery . The right coronary artery was small non-dominant and unobstructed. The patient underwent IVUS-guided PCI to the LMS bifurcation. An upfront two-stent crush technique was planned with initial stenting of the circumflex and crushing the side-branch stent. After re-wiring of the Cx, and final optimisation including POT, an Ellis type III coronary perforation occurred at the LAD–circumflex bifurcation as shown in Figure 1. This resulted in haemodynamic collapse with hypotension and bradycardia, and echocardiographic evidence of cardiac tamponade. Emergency pericardiocentesis was performed with drainage of approximately 750 mL of blood, supported by autotransfusion, vasopressors, and blood transfusion. Initial balloon tamponade to the Cx failed to control the perforation. A ping-pong guiding catheter technique was employed via femoral route to facilitate the delivery of two covered stents (Papyrus), 7F guiding catheter via the right femoral artery, allowing for simultaneous kissing covered stents (SKS), with successful sealing of the perforation. The patient stabilised and was discharged home and at 24-month follow-up, the patient remained clinically well, with no reported recurrent ischaemic symptoms or adverse cardiovascular events. Conclusions: This case demonstrates successful management of catastrophic coronary perforation during complex LMS bifurcation PCI using simultaneous kissing covered stents. Early recognition and advanced interventional techniques are critical to achieving favourable outcomes in such high-risk unexpected cases.

Figure 1a: LMS coronary perforation –PA caudal

Figure 1b: LMS coronary perforation – LAO projection

Figure 2: Cross-sectional IVUS image demonstrating dual covered stents. The IVUS catheter is positioned within the LAD stent, while the LCx stent is visible with an associated wire artefact

TRANSCATHETER AORTIC VALVE IMPLANTATION (TAVI) IN CARDIOGENIC SHOCK IN A TRANSGENDER PATIENT WITH MULTIPLE INTRACARDIAC THROMBI ON HORMONE THERAPY

IAN REHFELD DE ANDRADE1; LARISSA PARADA LEITE1; STEPHAN LACHTERMACHER1; CESAR ROCHA MEDEIROS1; GUILHERME DALCOL TORRES DE AMORIM1; GABRIEL PROTASIO QUINTAS1; MILENA BOTELHO CANELLAS1;

(1) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Bicuspid aortic valve (BAV) is the most common congenital heart disease, affecting 0.5% to 2% of the population, with a 3:1 male predominance. Frequently associated with early-onset aortic stenosis (AS) in young adulthood, BAV leads to the classic symptoms of angina, syncope, and dyspnea. Since there are no effective pharmacological therapies for severe AS, valve replacement remains the definitive treatment, with BAV accounting for half of the surgeries in patients under 70 years of age. Transcatheter Aortic Valve Implantation (TAVI) has established itself as a minimally invasive technique for high-risk patients, although BAV anatomy — characterized by asymmetric calcification and a non-circular annulus — makes the procedure challenging. Furthermore, thromboembolic complications in advanced stages of AS are significant concerns, particularly in transgender women on estrogen hormone therapy, a factor associated with hypercoagulability. Case Description: A 57-year-old transgender woman with hypertension sought medical attention in February 2025 presenting with NYHA class III dyspnea and edema. She reported continuous use of hormone therapy for 30 years. The echocardiogram revealed critical aortic stenosis (AS) in a bicuspid aortic valve (BAV) (valve area 0.5 cm, mean gradient 49 mmHg), severe pulmonary hypertension, and an ejection fraction of 20%. Cardiac magnetic resonance imaging identified intracavitary thrombi in the left atrium and both ventricles, while CT scans showed pulmonary infarctions. Considered high-risk (Euroscore II 4.85%), the patient progressed to cardiogenic shock, and emergency aortic valvuloplasty was performed as a bridge therapy, despite a cardiac arrest that was reversed in April 2025. After stabilization, TAVI (Myval® 26mm) was performed on April 29. The postoperative period included the need for a permanent pacemaker and treatment for pulmonary sepsis. A follow-up echocardiogram in August 2025 showed LVEF recovery to 58% and a mean gradient of 8 mmHg, with the patient being discharged in September 2025. Conclusions: The case highlights the complexity of TAVI in emergency scenarios and challenging anatomy. Although the presence of intracavitary thrombi is a relative contraindication, the Heart Team opted for the intervention due to the severity of the cardiogenic shock, using balloon valvuloplasty as a successful bridge therapy. It is concluded that emergency TAVI is a viable and effective rescue strategy for critically ill patients.

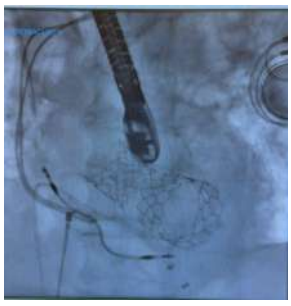
TRANSCATHETER EDGE-TO-EDGE MITRAL REPAIR (M-TEER) WITH THE PASCAL P10 SYSTEM IN COMPLEX MITRAL ANATOMY: LEAFLET CALCIFICATION AND REDUCED MITRAL VALVE AREA.

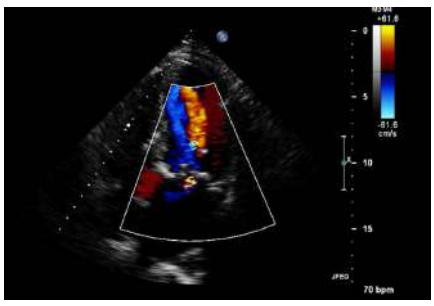
TIAGO PEDRINI CHAGAS1; JÚLIA ARRUDA1; MATEUS ALCICI LEITE1; LUIS GUSTAVO PIRES1; JULIA PEREIRA GOTTARDI1; GABRIELA AMADO BRITTO1; MARIA VASCONCELOS NOVAIS1; ISABELLA MIRANDA DE ALMEIDA1; JOSE AIRTON DE ARRUDA2;

(1) ESCOLA SUPERIOR DE CIENCIAS DA SANTA CASA DE MISERICORDIA DE VITORIA - VITÓRIA - ES - BRASIL; (2) HOSPITAL MERIDIONAL - VITORIA ES - VILA VELHA - ES - BRASIL;

Introduction: M-TEER has become an established alternative for patients with significant mitral regurgitation (MR) and high surgical risk. However, complex anatomies — such as anterior leaflet calcification, short posterior leaflet, and reduced mitral valve area (MVA) (< 4 cm²) — represent technical challenges that require expertise. The PASCAL Precision system, featuring spacer-based orifice filling technology and independent leaflet capture, may expand feasibility and safety in these borderline scenarios. Case Description: A 79-year-old male patient with multiple comorbidities (advanced multivessel disease, prior cardiac surgery, chronic kidney disease, diabetes mellitus, and peripheral arterial disease) presented with heart failure (profile B) due to significant functional MR and pulmonary hypertension, with prohibitive surgical risk (high STS score). Three-dimensional transesophageal echocardiography (3D TEE) revealed highly challenging anatomy: MVA of 3.1 cm², short posterior leaflet (7 mm), and calcification in the distal portion of the anterior leaflet. The procedure was performed under general anesthesia and guided by 3D TEE. A PASCAL P10 device was implanted at the A2-P2 scallop transition. The system's independent leaflet capture capability was essential to overcome both the calcification and the limited posterior leaflet length. Technical success was achieved, with reduction of MR from severe to mild and a residual mean left atrial–left ventricular gradient of only 3.54 mmHg, without evidence of iatrogenic mitral stenosis. The patient remained hemodynamically stable immediately after the procedure. Conclusions: This case demonstrates that the PASCAL P10 system is effective and safe even in mitral anatomies considered "outside" the classical guideline-based screening criteria. The independent leaflet capture technology and the P10 device profile enabled an excellent hemodynamic result in a patient with reduced MVA and valvular calcification, reinforcing the expansion of percutaneous intervention to scenarios of high anatomical complexity in reference centers.



21089



TREATMENT OF MITRAL STENOSIS IN A ELDERLY WOMAN WITH HIGH SURGICAL RISK: ''VALVE-IN-MAC'' TECHNIQUE COMBINED FOR OPTIMIZED RESULTS

GABRIEL NOVAES DOS SANTOS1; JULIA LASSERRE MOREIRA1; RAFAELA DA SILVA FERREIRA1; HUGO VINICIUS NEVES MORAIS1; LEONARDO GARCIA GÓES1; MARIANA CARVALHO VEIGA1; FELIPE AMBRÓSIO FONTES1; ROBERTO KALIL FILHO1; VICTORIA CERCHIARI AFONSO1;

(1) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introduction: Several conditions can cause mitral stenosis (MS), both in younger patients through inflammatory conditions such as rheumatic fever, rheumatoid arthritis, or Marfan syndrome, and in elderly patients through calcification and valvular tissue degeneration. Despite this, surgical valve replacement or repair are the first-line therapies. However, a large proportion of patients present with high morbidity, which can increase the in-hospital mortality rate by approximately 8 to 12%. Case Description: We describe a case of a multi-comorbid patient with significant, symptomatic MS, refractory to drug therapies, and with surgical contraindications. The patient, a female, 83 years old, diabetic, with non-dialysis chronic kidney disease, suffering from sleep apnea-hypopnea syndrome (OSAHS), coronary artery disease, with subsequent angioplasty in 2025, pacemaker implantation in the same year, transcatheter aortic valve implantation due to significant valvular insufficiency, subsequently evolving into significant mitral stenosis. During this hospitalization, the patient presented with hypoxemia and dyspnea on minimal exertion. Upon admission, a transthoracic echocardiogram (TTE) revealed a thickened mitral valve and significant calcification of the mitral valve annulus (MAC), significant stenosis, peak diastolic velocity of 2.4 m/s, maximum gradient of 27 mmHg and mean gradient of 10 mmHg, and an area of 1.2 cm² according to the continuity equation. Therefore, the need arose for intervention or replacement of this valve. Transcatheter mitral valve implantation in calcified annulus (Valve-in-MAC) has become a good therapeutic alternative, especially when there is a contraindication or high surgical risk. Conclusions: Therefore, the anterior mitral valve leaflet laceration technique to prevent outflow obstruction (LAMPOON) was used, combined with three-dimensional visualization software. These methods have proven to minimize the main anatomical challenge of the procedure, which is left ventricular outflow tract obstruction. After clinical stabilization, the patient underwent Valve-in-MAC, associated with LAMPOON and alcohol septal ablation (ASA). The procedure was uneventful, despite the use of vasoactive drugs and an intra-aortic balloon pump (IABP) during the intraoperative period. After the procedure, the patient showed improvement. Doppler ultrasound of the mitral valve prosthesis detected a peak diastolic velocity of 1.2 m/s, a maximum LA/LV gradient of 5.8 mmHg, and a mean gradient of 2.8 mmHg.

Introduction: Pulmonary vein stenosis is an underdiagnosed and potentially devastating complication of atrial fibrillation ablation, typically resulting from injury at the pulmonary vein ostia and potentially progressing to severe pulmonary hypertension with significant hemodynamic consequences. Case Description: A 42-year-old woman with a history of prior electrophysiological study and atrial fibrillation ablation developed severe pulmonary hypertension secondary to pulmonary vein stenosis, presenting with dyspnea (NYHA class IV). Right heart catheterization (April 7) demonstrated a mean pulmonary artery pressure of 60 mmHg and a systolic pressure of 100 mmHg. She underwent percutaneous intervention via a transseptal approach. Angioplasty was attempted in three affected pulmonary veins, but only one vessel was successfully treated. A 10 × 19 mm Palmaz Genesis stent was implanted in the left pulmonary vein. The pre-procedural pressure gradient between the pulmonary vein and the left atrium was 22 mmHg, with complete resolution following the intervention. Intraoperative echocardiography demonstrated a well-positioned stent in the left common pulmonary vein, with adequate expansion and laminar flow. The right ventricle showed preserved systolic function, and left-sided chambers were normal. Mild tricuspid regurgitation and a small residual atrial septal defect were observed. During follow-up, the patient was referred to cardiovascular rehabilitation, initially presenting significant functional limitation (≈60% of predicted for lower limbs and 76% on cardiopulmonary testing). She subsequently demonstrated progressive clinical improvement and is currently in NYHA class II. This case highlights a severe complication of a commonly performed procedure that is often overlooked during long-term follow-up. It underscores the hemodynamic impact of pulmonary vein stenosis and the role of percutaneous intervention in reversing pressure overload and improving clinical status. Conclusions: Pulmonary vein stenosis after atrial fibrillation ablation should be considered in patients presenting with dyspnea and pulmonary hypertension. Early recognition and targeted intervention may significantly modify the clinical course.

MINOCA IN A PATIENT WITH HEREDITARY THROMBOPHILIA: THE ROLE OF OCT IN THE ETIOLOGICAL REDEFINITION OF MYOCARDIAL INFARCTION – A CASE REPORT

CAMILA LEÃO1; CAROLINA LUCENA1; LUCAS REIS1; CAROLINA MARKMAN1; CAIO REZENDE1; DIOGO SUASSUNA1; DANIELA CARVALHO1; MILANE BARBACHAN1; BARBARA SILVA1; MARIA ELISA LUCENA1; ISABELLA COSTA1;

(1) REAL HOSPITAL PORTUGUES - RECIFE - PE - BRASIL;

Introduction: Myocardial infarction with non-obstructive coronary arteries (MINOCA) represents a heterogeneous clinical entity with difficult etiological definition. In patients with prothrombotic states, such as hereditary thrombophilias related to factor V Leiden and prothrombin gene mutation, angiographic findings suggestive of intracoronary thrombus may lead to misleading diagnostic interpretations. In this context, optical coherence tomography (OCT) plays a relevant role in identifying atherosclerotic plaque, endothelial erosion, and other substrates associated with MINOCA. Case Description: Patient P.F., 34 years old, transgender woman, smoker, with hereditary thrombophilia (G20210A mutation and factor V Leiden) and a history of pulmonary thromboembolism in 2016, was admitted with typical chest pain for 2 hours. She had previously been using Rivaroxaban 20 mg/day, which had been discontinued on her own 6 months earlier. Electrocardiogram showed ST-segment elevation in the inferior wall. She received ASA 200 mg and Ticagrelor 180 mg and was immediately referred to the catheterization laboratory. Coronary angiography demonstrated an image suggestive of thrombus in the distal third of the right coronary artery, without flow restriction, associated with proximal occlusion of the posterior descending artery, without significant coronary atheromatosis. Balloon angioplasty of the posterior descending artery was performed, with arterial recanalization, in addition to Tirofiban infusion due to the large thrombotic burden. The patient remained stable, without recurrence of chest pain. Based on the initial hypothesis of isolated coronary thrombosis, full anticoagulation was maintained without antiplatelet therapy. After four days, a new catheterization with OCT was performed, revealing thrombus associated with a dissection flap and a fibrotic/lipid-rich atherosclerotic plaque in the right coronary artery, with a minimal luminal area >6.8 mm². The patient was discharged on ASA 100 mg/day for 30 days, Clopidogrel 75 mg/day, and Rivaroxaban 20 mg/day. At outpatient follow-up after 1 month, she was asymptomatic and adherent to treatment. Conclusions: This case highlights the importance of OCT in the diagnostic elucidation of MINOCA, especially in the presence of inconclusive angiographic findings. The examination allowed identification of an atherosclerotic plaque associated with intracoronary thrombus, redefining the etiology of the ischemic event and appropriately guiding therapy.

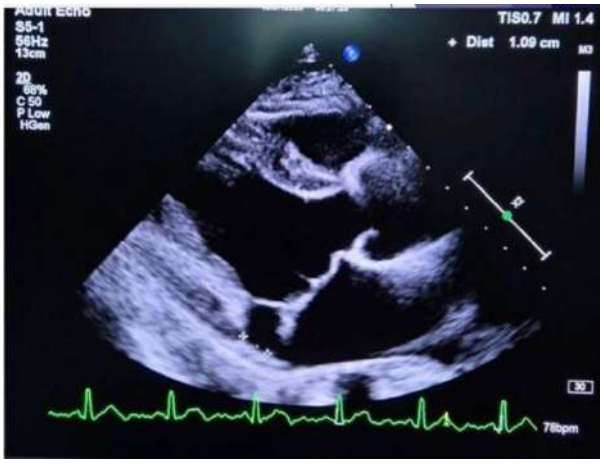
CARCINOID HEART DISEASE REVEALING A METASTATIC SMALL-BOWEL NEUROENDOCRINE TUMOR

LUÍS HENRIQUE SARDINHA BORBOREMA1; ANDEILE DE ALBUQUERQUE GALHARDO1; ALEXANDRE LEMOS BORTOLOTTO1; MARCUS VINICIUS DE LIMA1; GABRIELA BARSANTE NICOLELA1; GABRIELA PATRICIA ALLAUCA TINGO1; VITOR EMER EGYPTO ROSA1; GUILHERME SOBREIRA SPINA1; ANTONIO SÉRGIO DE SANTIS ANDRADE LOPES1; TARSO AUGUSTO DUENHAS ACCORSI1; RONEY ORISMAR SAMPAIO1; FLAVIO TARASOUTCHI1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction: Carcinoid syndrome (CS) is a paraneoplastic manifestation frequently observed in patients with neuroendocrine tumors that secrete bioactive amines and peptides. CS typically develops in the presence of hepatic metastatic disease or extra-portal tumors, leading to the secretion of serotonin into the post-portal venous territory. CS classic manifestations include flushing, diarrhea, bronchospasm, carcinoid heart disease, and hemodynamic instability. Cardiac involvement in CS is characterized by the deposition of fibrous plaques on the endocardial surfaces, predominantly affecting the right-sided heart chambers and valves, most commonly leading to tricuspid and pulmonary valve dysfunction. Case Description: A 57-year-old female patient was referred to a cardiologist in 2018 following the identification of a cardiac murmur. Concurrent cross-sectional imaging identified a primary small bowel mass with synchronous hepatic metastases. Histopathological analysis of intestinal and hepatic biopsy specimens confirmed a well-differentiated neuroendocrine tumor of carcinoid morphology. She was subsequently referred to a valvular heart disease team for assessment of surgical feasibility. At presentation, the patient was in New York Heart Association (NYHA) functional class III. Transthoracic echocardiography demonstrated a left ventricular ejection fraction (LVEF) of 69%; both tricuspid and pulmonary valves with thickening and fixed leaflets, causing severe tricuspid and pulmonary regurgitation. Surgical replacement of both the tricuspid and pulmonary valves was performed using bioprosthetic valves. The patient was discharged 20 days after surgery with no complications. During follow-up, she demonstrated progressive clinical improvement, achieving NYHA functional class I at five months postoperatively. Conclusions: Carcinoid heart disease represents a serious and frequently underdiagnosed complication of functioning neuroendocrine tumors. This case highlights the importance of considering neuroendocrine tumors in patients presenting with marked thickening and isolated involvement of the tricuspid and pulmonary valves. Management should be multidisciplinary, integrating oncology, cardiology, and cardiovascular surgery, with the goals of controlling tumor activity, reducing exposure to vasoactive substances, and determining the optimal timing of valvular intervention in symptomatic patients or those with significant hemodynamic compromise.



21396

DEGENERATIVE MITRAL REGURGITATION DUE TO BARLOW'S DISEASE ASSOCIATED WITH MITRAL ANNULAR DISJUNCTION AND VENTRICULAR ARRHYTHMIAS IN A YOUNG PATIENT: A CASE REPORT

MARIA CATARINA MELO DIAS GUERRA1; EDUARDO CAVALCANTI LAPA SANTOS1; LUCAS REIS COSTA1; BIANCA ALICE SOUZA1; DIEGO RAFAEL FREITAS BERENGUER1; RAFAELA LEANDRO LIMA1; ANA BEATRIZ POMPEU CARVALHO1; RAFAEL LEMOS GRANJA1; MATHEUS LEON HOLANDA DALLIER1; MARIA EDUARDA BARBOSA MELO1; MARCIA FERREIRA SANTOS OLIVEIRA1; ISIS GABRIELE CARDOSO CONTE1;

(1) HOSPITAL DAS CLINICAS - RECIFE - PE - BRASIL;

Introduction: Degenerative mitral regurgitation (MR) is one of the main primary valvular heart diseases in adults. Barlow's disease represents a complex phenotype of mitral valve prolapse, associated not only with progressive mitral regurgitation but also with ventricular arrhythmias and sudden cardiac death, with an estimated annual risk ranging from 0.2% to 1.9%. Mitral annular disjunction (MAD), present in a significant proportion of patients, is associated with a higher arrhythmic risk. Although the disease typically presents between the fifth and sixth decades of life, early-onset cases may occur. Case Description: A previously healthy 30-year-old man presented with a 6-year history of palpitations characterized by sudden onset, short duration, and no relation to exertion, associated with dizziness and no history of syncope. In recent months, he developed increased symptom frequency and dyspnea on moderate exertion. Physical examination revealed a grade 3/6 holosystolic murmur at the mitral area radiating to the axilla, associated with a third heart sound. Transthoracic echocardiography demonstrated preserved systolic function, mild enlargement of the left-sided chambers, and severe MR due to myxomatous degeneration consistent with Barlow's disease, associated with findings suggestive of MAD. Cardiac magnetic resonance imaging confirmed severe MR, bileaflet prolapse, and MAD measuring 8.9 mm, without late gadolinium enhancement or myocardial fibrosis. Twenty-four-hour Holter monitoring revealed 816 ventricular premature beats (<1%), predominantly isolated, in addition to two episodes of non-sustained ventricular tachycardia. The patient underwent mitral valve repair in January 2026, with favorable postoperative evolution. He was discharged on beta-blocker therapy and remains under outpatient follow-up. Conclusions: The association between Barlow's disease, MAD, and ventricular arrhythmias represents a complex phenotype within arrhythmic mitral valve syndrome. This case is notable for its early presentation, non-sustained ventricular tachycardia, and absence of myocardial fibrosis on cardiac magnetic resonance imaging, supporting the role of mechanical factors such as myocardial traction and curling in arrhythmogenesis, even without late gadolinium enhancement. Although mitral valve repair is the treatment of choice for degenerative mitral regurgitation, its effect on arrhythmic risk remains uncertain, emphasizing the need for multimodality assessment and long-term follow-up.

LIFE-SAVING FIBRINOLYSIS IN OBSTRUCTIVE AORTIC VALVE THROMBOSIS: THE ROLE OF MULTIMODAL IMAGING AND A MULTIDISCIPLINARY APPROACH

LUCA TERRACINI DOMPIERI1; PEDRO RODRIGUES CARVALHO2; DANIELA HARSANYI2; PEDRO PAULO GATTO DE OLIVEIRA THOME2; FERNANDO BALDISSERA PIOVESAN2; ISABELE NEVES SOLON PETROLA2; LEONARDO VEDOVATO VILELA DE SALIS2; JOSÉ ROBERTO DE OLIVEIRA SILVA FILHO2; TATIANA DE CARVALHO ANDREUCI TORRES LEAL2; GUSTAVO FIALHO COELHO2; MANUELA CRISTINA RIBEIRO DIAS BARROSO2; PAULO ROGÉRIO SOARES2;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - PE - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction: Prosthetic valve thrombosis (PVT) is a severe and potentially fatal complication, with an annual incidence ranging from 0.1% to 5.7% in mechanical valves. The main risk factors include subtherapeutic anticoagulation and valve positioning in the mitral or right-sided chambers. Valvular dysfunction manifests through leaflet thickening and restricted mobility, resulting in elevated transvalvular gradients and, in the most critical presentations, obstructive shock. Case Description: A 36-year-old male with a history of a Bentall-de Bono procedure and prior cardioembolic MI due to warfarin non-compliance presented with a 4-day history of progressive dyspnea. Admission labs revealed INR (1.2) and BNP (2,555 pg/mL). Initial imaging suggested acute aortic syndrome, delaying definitive diagnosis. The patient's clinical status rapidly deteriorated into obstructive shock followed by cardiac arrest; return of spontaneous circulation was achieved after three CPR cycles. A multidisciplinary review, multimodal imaging including transesophageal echocardiogram (TEE) subsequently confirmed mechanical valve thrombosis, showing restricted leaflet mobility, a 35 mmHg peak gradient, and an 8x5 mm thrombus. Given the extreme instability and high surgical risk, systemic thrombolysis with alteplase was performed. The patient showed significant improvement, weaning of vasopressors and extubation within 48 hours. A follow-up TEE at 10 days confirmed normal leaflet mobility, no residual thrombus, and a mean transvalvular gradient at 4 mmHg. Conclusions: PVT presents a broad clinical spectrum, from subclinical dysfunction to life-threatening obstructive shock. While guidelines favor surgery for stable obstructive PVT, systemic fibrinolysis proved to be a life-saving alternative in the context of profound hemodynamic collapse and cardiac arrest. Rapid clinical suspicion and a multidisciplinary approach are essential to ensure early diagnosis, reduce mortality, and avoid high-risk emergency reinterventions.

SEQUENTIAL MITRAL AND TRICUSPID TRANSCATHETER EDGE-TO-EDGE REPAIR IN A HIGH-RISK PATIENT: A CASE REPORT

CAMILA PIOLA BILHEIRO1; MARIANA OLIVEIRA REZENDE1; ALBERTO COLELLA CERVONE1; ANDREA ANDRADE VILELA1; ANTONIO TITO PALADINO1; MATHEUS OLIVEIRA SOUZA1; GISELI CASARINI1; DORVI JULLIO DELLA TOGNA1; DIMYTRI ALEXANDRE SIQUEIRA1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction: Valvular heart diseases, traditionally managed with surgery, have increasingly incorporated minimally invasive percutaneous approaches in recent decades. Transcatheter edge-to-edge repair (TEER) was initially established for the treatment of mitral regurgitation and, with technological advances and growing clinical experience, has expanded to tricuspid regurgitation. This strategy is now included in guidelines for carefully selected patients. Although combined mitral and tricuspid TEER has been described, it remains limited to a few reports, and further data on its safety and efficacy are needed. Case Description: An 81-year-old male with hypertension and dyslipidemia, diagnosed with mitral and tricuspid valve prolapse, presented with dyspnea. Transthoracic echocardiogram revealed posterior mitral leaflet prolapse with chordal rupture, flail, and severe mitral regurgitation. Due to significant and symptomatic mitral regurgitation, despite optimized medical therapy, interventional treatment was indicated. Considering the patient's age and high surgical risk, after a decision by the heat team, mitral TEER was indicated. The procedure was performed with implantation of three devices, resulting in mild residual regurgitation. Despite technical success, the patient remained symptomatic, with elevated biomarkers and progression of tricuspid regurgitation to torrential severity. Procedure-related complications, including mitral stenosis, were excluded by transthoracic echocardiogram, echocardiogram with cycleergometer and invasive hemodynamic assessment, which demonstrated an adequate valve area (2.4 cm²), stable gradients, normal pulmonary pressures, but low cardiac output. Given persistent symptoms, tricuspid TEER was performed with implantation of three devices, achieving reduction to moderate regurgitation and significant clinical improvement due to improved stroke volume. The results was sustained at one-month follow-up. Conclusions: This case highlights the feasibility and potential clinical benefit of TEER as a therapeutic strategy in selected patients with significant mitral and tricuspid regurgitation. A combined and sequential approach proved effective in reducing regurgitation severity, improving symptoms, and avoiding major complications. These findings support TEER as a safe and promising alternative, although further studies are required to better define indications and long-term outcomes.

19898

SEVERE AORTIC VALVE INFECTIOUS ENDOCARDITIS AND MECHANICAL VALVE REPLACEMENT IN A PATIENT WITH PRIMARY ANTIPHOSPHOLIPID SYNDROME AND RECURRENT THROMBOTIC EVENTS

ANA CARULINA GUIMARÃES BELCHIOR1;

(1) HOSPITAL REGIONAL DE MATO GROSSO DO SUL - CAMPO GRANDE - MS - BRASIL;

Introduction: Antiphospholipid Syndrome (APS) is a systemic autoimmune disorder characterized by arterial or venous thrombosis and pregnancy morbidity, associated with the persistence of antiphospholipid antibodies. Cardiac involvement is frequent, often manifesting as valvular thickening or sterile vegetations (Libman-Sacks endocarditis). The exacerbated prothrombotic state of APS complicates anticoagulation management, especially in scenarios of mechanical valve replacement, where therapeutic failure with direct oral anticoagulants (DOACs) can be fatal. This report describes a challenging case of destructive aortic endocarditis in a patient with primary APS and triple antibody positivity. Case Description: A 22-year-old male patient with a history of illicit substance use (cannabis and cocaine) and recurrent deep vein thrombosis (DVT) since 2021 was evaluated. Despite continuous therapy with rivaroxaban, he presented multiple thrombotic recurrences, including pulmonary embolism and chronic DVT in the lower limbs. Over a 4-year period, he developed severe infectious endocarditis of the aortic valve, requiring urgent surgical intervention, and underwent aortic valve replacement with a mechanical prosthesis. He was treated with meropenem and daptomycin. Blood cultures were negative.During hospitalization, the patient developed acute kidney injury requiring hemodialysis and hemolytic anemia.

Table 1: Summary of Echocardiographic Data

Category	Parameter	Result	Observation
Dimensions	LV Diastolic Diameter	68 mm	Increased
	LV Systolic Diameter	51 mm	Increased
	Left Atrium (LA)	52 mm	Severe enlargement (71 ml/m²)
	Right Atrium (RA)	-	Severe enlargement (49 ml/m²)
	Aorta	39 mm	-
Systolic Function	Ejection Fraction (Simpson)	40 %	Reduced (Mild/Moderate)
	LV Contractility	Diffuse hypokinesia	Global impairment
Aortic Valve	Mass/Vegetation	8 mm	Affects all three leaflets
	Aortic Regurgitation	Severe	Turbulent diastolic flow
	Aortic Stenosis	Moderate	Mean Gradient: 29 mmHg (corrected)
Other Valves	Mitral Regurgitation	Mild	-
	Tricuspid Regurgitation	Moderate	Estimated PASP: 63 mmHg
Hemodynamics	Pericardial Effusion	Mild	10 mm (posterior) / 7 mm (RA)
	Heart Rate	135 bpm	Tachycardic and tachypneic patient

Figura 1: Figure 1: Echographic image of the aortic valve with significant insufficiency and thickening due to a slightly mobile mass, which apparently "covers" the three valve leaflets, having more prominent areas, particularly in the left coronary leaflet (measuring 8 mm in "height") and non-coronary leaflet (measuring 8 mm in "height").

Immunological screening confirmed Primary APS, revealing triple positivity with high titers: Anti-cardiolipin IgG >250 U/mL, Anti-beta 2 glycoprotein 1 IgG 85 U/mL, and reduced C3/C4 levels. ANA was 1/80 (nuclear fine speckled). Systemic symptoms included chronic polyarthralgia in small and large joints and photosensitivity. After surgery, therapy was transitioned to warfarin, with rigorous PT/INR monitoring. A follow-up echocardiogram showed a normally functioning mechanical prosthesis (mean gradient of 12 mmHg) and minimal residual central leaks. Clinical evolution showed improvement in edema and stabilization of renal function (Creatinine 1.72 mg/dL). Conclusions: This case highlights the importance of investigating primary thrombophilias in patients with thrombosis refractory to DOACs. The association between APS and infectious endocarditis increases embolic risk and valvular dysfunction. A mechanical prosthesis requires lifelong warfarin therapy, as DOACs are contraindicated in high-risk APS and mechanical valves. A multidisciplinary approach is vital to manage both infection and autoimmunity.

19888

SPONTANEOUS HEMOPERICARDIUM LEADING TO CARDIAC TAMPONADE: A CASE REPORT OF DIAGNOSTIC COMPLEXITY AND EMERGENCY MANAGEMENT

ANA CARULINA GUIMARAES BELCHIOR1;

(1) HOSPITAL REGIONAL DE MATO GROSSO DO SUL - CAMPO GRANDE - MS - BRASIL;

Introduction: Hemopericardium is defined as the accumulation of blood within the pericardial sac. While often associated with trauma or iatrogenic procedures, spontaneous cases are rare and constitute a life-threatening emergency due to the risk of cardiac tamponade. Rapid accumulation of fluid compromises cardiac filling, leading to obstructive shock. This report describes a case of massive spontaneous hemopericardium, highlighting the challenges in identifying underlying etiologies in a non-traumatic context. Case Description: A female patient with a history of hypertension presented with a 5-day history of right hypochondrium pain, burning chest pain, vomiting, and dyspnea on mild exertion. Initial physical examination showed her to be afebrile and hemodynamically stable. However, computed tomography and echocardiography revealed a voluminous pericardial effusion with signs of cardiac tamponade (diastolic collapse of right chambers). Emergency pericardiocentesis was performed, draining 860 mL of hematic fluid. Analysis of the pericardial fluid characterized it as an exudative effusion with lymphomononuclear predominance; cultures, bacterioscopy, and GeneXpert were negative. Further investigation showed elevated LDH (832 U/L) and CA-125 (114 U/L), with normal CEA and CA 19.9 levels. Ancillary imaging identified a TI-RADS 5 thyroid nodule, suggesting the need for fine-needle aspiration. The clinical course was complicated by nosocomial pneumonia, which was successfully treated with antibiotics. Following drainage and stabilization, the patient reported significant symptomatic relief and remained hemodynamically stable during follow-up. Conclusions: Spontaneous hemopericardium is a critical clinical entity that requires immediate pericardiocentesis to prevent cardiovascular collapse. In the absence of trauma, the presence of hematic fluid necessitates a rigorous diagnostic workup to exclude occult malignancy or systemic inflammatory diseases, as suggested by the incidental thyroid findings and elevated tumor markers in this case. Multimodal imaging and fluid analysis are essential for both emergency management and long-term diagnostic orientation.

Table 1: Findings from imaging exams.

Exam	Key Findings	Classification/Relevance
Chest CT	Right-sided pleural effusion and ipsilateral basal infiltrate.	Acute Finding
Abdominal CT	Voluminous pericardial effusion.	Clinical Emergency
Thyroid Ultrasound	Nodule N3; Probable colloid cysts.	TI-RADS: 5
Breast Ultrasound	Probably benign findings.	BI-RADS: 3
Echocardiogram	LVEF 64%; Mild diastolic and valvular dysfunction; Mild effusion.	Post-Drainage
Abdominal Ultrasound	Mild hepatic steatosis (Grade I); Simple hepatic cysts.	Incidental Finding
Transvaginal Ultrasound	No detectable abnormalities.	Normal

Table 2: Laboratorial exams.

Category / Test	Result	Unit
Erythrocytes (RBC)	4.48	million/mm³
Hemoglobin	12.7	g/dL
Hematocrit	38.4	%

TAKOTSUBO SYNDROME FOLLOWING TRANSCATHETER EDGE-TO-EDGE MITRAL VALVE REPAIR

MAGNO MARTINS PINTO DE FARIA1; MARIANA OLIVEIRA REZENDE1; SAMIRA KAISSAR NASR GHORAYEB1; ANDREA DE ANDRADE VILELA1; DIMITRY ALEXANDRE SIQUEIRA1; ALBERTO COLELLA CERVONE1; LUCAS VELLOSO DUTRA1; DORIVAL JULIO DELLA TOGNA1; MATHEUS OLIVEIRA SOUZA1; ANTONIO TITO PALADINO1; ROBERTO TADEU MAGRO KROLL1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction: Transcatheter edge-to-edge mitral valve repair (M-TEER) is an established therapy for severe mitral regurgitation (MR) in patients at high surgical risk. Despite its favourable safety profile, acute left ventricular systolic dysfunction may occur following the procedure in up to 20% of cases and has important prognostic implications. Takotsubo syndrome represents a rare differential diagnosis in this setting, having been described only in sporadic case reports, with a causal relationship that remains uncertain and potential recovery of ventricular function within the first month. Case Description: A frail 73-year-old hypertensive, former smoker with stable coronary artery disease and chronic pulmonary embolism was admitted with decompensated heart failure, New York Heart Association class III symptoms and orthopnoea. Transthoracic echocardiography showed left ventricular ejection fraction (LVEF) of 60%, severe primary mitral regurgitation due to posterior leaflet prolapse with P2 flail, severe pulmonary hypertension and right ventricular dysfunction. Coronary angiography showed no obstructive coronary disease. Following Heart Team discussion, transcatheter edge-to-edge mitral valve repair (M-TEER) was performed because of prohibitive surgical risk. The procedure included implantation of three transcatheter mitral valve repair devices, reducing mitral regurgitation to mild severity with preserved LVEF. Shortly after the procedure, the patient developed nausea, epigastric discomfort, electrocardiographic repolarisation abnormalities and troponin elevation (peak 190 ng/L). Echocardiography demonstrated mid-apical akinesia with basal hypercontractility and LVEF reduction to 26%, consistent with Takotsubo syndrome. The patient remained haemodynamically stable with progressive clinical improvement and was discharged in functional class I. One month later, LVEF had recovered to 54%, with mild residual mitral regurgitation. Cardiac magnetic resonance demonstrated mid-apical myocardial oedema and non-ischaemic late gadolinium enhancement, compatible with Takotsubo syndrome Conclusions: This case illustrates a rare and clinically relevant occurrence of Takotsubo syndrome following M-TEER. Although the pathophysiological mechanisms and causal relationship remain incompletely established, early recognition is essential because it directly influences management and prognosis. Further studies are required to improve understanding of this association.

TRIVALVULAR ENDOCARDITIS – A RARE CONDITION WITH HIGH MORBIDITY AND MORTALITY

SÍLVIA BARRETO DE ALMEIDA ROCHA1; ALUISIO ROBERTO ANDRADE DE MACEDO1; ROMERO WANDERLEY DE ARRUDA FALCÃO1; LEONARDO GODOY DE MELLO MOTTA1; AFONSO BARRETO FILHO1; MARCELO PARENTE DE ANDRADE1; JOSÉ IGOR DA SILVA BATISTA1; YURI PIAULINO DO NASCIMENTO2;

(1) HOSPITAL DOM HELDER CAMARA - RECIFE - PE - BRASIL; (2) HOSPITAL UNIVERSITÁRIO DA UNIVERSIDADE FEDERAL DO VALE DO SÃO FRANCISCO - PETROLINA - PE - BRASIL;

Introduction: Infective endocarditis (IE) is a severe disease characterized by infection of the endocardium, usually associated with turbulent blood flow due to valvular disease or congenital abnormalities. Multivalvular involvement is uncommon and is associated with higher morbidity and mortality. Case Description: A 59-year-old male patient with hypertension, on dialysis for 2 years due to hypertensive nephropathy, presented with asthenia, hyporexia, weight loss of 13 kg over 2 weeks, fever and chills for 2 months, and dyspnea on minimal exertion. On physical examination, he was pale, with +1 lower pitting edema, a diastolic murmur at the aortic area radiating to the apex area, and a systolic murmur at the tricuspid area. Laboratory tests showed elevated C-reactive protein (88.9 mg/dL) and a normal white blood cell (WBC) count. Serial blood cultures were negative. Transesophageal echocardiography revealed preserved contractility and multiple vegetations: on the aortic valve (up to 8.4 mm) with significant regurgitation (EROA 0.32 cm²); on the mitral valve (4.9 mm), associated with perforation; and on the tricuspid valve (up to 29.4 mm). The patient underwent triple valve replacement (mitral, aortic, and tricuspid) with bioprostheses. Conclusions: In this case, the patient died within the first 24 hours after triple valve replacement surgery, highlighting the high severity of the condition and the need for early diagnosis and timely surgical management, despite its rarity.

UNMASKING Q FEVER: A TALE OF ENDOCARDITIS AND UNEXPECTED THROMBOSES

ANDREA OLIVIA CIOBANU1; IOANA PATRICIA ISFAN1; ANTONIA ANDREEA NICA1; LUCIAN NEGREANU2; DRAGOS VINEREANU1;

(1) UNIVERSITY OF MEDICINE AND PHARMACY CAROL DAVILA, BUCHAREST, ROMANIA; UNIVERSITY AND EMERGENCY HOSPITAL OF BUCHAREST (DEPARTMENT OF CARDIOLOGY AND CARDIOVASCULAR SURGERY), BUCHAREST, ROMANIA - ROMANIA; (2) UNIVERSITY OF MEDICINE AND PHARMACY CAROL DAVILA, BUCHAREST, ROMANIA; UNIVERSITY AND EMERGENCY HOSPITAL OF BUCHAREST (DEPARTMENT OF GASTROENTEROLOGY, BUCHAREST, ROMANIA - ROMANIA;

Introduction: Blood culture-negative infective endocarditis (IE) represents a diagnostic challenge, particularly in the context of concomitant atypical systemic manifestations. Case Description: A 56-year-old sailor, with no prior cardiovascular history, presented with persistent fever following treated interstitial pneumonia. On admission, he was subfebrile (37.8°C), hemodynamically stable, with elevated inflammatory markers, mild hepatic cytolysis and cholestatic pattern. Transthoracic echocardiography was unremarkable. Transesophageal echocardiography (TEE) showed 8 mm mitral vegetations with mild mitral regurgitation (Fig. 1). Empirical antibiotherapy was initiated for possible IE. Four sets of aerobic and anaerobic blood cultures were collected. In the context of abdominal pain developed during hospitalization, CT and MRI showed inferior mesenteric and splenic vein thrombosis, with no embolic complications (Fig. 2). The association of high suspicion of culture-negative IE and atypical venous thromboses raised concern of atypical pathogens involvement. Serological testing was positive for Coxiella burnetii, with positive IgM and high IgG titers, confirming definite acute C. burnettii IE. Targeted therapy with doxycycline and hydroxychloroquine was initiated, alongside rivaroxaban for atypical thromboses. The clinical course was favorable, with fever resolution, normalization of inflammatory syndrome and regression of mitral valve vegetations on follow-up TEE. Serological C. burnetii monitoring allowed for discontinuation of antibiotics after 18 months. Venous recanalization was documented on repeated MRI and anticoagulation was stopped after 6 months. Conclusions: This case highlights the importance of considering C. burnetii in patients with blood culture-negative IE, particularly those with prolonged fever and extracardiac atypical manifestations. Furthermore, it underscores the role of early serological testing and that of TEE in providing timely diagnoses, and suggests that uncommon venous thromboses may serve as an important clue to Q fever. The reassuring outcome of this case emphasizes that, despite its reputation as a chronic and difficult-to-treat condition, C. burnetii IE can be effectively cured when diagnosed early and managed as per current guidelines.

CARDIAC REHABILITATION AS A BRIDGE THERAPY TO HEARTMATE 3 IMPLANTATION IN AN ADVANCED HEART FAILURE INPATIENT: A CASE REPORT

DÊNIS KOMONSKI SELAU1; FERNANDA CECÍLIA DOS SANTOS DE VASCONCELLOS1; NATHÁLIA SOUZA DA SILVA1; ANDRIELI BARBIERI GARLET1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction: Advanced heart failure (HF) patients often present frailty, exercise intolerance and functional decline, limiting eligibility for advanced therapies. Cardiac rehabilitation (CR) can contribute as a strategy for clinical and functional improvement in this high-risk population. We report the case of an advanced HF patient who underwent inpatient CR during a prolonged hospitalization as a bridge therapy to a left ventricular assist device (HeartMate 3) implantation. Case Description: This study received ethical approval and is registered under CAAE number 12683519.9.0000.5327. A 69-year-old male patient admitted for advanced HF (LVEF 22%), dependence on continuous intravenous milrinone, classified as NYHA IV and INTERMACS 3. At initial assessment he presented clinical frailty, reduced peripheral muscle strength (Handgrip Strength [HGS]: 29 kgf, 79.8% of predicted / 5 Times Sit-to-Stand Test [STS]: 12.26 seconds), reduced respiratory strength (Maximal Inspiratory Pressure [MIP]: 40 cmH2O, Maximal Expiratory Pressure [MEP]: 95 cmH2O; 39.96% and 86.8% of predicted, respectively), Self-Selected Gait Speed [GS]: 0.36 m/s, SPPB Score: 8 points, unable to perform the Six-Minute Walk Test (6MWT). The patient underwent inpatient CR (low-intensity aerobic training, progressive muscle strengthening and inspiratory muscle training under continuous clinical monitoring). Four months later, on reassessment: improved muscle strength (HGS: 33 kgf, 83.5% of predicted / STS: 8.16s), improved physical performance (SPPB: 12 points, GT: 0.7 m/s), increase in MIP (55 cmH2O), and reduced submaximal cardiorespiratory capacity (6MWT: 330 meters / 56.3% of predicted). No clinical adverse events occurred during CR or assessments. The indication for HeartMate 3 implantation was made through multidisciplinary discussion and considered clinical stability, functional recovery and potential benefit. On early post-implantation reassessment, muscle strength kept stable (HGS: 31 kgf, 78.1% of predicted / STS: 10.54s), as physical performance (SPPB: 10 points, GT: 0.62 m/s), although decline of submaximal cardiorespiratory capacity (6MWT: 302 meters / 51.9% of predicted). Conclusions: Inpatient CR proved to be safe and was associated with significant functional recovery in an inotrope-dependent patient with advanced HF. This case increases CR potential as a strategy for mechanical circulatory support and access to advanced therapies for clinically frail patients.

Introduction: In recent decades, the evolution in the care of patients with heart failure (HF) has significantly reduced morbidity and mortality. However, new challenges have emerged, focused on understanding the mechanisms of functional capacity and the search for a better quality of life. Although Inspiratory Muscle Training (IMT) is an effective resource for improving respiratory strength and functional capacity, physical therapists must consider strategies to improve adherence when prescribing rehabilitation exercises for HF patients. This work presents a case report focused on the use of a technological tool to optimize adherence to IMT. Case Description: A 69-year-old white female patient with Heart Failure with Preserved Ejection Fraction (HFpEF) of hypertensive etiology, LVEF: 58%, and NYHA functional class II. The study was approved by the Research Ethics Committee. The patient underwent 8 weeks of home-based IMT using a linear load resistor for 20 minutes, 5 times a week, at a 60% load. To enable and monitor the intervention, a mobile application with a web interface was used, specifically developed for this purpose in partnership with Computer Science specialists. The software allowed for exercise scheduling, sent reminders for execution at prescribed times, and collected data on the completion or non-completion of sessions. Conclusions: After the 8-week protocol monitored via the application, the patient showed significant improvement in clinical indicators, exceeding predicted values: Respiratory Muscle Strength: MIP evolved from -50 cm/H2O to -80 cm/H2O (predicted: -77 cm/H2O) and MEP from 60 cm/H2O to 90 cm/H2O (predicted: 73 cm/H2O). In the 6MWT, the distance covered had a slight increase from 483 meters to 492 meters (predicted: 447 m). Handgrip strength evolved from 22 to 28 kg/f in the right upper limb (predicted: 26 kg/f) and from 20 to 24 kg/f in the left (predicted: 24 kg/f). Bendopnea remained negative at the initial and final evaluations. In this case report, IMT combined with mobile app monitoring proved to be an effective strategy for improving respiratory and peripheral muscle strength in HFpEF, with the potential to facilitate home management and treatment adherence. This report is part of an expanding line of research, and data collection will continue through a prospective, randomized, and controlled protocol.

PRE-EXISTING SARCOPENIA AND MUSCLE WEAKNESS AFTER HEART TRANSPLANTATION: A CASE REPORT

MARIA JÚLIA BÓRIO1; THIAGO DIPP1; GABRIELA JAROCESKI1; BRUNA EIBEL1; GUILHERME VIGANÓ1; JUGLANS ALVAREZ1; SANDRA SILVEIRA DE LIMA1; MANOELA VIEL PARAVISI1;

(1) ICFUC - PORTO ALEGRE - RS - BRASIL;

Introduction: Heart transplant recipients are at high risk for ICU-acquired weakness and diaphragmatic dysfunction, potentially affecting clinical outcomes. Early postoperative functional assessment is crucial to guide multidisciplinary management Case Description: A 52-year-old male with prior acute myocardial infarction and cardiac arrest, status post angioplasty, with chronic kidney disease, hypertension, liver cirrhosis, and pre-existing sarcopenia, underwent heart transplantation for end-stage heart failure (ejection fraction: 26%). Cardiopulmonary bypass time was 140 minutes. The patient required mechanical ventilation for 24 hours and chest drains for four days. At 48 hours post-extubation: Glasgow Coma Scale 15, heart rate 100 bpm, respiratory rate 25 breaths/min, and SpO□ 90% on room air. Diaphragmatic excursion was 3.08 cm with a thickening fraction of 50%. Quadriceps thickness was 19.48 mm (right) and 19.70 mm (left), and rectus femoris cross-sectional area was 1.80 cm² (right) and 1.11 cm² (left). MRC score was 36 and Perme score 16. Nutritional screening indicated moderate risk. Conclusions: : Early postoperative findings revealed significant peripheral muscle impairment despite preserved diaphragmatic function. This dissociation suggests a predominant systemic effect driven by baseline sarcopenia, surgical inflammatory response, and hypercatabolism, even without prolonged mechanical ventilation. Ultrasound findings were consistent with functional decline, reinforcing its role as a sensitive bedside tool. Pre-existing sarcopenia may amplify early functional impairment after heart transplantation, regardless of ventilation duration. Integrated assessment combining ultrasound and functional scales enables early risk stratification and supports targeted interventions, with potential to improve recovery and clinical outcomes.

ILIAC ARTERY ENDOFIBROSIS IN AN AMATEUR CYCLIST: FROM DIAGNOSTIC CHALLENGE TO DEFINITIVE TREATMENT

DAVID MACIEL DE SÁ GURGEL BANI1; MARCONI GOMES DA SILVA2; DANIEL MENDES PINTO2; LEONARDO NEUENSCHWANDER MAGALHÃES2; FELIPE MIRANDA PAIS2;

(1) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introduction: Iliac artery endofibrosis is a non-atherosclerotic arteriopathy causing exercise-induced claudication in high-performance cyclists, with prevalence up to 20%. Pathophysiology involves intimal fibrous thickening due to repetitive hip hyperflexion, psoas hypertrophy, and high blood flow, leading to microtrauma and stenosis. The external iliac artery is most affected, usually unilaterally. Symptoms include cramping, pain, and fatigue during intense effort. Diagnosis is often delayed by low clinical suspicion, making treatment challenging in athletes with high functional demands. Case Description: A 41-year-old male amateur cyclist, with several years of regular training, presented throughout 2024 with progressive cramping, pain, and weakness in the right lower limb during intense efforts, leading to reduced athletic performance. Initially, the condition was misinterpreted as a sports-related musculoskeletal injury. Conservative measures—including physical therapy, biomechanical adjustments to cycling posture, and training modifications—provided only partial relief. Persistent symptoms during high-intensity activity raised the clinical suspicion of arterial endofibrosis. Vascular Doppler ultrasound and CT angiography confirmed occlusion of the right external iliac artery. Conservative management and restriction from competition were initially recommended. However, due to ongoing symptoms and functional impairment, the patient sought specialized evaluation and elected surgical treatment via endarterectomy. The procedure was performed in November 2025 without perioperative complications. The patient demonstrated significant clinical improvement upon resuming activities, with follow-up imaging confirming restoration of arterial flow. He has progressed through a gradual training program and remains under clinical monitoring, with expectations of returning to competitive cycling. Conclusions: Iliac artery endofibrosis should be considered in the differential diagnosis of exercise-induced claudication in athletes, particularly cyclists, even in the absence of atherosclerotic risk factors. Diagnosis relies on clinical suspicion supported by imaging modalities such as vascular Doppler ultrasound and CT angiography. While conservative measures may be attempted initially, their efficacy is limited in symptomatic athletes. In such cases, endarterectomy offers an effective therapeutic option to restore arterial flow and enable functional return to sport.

CDI-RELATED INFECTIVE ENDOCARDITIS IN RECOVERED PERIPARTUM CARDIOMYOPATHY DURING SUBSEQUENT PREGNANCY: AN UNUSUAL PRESENTATION

JULIANA CRISTINA DUARTE BRAGA1; FERNANDA ROQUETTE DE ARAUJO2; GUSTAVO TOBIAS PIMENTA2; GUILHERME SOUZA LAMOUNIER2; ANNA LUISA RAMOS SILVA2; FILIPE ALBERTO MOREIRA LIESNER2; ESTEVAO LANNA FIGUEIREDO2; CLAUDIA MARIA VILAS FREIRE1;

Introduction: Peripartum cardiomyopathy (PPCM) is a rare condition characterized by left ventricular dysfunction occurring during late pregnancy or the postpartum period. Recurrence and the presence of intracardiac devices, such as implantable cardioverter-defibrillators (ICDs), may increase the risk of severe complications, including device-related infections. Case Description: A 27-year-old woman with previous PPCM diagnosed in 2017 underwent ICD implantation for primary prevention due to severe left ventricular dysfunction (LVEF 19%). In 2019, she received eight appropriate ICD shocks. Four years after the index pregnancy, complete recovery of ventricular function was documented (LVEF 61%). During a subsequent pregnancy, she remained under specialized follow-up, presenting preserved ventricular function and good functional status. Pregnancy evolved uneventfully until cesarean delivery at 38 weeks. One week postpartum, she developed acute uterine rupture with hemorrhagic shock, followed by endometritis and severe acute kidney injury requiring hemodialysis. Subsequently, she presented fever and systemic signs of infection. Blood cultures were positive for Staphylococcus aureus, and transesophageal echocardiography demonstrated vegetation attached to the ICD lead, confirming device-related infective endocarditis. The patient progressed with severe sepsis, requiring intensive care admission, ventilatory support, and prolonged intravenous antibiotic therapy. Complete ICD system removal was performed. Additional obstetric complications during hospitalization required multidisciplinary management. Conclusions: This case highlights the complexity of ICD management in patients with recovered PPCM, particularly regarding late ventricular recovery and subsequent pregnancies. Although bacteremia related to delivery is uncommon, obstetric complications may increase infectious risk. Early recognition and multidisciplinary management are essential to improve maternal outcomes in this rare and challenging scenario.

SECONDARY HYPERTENSION DUE TO PRIMARY ALDOSTERONISM IN PREGNANCY PRESENTING AS FLACCID QUADRIPARESIS: A CASE REPORT

LETICIA TIMBÓ MARTINS FERREIRA1; JOAO DA SILVA FERREIRA MARINHO1; MARIA SOFIA BEZERRA FREIRE GOMES1; CECILIA GABRIELA DANTAS DE SOUZA1; LUANA VELOSO MAGALHAES1; MARINA CARVALHO MENDONÇA1; ANA FLAVIA DE ARAUJO BARROS1; DAVI SEVERO MARQUES1; RENAN LOPES MENDONCA1; GIOVANNI LEAL HOLANDA1; FRANCISCO THIAGO SANTOS SALMITO2; RENAN GOMES MENDES DINIZ1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL;

Introduction: Primary Aldosteronism (PA) is the most common cause of secondary systemic arterial hypertension (SAH), yet it remains a frequently underdiagnosed etiology. In the context of pregnant patients, the diagnosis is even more challenging due to the physiological changes of pregnancy in the human body, which can mask mineralocorticoid hyperactivation. We present a clinical case of a patient with a history of hypertensive disease in a second pregnancy, controlled with losartan, who developed severe hypokalemia and transient tetraparesis, highlighting the importance of screening for this frequently overlooked condition. Case Description: A 36-year-old female patient with a history of hypertension initiated during her third pregnancy, previously controlled with Losartan 100 mg/day, with no history of hypertensive disease in previous pregnancies and no criteria for preeclampsia. Ten months after delivery, she was admitted to a tertiary hospital presenting with two episodes of transient flaccid tetraparesis and intense myalgia within a 48-hour interval, both episodes preceded by gastroenteritis. On admission, her blood pressure was 140/90 mmHg, and laboratory tests revealed mild anemia (hemoglobin 11.8 g/dL), severe hypokalemia (K□ 1.82 mEq/L), metabolic alkalosis (pH 7.54, HCO□ 36.6 mmol/L, pCO□ 43.6 mmHg), and rhabdomyolysis (CPK 1,488 U/L). Investigation for secondary hypertension, triggered by a hypertensive peak of 170/100 mmHg and refractory hypokalemia, showed an aldosterone level of 32.5 ng/dL and plasma renin activity of 0.33 ng/mL/h, with an aldosterone-to-renin ratio (ARR) of 98.4, confirming mineralocorticoid autonomy. Abdominal computed tomography *CT)identified a 1.6 × 1.1 cm nodule in the left adrenal gland. The patient was prepared with spironolactone and potassium replacement and underwent videolaparoscopic adrenalectomy. At outpatient follow-up, she showed improvement in hypertension and definitive normalization of serum potassium without the need for medications. Conclusions: This case demonstrates a challenging diagnosis of PA in pregnancy in a patient without resistant hypertension, presenting with neurological motor symptoms due to hypokalemia. Although poorly described, it highlights the importance of investigating secondary hypertension and the need for universal diagnostic criteria, as hormonal imbalance, especially the vasodilatory effects of progesterone and increased aldosterone and renin, that may mask the condition.

ALLOPURINOL IN CORONARY ARTERY DISEASE: FROM PROMISING MECHANISMS TO UNCERTAIN CLINICAL BENEFIT

GABRIELLA FRAIJI MELO1; PEDRO VECHI SANTOS1; RENATO JORGE ALVES2;

(1) FACULDADE DE CIENCIAS MEDICAS DA SANTA CASA DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) IRMANDADE DA SANTA CASA DE MISERICORDIA DE SAO PAULO, FACULDADE DE CIENCIAS MEDICAS DA SANTA CASA DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Background/Introduction: Coronary artery disease (CAD) is the leading global cause of death, affecting 197 million people and causing over 9.1 million deaths annually. Angina, a common manifestation, significantly impairs quality of life despite advances in therapy. Xanthine oxidase (XO) activity increases during ischemia, generating reactive oxygen species and reducing nitric oxide bioavailability. Allopurinol, an XO inhibitor, may improve ischemia by reducing oxidative stress and myocardial oxygen consumption. This systematic review evaluates its clinical role. Objectives: To evaluate the efficacy and safety of allopurinol in patients with angina or ischemic heart disease, focusing on its impact on clinical outcomes, symptom burden, and cardiovascular biomarkers. Methods: A systematic search of PubMed, Cochrane, and EMBASE was conducted to identify studies comparing allopurinol with placebo or usual care in patients with angina or ischemic heart disease. The review was prospectively registered in PROSPERO (CRD420250572006) and conducted in accordance with PRISMA guidelines. Primary outcomes included cardiac adverse events and all-cause mortality. Secondary outcomes included angina symptoms, serum uric acid, B-type natriuretic peptide (BNP), vascular function, and safety. Results and Conclusions: Six randomized controlled trials (n=6,267) were included, ranging from mechanistic studies to a large multicenter trial. Allopurinol consistently improved surrogate outcomes, including exercise capacity, with prolongation of time to ST-segment depression and total exercise duration (Noman et al, 2010), as well as improvements in endothelial function, arterial stiffness, and left ventricular structure (Rajendra et al, 2011; Rekhraj et al, 2013). Significant reductions in serum uric acid (~40–50%), BNP, oxidative stress, and inflammatory markers were also observed. One smaller study (Huang et al, 2017) demonstrated a reduction in cardiovascular events, whereas the largest trial (ALL-HEART, 2022) found no significant differences in major adverse cardiovascular events, all-cause mortality, angina frequency, or quality of life. These findings indicate that, although allopurinol improves physiological and mechanistic markers of ischemia, these benefits do not translate into improved hard clinical outcomes in unselected populations. Further large-scale studies targeting high-risk subgroups are warranted.

Allopurinol in Coronary Artery Disease: From Promising Mechanisms to Uncertain Clinical Benefit

Gabriella Fraiji Melo, Pedro Vechi, Renato J. Alves

Table 1. Effects on Angina, Vascular Function, and Biomarkers

Study	Angina Symptoms and Exercise Capacity	Vascular Function and Cardiac Structure	Biomarkers and Physiological Markers
ALL-HEART (2022)	No significant difference in angina frequency or physical limitation (SAQ).	Not assessed as a primary outcome.	Uric acid: ~50% reduction (0.34 to 0.18 mmol/L).
Noman et al. (2010)	↑ Time to ST depression: +43 s (p=0.0002); ↑ total exercise time: +58 s.	Suggestive reduction in afterload (ventricular resistance).	BNP reduced from 84.3 to 55.6 pg/mL (p=0.045); significant uric acid reduction.
Huang et al. (2017)	Angina efficacy: 93.2% vs 76% (p<0.05); ECG improvement: 96% vs 82%.	Increased nitric oxide (NO), indicating improved endothelial function.	Reductions in BNP, MDA, Ox-LDL, hs-CRP, and TNF-α (p<0.05).
Rajendra et al. (2011)	Not directly assessed.	↑ FMD (5.4% vs 4.1%); ↓ AIx (24.7% vs 27.6%) (p<0.001).	Vascular oxidative stress markedly reduced; ↓ Ox-LDL.
Rekhraj et al. (2013)	Not directly assessed.	↓ LV mass (−5.2 g vs −1.3 g); ↓ end-systolic volume; ↑ FMD and ↓ AIx.	Uric acid reduced by 46%; BNP trend toward reduction (p=0.08).

Table 2. Clinical Outcomes, Quality of Life, and Safety

Study	Clinical Outcomes and Mortality	Quality of Life (QoL) and Safety
ALL-HEART (2022)	No difference in composite outcome (11.0% vs 11.3%) or all-cause mortality.	QoL: No difference (EQ-5D/SAQ); Safety: 57.4% discontinuation, increased skin rash.
Noman et al. (2010)	Not assessed for long-term clinical outcomes.	Safety: Well tolerated; no adverse events reported.
Huang et al. (2017)	Lower CV events in allopurinol group (10% vs 30%) at 2 years.	QoL not formally assessed.
Rajendra et al. (2011)	Suggests potential mortality benefit based on endothelial improvement.	Safety: Well tolerated; no rash or renal impairment.
Rekhraj et al. (2013)	LV hypertrophy regression discussed as prognostically beneficial.	Safety: Generally well tolerated; one case of rash.

BARRIERS TO ACUTE CORONARY SYNDROME MANAGEMENT IN SMALL HOSPITALS IN BRAZIL: A SYSTEMATIC REVIEW

ANA KAROLLINY DAS NEVES SOUTO SILVA1; CAUET TRINDADE PADILHA CARVALHO CÂMARA1; ALEXANDRE JORGE DE ANDRADE NEGRI1;

(1) AFYA - FACULDADE DE CIENCIAS MEDICAS DA PARAIBA - CABEDELO - PB - BRASIL;

Background/Introduction: Introduction: ACS is one of the leading causes of cardiovascular mortality in Brazil. SIH-SUS data (2015–2026) reveal in-hospital mortality of 5.57% (men) and 7.05% (women) in the Northeast, above national averages, suggesting critical barriers to access to percutaneous coronary intervention (PCI)-capable services Objectives: Objective: To systematically review barriers to ACS management in non-PCI-capable hospitals, focusing on resource availability and clinical outcomes. Methods: Methods: Systematic review following PRISMA 2020, registered in PROSPERO (CRD420261350747). PubMed/MEDLINE, LILACS, and Cochrane Library were searched, yielding 328 records. After full-text filter (n=216), duplicate removal, and two-stage screening, titles/abstracts (n=124) and full-text peer-reviewed reading, 28 studies were included. Risk of bias was assessed using the Newcastle-Ottawa Scale. Results and Conclusions: Results: Twenty-eight studies were included (Brazil, Australia, China, New Zealand, Indonesia, Canada, and other low- and middle-income countries). Main barriers identified: only 41% of patients received ECG within ≤10 minutes of arrival; door-to-balloon times with medians of 114–189 minutes for transfers, with only 12–24% achieving ≤90 minutes; in-hospital mortality reaching 21.5% in public hospitals in low-income settings. Women experienced longer ECG delays (53 vs. 34 min; p=0.001) and higher mortality (23.6% vs. 13.9%). Telecardiology was associated with a 17% reduction in mortality (RR: 0.83; 95% CI: 0.73–0.95). Regional protocols and continuing education demonstrated potential to optimize time to reperfusion.Conclusion: ACS management in small hospitals is marked by ECG delays, prolonged transfers, and high in-hospital mortality — particularly in women. Telecardiology and regional protocols show potential to reduce these barriers, reinforcing the need for equity in care and infrastructure investment in underserved regions.

BASELINE RENAL DYSFUNCTION AND IN-HOSPITAL MORTALITY IN ACUTE MYOCARDIAL INFARCTION TREATED WITH A PHARMACOINVASIVE STRATEGY

PAULA SANTIAGO TEIXEIRA1; LIVIA TOSHIKO GONDO1; GUILHERME BOALENTO FIGUEIREDO1; KAIO VINICIUS CAMPOS MARQUES1; VLADIMIR AILTON CUMA NANCASSA1; FRANCISCO SANDRO MENEZES RODRIGUES2; PEDRO IVO DE MARQUI MORAES1; MARIA TERESA NOGUEIRA BOMBIG1; HENRIQUE TRIA BIANCO1; ADRIANO HENRIQUE PEREIRA BARBOSA1;

(1) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL; (2) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Background/Introduction: Ischemic heart disease remains the leading cause of mortality worldwide. Chronic kidney disease frequently coexists with acute myocardial infarction (AMI) and is associated with adverse outcomes. However, the prognostic impact of renal dysfunction in patients undergoing a pharmacoinvasive strategy remains incompletely defined. Objectives: To evaluate the association between baseline renal dysfunction and in-hospital mortality in patients with AMI treated with a pharmacoinvasive strategy. Methods: This cohort included 2,710 consecutive patients with AMI managed within a pharmacoinvasive network. All patients received fibrinolysis followed by early coronary angiography (2–24 hours) or rescue percutaneous coronary intervention when indicated. Multivariable logistic regression was performed to identify independent predictors of in-hospital mortality. Odds ratios (OR) with 95% confidence intervals (CI) were reported. Results and Conclusions: In-hospital mortality occurred in 162 patients (6%). Creatinine clearance estimated by the CKD-EPI equation showed good discrimination for in-hospital mortality (AUC 0.76; 95% CI 0.71–0.80; p<0.001). Reduced creatinine clearance was independently associated with mortality after adjustment for age (OR 1.07; 95% CI 1.05–1.08). Advanced Killip class (III–IV) was also independently associated with increased in-hospital mortality.Baseline renal dysfunction was independently associated with in-hospital mortality in patients undergoing a pharmacoinvasive strategy, supporting its role as an early and readily available marker for risk stratification in AMI.

DIGITAL INNOVATION IN EMERGENCY CARE: IMPACT OF CARDIOLOGY TELECONSULTATION ON MEDICAL DECISION-MAKING IN 150 URGENT CARE UNITS

DANIELLA CRISTINA BUENO IOZZI1; ADRIELLY DA SILVA SANTOS1; CAMILLA DO ROSARIO NICOLINO CHIORINO1; THAIS DOS SANTOS SILVA1;

(1) BENEFICENCIA PORTUGUESA - SAO PAULO - SP - BRASIL;

Background/Introduction: ST-segment elevation myocardial infarction (STEMI) and severe arrhythmias are time-sensitive conditions requiring early diagnosis and immediate intervention. In resource-constrained urgent care settings, limited access to specialist input may delay appropriate management. A large-scale initiative implemented 24-hour teleconsultation with remote electrocardiogram (ECG) interpretation to provide real-time specialist support, aiming to improve clinical decision-making and optimize healthcare resource utilization. Objectives: To evaluate the impact of synchronous cardiology teleconsultation on clinical decision-making and outcomes in patients with critical ECG findings (STEMI and severe arrhythmias), comparing cases managed with and without specialist consultation. Methods: This multicenter retrospective observational study was conducted from June 2024 to December 2025. Cases with teleconsultation were compared with those managed without specialist consultation in routine clinical practice. The analysis was restricted to ECG reports classified as critical. Clinical outcomes (discharge, death, hospitalization, and transfer) were assessed within 48 hours of the index ECG. Data were analyzed according to study periods (2024: 7 months; 2025: 12 months). Pearson's chi-square test (χ^2) and odds ratios (OR) with 95% confidence intervals (95% CI) were applied, with statistical significance set at $p < 0.05$. Results and Conclusions: A total of 18,832 critical cases were analyzed. Teleconsultation adherence increased from 59% in 2024 to 72% in 2025, reflecting progressive protocol uptake. In 2024, the teleconsultation group showed higher rates of hospitalization or transfer compared with controls (60% vs. 53%; $\chi^2 = 30.3$; $p < 0.001$), corresponding to a 32% higher likelihood of escalation of care (OR 1.32; 95% CI: 1.19–1.46). In 2025, this pattern persisted (59% vs. 55%; $\chi^2 = 21.9$; $p < 0.001$), with a 20% higher likelihood of these outcomes (OR 1.20; 95% CI: 1.11–1.30). Teleconsultation was also associated with higher transfer rates (48% vs. 41%) and lower discharge rates (35% vs. 40%). These findings provide real-world, system-level data indicating that teleconsultation-supported care is associated with more risk-adjusted clinical decision-making, favoring appropriate referral to higher-complexity care and reducing the likelihood of premature discharge. As a scalable system-level intervention, teleconsultation may enhance triage quality and patient safety in emergency cardiovascular care.

19433

DURATION OF DUAL ANTIPLATELET THERAPY AFTER ACUTE CORONARY SYNDROME: A SYSTEMATIC REVIEW AND META-ANALYSIS

THIAGO VITTOR SILVA FREITAS1; MATEUS HENRIQUE DE ALMEIDA BUCK1; BRUNO FREITAS SILVA1; RAFAEL ALVES DE OLIVEIRA1; POLIANA MARCELINO JOIA1; GIOVANA CASAGRANDE DE ALENCAR1; TAYNARA TAVARES DOS SANTOS1; LUCAS MARINHO REIS DA CUNHA SILVA1; AMANDA OLIVA SPAZIANI1; NICOLY MIGUEL FIORI1; TAÍS SANTANA GARGANTINI FERREIRA1; ALANA ARANTES SANTOS GONÇALVES1;

(1) UNIVERSIDADE BRASIL - FERNANDOPOLIS - SP - BRASIL;

Background/Introduction: Dual antiplatelet therapy (DAPT), consisting of aspirin and a P2Y12 receptor inhibitor, is a cornerstone in the treatment of acute coronary syndrome (ACS). However, the optimal duration of therapy remains controversial, particularly in balancing the reduction of ischemic events and the risk of bleeding. Objectives: To compare the efficacy and safety of different durations of DAPT in patients after acute coronary syndrome. Methods: A systematic review conducted according to PRISMA guidelines, with searches in PubMed, Embase, and Cochrane Library databases up to January 2026. Randomized clinical trials comparing short-duration DAPT (≤6 months) versus standard (12 months) or prolonged (>12 months) therapy were included. The outcomes analyzed were major cardiovascular events (MACE) and major bleeding. The meta-analysis was performed using a random-effects model, with calculation of relative risk (RR) and 95% confidence intervals (95% CI). Heterogeneity was assessed using the I^2 index. Results and Conclusions: Eleven studies were included, totaling 32,684 patients. Prolonged DAPT was associated with a reduction in major cardiovascular events (RR=0.86; 95% CI: 0.78–0.95; p=0.003), but with a significant increase in major bleeding (RR=1.42; 95% CI: 1.25–1.61; p<0.001). Short-duration DAPT showed a lower risk of bleeding (RR=0.74; 95% CI: 0.65–0.84; p<0.001), without a significant increase in ischemic events. The duration of dual antiplatelet therapy should be individualized, considering both ischemic and bleeding risk profiles. Short-duration strategies may be safe in selected patients, while prolonged therapy should be reserved for those at high ischemic risk.

EFFICACY AND SAFETY OF VERY EARLY P2Y12 INHIBITOR MONOTHERAPY AFTER PCI IN ACUTE CORONARY SYNDROMES: SYSTEMATIC REVIEW AND RANDOM-EFFECTS META-ANALYSIS OF RANDOMIZED TRIALS

LUIZ FERNANDO CAL SILVA1; MILENA PICCOLO SANTANA1; JÂNIO FELIPE RIBEIRO DE SOUZA1; ANDRÉ MELLO GERHARDT1; MARCELO HENRIQUE BARBOSA1; SORAIA RACHID YOUSSEF DE CAMPOS1; VIVIAN LERNER AMATO1; RICARDO PAVANELLO1; FAUSTO FERES1; VALÉRIA MOZETIC DE BARROS1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - Brasil;

Background/Introduction: Very early withdrawal of aspirin (<1 month of DAPT) after PCI in ACS, with continuation of a potent P2Y12 inhibitor as monotherapy, has been proposed to reduce bleeding. Although strategies with abbreviated DAPT of 1–3 months (TWILIGHT, NEJM 2019; TICO, JAMA 2020; ULTIMATE-DAPT, Lancet 2024) support hemorrhagic benefit, the <1-month window remains controversial: T-PASS (Hong, Circulation 2024) demonstrated superiority in net clinical benefit, whereas NEO-MINDSET (Guimarães, NEJM 2025) failed to demonstrate ischemic non-inferiority. The 2025 ACC/AHA/SCAI guideline endorses ticagrelor monotherapy after ≥1 month of DAPT (Class I/A); the <1-month interval remains an open question. Objectives: The aim of this review and meta-analysis was to focus on early aspirin discontinuation by integrating time-to-event estimates from randomized trials to quantify hemorrhagic, ischemic, and clinical effects during this very early de-escalation period. Methods: Systematic review and meta-analysis (PRISMA), DerSimonian–Laird random-effects model, comparing P2Y12 monotherapy initiated at <1 month of DAPT versus standard 12-month DAPT after PCI in ACS. From the initial search (156 records), 2 RCTs were eligible after exclusion of 4 due to inadequate comparator: T-PASS (n=2,850) and NEO-MINDSET (n=3,410); total 6,260 patients. Outcomes: ischemic composite/MACE, major or clinically relevant bleeding (BARC 2–5 or 2/3/5), and net adverse clinical events (NACE). Heterogeneity assessed by I^2. Results and Conclusions: Very early monotherapy robustly reduced major/clinically relevant bleeding (HR 0.38; 95% CI 0.27–0.53; I^2=0%; relative reduction ≈60%). For MACE, the effect was neutral (HR 0.98; 95% CI 0.53–1.81), with substantial heterogeneity (I^2≈75%), consistent with differences in the timing of aspirin discontinuation and outcome definitions. For NACE, there was a trend favoring monotherapy (HR 0.70; 95% CI 0.45–1.10; I^2≈76%). In ACS patients undergoing PCI, aspirin withdrawal at <1 month with potent P2Y12 monotherapy consistently reduces bleeding, with no uniform signal of increased ischemic risk. The low number of studies, substantial heterogeneity, and the pre-specified analysis of NEO-MINDSET (Tavares, JACC 2026) — suggesting harm in STEMI and safety in NSTEMI or Unstable Angina — indicate that thrombotic safety depends on the timing of discontinuation and individual ischemic profile. The findings support an individualized approach, prioritizing bleeding reduction, with caution in high thrombotic risk, particularly NSTEMI.

Background/Introduction: The definition of an invasive strategy in NSTEMI or unstable angina is based on risk stratification; however, determinants of this decision in real-world practice remain incompletely understood. Objectives: To identify factors associated with a conservative strategy in the management of NSTEMI or unstable angina. Methods: Multicenter retrospective study based on a nationwide registry from 14 Brazilian states (January 2020–June 2024). Patients were classified as NSTEMI, or unstable angina. Multivariable logistic regression was used to identify factors independently associated with conservative management. Analyses were performed using RStudio. Results and Conclusions: Invasive management decisions were largely driven by the acuity and clarity of clinical presentation, but also reflected important demographic and behavioral disparities. Male sex was consistently associated with lower odds of conservative management across NSTEMI and unstable angina, indicating a higher threshold for invasive referral in women regardless of disease severity. Lifestyle and risk profile also played a relevant role. A sedentary lifestyle independently predicted conservative management, possibly reflecting clinician perception of limited functional benefit. In contrast, traditional atherosclerotic risk factors such as dyslipidemia and smoking were inversely associated with conservative management, likely increasing physician confidence in obstructive coronary disease and favoring invasive investigation. Age demonstrated a bidirectional effect: it increased conservative management in NSTEMI, suggesting procedural risk aversion in older patients, but decreased it in unstable angina, consistent with a more proactive diagnostic approach. Chronic comorbidities showed limited independent influence. Conclusions: In both NSTEMI and unstable angina, invasive management was influenced by factors beyond clinical presentation, with male sex and traditional atherosclerotic risk factors consistently favoring invasive strategies, while a sedentary lifestyle was associated with conservative management. However, age showed a divergent pattern: it increased the likelihood of conservative management in NSTEMI, suggesting greater procedural risk aversion, but decreased it in unstable angina, reflecting a more proactive diagnostic approach. Overall, these findings highlight both shared and condition-specific drivers of decision-making, suggesting that non-clinical characteristics may contribute to variability and potential disparities in care.

Variable	Beta	OR (95% CI)	p-value	Events (n)
STEMI diagnosis	-1.245	0.29 (0.24–0.34)	<0.001	1213

IMPACT OF DOOR-TO-ECG DELAY ON CLINICAL OUTCOMES IN STEMI: INSIGHTS FROM A LARGE BRAZILIAN MULTICENTER REGISTRY

VINICIUS CARVALHO FIUSA1; RODRIGO GÓES DE OLIVEIRA GALVÃO2; NATAN TEIXEIRA DA SILVA2; GABRIEL CARVALHO FIUSA1; ERYCLAUDIA CHRYSTIAN BRASILEIRO JORQUEIRA3; LUCAS GABRIEL CASTRO CARVALHO1; MANOELA MASSA MOURA1; ANA CLARA PIEROTE RODRIGUES VASCONCELOS1; PEDRO CÉSAR REZENDE SEGURADO1; LALESCA MEDEIROS1; ANTONIO AURELIO FAGUNDES-JUNIOR3;

(1) UNIVERSIDADE DE BRASILIA - BRASÍLIA - DF - BRASIL; (2) ESCOLA SUPERIOR DE CIENCIAS DA SAUDE - BRASÍLIA - DF - BRASIL; (3) INSTITUTO D'OR DE PESQUISA E ENSINO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Timely electrocardiogram is a cornerstone of STEMI management and a key quality-of-care metric. However, the impact of door-to-ECG (DTE) delays on patient outcomes remains uncertain, particularly in large real-world populations. Objectives: To evaluate the association between DTE time and in-hospital clinical outcomes in STEMI patients from a Brazilian cohort. Methods: A multicenter study was conducted using data from a large retrospective registry with data from 14 Brazilian states between January 2020 and June 2024 from the largest private hospital network in Brazil (n=7,171). The DTE time of patients with acute coronary syndrome (ACS) was analyzed in categories (<10min, 10–29min and ≥30min) and as a continuous variable every 10 minutes. Multivariable regression models were used to evaluate the effect of the variables on clinical outcomes. Logistic regression was used for binary outcomes and linear regression for continuous outcomes, with adjustment for age and sex. Results and Conclusions: A total of 1,345 patients with STEMI were included (75.6% male, mean age 61.3±13.6 years). Patients with DTE ≥30min had significantly higher in-hospital mortality (OR 3.10; 95%CI 1.27–7.55; p=0.013) and overall complication rates (OR 3.49; 95%CI 1.71–7.14; p<0.001). Delayed diagnosis was associated with increased length of stay (>10 days) (OR 2.57; 95%CI 1.23–5.39; p=0.012). Prolonged ICU stay (>5 days) was also higher in the >30min group (OR 3.00; 95%CI 1.26–7.16; p=0.013). Conversely, DTE <10min was associated with reduced mortality (OR 0.57; 95%CI 0.34–0.97; p=0.039) and fewer overall complications (OR 0.49; 95%CI 0.34–0.71; p<0.001). Each 10 minutes increment in DTE time was associated with higher mortality (OR 1.12; 95%CI 1.03–1.22; p=0.012), more complications (OR 1.10; 95%CI 1.02–1.20; p=0.020), higher acute respiratory failure rates (OR 1.18; 95%CI 1.02–1.37; p=0.030) and longer hospital stay (β 0.27; 95%CI 0.02–0.53; p=0.038). In summary, delays in DTE time were independently associated with higher mortality, more complications, and longer hospitalization in STEMI patients, highlighting the importance of early ECG in ACS management.

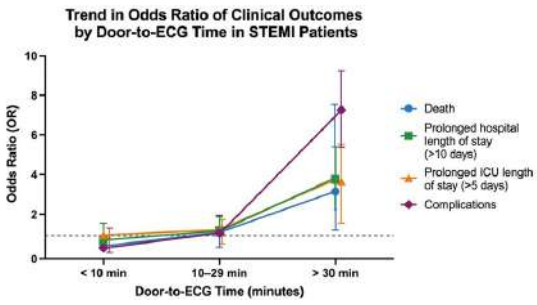

Table 1. Population characteristics.

IMPACT OF THE COVID-19 PANDEMIC ON ACUTE MYOCARDIAL INFARCTION HOSPITALIZATIONS IN MARANHÃO: AN ECOLOGICAL TIME-SERIES STUDY (2018–2024)

SAMUEL VICTOR SOARES DE CARVALHO1; TIAGO CORDEIRO MEDEIROS1;

(1) UFMA - CAMPUS SAO LUIS - SÃO LUÍS - MA - BRASIL;

Background/Introduction: Acute myocardial infarction (AMI) remains a leading cause of cardiovascular mortality in Brazil. During the COVID-19 pandemic, emergency avoidance and system overload may have delayed AMI care, with consequences on hospitalization patterns and outcomes. Evidence on this impact in the Brazilian Northeast, a region with disparities in cardiovascular care access, is limited. Objectives: To compare AMI hospitalizations, in-hospital mortality, and length of stay across pre-pandemic, pandemic, and post-pandemic periods in Maranhão. Methods: Ecological time-series study using data from SIH/SUS (ICD-10 I21–I22) via DATASUS. Monthly records were divided into pre-pandemic (Jan/2018–Dec/2019), pandemic (Jan/2020–Dec/2021), and post-pandemic (Jan/2022–Sep/2024). Variables: monthly hospitalizations, mortality rate (%), and mean length of stay (days). Given the non-normal distribution of monthly data, Kruskal-Wallis was used as the primary test with DSCF pairwise comparisons; one-way ANOVA with Games-Howell post-hoc served as confirmatory analysis. The post-pandemic period (33 vs. 24 months) and DATASUS reporting cutoff at September 2024 are acknowledged limitations; monthly means were used to mitigate temporal asymmetry. Results and Conclusions: Mean monthly hospitalizations: 128.8 ± 20.2 (pre), 118.8 ± 23.2 (pandemic), 163.0 ± 17.5 (post). Pre vs. pandemic difference was not statistically significant (ANOVA p = 0.260; Kruskal-Wallis p = 0.345); post-pandemic was significantly higher than both periods (p < 0.001). In-hospital mortality rose from 12.5% (pre) to 15.0% (pandemic), then fell to 11.5% (post); pandemic was higher than both pre (p = 0.030) and post (p < 0.001), with no significant pre-post difference (p = 0.350). Length of stay: 8.1, 7.8, and 8.7 days (overall p = 0.006); pandemic vs. post differed significantly (p = 0.005), while pre did not differ from either period. AMI hospitalizations did not decline significantly during the pandemic, possibly reflecting the obligatory nature of AMI presentations, unlike chronic HF where decompensation may be initially managed at home. Elevated pandemic mortality suggests reduced access to timely AMI care during that period. The post-pandemic rebound in hospitalizations with normalized mortality supports recovery of care pathways with persisting increased demand.

LEFT VENTRICULAR DYSFUNCTION AS A PREDICTOR OF MACE IN MYOCARDIAL INFARCTION WITH NON-OBSTRUCTIVE CORONARY ARTERIES (MINOCA): EVIDENCE FROM A BRAZILIAN TERTIARY REGISTRY

GUILHERME AGUIAR FORTE1; MATHEUS ALVES SILVA2; BRUNA PONTES DA SILVA2; CATHERINE MENEZES COSTA2; LUCAS MOURA STRELEC2; BRUNO NOSCHANG BLAAS2; BIANCA FERNANDES TÁVORA ARRUDA2; RAPHAEL MACHADO ROSSI2; ALEXANDRE ADAMES JORGE2; RICARDO PAVANELLO2; JESSICA BARBOSA CARVALHO2; KELVYN MELO VITAL2;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - CE - BRASIL; (2) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Background/Introduction: Myocardial Infarction with Non-Obstructive Coronary Arteries (MINOCA) represents a heterogeneous entity with diverse pathophysiology. Although most patients present with preserved ventricular function, a subgroup develops systolic dysfunction (LVEF ≤40%), whose clinical and prognostic characterization remains incomplete. Objectives: To describe the clinical characteristics, etiologies, and outcomes in patients with MINOCA and left ventricular dysfunction (LVEF ≤40%), comparing them to those with preserved ventricular function (LVEF >40%). Methods: A retrospective cohort of 197 patients diagnosed with MINOCA and followed at a tertiary cardiology center between 2018 and 2023 in Brazil was analyzed. A total of 162 patients with documented LVEF were included and divided into two groups: LVEF ≤40% (n=46) and LVEF >40% (n=116). The primary outcome was MACE (death, recurrent myocardial infarction, stroke, or cardiovascular hospitalization). Secondary outcomes included individual components and functional symptoms. Categorical variables were compared using the chi-square or Fisher's exact test; continuous variables were analyzed using the t-test or Mann–Whitney test. Multivariate logistic regression was used to identify independent predictors of MACE. Results and Conclusions: Patients with LVEF ≤40% were significantly younger (46.2±11.8 vs 52.3±11.7 years; p=0.004), with a lower proportion of females (45.7% vs 57.8%; p=0.18). MACE occurred in 43.5% of the dysfunction group versus 16.4% in the preserved function group (p<0.001; OR=3.93; 95% CI 1.83–8.42). Mortality was higher in the dysfunction group (8.7% vs 0.9%; p=0.023). Recurrent cardiovascular hospitalization was the main differentiating component (47.8% vs 9.6%; p<0.001; OR=5.60). Dyspnea was more prevalent in patients with LVEF ≤40% (65.2% vs 28.4%; p<0.001). In multivariate analysis, LVEF as a continuous variable was an independent predictor of MACE (OR=0.926 per 1% increase; 95% CI 0.895–0.958; p<0.001), as was hypertension (OR=6.17; p=0.003). Left ventricular dysfunction in patients with MINOCA identifies a high-risk subgroup with significant cardiovascular morbidity and mortality, greater symptom burden, and frequent hospitalizations. LVEF as a continuous variable is an independent predictor of MACE, reinforcing the need for systematic ventricular function stratification in this population.

MACHINE LEARNING OUTPERFORMS THE NAPLES SCORE FOR PREDICTING IN-HOSPITAL MORTALITY IN PATIENTS UNDERGOING CORONARY ANGIOGRAPHY

AHMET FERHAT KAYA1; MEHMET HASAN ÖZDIL2;

(1) VAN REGIONAL TRAINING AND RESEARCH HOSPITAL - TÜRKIYE; (2) PRIVASCY MEDIGUNES HOSPITAL - TÜRKIYE;

Background/Introduction: The Naples prognostic score integrates inflammatory and nutritional parameters; however, its discriminative ability in heterogeneous cardiovascular populations remains uncertain. Accurate risk stratification in patients undergoing coronary angiography is essential, particularly for predicting in-hospital mortality. Machine learning (ML) approaches may offer improved predictive performance by capturing complex nonlinear relationships between clinical variables. Objectives: To evaluate the predictive performance of the Naples score and to compare it with machine learning models for predicting in-hospital mortality in patients undergoing coronary angiography. Methods: This retrospective study included 462 patients undergoing coronary angiography. The Naples score was calculated using admission laboratory parameters, and patients were categorized into three groups (0–1, 2, and 3–4). Predictive performance was assessed using receiver operating characteristic (ROC) analysis. Multivariable logistic regression and machine learning models, including random forest and gradient boosting, were developed. Model performance was evaluated using area under the curve (AUC) analysis. Results and Conclusions: Although in-hospital mortality increased across Naples score categories (p for trend = 0.004), the score demonstrated poor discriminative ability (AUC 0.48). Logistic regression showed modest performance (AUC 0.67), while machine learning models provided improved discrimination, with the best-performing model achieving an AUC of 0.78. Age was the only independent predictor in multivariable analysis (OR 1.06, p = 0.009). These findings suggest that machine learning approaches outperform traditional composite scores and may better capture complex risk patterns in patients undergoing coronary angiography.

MINOCA IN YOUNG PATIENTS: PATHOPHYSIOLOGICAL MECHANISMS AND RISK FACTORS — A RETROSPECTIVE COHORT STUDY

CATHERINE MENEZES COSTA1; MATHEUS ALVES SILVA1; GUILHERME AGUIAR FORTE1; BRUNA PONTES SILVA1; LUCAS MOURA STRELEC1; DANIEL ROSA CORREA LEAL2; JOAO MARCOS MENEZES COSTA3; BRUNO NOSCHANG BLAAS1; BIANCA FERNANDES TÁVORA ARRUDA1; RAPHAEL MACHADO ROSSI1; RICARDO PAVANELLO1; KELVYN MELO VITAL1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (2) HOSPITAL EVANGELICO DE VILA VELHA - VILA VELHA - ES - BRASIL; (3) UNIVERSIDADE ESTADUAL DE RORAIMA - BOA VISTA - RR - BRASIL;

Background/Introduction: Myocardial infarction with non-obstructive coronary arteries (MINOCA) accounts for 5–15% of acute myocardial infarctions and represents a heterogeneous group of ischemic conditions without flow-limiting stenosis. It frequently affects younger adults and involves diverse mechanisms, including spontaneous coronary artery dissection (SCAD), vasospasm, and microvascular dysfunction. Accurate diagnosis requires exclusion of non-ischemic causes and often relies on advanced imaging. Objectives: To compare clinical characteristics and likely etiologic mechanisms of MINOCA in adults younger than 50 years versus those aged 50 years or older. Methods: We retrospectively analyzed 198 consecutive patients diagnosed with MINOCA between 2018 and 2023 at a tertiary cardiology center. Diagnosis followed the Fourth Universal Definition of Myocardial Infarction and required biochemical evidence of myocardial infarction, less than 50% stenosis in all major epicardial coronary arteries, and exclusion of alternative non-ischemic causes through clinical evaluation and imaging. Clinical and demographic characteristics, cardiovascular risk factors, and underlying mechanisms were compared according to age group. Continuous variables were analyzed using Student's t-test, and categorical variables using chi-square or Fisher's exact test. Logistic regression was performed to estimate the odds ratio (OR) for non-atherosclerotic mechanisms in younger versus older patients, with adjustment for clinically relevant confounders. Results and Conclusions: Among 198 patients, 90 (45.5%) were younger than 50 years. Younger individuals had lower prevalence of hypertension and higher rates of obesity and stimulant or illicit drug use. An underlying etiologic mechanism was identified in 47.7% of cases. Non-atherosclerotic mechanisms predominated in younger patients, particularly SCAD and vasospasm, whereas atherosclerotic causes were more frequent in older individuals. Younger age was independently associated with lower odds of atherosclerotic etiology (OR 0.36; 95% CI 0.15–0.88). MINOCA in young adults is characterized by a distinct clinical profile with fewer traditional risk factors and predominance of non-atherosclerotic mechanisms. These findings reinforce the importance of systematic etiologic investigation, including advanced cardiac imaging, and support age-tailored diagnostic and therapeutic strategies.

Mechanism	< 50 y (n = 90)	≥ 50 y (n = 108)	Test Statistic	p value
Atherosclerotic plaque injury	12 (23.1%)	19 (45.2%)	χ^2 = 4.81	0.029
SCAD	15 (28.8%)	5 (10.6%)	χ^2 = 7.02	0.008

MYOCARDIAL VIABILITY ASSESSED BY LATE GADOLINIUM ENHANCEMENT ON CARDIAC MAGNETIC RESONANCE DOES NOT PREDICT LV FUNCTIONAL RECOVERY NOR CLINICAL OUTCOMES AFTER CABG IN ISCHEMIC CARDIOMYOPATHY: SINGLE-CENTER COHORT (2022–2025)

MILENA PICCOLO SANTANA1; LUIZ FERNANDO CAL SILVA1; JÂNIO FELIPE RIBEIRO RIBEIRO DE SOUZA1; ANDRÉ MELLO GERHARDT1; MARCELO HENRIQUE BARBOSA1; SORAIA RACHID YOUSSEF DE CAMPOS1; RICARDO PAVANELLO1; VIVIAN LERNER AMATO1; FAUSTO FERES1; VALÉRIA MOZETIC DE BARROS1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Background/Introduction: In patients with ischemic cardiomyopathy and severe LV dysfunction, viability testing has been losing its decision-making weight. The STICH substudy (Bonow, NEJM 2011; Panza, NEJM 2019) — based on SPECT/echo — did not demonstrate a significant interaction between viability and CABG benefit, and REVIVED-BCIS2 (Perera, NEJM 2022) reinforced this limitation in the percutaneous context. The 2024 ESC guideline on chronic coronary syndromes leaves its isolated decision-making role open. The incremental value of late gadolinium enhancement (LGE) on cardiac magnetic resonance imaging (CMRI) for predicting functional recovery and outcomes after CABG remains uncertain. Objectives: The aim of the study was to evaluate the prognostic value of late gadolinium enhancement on cardiac magnetic resonance imaging for left ventricular functional recovery and the occurrence of clinical outcomes after coronary artery bypass grafting. Methods: Single-center observational cohort of patients with CAD and LVEF <40% who underwent preoperative CMRI before CABG (2022–2025). Viability was pre-defined in the revascularized territories, based on the AHA 17-segment model: absent — transmural LGE >50% in ≥4 segments; present — LGE <50% in ≥4 segments. Outcomes: functional remodeling (ΔLVEF and ΔLVESD pre- vs. postoperative) and extended MACE at follow-up. Analysis: paired non-parametric tests, ANCOVA adjusted for baseline LVEF, and Kaplan–Meier with log-rank. Results and Conclusions: Fifty-seven patients were included; 8 extended MACE occurred over a median follow-up of 3 years. In the overall cohort, significant reverse remodeling was observed: ΔLVEF +4.1% (p<0.001) and ΔLVESD −9.3 mm (p<0.001). LGE-based viability did not discriminate functional recovery, even after adjustment for baseline LVEF (ANCOVA p=0.786). Extended MACE-free survival was similar between groups (log-rank p>0.05). In patients with ischemic cardiomyopathy and LVEF <40% undergoing CABG, significant LV functional improvement and reverse remodeling occurred regardless of LGE viability status, which also failed to discriminate clinical outcomes. Limitations include the single-center observational design and modest sample size. These real-world data reinforce — in alignment with STICH, REVIVED-BCIS2, and the 2024 ESC guideline — that CMRI-based viability should not be an isolated criterion for surgical indication, but rather integrated into multidisciplinary assessment (coronary anatomy, symptoms, comorbidities, and surgical risk).

PLEIOTROPIC EFFECTS OF DAPAGLIFLOZIN ON ANGINA PECTORIS: A RETROSPECTIVE ANALYSIS

JÚLIA FERNANDES AGUIAR1; BRUNO MAHLER MIOTO1; NILSON TAVARES POPPI1; GUSTAVO HENRIQUE MENDES FERREIRA1; LUIZ ANTONIO MACHADO CESAR1; LUCIANA OLIVEIRA CASCAES DOURADO1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Background/Introduction: Sodium-glucose cotransporter-2 inhibitors (SGLT2i) provide cardiovascular benefits beyond glycemic regulation, potentially through improved myocardial bioenergetics and reduced oxidative stress. While SGLT2i may enhance coronary flow reserve, clinical evidence regarding sustained angina reduction remains limited. Objectives: To evaluate the impact of dapagliflozin on Canadian Cardiovascular Society (CCS) angina class improvement and to determine its correlation with HbA1c reduction. Methods: This single-center retrospective study (2022–2025) enrolled diabetic patients (HbA1c ≥ 6.5%) with stable angina (> 6 months) at first prescription of dapagliflozin 10mg/day. Patients with concurrent antianginal titration or revascularization were excluded. The primary endpoint was a ≥ 1 CCS class improvement over 3 to 12 months. To isolate pleiotropic effects, patients were stratified into Glycemic Responders (GR; ΔHbA1c ≥ 0.5%) and Non-Glycemic Responders (NGR; ΔHbA1c < 0.5%). Results and Conclusions: Results: The study analyzed 157 patients (53,1% male; mean age 69.3 ± 6.7 years), characterized by a high prevalence of obstructive coronary artery disease (94.7%). At baseline, the NGR group had higher HbA1c (8.6% IQR [8,00 - 9,85] vs. 7.0% IQR [6,50 - 8,20]; p < 0.001), but lower multi-vessel disease prevalence (16.7% vs 45%; p = 0.018) compared to GR. Initial CCS distribution was balanced between groups (p = 0.47). At a median 6-month follow-up, significant CCS reduction occurred in both cohorts: 49.1% in the GR group (mean CCS 1.85 ± 0,7 to 1.18 ± 1,09; p < 0.001) and 42.2% in the NGR group (mean CCS 2.05 ± 0,75 to 1.33 ± 1,0; p < 0.001). Complete symptom resolution (CCS 0) was achieved in 38% of GR and 28% of NGR (p = 0.42). The use of standard antianginal and cardioprotective medications was high and balanced across both groups, ensuring comparable background therapy. Clinical response was independent of baseline ventricular function, though the LVEF < 35% subgroup analysis was limited by sample size. Notably, scatter plot analysis revealed a complete lack of linear correlation between the magnitude of HbA1c reduction and CCS improvement (Spearman's ρ = - 0.043; p = 0.59). Conclusion: Dapagliflozin was associated with significant improvement in angina pectoris regardless of glycemic response or ventricular function. These findings support the hypothesis of direct cardioprotective mechanisms on microcirculation and myocardial efficiency.

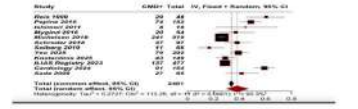
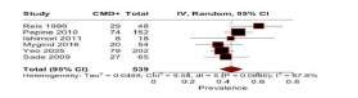
PREVALENCE OF CORONARY MICROVASCULAR DYSFUNCTION IN WOMEN WITH ANGINA AND NON-OBSTRUCTIVE CORONARY ARTERIES: A META-ANALYSIS WITH UNIFORM DIAGNOSTIC CRITERIA



SUELEN QUEIROZ1; JÚLIA GONÇALVES GADELHA2; NOOR HUSAIN3; CRISTINA SICORSCHI GUTU4; RAMON AUGUSTO TEIXEIRA1;

(1) UNIVERSIDADE ESTADUAL DE PONTA GROSSA - PONTA GROSSA - PR - BRASIL; (2) AFYA - FACULDADE DE CIENCIAS MEDICAS DA PARAIBA - CABEDELO - PB - BRASIL; (3) INDIRA GANDHI INSTITUTE OF MEDICAL SCIENCES, PATNA, ÍNDIA. - INDIA; (4) PARACELSUS MEDICAL UNIVERSITY; - AUSTRIA;



Background/Introduction: Angina with non-obstructive coronary arteries (ANOCA) disproportionately affects women, and coronary microvascular dysfunction (CMD) is recognized as a central pathophysiological mechanism. However, accurate estimates of its prevalence are limited by methodological heterogeneity among studies. Objectives: To estimate the prevalence of CMD in women with ANOCA using a uniform diagnostic criterion (coronary flow reserve – CFR ≤ 2.5) assessed by invasive thermodilution. Methods: Systematic review of the PubMed, Embase, and Scopus databases (2000–2026). Three observational studies were included that evaluated women with confirmed ANOCA by coronary angiography, who underwent invasive microvascular function testing, with CMD defined as CFR ≤ 2.5. Data extraction was performed independently, and methodological quality was assessed using the Newcastle-Ottawa Scale. A fixed-effects model was used for meta-analysis (PROSPERO protocol CRD420261320465). Results and Conclusions: Three studies were included (Michelsen 2018, n=919; ILIAS Registry 2023, n=477; Kostantinis 2025, n=149), totaling 1,545 women (mean age: 57–64 years). Individual CMD prevalence ranged from 26.2% to 28.9%. The pooled prevalence was 27.2% (95% CI: 24.8%–29.7%), with no heterogeneity (I^2 = 0%; p = 0.42). Sensitivity analyses confirmed the robustness of the findings. All studies had good methodological quality (Newcastle-Ottawa ≥ 8).

RECLASSIFICATION OF SCAI SHOCK STAGING AND MORTALITY RISK IN ST-SEGMENT ELEVATION MYOCARDIAL INFARCTION PATIENTS USING LVOT-VTI AND POINT-OF-CARE LUNG ULTRASOUND

GUILHERME PINHEIRO MACHADO1; GUSTAVO NEVES DE ARAÚJO1; FELIPE LUIS SCOLARI1; GUILHERME HEIDEN TELO1; JÚLIA REI PIRES2; JÚLIA BRIGONI MACIEL2; DILLERMANDO DE OLIVEIRA SCHÄFFER2; JOÃO GABRIEL OGNIBENI PORTO2; ANTONIO CRODA CHIES2; ANDERSON DONELLI DA SILVEIRA1; RODRIGO VUGMAN WAINSTEIN1; MARCO VUGMAN WAINSTEIN1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL; (2) UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: The Society for Cardiovascular Angiography and Interventions (SCAI) shock classification categorizes patients with cardiogenic shock (CS) to standardize severity and guide management. The LUV classification combines lung ultrasound (LUS) and the left ventricular outflow tract velocity-time integral (LVOT-VTI), enhancing prognostic capability in patients with ST-segment elevation myocardial infarction (STEMI) compared to clinical assessment alone. Objectives: We aimed to evaluate whether LUV can improve the early classification of SCAI stages to guide CS management. Methods: A cohort of STEMI patients treated with primary percutaneous coronary intervention (pPCI) at a single-center general hospital was evaluated. LUS, LVOT-VTI, and SCAI stages were obtained upon hospital admission. The primary endpoint was in-hospital mortality. Results and Conclusions: A total of 549 patients were included, with a mean age of 61.9 years, and 64.1% were male. In-hospital mortality was observed in 57 (10.4%) patients and increased with worsening SCAI stage (A: 2.7%; B: 10.7%; C: 37.8%; D: 66.7%; E: 80%) and SCAI-LUV stage (A: 1.0%; B: 3.6%; C: 37.8%; D: 66.7%; E: 80%). A total of 100 patients (18.2%) were reclassified into different risk categories with the addition of LUV to SCAI. Considering only the 452 patients in SCAI stages A and B, the areas under the ROC curve for SCAI staging and SCAI-LUV were 0.645 and 0.828, respectively, with a net reclassification index (NRI) of 0.122. In patients with STEMI, pulmonary congestion identified by LUS and indirect cardiac output estimation by LVOT-VTI are associated with in-hospital mortality and correlate with the severity and progression of the SCAI shock stage. Furthermore, the LUV classification presented an NRI of 0.122 in patients in SCAI stages A and B. Therefore, integrating non-invasive point-of-care ultrasound into the initial assessment of cardiogenic shock may facilitate the early identification of high-risk patients and allow for more individualized initial therapeutic strategies.

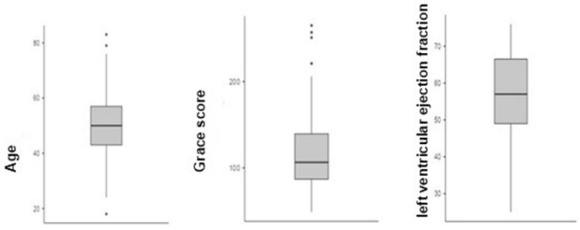
ST-SEGMENT ELEVATION MYOCARDIAL INFARCTION WITH NON-OBSTRUCTIVE CORONARY ARTERIES AFTER EARLY ANGIOGRAPHY: CHARACTERIZATION OF A MINOCA PHENOTYPE WITHIN A PHARMACOINVASIVE STRATEGY

PAULA SANTIAGO TEIXEIRA1; KAIO VINICIUS CAMPOS MARQUES1; GUILHERME BOALENTO FIGUEIREDO1; LIVIA TOSHIKO GONDO1; PEDRO IVO DE MARQUI MORAES1; SIDNEY RAMOS BORGES FILHO1; MARCO TULIO DE SOUZA1; VLADIMIR AILTON CUMA NANCASSA1; MARIA TERESA NOGUEIRA BOMBIG1; HENRIQUE TRIA BIANCO1; ADRIANO HENRIQUE PEREIRA BARBOSA1;

(1) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL;



Background/Introduction: ST-segment elevation myocardial infarction (STEMI) treated with a pharmacoinvasive strategy combines immediate fibrinolysis followed by early coronary angiography. A relevant proportion of patients undergoing this approach present without significant obstructive coronary artery disease, representing myocardial infarction with non-obstructive coronary arteries (MINOCA), a heterogeneous condition associated with diagnostic uncertainty and therapeutic challenges. Objectives: To characterize the clinical, epidemiological, laboratory, and angiographic profile of patients with STEMI undergoing a pharmacoinvasive strategy who presented without obstructive coronary lesions, exploring phenotypes compatible with MINOCA and potential diagnostic mimickers. Methods: This single-center descriptive study included consecutive patients with STEMI treated with a pharmacoinvasive strategy. Demographic, clinical, laboratory, and angiographic variables were collected, including ischemic presentation, functional class, risk scores, renal function, and markers of myocardial injury. Continuous variables were expressed as mean±SD or median [IQR], and categorical variables as frequencies (%). Results and Conclusions: Among 2,418 patients undergoing a pharmacoinvasive strategy, 67 (3%) presented without obstructive coronary lesions (≥50%) at angiography. Patients were predominantly male (80%), with hypertension in 60%, diabetes in 9%, and active smoking in 55%. Clinical presentation was mainly typical chest pain and was comparable to patients with obstructive coronary artery disease. In-hospital mortality occurred in one patient (1.5%) in the non-obstructive group compared with 161 patients (7%) among patients with obstructive disease. Patients with a MINOCA phenotype demonstrated marked clinical and laboratory heterogeneity. Conclusion: A clinically relevant proportion of patients undergoing a pharmacoinvasive strategy for STEMI presented with non-obstructive coronary arteries, consistent with a MINOCA phenotype. Despite similar clinical presentation, these patients showed lower in-hospital mortality compared with obstructive STEMI. Recognition of this phenotype highlights the need for systematic etiological investigation to differentiate ischemic mechanisms from mimickers and to guide tailored therapeutic management.

Table. Clinical, functional, and biomarker characteristics of the "MINOCA" group

Age (m ± sd)	51,27 ± 13,22
BMI (m ± sd)	26,18 ± 4,55
MDRD (m ± sd)	91,96 ± 34,54
Killip-Kimball I-IV (%)	85; 7,5; 1,5;6
GRACE (m ± sd)	119± 48,46
LVEF (m ± sd)	55,66 ± 13,01
Tropo adm md (IIQ)	265 (15,9-2219)

Legend: BMI: body mass index; MDRD (Modification of Diet in Renal Disease): creatinine clearance; Killip-Kimball classification on admission; GRACE (Global Registry of Acute Coronary Events): mortality score on admission; LVEF: left ventricular ejection fraction; Tropo adm: troponin on admission. Data are expressed as mean ± SD; median and interquartile range.

TELECARDIOLOGY AND MORTALITY IN CRITICAL CARDIOVASCULAR PATIENTS IN URGENT CARE UNITS

ADRIELLY SILVA SANTOS1; DANIELLA CRISTINA BUENO IOZZI1; TAMIRES SALLES OLIVEIRA1; CAMILLA ROSARIO NICOLINO CHIORINO1; THAIS SANTOS SILVA1;

(1) BENEFICENCIA PORTUGUESA - SAO PAULO - SP - BRASIL;

Background/Introduction: Cardiovascular diseases are the leading cause of death worldwide. ST-segment elevation myocardial infarction (STEMI) and severe arrhythmias are acute conditions in which early diagnosis and immediate treatment are essential for favorable clinical outcomes. A project aimed at optimizing the quality of emergency care implemented 24-hour teleconsultation with remote electrocardiogram (ECG) interpretation, providing real-time specialist support for urgent care units. Objectives: To evaluate the association between specialist teleconsultation and mortality among critical patients with STEMI and severe arrhythmias during the implementation of a cardiovascular care protocol. Methods: Longitudinal observational study with a comparative time-period design conducted in 24 urgent care units during the second implementation cycle of the care protocol. Two consecutive four-month periods were analyzed (June–September 2025 and October 2025–January 2026). Critical cases were defined according to operational criteria, with outcomes including discharge, hospitalization, transfer, or death. Follow-up was performed through contact with the units 48 hours after ECG acquisition. The indicators evaluated were mortality rate and teleconsultation rate. Exploratory analysis included calculation of odds ratio (OR) for mortality associated with teleconsultation. Results and Conclusions: A total of 1,406 critical cases were recorded. Overall mortality decreased from 5.06% in the first period to 4.42% in the second, representing a relative reduction of 12.6%, without statistical significance (p = 0.58). Teleconsultation rates increased from 77.9% to 79.0%. Exploratory analysis demonstrated an OR for mortality of 0.55 (95% CI: 0.22–1.38) among patients discussed with a specialist, suggesting a lower likelihood of death, although without statistical significance. The proportion of teleconsulted cases among patients who died decreased from 97% to 86% between periods. Implementation of a telecardiology-supported care protocol was associated with an observed trend toward reduced mortality and sustained high teleconsultation adherence. Although statistical significance was not achieved, findings suggest potential clinical benefit of synchronous specialist support in critical cardiovascular scenarios. Continued follow-up and expanded sample size may allow more robust evaluation of the impact on mortality.

TEMPORAL TRENDS AND REGIONAL DISPARITIES IN CORONARY ANGIOPLASTY PROCEDURES PERFORMED IN THE BRAZILIAN PUBLIC HEALTH SYSTEM BETWEEN 2020 AND 2025: A NATIONWIDE SIH/SUS ANALYSIS

LUCAS DALSENTER ROMANO DA SILVA1; KALEC THIAGO SIMONEK DE MORAES1; GABRIEL CHEHAB DE CARVALHO MELO1; MICHELLE DA CRUZ PONTES DA SILVA1; LUISA DE CAMPOS GUIMARÃES E FIGUEIREDO1; PAULO ANDRÉ DA SILVA1; CAROLINA CUNTO DE ATHAYDE1; HELENA DE CASTRO CANHEO1;

(1) HOSPITAL NAVAL MARCILIO DIAS - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Percutaneous coronary intervention (PCI) remains a cornerstone therapy for acute coronary syndromes and selected patients with chronic coronary artery disease, improving symptoms and clinical outcomes. Contemporary guidelines emphasize timely access to revascularization, particularly for ST-elevation myocardial infarction and high-risk ischemic presentations. However, in middle-income countries, unequal distribution of specialized cardiovascular services may limit access to PCI. In Brazil, updated nationwide analyses evaluating post-pandemic procedural trends within the Unified Health System (SUS) are scarce. Recent evidence also highlights persistent global disparities in cardiovascular care delivery. Objectives: To evaluate temporal trends and regional distribution of coronary angioplasty procedures performed in the Brazilian Public Health System from 2020 to 2025. Methods: Ecological retrospective study using publicly available data from the Brazilian Hospital Information System (SIH/SUS), accessed through DATASUS. Approved hospital admissions (AIH) related to the following procedures were included: coronary angioplasty, angioplasty with one stent, two stents, primary angioplasty, and angioplasty in coronary grafts. The study period comprised January 2020 to December 2025. Annual procedural volume and regional distribution were analyzed descriptively. Results and Conclusions: A total of 645,888 PCI-related hospital authorizations were identified during the study period. Annual volume increased progressively from 89,099 procedures in 2020 to 133,935 in 2025, representing a 50.3%. Marked regional concentration was identified: Southeast (46.8%), South (27.1%), Northeast (15.3%), Midwest (7.8%), and North (3.0%). Between 2020 and 2025, coronary angioplasty volume in the Brazilian public health system increased substantially, suggesting recovery after the COVID-19 disruption and expansion of interventional cardiology capacity. Nevertheless, pronounced regional disparities persisted, with nearly three-quarters of procedures concentrated in the Southeast and South regions. These findings support the need for public policies aimed at decentralizing high-complexity cardiovascular care, improving referral networks, and expanding equitable access to PCI across Brazil.

Table 1. Annual Coronary Angioplasty Volume in Brazil (SUS), 2020–2025

Year	Number of Procedures	Annual Change
2020	89,099	—
2021	92,197	+3.5%
2022	100,126	+8.6%
2023	107,211	+7.1%
2024	123,320	+15.0%
2025	133,935	+8.6%
Total	**645,888**	—

Table 2. Regional Distribution of Coronary Angioplasty Procedures

Region	Procedures	Share of Total
Southeast	302,093	46.8%
South	174,968	27.1%
Northeast	99,037	15.3%
Midwest	50,348	7.8%
North	19,442	3.0%

(1) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL;

Background/Introduction: Spontaneous coronary artery dissection (SCAD) is an underrecognized, non-atherosclerotic cause of acute myocardial infarction, predominantly affecting women and often occurring in the absence of traditional cardiovascular risk factors. Its heterogeneous presentation and uncertain triggers pose diagnostic and therapeutic challenges, highlighting the need for real-world data. Objectives: Prospective cohort study including consecutive patients diagnosed with SCAD between 2018 and 2026 in a university hospital. Clinical, angiographic, and therapeutic characteristics, as well as in-hospital and long-term outcomes, were analyzed. Methods: A total of 47 patients were included, with a marked female predominance (93.9%) and mean age of 47.5 ± 11.5 years. Most patients had few or no traditional cardiovascular risk factors.Triggers were absent in 81% of cases, with emotional stress identified in 12.1% and no cases related to physical stress. Type 2 SCAD was the most frequent angiographic pattern.Notably, 45.4% of patients received thrombolysis prior to diagnosis. During hospitalization, 27.3% required intensive care, with cardiogenic shock in one case and one in-hospital cardiovascular death.At follow-up, recurrence was low (3 cases), and no patients required revascularization or developed heart failure. Results and Conclusions: SCAD predominantly affected women without typical risk factors and was frequently not associated with identifiable triggers. Outcomes were favorable with a conservative approach. These findings support increased clinical awareness, avoidance of unnecessary interventions, and individualized management. Importantly, these findings call for a paradigm shift in the evaluation of myocardial infarction in women.

ACUTE KIDNEY INJURY AS AN INDEPENDENT PREDICTOR OF HOSPITAL MORTALITY IN A CARDIAC INTENSIVE CARE UNIT

RENATO DE FARIAS VIGOLO1; RAPHAEL FERNANDES CARDOSO VIANNA ALVES1; CINTIA PERINETTI ALVES MARTINS1; PAULO GONÇALVES MARTIN1; VITOR AZEM ARANTES CALIL1; EDUARDO ESTEVES BRAMBATTI1; CAROLINA BERTINI BONINI1; ADIEL CARVALHO JUNIOR1; LIVIA MARIANA LIMA GAVA1; MAURICIO DE NASSAU MACHADO1;

(1) HOSPITAL DE BASE DE SÃO JOSÉ DO RIO PRETO - SÃO JOSÉ DO RIO PRETO - SP - BRASIL;

Background/Introduction: Acute kidney injury (AKI) is a frequent complication in critically ill cardiac patients, associated with increased morbidity and mortality. However, its independent impact on mortality in cardiac intensive care units (CICU) in Brazil remains poorly characterized, particularly after adjustment for severity scores such as SAPS3 and SOFA. Objectives: To evaluate the incidence of AKI and its independent impact on hospital mortality in patients admitted to a public tertiary hospital CICU. Methods: Retrospective cohort including consecutive admissions to a 23-bed CICU between October 2024 and April 2026. AKI was defined according to KDIGO criteria during ICU stay. The primary outcome was hospital mortality. Secondary outcomes included ICU mortality, need for advanced organ support, and length of stay. Multivariable logistic regression was adjusted for age, sex, SAPS3, SOFA, and admission type. Data from the Epimed Monitor system. Results and Conclusions: A total of 1,706 patients were included (median age 65 years, 62.1% male). AKI incidence was 12.0% (n=204). Patients with AKI were older (median 68 vs 65 years; p=0.002), with higher SOFA (6 vs 1; p<0.001) and SAPS3 scores (63 vs 41; p<0.001). Hospital mortality was 39.2% in AKI patients vs 8.9% without AKI (p<0.001). ICU mortality followed a similar pattern (29.4% vs 6.2%; p<0.001). AKI patients required more vasopressors (58.3% vs 16.0%), mechanical ventilation (49.0% vs 18.2%), and renal replacement therapy (12.3% vs 1.7%), all p<0.001. On logistic regression, AKI was an independent predictor of hospital mortality (OR 1.73; 95%CI 1.12–2.65; p=0.013), along with SOFA (OR 1.24; p<0.001), SAPS3 (OR 1.03; p=0.002), and medical admission (OR 2.47; p<0.001). The model achieved an AUC of 0.861. AKI during CICU stay is an independent predictor of hospital mortality, even after adjustment for severity scores. Its high incidence and association with advanced organ support requirements underscore the importance of early renal monitoring and nephroprotective strategies in this population.

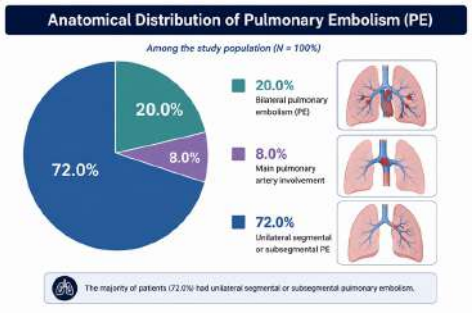
ANATOMICAL DISTRIBUTION AND OUTCOMES IN ACUTE PULMONARY EMBOLISM: DOES LOCATION REALLY MATTER?

LUCÍA DE LA COSTA1; JESICA ARANDA1; PAULINA BRAIDOTTI1; JUAN IGNACIO MIEREZ1; FLORENCIA DRIUSSI1; LUCAS ILARREGUI1; PILAR CASTRO1; SEBASTIÁN GARCIA-ZAMORA1;



(1) SANATORIO DELTA, ROSARIO - ARGENTINA;

Background/Introduction: Acute pulmonary embolism (PE) is the third leading cause of cardiovascular mortality. Its prognosis ranges from mild cases to cardiogenic shock with high mortality. Early risk stratification is based on clinical evaluation, hemodynamic status, biomarkers, and right ventricular (RV) dysfunction. However, the anatomical extent of PE may influence RV overload and outcomes, particularly in elderly patients. Objectives: To evaluate the association between the anatomical extent of acute pulmonary embolism and mortality in elderly patients. Methods: A retrospective, single-center registry was conducted between May 2024 and February 2026, including patients hospitalized with a diagnosis of PE in a high-complexity private institution. Variables included age, sex, risk factors, clinical presentation, anatomical extent, complications, treatment, and mortality. Results and Conclusions: A total of 105 patients were included, with a median age of 72 years (IQR 66–77); 61.0% were female. Baseline characteristics of the study participants are summarized in Table 1. At admission, 79.8% presented dyspnea, 21.2% chest pain, 16.3% palpitations, 2.3% hemoptysis, and 2.9% syncope. Lower limb pain was reported in 35.2%, and altered mental status in 7.7%. Deep vein thrombosis was diagnosed in 41.8%. According to the PESI score, 8.7% were class I, 16.3% class II, 28.3% class III, 15.2% class IV, and 31.5% class V. On echocardiography, 6.0% had isolated right atrial dilation, 12.1% right ventricular dilation, and 14.5% both; mild RV dysfunction was observed in 10.5% and severe in 4.5%. Regarding anatomical distribution, 20.0% had bilateral PE, 8.0% main pulmonary artery involvement, and 72.0% unilateral segmental or subsegmental PE (Figure 1). During hospitalization, 6.7% developed hemodynamic instability, 5.0% required inotropes, and 4.9% mechanical ventilation. Overall mortality was 9.2%, with no significant differences between bilateral and unilateral PE (4.4% vs 11.3%; p=0.445) or in hemodynamic instability (7.1% vs 5.6%; p=0.540). Patients with bilateral localization showed a trend toward higher right ventricular dysfunction (23.1% vs 13.5%; p=0.317). Mortality was higher in patients >70 years (11.9% vs 5.1%; p=0.224). Patients with hemodynamic instability had higher mortality (50.0% vs 6.5%; p=0.010). These findings suggest that bilateral anatomical involvement is not associated with worse prognosis or increased hemodynamic instability compared with unilateral PE in elderly patients.

Table 1. Baseline Characteristics of the Registry Participants

Characteristics	Total (n=105)
Female sex	61.0%
Male sex	39.0%
Median age	72 (66–77)
Temporary immobilization	38.5%
Major trauma	12.0%
Recent surgery	26.0%
Autoimmune disease	2.0%
Active malignancy	29.0%
Malignancy in remission	3.0%
Previous PE	8.7%
Previous DVT	16.5%
Previous DVT and PE	3.9%

PE = pulmonary embolism; DVT = deep vein thrombosis.

DIAGNOSTIC ACCURACY OF POINT-OF-CARE ULTRASOUND IN IDENTIFYING ABDOMINAL AORTIC ANEURYSM IN EMERGENCY SETTINGS: A SYSTEMATIC REVIEW

MARYA EDUARDA SOUZA ANICETO1; ANTÔNIO JACKSON DA SILVA AGRA1; IZADORA TAVARES FARIAS1; MANUELA CARLIN PELEGRIN1; ENZO MARÇAL ABRÃO DE ANDRADE1; ISABELLE BEZERRA ASSUMÇÃO1; ANA PATRÍCIA DA SILVA ARRUDA CAVALCANTE1;

(1) AFYA FACULDADE DE CIENCIAS MEDICAS DE PALMAS - PALMAS - TO - BRASIL;

Background/Introduction: Abdominal aortic aneurysm (AAA), defined as a dilation ≥ 3 cm, presents a mortality rate of up to 90% following rupture. In the emergency department, diagnosis is challenging, as approximately 50% of patients do not manifest the classic triad (hypotension, back pain, and pulsatile mass), leading to misdiagnoses such as renal colic or diverticulitis. Point-of-care ultrasound (POCUS) has established itself as an essential bedside tool due to its rapid and non-invasive nature. Studies indicate that, when performed by emergency physicians, the technique has a sensitivity of 99% and a specificity of 98%, streamlining surgical consultation and definitive management, especially in unstable patients. Objectives: To evaluate the diagnostic accuracy of POCUS in identifying AAA in emergencies, analyzing sensitivity, specificity, predictive values, and clinical applicability. Methods: A systematic review conducted according to the PRISMA protocol. The search was performed across PubMed, EMBASE, and Cochrane Library databases, using descriptors such as “point-of-care ultrasound”, “POCUS”, “abdominal aortic aneurysm”, “emergency ultrasound”, and “diagnostic accuracy”. Out of 1,787 initial studies, 9 articles (observational studies, prospective studies, and meta-analyses) were selected for the final review after applying eligibility criteria. The primary outcome was the diagnostic accuracy of the method. Results and Conclusions: Among the 9 studies included, POCUS demonstrated high diagnostic accuracy for AAA identification in emergency settings. In the studies by Rubano et al., sensitivity ranged from 97.5% to 100% and specificity from 94.1% to 100%. Rowland et al. and Costantino et al. reported 100% sensitivity and specificity, while Jones et al. demonstrated 97.5% sensitivity and 100% specificity. A near-zero negative likelihood ratio reinforced the method’s ability to exclude AAA in symptomatic patients. The studies also demonstrated reduced diagnostic time and faster clinical decision-making in unstable patients. Despite limitations related to operator dependence and technical difficulties, POCUS demonstrated high applicability as a rapid, non-invasive diagnostic tool in emergency settings.

IMPACT OF FRAILTY ON IN-HOSPITAL MORTALITY IN A CARDIAC INTENSIVE CARE UNIT: A RETROSPECTIVE COHORT

PAULO GONÇALVES MARTIN1; RENATO DE FARIAS VIGOLO2; ADIEL CARVALHO JÚNIOR2; RAPHAEL RAPHAEL FERNANDES CARDOSO VIANNA ALVES2; CYNTHIA SPERANDIO2; CINTIA PERINETTI ALVES MARTIN2; LUIZ CARLOS VOLPI JUNIOR2; MAURICIO DE NASSAU MACHADO2;

(1) HOSPITAL DE BASE DE SAO JOSE DO RIO PRETO - SÃO JOSE DO RIO PRETO - SP - BRASIL; (2) HOSPITAL DE BASE DE SAO JOSE DO RIO PRETO - SAO JOSE DO RIO PRETO - SP - BRASIL;

Background/Introduction: Frailty is a multidimensional syndrome associated with adverse outcomes in critically ill patients. Even though it is widely studied in geriatric and surgical scenarios, its impact on the cardiac intensive care unit (CICU) remains poorly studied in Brazil. The “Modified Frailty Index” (MFI) is a validated and easy-to-use tool for the point-of-care assessment of frailty. Objectives: To analyze the association between frailty measured by MFI and hospital mortality in patients admitted to the CICU of a public tertiary hospital. Methods: A retrospective cohort study was conducted, including all consecutive admissions to a 23-bed CICU of a tertiary hospital from October 2024 to April 2026. Patients were classified by the MFI tool as “non-frail” (MFI=0), “pre-frail” (MFI=1-2) and “frail” (MFI ≥ 3). Primary outcome was defined as hospital mortality. Secondary outcomes included mortality in the intensive care unit, need for organ support and length of stay. Data was prospectively collected from the “Epimed Monitor” system. Results and Conclusions: A total of 1,706 patients were included (median age of 65 years, 62.1% men, 62.5% clinical admissions). Patients were distributed as follows: 278 (16.3%) non-frail, 897 (52.6%) pre-frail and 526 (30.8%) frail. Frail patients were older (median 68 vs 60 years; p<0.001) and had higher SOFA (median 2 vs 0; p<0.001) and SAPS 3 (48 vs 36; p<0.001) scores. Hospital mortality increased progressively across frailty groups: 7.9%, 9.9%, and 19.4% (p<0.001, test for trend). Mortality in the intensive care unit followed a similar pattern: 5.0%, 7.1% and 14.3% (p<0.001). Frail patients needed more vasopressors (31.6% vs 8.3%; p<0.001), mechanical ventilation (19.2% vs 8.6%; p<0.001) and developed more acute kidney injury (21.3% vs 3.6%; p<0.001). Length of stay was longer in frail patients (median 12 vs 7 days; p<0.001). In clinical patients, mortality reached 24.3% vs 8.4% in non-frail (p<0.001). Frailty measured by MFI was associated, in a progressive and significant manner, with hospital mortality, as well as mortality in the intensive care unit and with the need for advanced organ support in the CICU. The systematic incorporation of MFI in the admission assessment may be useful in risk stratification and clinical decision-making in this population.

LATE PALLIATIVE CARE INTEGRATION AND INTENSIVE CARE UTILIZATION IN ADVANCED CARDIOVASCULAR DISEASE

GABRIEL CIMADA DA SILVA1; ALEXANDRE BERALDI SANTOS2; ROBISOM DAMASCENO CALADO2; DIANE XAVIER DE ÁVILA2; ISABELLE MENDES RODRIGUES SALOMÃO2; CAMILA MOREIRA DOS SANTOS DE OLIVEIRA2; LILIAN KAZUKO SHIO2; ANA LÍDIA SILVA MARINS DE NAZARENO CIMADA2; ANDRE LUIS SILVA MORAIS2; ANA CAROLINA SANCHES ZEFERINO2; HERMES FRITZ PETERMANN SILVA2; ERITO MARQUES DE SOUZA FILHO2;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - SP - BRASIL; (2) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL;

Background/Introduction: Patients with advanced cardiovascular disease are frequently exposed to low-value interventions at the end of life, often associated with late integration of palliative care. Delayed identification of palliative care eligibility may limit the clinical impact of this approach on critical care resource use, particularly intensive care units. Objectives: To evaluate the association between implementation of a Palliative Care Committee, recognition of palliative care eligibility, time to referral, and intensive care unit (ICU) utilization in patients with advanced cardiovascular disease. Methods: Retrospective observational study conducted in a public emergency hospital in Rio de Janeiro state, Brazil. Patients aged ≥18 years, with in-hospital death and hospital stay >24 hours, eligible for palliative care according to Murtagh criteria and age-adjusted Charlson Comorbidity Index ≥3 were included. The period from November 2022 to October 2024 was divided into pre-implementation (n=210) and post-implementation (n=264) phases of the Palliative Care Committee. Analyses of time to referral and ICU utilization were restricted to the post-implementation period to reduce selection bias. Pearson's chi-square or Fisher's exact test were used for categorical variables, and multivariable logistic regression was adjusted for age, sex, and comorbidities. Results and Conclusions: After implementation, there was a significant increase in recognition of cardiovascular patients eligible for palliative care (≈18% to 55%; p<0.001), corresponding to an absolute increase of 37 percentage points. Despite this, time to referral remained longer compared with non-cardiovascular patients (up to 2.4-fold longer; p<0.001), suggesting later recognition in the cardiovascular population. Among cardiovascular patients, palliative care referral was not associated with reduced ICU utilization after multivariable adjustment (aOR=0.81; 95%CI 0.40–1.63; p=0.564). In contrast, among non-cardiovascular patients, palliative care referral was associated with reduced ICU utilization (aOR=0.36; 95%CI 0.18–0.68; p=0.002), corresponding to an approximately 64% reduction in intensive care use. These findings suggest that, despite improved recognition of cardiovascular patients eligible for palliative care, late integration may limit its influence on ICU utilization. The results reinforce the need for early identification strategies to reduce low-value interventions at the end of life

POST-CPB MYOCARDIAL INJURY AS A DETERMINANT OF RESPIRATORY FAILURE AFTER CORONARY ARTERY BYPASS GRAFTING: AN ANALYSIS OF 1,467 PATIENTS

RENATO DE FARIAS VIGOLO1; RAPHAEL FERNANDES CARDOSO VIANNA ALVES1; LUDMILA SOUZA DA CUNHA1; LAURA DE OLIVEIRA MACHADO1; JULIA DE OLIVEIRA MACHADO1; MAURICIO DE NASSAU MACHADO1; CYNTHIA SPERANDIO1; CINTIA PERINETTI ALVES MARTINS1; VITOR AZEM ARANTES CALIL1; EDUARDO ESTEVES BRAMBATTI1; PAULO GONÇALVES MARTINS1; CAROLINA BERTINI BONINI1;

(1) HOSPITAL DE BASE DE SÃO JOSÉ DO RIO PRETO - SÃO JOSÉ DO RIO PRETO - SP - BRASIL;

Background/Introduction: Postoperative respiratory failure in cardiac surgery is multifactorial, frequently attributed to pre-existing pulmonary conditions or cardiopulmonary bypass (CPB) duration. However, cardiopulmonary interaction suggests that myocardial injury, detected by high-sensitivity cardiac troponin T (hs-cTnT), plays a central role in pulmonary congestion and weaning failure. Objectives: To analyze the impact of post-CPB myocardial injury magnitude on a composite respiratory outcome (prolonged mechanical ventilation > 24 hours or reintubation within 7 postoperative days) in patients undergoing coronary artery bypass grafting (CABG). Methods: Retrospective cohort (n = 1,467). The composite outcome "Respiratory Failure" was defined as tracheal reintubation within 7 postoperative days or mechanical ventilation > 24 hours. Patients were compared regarding demographic, laboratory, and surgical profiles. Multivariable logistic regression was adjusted for age, COPD, ejection fraction, CPB time, and surgical priority, using the < 20× URL group as reference. Results and Conclusions: The incidence of respiratory failure was 9.7% (n = 142). Patients with failure were older (67 vs. 62 years; P < 0.001) and had higher COPD prevalence (8.5% vs. 2.9%; P < 0.001). Peak hs-cTnT was significantly higher in the failure group (537 vs. 259 ng/L; P < 0.001). Notably, 19.7% of patients with respiratory failure reached extreme injury (≥ 100× URL), compared to 3.6% in the success group. There was a strong association with multiorgan failure: 76.3% developed acute kidney injury and 15.5% required dialysis (P < 0.001). 30-day mortality was 33.8% vs. 1.0% (P < 0.001). Multivariable analysis revealed a dose-response effect: 20 to < 40× URL (OR 2.55; 95% CI 1.54–4.21); 40 to < 100× URL (OR 5.45; 95% CI 3.19–9.32); and ≥ 100× URL (OR 12.99; 95% CI 6.77–24.90), all P < 0.001. Respiratory failure after CABG with CPB directly correlates with the magnitude of myocardial injury. Risk triples above 20× URL and becomes critical above 100× URL, surpassing the clinical impact of COPD. The high associated lethality reinforces that respiratory insufficiency frequently represents an underlying cardiovascular failure.

SINGLE-DOSE HIGH-SENSITIVITY CARDIAC TROPONIN FOR PROGNOSTIC EVALUATION IN SYNCOPE

JULIA GIACOMONI BRAGAGNOLO1; RAQUEL BUSANELLO SIPMANN1; JORGE LUIS BERNAL DIAZ1; JOÃO PEDRO BARBOSA1; MATEUS SILVA DE CARVALHO1; VANDER JOSÉ DALL AQUA DA ROSA1; EVALDO JORGE MARTINS CASSOMA1; CÍCERO DE CAMPOS BALDIN1; DYEGO ANTONIO PEQUENO CAMPIONI2; ALEXANDRE DO CANTO ZAGO1;

(1) HOSPITAL MÃE DE DEUS - PORTO ALEGRE - RS - BRASIL; (2) HOSPITAL MAE DE DEUS - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: Measurement of cardiac troponin (Tn) has been used in patients presenting to the emergency department (ED) with syncope. However, the specific interpretation of results and the necessity for serial Tn measurements in this context have not yet been established. Objectives: Evaluate the prognostic value of a single high-sensitivity Tn measurement in patients presenting to the ED with syncope, and to determine whether additional measurements improve prognostic accuracy Methods: A historical cohort study was conducted using medical records from 220 patients aged 18 years or older who presented to an ED with syncope between 2021 and 2023. Four strategies were assessed and compared for their prognostic value: (1) a single Tn measurement, (2) the ESC 0/1-Hour Algorithm (as applied in chest pain assessment), (3) a 'classical' syncope risk score (Osservatorio Epidemiologico della Sincope nel Lazio – OESIL), and (4) a 'modern' risk score (Canadian Syncope Risk Score – CSRS). Telephone contact was made to obtain consent for medical record review and to evaluate out-of-hospital outcomes. The primary outcome was a composite event of all-cause mortality and/or major cardiovascular events (stroke, life-threatening arrhythmia, pacemaker or cardioverter-defibrillator implantation, acute myocardial infarction, pulmonary embolism, intracranial haemorrhage, or percutaneous/surgical valve intervention) within 30 days. The secondary outcome was all-cause mortality within 30 days. Results and Conclusions: Optimal Tn cut-off points determined by ROC curve analysis for the composite outcome and 30-day mortality were 12 ng/L and 41 ng/L, respectively. The numerically highest AUC for the composite endpoint was observed for CSRS (0.85), and for mortality, for troponin (0.94). Multivariate analysis showed that high-sensitivity Tn levels above 12 ng/L were independently associated with the composite outcome (relative risk [RR] 2.63; 95% CI: 1.11–6.26). The ESC 0/1-Hour Algorithm was associated with an RR of 3.45 (95% CI: 1.09–11.0), and CSRS with an RR of 6.18 (95% CI: 2.58–14.8), whereas OESIL was not an independent predictor. Tn levels above 41 ng/L were independently associated with death (RR 38.7; 95% CI: 6.85–218), CSRS with RR 4.48 (95% CI: 1.45–13.8), and OESIL with RR 11.3 (95% CI: 2.87–44.1). The ESC 0/1-Hour Algorithm classified as very low or low demonstrated a negative predictive value of 100%. A single high-sensitivity Tn measurement demonstrated satisfactory accuracy as a prognostic tool for evaluating syncope in the ED

TEMPORAL DISPARITIES IN FIRST MEDICAL CONTACT BETWEEN MEN AND WOMEN WITH ACUTE MYOCARDIAL INFARCTION

JULIA AKEMI RODRIGUES TOMO1; MURILO PEDREIRA NEVES JUNIOR1;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL;

Background/Introduction: Cardiovascular diseases are the leading cause of death worldwide, with acute myocardial infarction (AMI) as a major contributor. Early recognition and timely treatment are critical, as outcomes are strongly time-dependent. Women more frequently present atypical symptoms, which may delay symptom recognition and access to care. These differences contribute to disparities in diagnosis and management of AMI. Despite advances in care systems, most evidence regarding sex-related delays is derived from North American and European populations, with limited data from Brazil. Objectives: To evaluate sex-related differences in the time from symptom onset to first medical contact in patients with AMI, as well as clinical presentation and mortality. Methods: Retrospective observational study including 539 patients admitted through the Salvador AMI Protocol (2021–2023). Demographic, clinical, and time-to-care variables were analyzed. Statistical tests included Student's t-test, Mann–Whitney, and chi-square, with significance set at $p < 0.05$. Results and Conclusions: Among 539 patients, 62.5% were male and 37.3% female, with most individuals aged between 40 and 80 years. Hypertension and diabetes mellitus were the most prevalent comorbidities. Women presented a significantly longer time from symptom onset to first medical contact compared to men (5.1 vs. 3.4 hours; $p < 0.05$). Only 21.7% of patients sought care within the first hour, with a higher proportion of men in this group. Analysis of time distribution showed that 75% of men sought medical care within approximately 3 hours, whereas 75% of women required more than 5 hours, indicating greater variability and delay among female patients. Chest pain was the most frequent symptom in both sexes (>94%); however, women more commonly presented atypical symptoms, including nausea/vomiting (31.1%), dyspnea (12.6%), syncope (3.7%), and epigastric pain (3.9%). Overall in-hospital mortality was 8.7%, with no significant difference between sexes. However, diabetic patients showed significantly higher mortality compared to non-diabetic patients (13.9% vs. 7.0%; $p = 0.0126$). These findings highlight a consistent pattern of delayed access to care among women, associated with differences in clinical presentation.

ARTIFICIAL INTELLIGENCE IN ECG INTERPRETATION OF ARRHYTHMIAS: CONCORDANCE WITH ELECTROPHYSIOLOGICAL STUDY AND LIMITATIONS IN MECHANISM DEFINITION

LUCAS CARVALHO DIAS1; RAFAELLA BARBOSA DE ASSUNÇÃO ALVES1; VITOR BASTOS LOVISI1; ANDRE LUIS PAIS MOREIRA1; MARCELLE PEREIRA DE MENEZES CAMARA1; LEONARDO NANES CORREA DOS SANTOS1; LUIZ EDUARDO MONTENEGRO CAMANHO1;

(1) HOSPITAL PRO CARDIACO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: The use of artificial intelligence (AI) in electrocardiogram (ECG) analysis has expanded rapidly, with algorithms capable of recognizing complex patterns associated with different arrhythmias. However, its clinical applicability still requires validation against the diagnostic gold standard, the electrophysiological study (EPS). Objectives: To compare the diagnostic accuracy of an AI algorithm in ECG interpretation against the definitive diagnosis obtained by EPS. Methods: This is a retrospective, observational, single-center study including 24 consecutive patients who underwent electrophysiological study (EPS) in 2025. The study population comprised patients with paroxysmal supraventricular tachycardia (PSVT), premature ventricular complexes (PVC), and ventricular tachycardia (VT). Patients with atrial fibrillation were excluded. Pre-procedural ECGs were analyzed using an artificial intelligence algorithm through up to three sequential interactions (prompts): Prompt 1 (standard text), Prompt 2 (oriented toward generic diagnosis — GDO) and Prompt 3 (oriented toward specific diagnosis — SDO). Results were compared against the definitive electrophysiological diagnosis. The analysis considered: (1) accuracy for generic diagnosis (PSVT, PVC, or VT), and (2) concordance with the specific arrhythmic mechanism identified at EPS. Results and Conclusions: Of the 24 cases, 66.7% were PSVT, 25% PVC, and 8.3% VT. Accuracy for generic diagnosis was 58% with Prompt 1, 75% with Prompt 2, and 100% with Prompt 3. For specific diagnosis, concordance rates were 58%, 75%, and 75%, respectively, with no statistically significant difference among interactions (p = 0.351). The main errors occurred in the differentiation of supraventricular mechanisms and in the precise localization of ventricular foci. AI demonstrated progressive improvement in the generic classification of arrhythmias with successive interactions, achieving high accuracy. However, precision in identifying the specific arrhythmic mechanism was lower, highlighting current limitations in the differentiation of complex substrates. AI shows potential as an auxiliary tool, but does not replace EPS in defining the arrhythmic mechanism.

ASSESSMENT OF THE INCIDENCE OF MAJOR ELECTROCARDIOGRAPHIC ABNORMALITIES IN PATIENTS WITH CHAGAS DISEASE, SAMI TROP COHORT

MARCOS GABRIEL DE JESUS RODRIGUES1; ESTER CERDEIRA SABINO CERDEIRA SABINO2; ANTONIO LUIZ PINHO RIBEIRO3; LUCIANO FREITAS FERNANDES1; ANA CLARA SILVA RODRIGUES PEREIRA1; DARDIANE SANTOS CRUZ1; ANA BEATRIZ CARDOSO SENA1; MATHAUS HENRIQUE REIS SILVA1; SÂMARA FERNANDES LEITE1; MARIA GEOVANIA CARDOSO BATISTA1; ARIELA MOTA FERREIRA1;

(1) UNIVERSIDADE ESTADUAL DE MONTES CLAROS - MONTES CLAROS - MG - BRASIL; (2) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (3) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Chagas disease (CD) remains one of the main neglected tropical diseases in Latin America, with a high cardiovascular impact and a predominance among socially vulnerable populations. Individuals with CD have twice the likelihood of developing electrocardiographic abnormalities, classified as minor and major. Major electrocardiographic abnormalities (MEA) represent early manifestations of chagasic cardiac involvement and are associated with worse clinical outcomes. Objectives: To investigate the incidence of MEA in individuals with CD participating in a cohort with nine years of follow up in endemic regions of northern Minas Gerais and the Jequitinhonha Valley. Methods: This is a longitudinal study using data from the SaMi-Trop cohort (Center for Research on Biomarkers in Neglected Tropical Diseases of São Paulo/Minas Gerais) which included individuals aged over 18 years with CD and followed them through two follow up assessments between 2013 and 2021. During the cohort, interviews and electrocardiograms (ECG) were performed. The dependent variable of this study was defined based on ECG results, and electrocardiographic abnormalities were classified according to the Minnesota Code. Incidence was estimated among selected participants who did not present MEA at baseline and was subsequently stratified by sex. Incidence was analyzed using Poisson regression. Results and Conclusions: A total of 2.159 individuals participated at the cohort baseline, of whom 1.709 took part in the first follow up and 1.115 in the second follow up. A total of 158 individuals were excluded for not having reactive serology for CD, and 12 due to the absence of this information. For this study, 706 individuals who did not present MEA at baseline were considered. The presence of MEA showed an incidence of 66 new cases among men, corresponding to 60.38 (95% CI: 46.70; 76.82) events/1.000 person-years, and 169 new cases among women, corresponding to 58.93 (95% CI: 50.38; 68.52) events/1.000 person-years. In the stratified analysis, regardless of sex, the presence of MEA showed an incidence of 59.33 events/1.000 person-years (95% CI: 51.99; 67.42). The findings indicate a significant incidence of MEA in this population, reinforcing MEA as a marker of progression of cardiac involvement in CD and the role of the ECG as a fundamental tool for surveillance and clinical management in endemic areas.

Incidence of major electrocardiographic abnormalities on ECG by sex during follow up in the group without major electrocardiographic abnormalities at baseline, Minas Gerais (n= 706), Brazil, 2013-2021.

Abnormality	Number at risk	Follow up time (person- years)	Number of events	Incidence of eventos/ 1000 person-years (95% CI)	Incidence rate difference (95% CI)
Presence of major electrocardiographic abnormality					
Male	200	1093.07	66	60.38 (46.70 ; 76.82)	1.45 (-15.61 ; 18.51)
Female	506	2867.74	169	58.93 (50.38 ; 68.52)

ATRIAL FIBRILLATION EPISODE DURATION AND STROKE RISK: BEYOND THE 30-SECOND STANDARD THRESHOLD

PEDRO HENRIQUE GIANJOPPE DOS SANTOS1; PALOMA RODRIGUES ROCHA1; DIEGO MUNDURUCA DOMINGUES1; SARA QUAGLIA DE CAMPOS GIAMPÁ1; CÉSAR JOSÉ GRUPPI1; GERALDO LORENZI-FILHO1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Background/Introduction: Atrial fibrillation (AF) is a major risk factor for stroke and is highly prevalent among patients with obstructive sleep apnea (OSA). While electrocardiography (ECG) remains the gold standard for AF diagnosis, current clinical guidelines require a minimum of 30 seconds of irregular RR intervals (RRI) and absent P waves to confirm it. However, the thromboembolic risk associated with short AF episodes just above this threshold remains unclear. Objectives: To evaluate different AF episode duration thresholds for AF diagnosis, assess their association with incident stroke, and determine whether this risk varies according to OSA severity. Methods: This observational cohort analysis used data from the Sleep Heart Health Study (SHHS), excluding participants with prior stroke or missing valid ECG recordings. A validated, proprietary deep neural network was used to detect AF from ECG-derived RRI. Cox proportional hazards models determined the association between incident stroke and AF episode duration thresholds (30s, 1min, 2min, 3min, 4min, 5min, 6min, 30min, and 1h), adjusting for age, sex, race, body mass index, smoking status, diabetes, hypertension, prevalent cardiovascular heart disease/myocardial infarction, apnea-hypopnea index (AHI), and ECG duration. Stroke-free survival was estimated using Kaplan-Meier curves and compared with log-rank tests. Participants were further stratified by OSA severity using standard AHI categories (0-5, 5-15, 15-30, and ≥30 events/h). Results and Conclusions: The cohort included 5,451 patients with 212 incident strokes over a mean follow-up of 10.95 years. Adjusted models revealed that neither the standard 30s threshold (HR 1.11 [0.85-1.45], p=0.437) nor any other threshold below six minutes was significantly associated with stroke. In contrast, longer AF episodes were significant predictors: ≥6min (HR 1.31 [1.02-1.68], p=0.035), ≥30min (HR 1.52 [1.05-2.19], p=0.025), and ≥1h (HR 1.92 [1.21-3.05], p=0.006), with the strongest association observed in severe OSA for episodes ≥1h (HR 3.32 [1.54-7.14], p=0.002). Stroke-free survival differed significantly across AF exposure groups (no AF, 30s to <6min, and ≥6min; log-rank p=0.014), driven by reduced survival for episodes ≥6min in moderate (p=0.028 vs no AF) and severe (p=0.018 vs no AF) OSA. These findings suggest that the traditional 30-second threshold may not adequately capture thromboembolic risk, whereas AF episodes longer than six minutes are stronger predictors of incident stroke, particularly among severe OSA patients.

ATRIAL FIBRILLATION, SOCIOECONOMIC VULNERABILITY, AND MORTALITY IN DECOMPENSATED HEART FAILURE: AN INTERSECTIONAL ANALYSIS

LUCAS DE SOUZA MARTINS PEREIRA1; GIOVANNI POSSAMAI DUTRA1; BRUNO FERRAZ DE OLIVEIRA GOMES2; DAVI DE VASCONCELLOS DIAS2; FABIANA CARDOSO DE OLIVEIRA2; JOÃO LUIZ FERNANDES PETRIZ1; PLINIO RESENDE DO CARMO JUNIOR1; EMILIA MATOS NASCIMENTO3; BASILIO DE BRAGANÇA PEREIRA2; GLAUCIA MARIA MORAES DE OLIVEIRA2;

(1) BARRA D`OR - RIO DE JANEIRO - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (3) UNIVERSIDADE ESTADUAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Atrial fibrillation (AF) affects 25–50% of patients with decompensated heart failure (DHF) and independently worsens outcomes. However, its prognostic impact may vary by mortality timing and intersect with social determinants of health (SDH) such as hospital-level socioeconomic deprivation and ethnicity. Whether arrhythmia type and socioeconomic vulnerability jointly shape competing mortality outcomes in DHF remains underexplored. Objectives: To characterize the differential prognostic impact of AF and non-AF arrhythmias on competing mortality outcomes and examine how SDH modulate arrhythmia-related risk across two tertiary centers in contrasting socioeconomic zones. Methods: From 1,023 consecutive DHF patients at two centers (West Zone HDI 0.959 vs. North Zone HDI 0.814; median follow-up 6.9 years, IQR 4.4–9.9), arrhythmias were classified as: no arrhythmia (n=618; 60.4%), chronic AF (n=222; 21.7%), acute AF (n=59; 5.8%), and non-AF cardiac arrhythmia (n=124; 12.1%). Fine–Gray competing risk models and Elastic Net Cox regression assessed independent prognostic contributions. Subgroup analyses by hospital zone (SDH proxy) and ethnicity evaluated SDH–arrhythmia interactions. Results and Conclusions: Compared with no-arrhythmia patients (total mortality 443/618; 71.7%; in-hospital 53/618; 8.6%), chronic AF independently predicted higher total mortality (179/222; 80.6%; P=0.010) and in-hospital death (36/222; 16.2%; P=0.002), with Fine–Gray SHR 1.85 (95%CI 1.24–2.75; P=0.003). Non-AF arrhythmia showed paradoxically lower post-discharge mortality in adjusted models (SHR 0.74; P=0.0003) yet elevated in-hospital risk (SHR 1.75; P=0.008). SDH substantially modified arrhythmia risk: in-hospital mortality for chronic AF was 26.4% at the higher-HDI West Zone vs. 9.2% at the North Zone (P<0.001), reflecting differential acute management capacity across socioeconomic contexts. Brown/Black patients with chronic AF had higher overall mortality than White counterparts (84.6% vs. 79.0%). Arrhythmia type and socioeconomic context jointly determine mortality trajectories in DHF, arguing for integrated management strategies that account for both electrical substrate and social vulnerability.

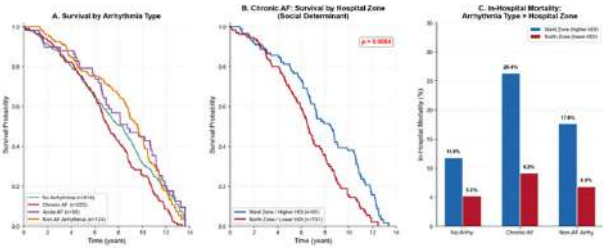

Table. Clinical Profile and Mortality by Arrhythmia Type and Hospital Zone (n=1,023)

Characteristic	No Arrhythmia (n=618)	Chronic AF (n=222)	Non-AF Arrhy. (n=124)	P*

Background/Introduction: Background: Several predictors of recurrence after atrial fibrillation (AF) ablation have been described. Clinical and technical factors influence outcomes regardless of energy source or technique. Cryoablation and pulsed-field ablation show better long-term results, possibly due to closer contact with the carina region. Objectives: Objective: To evaluate whether, in patients achieving first-pass pulmonary vein isolation (FPI), additional carina ablation reduces recurrence. Methods: Methods: Prospective, randomized study from December 2023 to May 2025 with 63 patients undergoing first-time AF ablation in whom FPI was achieved. All patients perform antral pulmonary vein isolation and in patients randomized to carina ablation this approach was performed. Follow-up was for 10 ± 4.8 months. High-power short-duration protocol was performed using 50 W (TactiCath catheter) /6–12 s (30 ml/min flow) in 34 patients and 60W (Tactiflex catheter) for 6/9 s (20 ml/min flow) in 29 patients. Contact force was 10–20 g on the anterior wall and 5–10 g on the posterior wall of the left atrium. Intracardiac echocardiogram was used ant the descrition of the operator. Results and Conclusions: Results: Male were 49 (77,8%) with baseline characteristics similar between success and recurrence groups except for a higher CHA2DS2VA score (3.1 ± 1.6 vs 1.9 ± 1.7, p=0.008) in the carina group. The total recurrence rate was 31,7% (20 of 63). Recurrence occurred in 5/31 (16.1%) patients with carina ablation versus 15/32 (46.9%) without (p=0.014; OR 0.22, 95% CI 0.07–0.71). After multivariable adjustment for persistent AF, sex, BMI, CHA2DS2VA, left atrial diameter, and LVEF, carina ablation remained strongly protective (adjusted OR 0.07, 95% CI 0.01–0.41; p=0.003) with a NNT of 3.2. Follow-up period was 11.6±4.8 months. One pericardial effusion occurred 20 days post-ablation in the success group (with 60W). One patient died 13 months after ablation in complication of a stroke (recurrence group). Conclusion: In patients with FPI, additional carina ablation is associated with an 81% relative reduction in atrial tachyarrhythmia recurrence, supporting its use as a simple and effective adjunctive strategy during AF ablation.

COMPARATIVE EFFICACY OF PULMONARY VEIN ISOLATION WITH OR WITHOUT POSTERIOR WALL ISOLATION IN PAROXYSMAL ATRIAL FIBRILLATION ACROSS DIFFERENT ENERGY SOURCES: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

ENZO TUNALA MENDONÇA1; JOAO VITOR JACOBSEN RAMOS2; TIAGO MOURA FAÇANHA3; MARIA FERNANDA CARVALHO GARCIA4; ANNA ISABELLE GOMES PEREIRA5; LEONARDO ANTUNES MESQUITA6;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) ESCOLA SUPERIOR DE CIENCIAS DA SANTA CASA DE MISERICORDIA DE VITORIA - VITÓRIA - ES - BRASIL; (3) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (4) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL; (5) CENTRO UNIVERSITARIO FAMETRO - MANAUS - AM - BRASIL; (6) HOSPITAL MADRE TERESA - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Catheter ablation is a cornerstone therapy for atrial fibrillation (AF), with pulmonary vein isolation (PVI) as the standard approach. However, recurrence rates remain significant, prompting the evaluation of adjunctive strategies such as posterior wall isolation (PWI). The incremental benefit of adding PWI to PVI, particularly across different energy sources, remains uncertain in patients with paroxysmal AF. Objectives: To compare the efficacy and safety of PVI alone versus PVI combined with PWI across different energy sources in patients with paroxysmal AF using a network meta-analysis. Methods: PubMed, Embase, and the Cochrane Library were systematically searched. Randomized and observational studies comparing PVI versus PVI+PWI were included. A frequentist network meta-analysis was performed using R. The primary outcome was arrhythmia freedom at 12 months. Secondary outcomes included arrhythmia freedom at 6 months, total procedural time, and major procedural complications. Results and Conclusions: Five studies (n=1,052) were included. Using radiofrequency (RF) PVI as the reference, no strategy showed a statistically significant benefit in arrhythmia freedom at 12 months: cryoballoon (Cryo) PVI (OR 0.39, 95% CI 0.13–1.18), Cryo PVI+PWI (OR 0.48, 95% CI 0.08–3.01), and RF PVI+PWI (OR 0.63, 95% CI 0.35–1.16). Results at 6 months were similarly non-significant. Procedural time was consistently longer in strategies incorporating posterior wall isolation (PWI), without a clear increase in major complications. Catheter ablation is an established rhythm control strategy for atrial fibrillation (AF), with pulmonary vein isolation (PVI) as its cornerstone. However, recurrence after PVI alone remains substantial, prompting investigation of adjunctive approaches such as PWI. The posterior left atrial wall shares embryological and electrophysiological features with pulmonary veins, suggesting a role in AF maintenance. Despite this rationale, clinical evidence supporting PWI remains inconsistent, particularly in paroxysmal AF, where arrhythmogenesis is more trigger-dependent. Moreover, differences in energy sources (radiofrequency vs cryoballoon) may influence lesion durability and outcomes. In patients with paroxysmal AF, adding PWI to PVI did not significantly improve arrhythmia freedom. Although PWI strategies increased procedural time, safety outcomes were comparable. These findings support PVI alone as an effective first-line ablation strategy.

(1) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Background/Introduction: Congenital atrioventricular block (CAVB) is a rare cause of severe bradycardia in neonates and children. ESC/ACC guidelines recommend pacemaker implantation in the presence of symptoms, ventricular dysfunction, or very low ventricular rates. However, the optimal timing for implantation in infants remains controversial due to anatomical limitations and a lack of longitudinal data. Objectives: To evaluate clinical outcomes in children with CAVB, compare heart failure-free survival between those undergoing early pacemaker implantation and those managed clinically, and identify factors associated with the need for implantation. Methods: Retrospective cohort study of 25 children diagnosed with CAVB and followed between 2012 and 2024. Fifteen children received a pacemaker (PM group) and ten remained under clinical follow-up (non-PM group). Variables analyzed included age at diagnosis, baseline heart rate, symptoms (syncope, heart failure), left ventricular ejection fraction (LVEF), maternal autoimmune etiology, and follow-up duration. Kaplan-Meier curves estimated heart failure-free survival, and Cox regression adjusted for age and LVEF evaluated risk factors. Results and Conclusions: The mean age at diagnosis was 3.5 ± 2.1 months, and 60% had an autoimmune etiology. Pacemaker indications included LVEF <45% or symptomatic bradycardia (<55 bpm). After a median follow-up of 8 years, heart failure-free survival was 93% in the PM group (95% CI 79–100%) versus 60% in the non-PM group (95% CI 31–89%), corresponding to an adjusted hazard ratio of 0.25 (95% CI 0.07–0.89; p=0.03). Two children in the non-PM group required late implantation due to syncope, and one developed significant ventricular dilation. There were two deaths from heart failure in the non-PM group and none in the PM group. Device-related complications included two lead dislodgements corrected by surgical revision, and one generator infection treated without removal. Maternal autoimmune etiology was associated with an earlier need for implantation (p=0.02). Early pacemaker implantation in children with CAVB is associated with higher heart failure-free survival and lower mortality, with a low incidence of complications. These findings support guideline recommendations for implantation in symptomatic patients or those with ventricular dysfunction and highlight the importance of continuous electrocardiographic follow-up in infants with CAVB.

DIAGNOSTIC PERFORMANCE OF ELECTROCARDIOGRAPHIC CRITERIA FOR LEFT VENTRICULAR HYPERTROPHY: A META-ANALYSIS AND BAYESIAN LATENT CLASS MODEL APPROACH

LUCAS YUGI SOUZA TERUI1; LOURDES MARIA ARAÚJO MARIALVA1; HENRIQUE ALEXSANDER FERREIRA NEVES1; EMILY LINDSEY PILATO1; JOSÉ NUNES DE ALENCAR2; GUSTAVO LENCI MARQUES1;

(1) UNIVERSIDADE FEDERAL DO PARANÁ (UFPR) - CURITIBA - PR - BRASIL; (2) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Background/Introduction: The low sensitivity of electrocardiographic (ECG) criteria for left ventricular hypertrophy (LVH) is traditionally attributed to the intrinsic limitations of the ECG. However, echocardiography (ECHO), frequently used as the reference standard, also has diagnostic imperfections that may distort ECG performance estimates. Objectives: To evaluate the diagnostic performance of the main ECG criteria for LVH using both frequentist and Bayesian latent class model (BLCM) approaches. Methods: Retrospective study of 142 adults randomly selected from the ECHO database of a Brazilian tertiary center. Medical records were reviewed to identify ECGs performed within ±3 months of ECHO. Sokolow-Lyon, Cornell, Romhilt-Estes, and Peguero-Lo Presti criteria were evaluated. Frequentist analysis used ECHO as reference; BLCM was applied accounting for the inaccuracy of ECHO. Priors were derived from a systematic review and diagnostic accuracy meta-analysis conducted by the authors for this study, including more than 100,000 individuals (Table 1). Results and Conclusions: Of 142 included patients, 100 (70.4%) had LVH on ECHO. Mean age was 66.4±11 years (LVH group) and 60.0±14.4 years (controls), with similar sex distribution between groups.
In the frequentist analysis, all criteria showed low sensitivity, particularly Sokolow-Lyon (6.4%). Peguero-Lo Presti showed the highest sensitivity, whereas Cornell presented the highest positive likelihood ratio (LR+). In the Bayesian analysis, sensitivity remained globally low. Higher specificity and LR+ were observed for Cornell (96.8% and 7.44) and Romhilt-Estes than in frequentist results, suggesting their greater confirmatory value after accounting for ECHO imperfection. Peguero-Lo Presti maintained the best balance between sensitivity and negative likelihood ratio (LR−) (41.0% and 0.67). Complete results are presented in Table 2. Even after Bayesian modeling, ECG criteria maintained low sensitivity and limited utility for LVH screening. However, the Bayesian approach suggested partial underestimation of the confirmatory value of some criteria by frequentist analysis, particularly Cornell and Romhilt-Estes. These findings suggest that the ECG should not be interpreted as a direct anatomical marker of ventricular mass, but rather as an expression of left ventricular electrical remodeling, more related to cardiovascular risk and prognosis than to the isolated estimation of anatomical hypertrophy.

Criteria	Number of Studies	Number of patients	Sensitivity		I^2 (%)	Specificity		I^2 (%)
			Overall (%)	95% CI		Overall (%)	95% CI	
Sokolow-Lyon	35	107,446	11	[0.07; 0.16]	99.6	95	[0.93; 0.97]	99.2
Cornell	34	107,120	21	[0.17; 0.27]	99.5	95	[0.93; 0.97]	99.6
Romhilt-Estes	8	5,135	21	[0.12; 0.36]	98	93	[0.85; 0.97]	97.2
Peguero-Lo Presti	16	89,484	42	[0.35; 0.49]	99.3	84	[0.78; 0.88]	98.8

Table 01. Systematic review and meta-analysis of diagnostic accuracy evaluating the electrocardiographic criteria for left ventricular hypertrophy (LVH) detection. Only studies using standard ECG cutoffs and echocardiography as the reference test were included. LVH was defined by left ventricular mass indexed to body surface area using established sex-specific thresholds (>115 g/m² for men and >95 g/m² for women). Pooled sensitivity and specificity were estimated separately using random-effects proportional meta-analysis with logit transformation (PLOGIT). Between-study heterogeneity was assessed using I^2 and τ^2 estimated by maximum likelihood.

Criteria	Sensitivity %		Specificity %		LR+		LR−	
	Frequentist (95%CI)	Bayesian (97.5%CrI)	Frequentist (95%CI)	Bayesian (97.5%CrI)	Frequentist (95%CI)	Bayesian (97.5%CrI)	Frequentist (95%CI)	Bayesian (97.5%CrI)
Sokolow-Lyon	**6.4** (2.4–13.4)	**7.2** (3.8–12.2)	**100.0** (92.6–100.0)	**97.4** (92.6–99.5)	NA	**2.82** (0.81–16.58)	**0.94** (0.05–17.12)	**0.95** (0.90–1.01)
Cornell	**26.6** (18.0–36.7)	**24.0** (17.6–31.4)	**95.8** (85.7–99.5)	**96.3** (91.4–99.3)	**6.38** (1.44–28.26)	**7.44** (2.58–36.06)	**0.77** (0.17–3.39)	**0.79** (0.71–0.87)
Romhilt-Estes	**27.7** (18.9–37.8)	**26.7** (19.9–34.1)	**77.1** (62.7–88.0)	**90.5** (80.9–97.0)	**1.21** (0.54–2.72)	**2.83** (1.25–9.33)	**0.94** (0.42–2.11)	**0.81** (0.71–0.95)
Peguero-Lo Presti	**41.5** (31.4–52.1)	**41.0** (33.2–49.3)	**89.6** (77.3–96.5)	**88.4** (80.0–94.4)	**3.98** (1.45–10.97)	**3.55** (1.95–7.53)	**0.65** (0.24–1.80)	**0.67** (0.56–0.79)

Table 2. Diagnostic performance of electrocardiographic criteria for left ventricular hypertrophy by frequentist and Bayesian latent class approaches. The Bayesian model assumed conditional independence between tests ($\rho=0$) and incorporated beta priors for ECG sensitivity and specificity derived from a systematic review and meta-analysis using the same conventional ECG cutoffs and echocardiographic reference standard. Priors for echocardiographic performance were defined from established literature assuming high, but imperfect, diagnostic accuracy (mean sensitivity 85% and specificity 95%). The prior prevalence of LVH was centered on the observed prevalence and clinical profile of the study population. Moderately informative priors (effective sample size ≈50 for test performance and ≈30 for prevalence) were adopted due to substantial between-study heterogeneity in the meta-analysis (I^2 >97%).

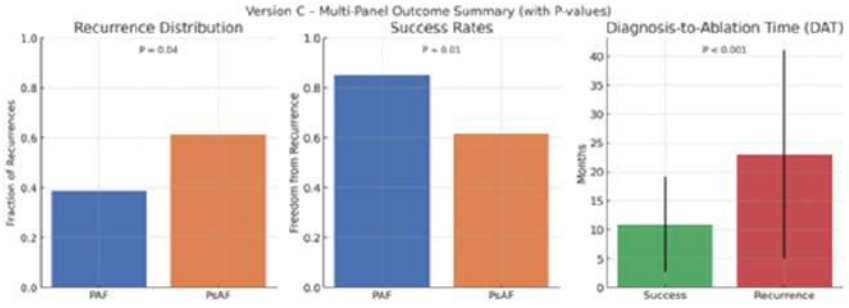
DOES THE TIME FROM FIRST ATRIAL FIBRILLATION DIAGNOSIS TO CATHETER ABLATION INFLUENCE IN LONG-TERM OUTCOMES?

GUILHERME MOREIRA PIZETTA1; HENRIQUE TEIXEIRA GIESTAS SERPA1; THAIS COUTINHO NICOLA1; EDUARDO SERPA1; LUISA CARVALHO BENEDITO1; CHRISTIANO LEMOS DA CUNHA1; CARLOS ALEXANDRE VOLPONI LOVATTO1; ALOYR SIMOES JR.1; FABRICIO SARMENTO VASSALLO1; LUIZ FERNANDO MACHADO BARBOSA1;



(1) HOSPITAL SANTA CASA DE MISERICORDIA DE VITORIA - VITÓRIA - ES - BRASIL;

Background/Introduction: Background A substantial proportion of patients with atrial fibrillation (AF) experience arrhythmia progression over time. The optimal timing of catheter ablation in the natural history of AF remains debated. Recent data suggest that delays in rhythm-control interventions may negatively impact outcomes. Objectives: Objective To evaluate the impact of the interval between the first documented AF episode and catheter ablation, defined as diagnosis-to-ablation time (DAT), on long-term arrhythmia recurrence. Methods: Methods We prospectively evaluated consecutive patients who underwent first-time AF ablation with pulmonary veins isolation between December 2018 and December 2023 that started the procedure in sinus rhythm. Ablation was performed using 50 W radiofrequency power, target contact force 10–20g (anterior wall) and 5–10g (posterior wall). Results and Conclusions: Results A total of 282 patients were included (mean age 64.9±11.8 years; 61.3% male). Paroxysmal AF (PAF) in 175 (62.1%) and mean CHA_2DS_2VA of 2.8±1.9. Mean follow-up was 36.1±14.2 months. Late AF recurrence (>90 days) occurred in 67 patients (23.8%), including 26 (38.8%) with PAF and 41 (61.2%) with PsAF (p = 0.04). In PAF we observed 85.1% and in PsAF 61.7% of freedom from recurrence (p=0.01), respectively. Patients free from recurrence had a significantly shorter DAT (10.9±8.2 months) compared with those with recurrence (23.0±18.1 months, p< 0.001). Conclusion A delay between first AF diagnosis to catheter ablation is a strong predictor of long-term recurrence. Patients with persistent AF exhibited substantially higher recurrence rates, suggesting that delayed referral for catheter ablation may contribute to progression from paroxysmal to persistent AF, subsequently reducing procedural success.

Table 1

Variable	Value
N	282
Age (years)	64.9 ± 11.8

EFFECTIVENESS OF CARDIAC RESYNCHRONIZATION THERAPY IN LEFT BUNDLE BRANCH BLOCK-INDUCED CARDIOMYOPATHY: A SYSTEMATIC REVIEW AND META-ANALYSIS

ALFREDO AURÉLIO MARINHO ROSA FILHO1; RICARDO FONSECA OLIVEIRA SURUAGY MOTTA2; GUILHERME DAGOSTIN DE CARVALHO1; LUCIANA VIDAL ARMAGANIJAN1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (2) CENTRO UNIVERSITARIO CESMAC - MACEIO - SP - BRASIL;

Background/Introduction: Introduction: LBBB-induced cardiomyopathy (LBBB-CM) is a recognized non-ischemic cardiomyopathy subtype with mechanical dyssynchrony and progressive left ventricular dysfunction from long-standing LBBB. Cardiac resynchronization therapy (CRT) is a targeted therapy, but its precise clinical impact in this scenario remains incompletely defined. Objectives: To systematically evaluate CRT efficacy in adult LBBB-CM patients via single-arm meta-analysis of observational evidence, focusing on LVEF changes and all-cause mortality. Methods: A systematic search was performed in PubMed, Scopus, Embase, and Web of Science from inception to May 2025. The review followed PRISMA guidelines and was prospectively registered in PROSPERO. We included observational studies reporting outcomes of CRT in adult patients with LBBB-induced cardiomyopathy, defined by the presence of LBBB, left ventricular systolic dysfunction, and exclusion of alternative cardiomyopathy etiologies. Studies without relevant clinical outcomes were excluded. The primary outcome was change in left ventricular ejection fraction (LVEF). Secondary outcome was all-cause mortality. Meta-analysis was performed using a random-effects model in R (version 4.2.3). Risk of bias was assessed using ROBINS-I. Follow-up duration varied across included studies. Results and Conclusions: Results: Eight studies (628 patients) met criteria. CRT significantly improved LVEF (pooled mean increase 20.12 percentage points; MD 20.12; 95% CI 13.95–26.28; p < 0.001). Pooled all-cause mortality was 15% (0.15; 95% CI 0.06–0.31; p < 0.001) across studies with heterogeneous follow-up. Heterogeneity was moderate to high for primary (I^2 = 75%) and secondary (I^2 = 82%) outcomes. Conclusion: CRT in LBBB-CM is associated with substantial LVEF improvement. Despite functional recovery, observed mortality remains clinically relevant. Findings emphasize early LBBB-CM recognition and further research on prognostic determinants, patient selection, and optimal CRT timing for long-term benefits.

EFFICACY AND SAFETY OF ANTICOAGULATION VERSUS DUAL ANTIPLATELET THERAPY FOLLOWING LEFT ATRIAL APPENDAGE OCCLUSION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

LETICIA DE FREITAS BARRADAS SIEBRA1; GIANLUCA GOMES SIEBRA1; LARISSA ARAUJO DE LUCENA1; ANA KARENINA CARVALHO DE SOUZA1; CREUZA MACEDO GOES ROCHA1;

(1) UFRN - NATAL - RN - BRASIL;

Background/Introduction: Left atrial appendage occlusion (LAAO) is an established strategy for stroke prevention in patients with atrial fibrillation (AF), particularly in those with contraindications to long-term oral anticoagulation. However, the optimal antithrombotic regimen following LAAO remains uncertain. While dual antiplatelet therapy (DAPT) has traditionally been used in patients at high bleeding risk, emerging evidence suggests that direct oral anticoagulants (DOACs) may offer improved protection against device-related thrombosis with a potentially favorable safety profile. Although previous meta-analyses have explored this topic, most included observational studies and heterogeneous populations, and none have exclusively evaluated randomized controlled trials (RCTs). Therefore, robust high-level evidence directly comparing these strategies remains limited. Objectives: This study aimed to systematically compare the efficacy and safety of DOAC-based anticoagulation versus DAPT after LAAO, including only evidence from RCTs. Methods: PubMed, Embase and Cochrane databases were systematically searched for RCTs comparing DOAC-based anticoagulation versus DAPT in patients with AF following LAAO. Outcomes of interest included: (1) major bleeding; (2) all-cause mortality; and (3) stroke. Results and Conclusions: Three RCTs (ANDES, ADRIFT, and ADALA) including 704 patients undergoing left atrial appendage occlusion were analyzed, with 368 patients assigned to DOAC-based anticoagulation and 336 to DAPT. The mean follow-up duration was 3 months. DOAC-based anticoagulation was associated with a significantly lower risk of major bleeding compared with dual antiplatelet therapy (OR 0.61; 95% CI 0.38–0.96; p = 0.03 - Figure 1A), with no significant differences in all-cause mortality (OR 0.60; 95% CI 0.24–1.53; p = 0.29 - Figure 1B) or stroke (OR 0.46; 95% CI 0.06–3.33; p = 0.45 - Figure 1C) at short-term follow-up. These findings suggest that anticoagulation may represent a safer and effective alternative to DAPT in the early post-procedural period following LAAO. A limitation of this analysis is the heterogeneity in the definition of major bleeding across the included trials. Given the limited number of RCTs and short follow-up duration, further large-scale randomized trials are warranted to confirm these findings and to define the optimal long-term antithrombotic strategy.

ELECTRICAL STORM IN CHAGAS CARDIOMYOPATHY: IN-HOSPITAL OUTCOMES FROM A CONTEMPORARY BRAZILIAN TERTIARY-CARE COHORT

LARISSA FONSECA REIS1; BÁRBARA CAROLINA SILVA ALMEIDA1; EDUARDA MIRANDA PEIXOTO1; TALITA LOPES DO NASCIMENTO DA SILVA1; THAÍS LANY DE OLIVEIRA LEÃO1; ANDRÉ ASSIS LOPES DO CARMO1; GABRIEL ASSIS LOPES DO CARMO1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Electrical storm (ES) is a life-threatening arrhythmic emergency associated with high in-hospital morbidity and mortality. Data from Chagas cardiomyopathy, a major cause of advanced heart disease in Latin America, remain scarce. Objectives: To describe the clinical profile, management strategies and in-hospital outcomes of patients admitted with ES, comparing Chagas and non-Chagas etiologies. Methods: We performed a retrospective cross-sectional analysis of consecutive patients admitted to a tertiary university hospital in 2024-2025 with ES. Baseline characteristics, triggers, therapies and outcomes were compared according to Chagas etiology. Categorical variables were compared using chi-square tests and continuous variables using Mann-Whitney tests. Results and Conclusions: Thirty-six patients were included; median age was 66.5 years (IQR 58-72), 72.2% were male and 94.4% had an implantable cardioverter-defibrillator. Chagas cardiomyopathy was the leading etiology (55.6%), followed by ischemic heart disease (13.9%). Median left ventricular ejection fraction was 34.7% (IQR 25.5-40.0), and right ventricular dysfunction was present in 33.3%. No trigger was identified in 72.2% of cases. During admission, catheter ablation was performed in 61.1%, amiodarone was used in 58.3%, non-selective beta-blockers in 52.8%, stellate ganglion block in 22.8% and lidocaine in 22.8%. Compared with non-Chagas patients, those with Chagas cardiomyopathy more frequently required stellate ganglion block and lidocaine (both 35.0% vs 6.2%; p=0.039). The combined in-hospital endpoint of death, heart transplantation or transition to palliative care occurred in 7 patients (19.4%). Although not statistically significant, this endpoint was numerically higher in Chagas versus non-Chagas patients (30.0% vs 6.2%; p=0.074). Individual outcomes did not differ significantly between groups. In this contemporary tertiary-care cohort, ES was predominantly associated with Chagas cardiomyopathy and carried a substantial in-hospital burden, with nearly one in five patients experiencing death, transplantation or palliative-care transition. The higher use of advanced antiarrhythmic rescue strategies and the numerical excess of adverse outcomes in Chagas cardiomyopathy highlight the need for dedicated research in this neglected high-risk population.

ELECTROCARDIOGRAPHIC PREDICTORS OF ADVERSE CARDIAC OUTCOMES IN MYOTONIC DYSTROPHY TYPE 1: AN EXPLORATORY META-ANALYSIS

ISADORA CRISTINE REIS SGUIZZATO BOZZI1; MARIA CLARA DE ARAUJO GONTIJO LIMA1; ANTONIO LUIZ PINHO RIBEIRO1; GABRIELA MIANA DE MATTOS PAIXÃO1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Myotonic dystrophy type 1 (DM1) is a multisystemic genetic disorder with frequent cardiac involvement, marked as one of the leading causes of death in affected adults. Electrocardiographic (ECG) findings can be useful in predicting the progression of conduction disease and clinically significant outcomes, but a formal quantitative synthesis of their prognostic value is lacking. Objectives: To assess the prognostic value of ECG parameters for predicting conduction system disease and clinically relevant outcomes in adults with DM1. Methods: Eight databases were systematically searched from inception to December 30, 2025. Eligible studies included patients >15 years with genetically confirmed DM1 and reported ECG predictors to clinically relevant conduction outcomes, such as advanced atrioventricular block, pacemaker or ICD implantation, and sudden cardiac death. Two reviewers independently screened articles and extracted data. When different ECG predictors were reported, the measure most comparable across studies and most representative of conduction disease was selected. Continuous measures were included when categorical thresholds were not consistently available across studies. Hazard ratios, risk ratios, and odds ratios were pooled as measures of relative risk, assuming equivalence for rare events. Studies reported different clinically related outcomes and heterogeneous ECG features, so these endpoints were analyzed together in an exploratory random-effects meta-analysis. The protocol was registered in PROSPERO. Results and Conclusions: Fifteen studies, including 3,699 patients with DM1, met the inclusion criteria, and 6 were included in the meta-analysis (n=2,907). ECG predictors evaluated included rhythm abnormalities, PR ≥240 ms and/or QRS ≥120 ms, QRS duration increase (per 10ms), and bundle branch block. Outcomes included major conduction defects, major bradyarrhythmic events, or sudden death. ECG abnormalities were associated with an increased risk of adverse cardiac outcomes, with a pooled hazard ratio of 2.90 (95%CI 1.18–7.15). Heterogeneity was high (I^2=82.6%), likely due to differences in ECG predictors and outcome definitions across studies, as well as the inclusion of different but clinically related endpoints. The results should be interpreted as exploratory, given the clinical heterogeneity of outcomes. ECG findings are significant predictors of clinically important conduction system disease and adverse cardiac outcomes in adults with DM1, supporting their role in risk stratification.

Background/Introduction: Traditional electrocardiographic (ECG) criteria for left ventricular hypertrophy (LVH) are poor surrogates for increased left ventricular mass. However, recent studies have highlighted the prognostic significance of exaggerated voltages. The Multi-Ethnic Study of Atherosclerosis LVH criterion (MESA-LVH), defined as SV1 + SV2 + RV5, has been investigated as a spectrum-based diagnostic and prognostic marker, identifying patients with extreme voltages who, despite lacking true hypertrophy, carry risks comparable to those with confirmed LVH — a finding that warrants validation in diverse populations. Objectives: To assess whether the MESA-LVH criterion can predict a higher incidence of adverse outcomes independently of LVH. Methods: We retrospectively analyzed data from the Jackson Heart Study, a prospective cohort of self-identified African American (aged 21–94 years). LVH was defined using Echocardiogram (ECO) by LV mass indexed to height$^{2.7}$, with cutoffs of ≥49 g/m$^{2.7}$ for men and ≥45 g/m$^{2.7}$ for women. Participants' 12-lead ECGs were assessed for the presence of MESA-LVH. Extreme-Voltage Electrical Remodeling (EVER) was defined as participants with high electrocardiographic voltage meeting the MESA threshold (≥60 mm) without structural LVH by imaging. Cox proportional hazards models were used to evaluate associations between EVER and heart failure, mortality, coronary heart disease and stroke with adjustments for age, sex, body mass index, and systolic blood pressure. An LVH-adjusted model simultaneously included MESA-LVH and conventional echocardiographic LVH to assess each criterion's independent prognostic contribution. Hazard ratios (HR) and 95% confidence intervals (CI) were reported. Results and Conclusions: Table 1 presents baseline characteristics of the study population. Among 2,348 participants, echocardiographic LVH prevalence was approximately 13%, and 155 participants met the EVER phenotype. In fully adjusted analyses, EVER did not significantly predict any outcome. In the LVH-adjusted model, MESA-LVH showed borderline associations with all-cause mortality and heart failure, though these remained statistically insignificant. All data are summarized in Table 2. Conventional echocardiographic LVH, in contrast, independently predicted all outcomes analyzed. In this African American cohort, the EVER phenotype lost independent prognostic significance after adjustment, whereas LVH in ECO predicted all adverse outcomes analyzed, reinforcing the prognostic superiority of imaging-based LVH detection.

Table 1. Characteristics of EVER vs echo-LVH-positive participants among high-voltage individuals

Comparison within MESA ≥50 mm and MESA ≥60 mm subgroups. Values are mean ± SD or n (%). Bold p-values indicate p < 0.05.

FAST ANATOMICAL MAPPING (FAM) INTEGRATED WITH CARTOSOUND®: OPTIMIZATION OF ANATOMICAL RECONSTRUCTION IN ZERO-FLUOROSCOPY ABLATION.

LUCAS CARVALHO DIAS1; RAFAELLA BARBOSA DE ASSUNÇÃO ALVES1; VITOR BASTOS LOVISI1; ANDRÉ LUIS PAIS MOREIRA1; MARCELLE PEREIRA DE MENEZES CAMARA1; LEONARDO NANES CORREA DOS SANTOS1; LUIZ EDUARDO MONTENEGRO CAMANHO1;

(1) HOSPITAL PRO CARDIACO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Arrhythmia ablation using a zero-fluoroscopy strategy has been established as a safe and effective approach, particularly with the integration of intracardiac echocardiography (ICE) into electroanatomical mapping systems. The Fast Anatomical Mapping (FAM) algorithm, incorporated into the CartoSound system, uses artificial intelligence to accelerate and automate three-dimensional anatomical reconstruction. However, its application in fully fluoroscopy-free procedures remains poorly described. Objectives: To evaluate the initial experience with FAM in zero-fluoroscopy atrial fibrillation (AF) ablation procedures, analyzing anatomical accuracy, mapping time, and potential interferences in reconstruction. Methods: A prospective study including 20 patients undergoing AF ablation without fluoroscopy. Reconstructions obtained by FAM were compared to those performed with a conventional multipolar catheter. Mapping time, volumetric differences, need for manual corrections, and interferences in automatic reconstruction were assessed. Results and Conclusions: Mean age was 68 years (range 44–78), mean ejection fraction was 68%, and mean left atrial diameter was 44 mm (range 35–55). FAM produced more accurate reconstructions, particularly of the posterior wall and roof of the left atrium, reducing the need for manual corrections. Mean mapping time was significantly shorter with FAM (333 s vs. 712 s). Eight patients had intracavitary devices during reconstruction (6 catheters and 2 pacemakers). No relevant interference was observed, except in one pacemaker patient, in which electrode imaging distorted the left atrial anatomy, requiring multipolar complementation. Three patients (15%) required remapping. FAM demonstrated better volumetric correlation and greater detail of critical structures such as the mitral ridge and left atrial appendage, although apparent shortening of the pulmonary veins was noted in some cases. No complications occurred. The FAM algorithm proved to be a promising tool in zero-fluoroscopy AF ablation, providing more faithful anatomical reconstructions, significant reduction in mapping time, and better definition of critical structures compared to conventional multipolar mapping. Specific cases may require manual complementation, and full efficacy depends on the operator's experience with ICE and image integration.

Variáveis	Valores
Total de pacientes	20

FEMORAL ACCESS-GUIDED IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR AND CARDIAC RESYNCHRONIZATION THERAPY (CRT-D) IMPLANTATION: A SINGLE-CENTER EXPERIENCE IN 903 CASES FROM NORTHEAST BRAZIL

ALFREDO AURÉLIO MARINHO ROSA FILHO1; MARIA CLARA DE SOUZA XAVIER2; LUCAS BRANDAO CAVALCANTE3; ADRIANO DE HOLANDA PEDROSA2; PEDRO VINICIUS SANTOS DE MEDEIROS4; JORGE FRANCISCO DA SILVA FILHO5; ALFREDO AURELIO MARINHO ROSA6; EDVALDO FERREIRA XAVIER JUNIOR6;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - Brasil; (2) CENTRO UNIVERSITARIO CESMAC - MACEIO - SP - Brasil; (3) CENTRO UNIVERSITARIO DE MACEIO - UNIMA / AFYA - MACEIO - SP - Brasil; (4) UNCISAL - MACEIO - AL - Brasil; (5) REAL HOSPITAL PORTUGUES - RECIFE - PE - Brasil; (6) SANTA CASA DE MISERICORDIA DE MACEIO - MACEIÓ - SP - Brasil;

Background/Introduction: Introduction: Cardiac resynchronization therapy with defibrillator (CRT-D) is the established treatment for patients with dilated cardiomyopathy, left bundle branch block (LBBB), and ventricular tachycardia (VT). However, procedure time can be prolonged due to difficulties in navigating to the coronary sinus (CS). Objectives: Objective: To present our extensive experience with a novel femoral vein puncture technique guiding subclavian sheath insertion, optimizing CS lead placement and reducing procedural complexity in 903 ICD-CRT implantations. Methods: Material and Methods: From March 2010 to August 2025, 903 ICD-CRT implantations were performed. The cohort (65% male) presented with refractory heart failure, LVEF ≤ 35%, LBBB, and VT. CS access was systematically facilitated by a femoral approach: initial femoral vein puncture and introduction of a steerable quadripolar catheter into the CS. This catheter guided a second quadripolar catheter coaxially within the subclavian sheath directly into the CS, enabling detailed venography and optimal LV electrode branch selection. Immediate success was defined by significant QRS narrowing. Results and Conclusions: Results: CS access was 99.8% successful, without major complications (perforation, rupture, tamponade). Clinically, 74% achieved significant QRS narrowing (mean post-implantation 110 ms vs. pre-implantation 165 ± 15 ms, p<0.001). Late LV lead dislodgement was 0.44% (n=4). Right subclavian implantation was needed in 0.88% (n=8); PLSVC in 0.44% (n=4). Immediate phrenic nerve stimulation (3.32%, n=30) was managed by reprogramming. Average procedure time was 1h 30min (range 1h 20min to 2h 30min), demonstrating significant efficiency gains. Conclusion: Systematic femoral access guiding subclavian sheath introduction effectively reduced procedure time to 1h 30min, significantly lowering ionizing radiation exposure. This robust single-center experience (903 cases) demonstrates a safe, efficient, and reproducible strategy for complex ICD-CRT implantations, particularly relevant in regions like Northeast Brazil.

IMPACT OF CORONARY ARTERY DISTRIBUTION ON PULSED FIELD ABLATION IN REFRACTORY PERSISTENT ARRHYTHMIAS

THIAGO YUZO HAZUMA1; MICHELL FAYAD ANDRE HADDAD1; LUIS AUGUSTO AMBROSIO DE AGUIAR MUNHOZ1; PEDRO HENRIQUE CORREIA FILGUEIRAS1; CLAUDIO CIRENZA1; JOAO VICTOR LIMA DANTAS1; BRENO COTRIM REIS1; BARBARA OLIVEIRA DE EIRA1; LAURA CENTURIAO NUNES1; LUCAS HENRIQUE FARIA ROSA1; LEONARDO IZZO SILVA1; ANGELO AMATO VINCENZO DE PAOLA1;

(1) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Background/Introduction: Patients with persistent arrhythmias have a greater substrate related to arrhythmogenesis, frequently requiring more extensive ablations. These may occasionally involve areas adjacent to the coronary vessels, with the potential occurrence of ischemic events during pulsed field ablation (PFA) applications. Strategies for defining coronary anatomy have not been sufficiently studied and may contribute to the efficacy and safety of the procedure." Objectives: Study the impact of the relationship between coronary artery proximity to regions undergoing electroporation and the occurrence of local effects on coronary and systemic vasomotility in patients with atrial fibrillation (AF), typical and atypical flutter (AFL), and refractory ventricular ectopy. Methods: A total of 20 patients submitted PFA using the FARAWAVE catheter (Boston Scientific) from April 2025 to April 2026: 18 with persistent and refractory AF/AFL, undergoing pulmonary vein antral ablation with extension to the mitral, pulmonary, and cavotricuspid isthmuses, as well as other atrial areas; and 2 patients with right ventricular outflow ectopy. Angiographies were performed in right and left anterior oblique (RAO/LAO) views and analyzed using the Vue Motion Picture Archiving and Communication System software, version 12 (Philips), measuring the distances between the coronary arteries and the electroporation areas. Projections showing the shortest distance between the ablation catheter and the evaluated coronary artery were considered, with distances of less than 5 mm defined as critical. Results and Conclusions: Mean arrhythmia duration was 5.7 years (0.1–20.5); 50% were male and 55% had undergone previous ablation. In areas related to the coronary course, RAO and LAO luminographies were performed, followed by 200 µg of intracoronary nitroglycerin (NTG) immediately before electroporation. Concomitant cavotricuspid isthmus ablation was performed in 60% of patients. Acute success was achieved in all cases. The right coronary artery (RCA) most frequently met the critical proximity criteria (p= 0.042), occurring in 50% of cases (95% CI: 29.9–70.1). There were 4 episodes of transient vasospasm, which correlated with critical proximity to the RCA (p= 0.043). No complications or arterial hypotension occurred. Conclusions: In the studied sample, the ablation strategy with coronary anatomy definition was safe and effective. Intracoronary NTG did not cause systemic hemodynamic changes. The RCA presented vasospasm in 33% of cases.

Coronary Artery	Distance > 5 mm	Distance < 5 mm	Vasospasm	Arterial Hypotension

IMPACT OF GLP-1 RECEPTOR AGONISTS ON ATRIAL FIBRILLATION RECURRENCE AFTER CATHETER ABLATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

JULIANA FERRAZ DE SOUSA1; FRANCINNY ALVES KELLY2; ARTUR DE OLIVEIRA MACENA3; LUIZA TREVISOL DAL PONTE4;

(1) UEMASUL - IMPERATRIZ - MA - BRASIL; (2) BETH ISRAEL DEACONESS MEDICAL CENTER - UNITED STATES; (3) UNIVERSIDADE FEDERAL DE PERNAMBUCO - RECIFE - PE - BRASIL; (4) UNIVERSIDADE DE CAXIAS DO SUL - CAXIAS DO SUL - RS - BRASIL;

Background/Introduction: Atrial fibrillation (AF) recurrence after catheter ablation remains frequent, particularly among patients with obesity and metabolic dysfunction — conditions that drive structural and electrical atrial remodeling. GLP-1 receptor agonists (GLP-1RAs), through their anti-inflammatory, antifibrotic, and cardiometabolic effects, may target key mechanisms underlying post-ablation recurrence. Objectives: To evaluate whether GLP-1RA use is associated with reduced atrial arrhythmia recurrence and all-cause mortality in patients submitted to catheter ablation for AF. Methods: This systematic review and meta-analysis was conducted following PRISMA guidelines. A systematic search of PubMed, Embase, and Web of Science identified randomized controlled trials and cohort studies comparing GLP-1RA use versus control in patients who underwent AF ablation. Pooled estimates were calculated using a random-effects model. Heterogeneity was assessed with the I-squared statistic. Effects were reported as hazard ratios (HR) with 95% confidence intervals (CI). Results and Conclusions: Five cohort studies were included, comprising 10,799 patients, of whom 5,263 (48.7%) received GLP-1RAs. For AF recurrence (four studies; n = 7,489), GLP-1RA use was associated with a 43% risk reduction (HR 0.57; 95% CI 0.35–0.91; I-squared = 88%; p = 0.020). The substantial heterogeneity observed may reflect differences in AF phenotype, concomitant pharmacotherapy, and ablation techniques across centers. For all-cause mortality (two studies; n = 9,950), a 24% risk reduction was observed (HR 0.76; 95% CI 0.62–0.92; I-squared = 0%; p = 0.006), without significant heterogeneity. GLP-1RA use was associated with lower AF recurrence and reduced all-cause mortality after catheter ablation. The observational design of the included studies limits causal inference; however, these findings support GLP-1RAs as a potential adjunctive strategy in post-ablation AF management and warrant confirmation through randomized trials.

Background/Introduction: Atrial fibrillation (AF) is the most common sustained cardiac arrhythmia and is associated with an increased risk of thromboembolic events and mortality. Left atrial appendage occlusion (LAAO) has emerged as an alternative strategy to direct oral anticoagulants (DOACs) for stroke prevention in patients with AF. However, comparative evidence regarding ischemic and bleeding outcomes remains limited and heterogeneous. Objectives: To compare the efficacy and safety of LAAO versus DOAC therapy exclusively in NVAF, excluding warfarin comparisons through a systematic review and meta-analysis of RCTs and propensity-matched studies. Methods: A systematic review and meta-analysis were conducted following PRISMA recommendations. Studies comparing LAAO and DOAC therapy in patients with atrial fibrillation were included. Risk ratios (RRs) with 95% confidence intervals (CIs) were pooled using a random-effects model. Heterogeneity was assessed using the I² statistic. Outcomes included all-cause mortality, ischemic stroke, hemorrhagic stroke, cardiovascular death, systemic embolism, major bleeding, intracranial hemorrhage, and gastrointestinal bleeding. Results and Conclusions: Nine studies comprising 6,869 patients were included. Compared with DOAC therapy, LAAO was associated with a lower risk of gastrointestinal bleeding (RR: 0.52; 95% CI: 0.31–0.87; p = 0.013; I² = 0%). No significant differences were found between groups for all-cause mortality (RR: 0.66; 95% CI: 0.43–1.01; p = 0.054; I² = 82%) major bleeding (RR: 0.96; 95% CI: 0.69–1.33; p = 0.811; I² = 45.1%), intracranial hemorrhage (RR: 0.88; 95% CI: 0.49–1.57; p = 0.661; I² = 2.7%), ischemic stroke (RR: 0.85; 95% CI: 0.53–1.35; p = 0.484; I² = 63.7%), hemorrhagic stroke (RR: 0.56; 95% CI: 0.16–1.96; p = 0.362; I² = 21.1%), cardiovascular death (RR: 0.95; 95% CI: 0.67–1.34; p = 0.774; I² = 33.8%), or systemic embolism (RR: 0.43; 95% CI: 0.08–2.42; p = 0.342; I² = 0%). In patients with atrial fibrillation, LAAO was associated with a lower risk of gastrointestinal bleeding compared with DOAC therapy, while showing comparable rates of ischemic and major adverse cardiovascular outcomes. Further randomized studies are warranted to better define the long-term comparative effectiveness of these strategies

ORAL ANTICOAGULATION WITH OR WITHOUT SINGLE ANTI-PLATELET THERAPY AFTER ISCHEMIC STROKE IN ATRIAL FIBRILLATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

SHRUTHI KARTHIKEYAN1; FEDERICO NAPOLI2; MAJED SHEIKH1; BERNARDO TEMER TEIXEIRA GOLDWASSER3; CAROL PIRES4; ESTEBAN AREVALO5;

(1) CANTON MEDICAL EDUCATION FOUNDATION - UNITED STATES; (2) SAN GIUSEPPE HOSPITAL, IRCCS MULTIMEDICA - ITALY; (3) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (4) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (5) LOMA LINDA UNIVERSITY - UNITED STATES;

Background/Introduction: The addition of single antiplatelet therapy (SAPT) to oral anticoagulation (OAC) in patients with atrial fibrillation (AF) following ischemic stroke is common in clinical practice, particularly among patients with concomitant atherosclerotic disease. However, the net clinical benefit of this strategy remains uncertain. Objectives: To evaluate the safety and efficacy of OAC plus SAPT compared with OAC alone in patients with Atrial fibrillation following ischemic stroke or transient ischemic attack (TIA). Methods: We performed a systematic review and meta-analysis of observational cohort studies comparing OAC plus SAPT versus OAC alone in adults with AF and recent ischemic stroke or TIA. Adjusted hazard ratios (HRs) were pooled using random-effects models. The primary outcome was major bleeding. Secondary outcomes included recurrent ischemic stroke and all-cause mortality. Sensitivity analyses excluding vitamin K antagonist (VKA) based comparisons were performed. Results and Conclusions: Six observational cohort studies comprising 14,393 patients were included. Five studies contributed adjusted estimates for quantitative synthesis. Combination therapy was associated with a numerically increased though not statistically significant risk of major bleeding (HR 1.26, 95% CI 0.98–1.61; p=0.068), which became significant in DOAC-only analyses (HR 1.35, 95% CI 1.13–1.61; p=0.0008). There was no reduction in recurrent ischemic stroke (HR 1.32, 95% CI 0.94–1.85; p=0.111). Combination therapy was associated with higher all-cause mortality (HR 1.13, 95% CI 1.04–1.23; p=0.0049), although this finding should be interpreted cautiously given the likelihood of residual confounding by indication. Conclusions: In patients with AF following ischemic stroke or TIA, the addition of SAPT to OAC was not associated with reduced recurrent ischemic stroke and was associated with increased bleeding risk in DOAC-based analyses. These findings support a conservative approach to combination antithrombotic therapy outside established indications.

Study Selection

A total of 4677 records were identified through database searching. After removal of duplicates and screening, six studies met inclusion criteria. Study selection is summarized in Figure 1 (PRISMA flow diagram). Tsai et al. was included in the qualitative synthesis but excluded from quantitative synthesis due to non-comparable exposure definitions.

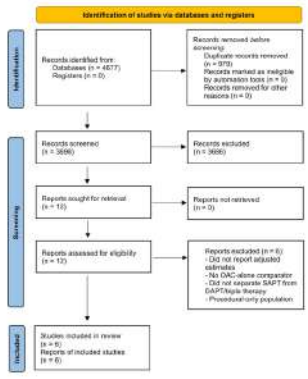

Figure 1. PRISMA 2020

Major Bleeding

Four comparisons were included in the primary analysis. Combination therapy was associated with a numerically increased though not statistically significant risk in major bleeding (HR 1.26, 95% CI 0.98–1.61; p = 0.068) (Figure 2).

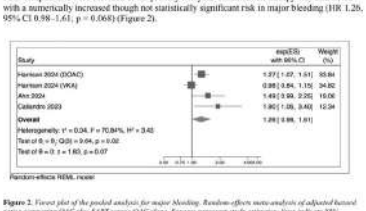

Figure 2. *Forest plot of the pooled analysis for major bleeding. Random-effects meta-analysis of adjusted hazard ratios comparing OAC plus SAPT versus OAC alone. Squares represent study estimates; lines indicate 95% confidence intervals; diamond represents the pooled effect. HR, hazard ratio; CI, confidence interval; OAC, oral anticoagulation; SAPT, single antiplatelet therapy.*

In sensitivity analysis excluding the VKA subgroup, combination therapy was associated with **significantly increased major bleeding** (HR 1.35, 95% CI 1.13–1.61; p = 0.0008) (Figure 3).

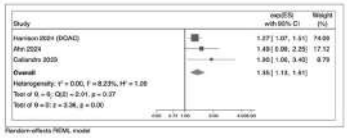

Figure 3. *Sensitivity analysis for major bleeding restricted to DOAC-based comparisons (excluding VKA subgroup). Combination therapy was associated with significantly increased major bleeding (HR 1.35, 95% CI 1.13–1.61; p = 0.0008). HR, hazard ratio; CI, confidence interval; DOAC, direct oral anticoagulant; VKA, vitamin K antagonist.*

PACEMAKER IMPLANTATION IN MYOTONIC DYSTROPHY TYPE 1: INCIDENCE ACROSS CLINICAL COHORTS

ISADORA CRISTINE REIS SGUIZZATO BOZZI1; MARIA CLARA DE ARAUJO GONTIJO LIMA1; ANTONIO LUIZ PINHO RIBEIRO1; GABRIELA MIANA DE MATTOS PAIXÃO1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Cardiac conduction disease is a frequent manifestation of myotonic dystrophy type 1 (DM1), and is one of the leading causes of death in affected adults. Pacemaker (PM) implantation is commonly required during follow-up, but reported rates vary across studies and clinical strategies. Objectives: To estimate the incidence of pacemaker implantation in patients with DM1 and explore factors associated with variability across studies. Methods: A systematic search of eight databases (LILACS, SciELO, PubMed/MEDLINE, ScienceDirect, EMBASE, CENTRAL, Web of Science, and Scopus) was conducted from inception to December 30, 2025, to identify studies evaluating cardiac conduction disease and related outcomes in patients ≥16 years with genetically confirmed DM1. Studies that reported pacemaker implantation during follow-up were eligible for this analysis. A random-effects meta-analysis of proportions was performed to estimate the pooled incidence of PM implantation. Subgroup analyses were conducted according to the electrophysiological study (EPS) strategy (no EPS, selective EPS, or systematic EPS). Results and Conclusions: Twelve studies (n = 3,496) reported pacemaker implantation during follow-up and were included in the quantitative analysis. A total of 752 pacemaker implantations occurred during follow-up. The pooled incidence of PM implantation was 14% (95% CI 10–20%), with high heterogeneity across studies (I^2 = 93.4%). When stratified by EPS strategy, studies without EPS reported a pooled PM implantation rate of 7% (95% CI 4–12%), whereas studies using selective EPS reported a rate of 17% (95% CI 12–24%). In studies employing systematic EPS strategies, the pooled rate increased to 21% (95% CI 11–38%). Meta-regression showed that the EPS strategy was significantly associated with PM implantation rates, whereas follow-up duration was not. Figure 1 summarizes these findings. In summary, higher PM implantation rates in studies adopting systematic electrophysiological evaluation suggest that the screening strategy may substantially influence device indication and clinical management in DM1 patients.

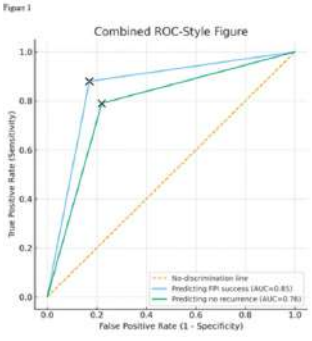
PREDICTORS OF SUCCESS USING AUTOMARK ANALYSIS AND A CONTACT FORCE FLEXIBLE-TIP CATHETER IN ATRIAL FIBRILLATION ABLATION



GUILHERME MOREIRA PIZETTA1; HENRIQUE TEIXEIRA GIESTAS SERPA1; THAIS COUTINHO NICOLA1; EDUARDO SERPA1; LUISA CARVALHO BENEDITO1; CHRISTIANO LEMOS DA CUNHA1; CARLOS ALEXANDRE VOLPONI LOVATTO1; ALOYR SIMOES JR.1; FABRICIO SARMENTO VASSALLO1; LUIZ FERNANDO MACHADO BARBOSA1;

(1) HOSPITAL SANTA CASA DE MISERICORDIA DE VITORIA - VITÓRIA - ES - BRASIL;

Background/Introduction: Background: Ultra-HPSD (90 W/4 s) ablation is effective and safe but requires dedicated RF generators. Contact-force flexible-tip catheters (FTC) allow higher power with conventional generators. Automark Analysis ApplicationTM (AAA) enables post-procedure lesion analysis to optimize quality. Objectives: Objective: To assess AAA in identifying variables associated with first-pass isolation (FPI) and arrhythmia recurrence using FTC with high-power short-duration (HPSD) and Very-HPSD strategies. Methods: Methods: First-time AF ablation was performed in 38 consecutive patients, mean follow-up 11.9±6.3 months. Power 60–70W, contact force 10–20 g anterior and 5–10 g posterior wall, irrigation 20 ml/min. If current >850 mA, power reduced to 55–50W. Results and Conclusions: Results: 29 male, 63.5±13.5 years, BMI 28.6±4.2, 22 (57.9%) paroxysmaL, CHA2DS2-VA 2.6±1.6, LA volume index 42.±14.5mm, ejection fraction 62±8.4%. Mean LA dwell time and procedure time 55±10.3 and 72.5±11.5min, respectively. Total RF delivery time 983.2±218.8 and first-pass isolation (FPI) in 29 (76.3%) patients. Esophageal temperature rise >1°C in 14 patients [(36.8%) mean increase of 1.3±0.5°C]. According to AAATM, predictors of success were: FPI, average Automark IndexTM (AI), average contact force, average tip stability and lateral force (Table 1). Average AI of ≥38 was the strongest independent predictor of first-pass isolation (adjusted OR 18.4, 95% CI 3.1–109; p=0.003) with 96% success rate versus 67% below this threshold (figure 1). FPI was the strongest predictor of arrhythmia-free survival (adjusted OR 0.05, 95% CI 0.006–0.42, p=0.006). Predictors of achievement of FPI: higher average contact force (9.9vs7.2g, p=0.048) and better catheter tip stability (1.0vs1.6mm, p=0.032). Independently of FPI, each 10-unit increase in AI was associated with a 56% reduction in recurrence risk (adjusted OR 0.44, 95% CI 0.20–0.97, p=0.043). One pericardial effusion occurred 20 days post-procedure in a patient treated with 60W. Conclusion: In HPSD and Very-HPSD AF ablation, AI independently predicts procedural success and long-term arrhythmia-free survival. Targeting AI ≥38 with optimal catheter stability should be adopted to improve outcomes.

Table 1: predictors of success (no recurrence) and First-Pass Isolation (FPI)

Variable	No recurrence (n=29)	Recurrence (n=9)	p-value	FPI achieved (n=32)	FPI not achieved (n=6)	p-value
First-Pass Bilateral Isolation	97%	56%	0.004	—	—	—
Recurrence rate with FPI	—	—	—	6%	50%	0.004
Average Automark Index	46.0 ± 16.4	34.2 ± 18.1	0.047	47.1 ± 16.1	29.3 ± 15.5	0.009
Average contact force (g)	10.1 ± 4.4	8.0 ± 3.3	0.08	10.2 ± 4.3	7.1 ± 2.9	0.035
Average tip stability (mm)	1.1 ± 0.6	1.4 ± 0.8	0.19	1.0 ± 0.5	1.8 ± 0.9	0.012
Lateral force (%)	81.5 ± 5.5	78.9 ± 6.2	0.21	81.8 ± 5.3	77.2 ± 6.8	0.06

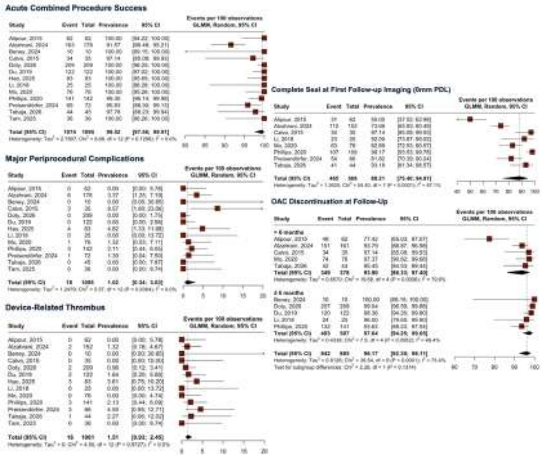
PURELY ANGIOGRAPHIC GUIDANCE FOR TRANSSEPTAL PUNCTURE IN ATRIAL FIBRILLATION ABLATION: A SINGLE-CENTER EXPERIENCE IN 476 CASES FROM BRAZIL

ALFREDO AURÉLIO MARINHO ROSA FILHO1; MARIA CLARA DE SOUZA XAVIER2; PEDRO VINICIUS SANTOS DE MEDEIROS3; LUCAS BRANDAO CAVALCANTE4; ADRIANO DE HOLANDA PEDROSA2; JORGE FRANCISCO DA SILVA FILHO5; ALFREDO AURELIO MARINHO ROSA6; EDVALDO FERREIRA XAVIER JUNIOR6;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (2) CENTRO UNIVERSITARIO CESMAC - MACEIO - SP - BRASIL; (3) UNCISAL - MACEIO - AL - BRASIL; (4) CENTRO UNIVERSITARIO DE MACEIO - UNIMA / AFYA - MACEIO - SP - BRASIL; (5) REAL HOSPITAL PORTUGUES - RECIFE - PE - BRASIL; (6) SANTA CASA DE MISERICORDIA DE MACEIO - MACEIÓ - SP - BRASIL;

Background/Introduction: Introduction: Pulmonary Vein Isolation (PVI) is the gold standard for rhythm control in atrial fibrillation (AF). Access to the pulmonary veins is universally achieved via transseptal puncture, traditionally guided by transesophageal echocardiography (TEE) or, as in this study, by angiography alone. Optimizing the safety and efficacy of transseptal puncture is crucial. Objectives: Objective: To present our center's experience with purely angiographic transseptal puncture guidance, evaluating its safety, efficacy, and impact on procedure time in 476 patients undergoing AF ablation. Methods: Material and Methods: Between March 2006 and September 2025, 476 patients underwent PVI. In 100% of cases, transseptal puncture was guided exclusively by angiography. Patients were sedated. Catheters were positioned in the coronary sinus (CS) and a "pigtail" catheter in the aortic valve plane. Fluoroscopy was set to 45° Left Anterior Oblique (LAO) projection. The puncture needle was advanced to the fossa ovalis, and the interatrial septum marked by contrast injection. After puncture, the sheath was advanced. Two transseptal punctures were typical for conventional or EnSite mapping. 5,000 IU of Heparin administered post-puncture. Catheters removed after isolation confirmation, followed by local compressive dressing. Results and Conclusions: Results: The cohort (23-83 years, 72.9% male) presented with Paroxysmal AF (67%), Persistent (16.37%), and Permanent (16.63%). Ablation methods: conventional PVI (3.7%), EnSite mapping (46.8%), PVAC (10.8%), and Cryoablation (38.7%). Complications were minimal: one cardiac tamponade (0.21%), managed by pericardiocentesis without sequelae; two cases (0.42%) of impossible puncture due to post-cardiac surgery anatomy. Crucially, zero esophageal injuries. Two transient phrenic nerve palsies (0.42%) occurred with Cryoablation. Average procedure time was 90 ± 15 minutes, demonstrating efficiency. Conclusion: Despite technological advancements in guidance, this large, experienced cohort demonstrates that the purely angiographic method for transseptal puncture remains a safe and effective strategy. Its continued use in experienced centers offers low complication rates, reduced cost, optimized operating room time, and lower ionizing radiation exposure.



19319

SAFETY AND EFFICACY OF CONCOMITANT ATRIAL FIBRILLATION ABLATION AND LEFT ATRIAL APPENDAGE OCCLUSION: A SYSTEMATIC REVIEW AND SINGLE-ARM META-ANALYSIS

CAIO RODRIGUES ROSA1; RICARDO FONSECA OLIVEIRA SURUAGY MOTTA2; RONALDO VICTOR SANTOS CASADO2; LEONARDO DEXHEIMER DA SILVA3; NATHALIA SCHETTINO SAMAD4; ANISIO UCHOA LEITE SANTANA3; ALFREDO AURÉLIO MARINHO ROSA5; SAULO RODRIGO RAMALHO DE MORAES2; ALEXANDRA RÉGIA DANTAS BRIGIDO6; GUILHERME DAGOSTIN DE CARVALHO7;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) CENTRO UNIVERSITARIO CESMAC - MACEIO - AL - BRASIL; (3) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (4) NEW YORK UNIVERSITY - UNITED STATES; (5) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (6) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - MG - BRASIL; (7) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - MG - BRASIL;

Background/Introduction: Catheter ablation (CA) and left atrial appendage occlusion (LAAO) address the two pillars of atrial fibrillation (AF) management: rhythm control and stroke prevention. Although both are well established individually, combining them in a single session has raised concerns about longer procedural duration, incremental procedural risk, device sealing performance, and device-related thrombus (DRT). Emerging evidence suggests that performing both during the same session is feasible and cost-effective, but pooled estimates across the growing literature remain lacking. Objectives: This systematic review and meta-analysis seeks to provide pooled estimates of procedural success, safety, device performance, and anticoagulation (OAC) discontinuation following same-session AF ablation and LAAO. Methods: We systematically searched PubMed, Embase, Web of Science, Scopus, and the Cochrane Central Register of Controlled Trials, following PRISMA guidelines. Eligible studies were prospective or retrospective cohorts that reported device-level outcomes of combined CA and percutaneous LAAO. The outcomes of interest included procedural success, major periprocedural complications, DRT at first follow-up imaging, complete seal (0 mm peri-device leak), and OAC discontinuation. Pooled prevalences with 95% confidence intervals (CIs) were estimated using generalized linear mixed models under random effects. Heterogeneity was assessed with the I² statistic. Analyses used the meta package in R (version 4.5.2). Results and Conclusions: After screening the records, fourteen studies met the inclusion criteria, and thirteen (n=1,095) provided device-level data for the meta-analysis. Acute procedural success was 99.5% (95% CI 97.6–99.9; I²=0%). Major periprocedural complications occurred in 1.0% (95% CI 0.3–3.0; I²=0%). DRT at first follow-up imaging was 1.5% (95% CI 0.9–2.5; I²=0%). The pooled analysis reported a complete seal (0mm PDL) at first follow-up of 88.2% (95% CI 75.4–94.8; I²=87.1%). OAC was discontinued in 96.2% (95% CI 92.4–98.1; I²=75.4%); the lower rate in longer-follow-up studies likely reflects reinitiation for AF recurrence. Same-session AF ablation and LAAO is feasible with high procedural success (99.5%), low rates of major complications (1.0%) and DRT (1.5%), and OAC discontinuation in over 96% of patients. Complete seal was achieved in 88.2% of patients, though definitions varied across studies. These findings support the combined approach for selected patients, but warrant confirmation through comparative trials.

Background/Introduction: Introduction: Atrial fibrillation (AF) is associated with an increased risk of adverse outcomes, particularly in older patients and those with comorbidities. Recent studies have demonstrated the efficacy of switching from vitamin K antagonists (VKAs), such as warfarin, to direct oral anticoagulants (DOACs) in the treatment of patients with AF. However, the benefits of this transition in frail elderly patients are still unclear. Objectives: Objectives: This study aimed to evaluate the safety of switching from VKA to DOACs, compared with continued VKA use, in frail older patients with AF. Methods: Methods: PubMed, Embase, Cochrane and Web of Science were systematically searched from inception to January 2026. We included randomized controlled trials (RCTs) and cohort studies comparing switching from VKA to DOACs versus continued VKA use in frail older patients (≥60 years) with AF. The outcomes assessed were thromboembolic events, all-cause death, major bleeding, intracranial hemorrhage, and gastrointestinal bleeding. Risk ratios (RRs) with 95% confidence intervals (CIs) were pooled using a random-effects model, and statistical heterogeneity was assessed using the I² statistic. Results and Conclusions: Results: Three studies were included, totaling 267,746 patients (133,922 in the DOACs group and 133,824 in the VKA group), with a mean age ranging from 79.33 to 83.0 years. Switching to DOACs was associated with a significantly lower overall risk of intracranial hemorrhage (RR: 0.54; 95% CI: 0.31–0.95) and mortality (RR: 0.84; 95% CI: 0.75–0.93) compared with continued use of VKA. Furthermore, no significant differences were observed for thromboembolic events, major bleeding, and gastrointestinal bleeding. Conclusion: Switching from VKA to DOACs in frail older patients with AF was associated with a lower risk of intracranial hemorrhage and mortality, with no significant differences in thromboembolic events or bleeding compared with continued VKA use. These results suggest a potential safety in switching from VKAs to DOACs in this population.

Background/Introduction: Historically, clinical guidelines have underestimated the thrombogenic risk of thyrotoxic atrial fibrillation (AF), based on the premise that the arrhythmia would be benign once euthyroidism is restored. However, evidence indicates that the acute risk is critical. This study proposes a paradigm shift: in the acute phase, hormonal imbalance acts as a potent prothrombotic and arrhythmogenic trigger. In the chronic phase, prolonged cardiotoxicity leads to atrial remodeling and persistent fibrosis, which perpetuate the arrhythmia and increase failure rates in ablation and cardioversion procedures, even after thyroid stabilization. Objectives: To compare the ischemic risk and prognostic outcomes of thyrotoxic AF versus non-thyroid AF. Methods: Systematic review following PRISMA(Fig. 1.D) guidelines, with a meta-analysis based on the random-effects model. The PICO(Fig. 1.A) protocol was used to assess outcomes (stroke, mortality, and AF) and descriptors(Fig. 1.B). On search platforms (Fig. 1.C) Longitudinal cohort studies were prioritized to ensure temporal validity, while cross-sectional studies were used only for narrative support. Hazard ratio (HR) and odds ratio (OR) data were standardized via logarithmic transformation and standard error. Heterogeneity was controlled using the I² statistic in the meta package (R software). The study is registered on the OSF platform. Results and Conclusions: A temporal difference in the risk profile was identified: Acute Ischemic Risk (<1 year) showed an HR of 1.14 [1.09; 1.19], confirming the first year post-diagnosis as a window of high thrombogenic vulnerability. In the Long-Term (>1 year), the risk declines (HR 0.74 [0.65; 0.85])(Fig. 2), suggesting an overlap of traditional comorbidities. Patients with a history of thyrotoxicosis exhibit greater resistance to interventions, evidencing permanent structural damage to the atrial myocardium. The data suggest a distinct progression of atrial remodeling; the window of opportunity observed in the data trends indicates that if reversion to sinus rhythm does not occur within the first 6 months post-euthyroidism, the probability of success in interventions drops drastically. Thus, anticoagulation should be immediate, without awaiting thyroid normalization. In late follow-up, decision-making should be based on the CHA2DS2-VASc score and patient comorbidities. The clinical challenge of thyrotoxic AF lies in its temporality: high acute risk and persistent atrial damage require protocol that consider the duration of disease.

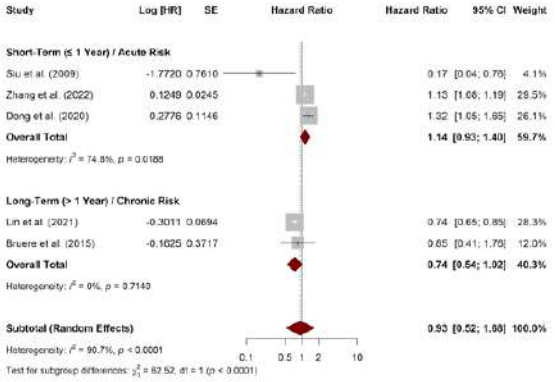

Figure 2. Ischemic Risk and MACE in Thyrotoxic vs. Non-Thyroidal Atrial Fibrillation.
Forest plot demonstrating the temporal dichotomy of ischemic risk. In the short-term phase (≤ 1 year), thyrotoxicosis acts as a severe arrhythmogenic trigger, significantly increasing the risk of adverse events (HR 1.14; 95% CI: 1.09–1.19). In the long-term phase (> 1 year), following the restoration of the euthyroid state, the relative risk decreases (HR 0.74; 95% CI: 0.65–0.85), indicating that chronic prognosis is primarily driven by traditional CHA2DS2-VASc comorbidities rather than baseline thyroid status.

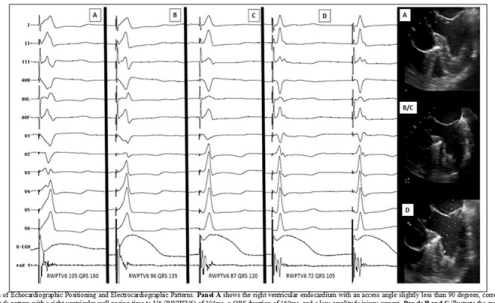
TRANSESOPHAGEAL ECHOCARDIOGRAPHY VERSUS FLUOROSCOPY-GUIDED LEFT BUNDLE BRANCH AREA PACING: A SINGLE-CENTER COMPARATIVE COHORT STUDY

GABRIEL ODOZYNSKI1; GRAZYELLE DAMASCENO2; CLÓVIS FROEMMING2; THIAGO VIÇOSO DOS SANTOS2; BRUNA MAY2; MARCIO LOSSO2; MARIO ZUNINO2; PEDRO BURIGO COSTA2; JONATHAN WARREN WAKS1; ANDRE D'AVILA2; ALEXANDER DAL FORNO2;

(1) BETH ISRAEL DEACONESS MEDICAL CENTER - UNITED STATES; (2) HOSPITAL DE CARDIOLOGIA SOS CARDIO - FLORIANOPOLIS - SC - BRASIL;

Background/Introduction: Left bundle branch area pacing (LBBAP) has emerged as a physiological alternative to conventional ventricular pacing. However, optimal intraseptal lead placement remains technically challenging, and the role of intraprocedural imaging guidance has not been systematically evaluated. Objectives: To determine whether transesophageal echocardiography (TEE) guidance improves procedural efficiency and electrical outcomes compared with conventional fluoroscopy-only guidance during LBBAP implantation. Methods: Single-center, retrospective, non-randomized cohort study enrolling 405 consecutive patients undergoing LBBAP between January 2018 and March 2025. The initial 198 patients were implanted under fluoroscopy guidance alone; the subsequent 207 patients underwent TEE-guided implantation. Primary endpoints included total procedure time, fluoroscopy time, post-procedural QRS duration, R-wave peak time in lead V6, and final lead impedance. Subgroup analysis was performed for patients with baseline wide QRS (<120 / 120-140 / >140 ms). Results and Conclusions: TEE-guided LBBAP was associated with significantly shorter total procedure time (65.5±25.2 vs. 89.9±37.9 min; p<0.001) and fluoroscopy time (12.8±9.9 vs. 15.8±10.5 min; p<0.001). Post-procedural QRS duration was narrower in the TEE group (108±16 vs. 116±15 ms; p<0.001), with a greater reduction in patients with baseline wide QRS (ΔQRS: −54±23 vs. −46±21 ms; p<0.001). Lead impedance was significantly lower with TEE guidance (523.6±115.6 vs. 611.3±155.9 Ω; p<0.001), while pacing thresholds and R-wave amplitudes were comparable. Complication rates were low and similar between groups. TEE-guided LBBAP implantation improves procedural efficiency and electrical resynchronization, supporting its incorporation into conduction system pacing protocols. Prospective randomized evaluation is warranted.



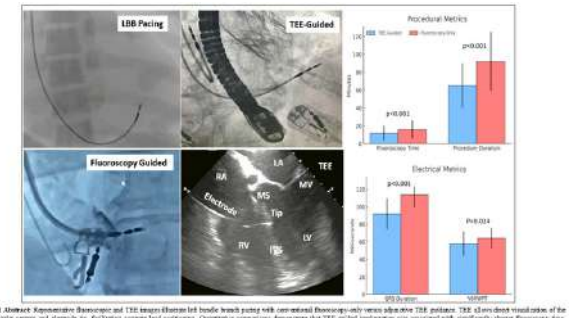


Fig 1 Correlation of Echocardiographic Positioning and Electrocardiographic Patterns. **Panel A** shows the right ventricular endocardium with an access angle slightly less than 90 degrees, corresponding to a left bundle-branch block pattern with a right ventricular wall pacing time to V6 (RWPTV6) of 105ms, a QRS duration of 160ms, and a low-amplitude injury current. **Panels B and C** illustrate the gradual narrowing of the QRS complex, shortening of the RWPTV6, and an increase in the injury current as the electrode advances through the mid-interventricular septum toward the left ventricular endocardium, without the development of an r wave in lead V1. **Panel D** depicts the final electrode position, with an access angle slightly less than 90 degrees and in intimate contact with the left ventricular endocardium. This position is associated with a QRS duration of 105ms and an RWPTV6 of 72ms. The electrode's proximity to the left ventricular outflow tract and the aortic root is noted.

Graphical Abstract Representative fluoroscopic and TEE images illustrate left bundle branch pacing with conventional fluoroscopy-only versus adjunctive TEE guidance. TEE allows direct visualization of the interventricular septum and electrode tip, facilitating accurate lead positioning. Quantitative comparisons demonstrate that TEE-guided implantation was associated with significantly shorter fluoroscopy time, comparable or reduced procedure duration, and improved electrical outcomes, including narrower QRS durations and shorter V6 R wave peak time. RA = right atrium; RV = right ventricle; LA = left atrium; LV = left ventricle; MV = mitral valve; MS = membranous septum; IVS = interventricular septum. TEE = transesophageal echocardiography; LBBP = left bundle branch pacing; RWPT = R-wave peak time.

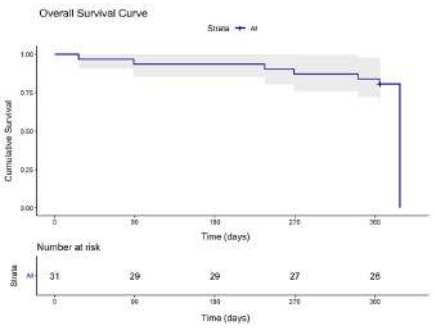
UNMASKING THE RISK: CLINICAL PROFILE AND OUTCOMES IN PATIENTS WITH MASQUERADING BUNDLE BRANCH BLOCK



MATHEUS SACCO GOMES1; MARIO HENRIQUE CALIANO1; PATRICIA DE SOUZA MAGALHÃES1; BRUNO LEAL MARTINS1; AMANDA RAQUEL COSTA CRUZ1; JOSE NUNES DE ALENCAR1; MATHEUS KISZKA SCHEFFER1; MARIANA FUZIY NOGUEIRA DE MARCHI1; SANDRO PINELLI FELICIONI1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Background/Introduction: Masquerading bundle branch block (MBBB) is a rare electrocardiographic pattern characterized by the concomitance of right bundle branch block (RBBB) and left anterior fascicular block (LAFB). Unlike classic RBBB, lead I presents with a pure and slurred R wave, mimicking the pattern observed in left bundle branch block (LBBB). Initially described by Richman and Wolff, MBBB usually reflects diffuse and advanced left ventricular impairment. Although recognized for decades, this condition remains poorly characterized in contemporary populations. Objectives: To determine the epidemiological, etiological, and prognostic profile of patients diagnosed with masquerading bundle branch block from July 2022 to December 2024. Methods: This is an observational, exploratory, and retrospective study. Consecutive patients meeting the electrocardiographic criteria for MBBB were included. A descriptive analysis of demographic, clinical, and echocardiographic variables was performed. Data normality was verified using the Shapiro-Wilk test. For the univariate association analysis with the outcome of death, Student's t-test or Fisher's exact test was used as appropriate. Overall survival was estimated using the Kaplan-Meier method. A p-value < 0.05 was considered statistically significant. Results and Conclusions: The sample consisted of 31 predominantly male patients (74.2%), with a mean age of 70.8 years. The predominant etiologies were ischemic heart disease (32.2%) and Chagas disease (29.0%). Baseline analysis showed a mean QRS duration of 150 ms and a mean LVEF of 38%. Overall 1-year survival was 80.6% (95% CI: 67.9% – 95.8%). In the univariate analysis, LVEF demonstrated a statistical association with mortality: patients who died had a significantly lower LVEF than survivors (21.8% vs. 42.8%; p < 0.001). There were no deaths among patients with an LVEF > 40%. Exploratory variables suggested a higher risk profile, although lacking statistical significance in this sample: Chagasic etiology (OR 4.02; p = 0.16), previous AMI (OR 3.80; p = 0.17), and longer QRS duration (169 ms in deaths vs. 147 ms in survivors; p = 0.17). Reduced LVEF was the main determinant of short-term mortality. Additionally, the high prevalence of ischemic and Chagasic etiologies, coupled with a potentially worse outcome associated with QRS widening, reinforces the need for rigorous clinical surveillance and early therapeutic optimization in these patients.

Demographics

Background/Introduction: Chronic right ventricular (RV) apical pacing in dual-chamber pacemaker recipients can induce electrical and mechanical dyssynchrony, culminating in pacing-induced cardiomyopathy, compromised systolic function, and symptomatic heart failure (HF). Upgrading to multisite pacing (MSP), or cardiac resynchronization therapy (CRT), is a physiological intervention designed to restore ventricular synchrony and optimize hemodynamics. Current evidence highlights its efficacy in improving left ventricular ejection fraction (LVEF) and functional capacity. Objectives: To evaluate the clinical and hemodynamic outcomes of patients undergoing an upgrade from a conventional dual-chamber pacemaker to MSP at a specialized tertiary center. Methods: A retrospective analysis was conducted on 71 patients out of 914 MSP implantations performed between March 2006 and October 2025. Inclusion criteria comprised patients upgraded from a dual-chamber pacemaker to MSP due to widened QRS complexes secondary to chronic RV pacing, ventricular dyssynchrony, and refractory HF symptoms despite guideline-directed medical therapy (GDMT). The surgical technique involved coronary sinus cannulation and left subclavian vein puncture, guided by venography for optimal left ventricular lead placement. Device programming was tailored to achieve the narrowest QRS duration. Baseline characteristics and follow-up echocardiographic data, specifically LVEF, were analyzed. Results and Conclusions: The study cohort (n=71) accounted for 7.8% of all MSP procedures. The mean patient age was 60.5 years (range: 45–76), with a male predominance (64.8%). The primary underlying etiologies were Chagas cardiomyopathy (47.9%), ischemic heart disease (22.5%), and valvular heart disease (11.3%). The procedural and clinical success rate was 77.5%, with no peri- or post-procedural complications reported. A majority of the cohort (77.5%) received a CRT-defibrillator (CRT-D) device. At the 12-month follow-up, a clinically significant improvement in LVEF was observed in 52 patients (73.2%). Upgrading from a dual-chamber pacemaker to MSP is a safe and effective intervention for patients with pacing-induced dyssynchrony and refractory heart failure. The procedure yields a high success rate and promotes significant echocardiographic improvement, evidenced by increased LVEF in 73.2% of patients, thereby conferring substantial hemodynamic and functional benefits.

WARFARIN USE IS ASSOCIATED WITH WORSE BONE MARKERS COMPARED WITH DOACS

RAFAEL VIANNA BEHR1; CAUAN TRAMONTINI DIAS1; PATRICIA AMORIM GROISMAN1; ANA LAURA ROCHA MACHADO1; POLI MARA SPRITZER1; FERNANDO PIVATTO JÚNIOR1; TAYANE MUNIZ FIGHERA1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: Warfarin has been associated with impaired bone health, likely due to its antagonism of vitamin K, which plays a role in bone matrix formation. However, the impact of direct oral anticoagulants (DOACs) remains unclear. The main bone markers, obtained by densitometry, are the quantitative assessment by bone mineral density (BMD) and the qualitative assessment by trabecular bone score (TBS). Objectives: To evaluate bone markers in patients using DOACs and warfarin. Methods: Matched cross-sectional study design, including patients from Cardiology or Internal Medicine outpatient clinics of a tertiary hospital, aged 40 - 75 years, on anticoagulation for > 1 year, divided into DOAC and warfarin groups. A control group not receiving anticoagulation was included. The groups were matched by sex, age ± 4.0 years, and body mass index (BMI) ± 4.0 kg/m². Patients underwent BMD and TBS assessments. Results and Conclusions: A total of 108 patients were included (36 per group); mean age 65.3 ± 7.5 years; BMI 29.4 ± 3.7 kg/m²; 52.8% male; 78.7% with hypertension; 30.6% with diabetes; 25.9% with eGFR < 60 mL/min/1.73 m²; and 8.3% smokers. Baseline characteristics did not differ between groups. Warfarin users had lower lumbar spine BMD, both in absolute values (warfarin 1.141 ± 0.161; DOACs 1.265 ± 0.238; control 1.191 ± 0.179; p = 0.029) and in T-score assessment (warfarin 0.0 ± 1.3; DOACs +0.7 ± 2.0; control +0.1 ± 1.5; p = 0.029). There was no statistically significant difference in femoral neck or total hip BMD. No statistically significant difference was observed in TBS in the overall sample; however, in the female subgroup, warfarin users showed a trend toward lower TBS compared with controls. In conclusion, patients receiving warfarin exhibited worse bone-related markers, suggesting a potential increased risk of bone deterioration. Conversely, this study is among the first to evaluate bone markers in DOAC users, with findings that do not suggest a detrimental effect.

Background/Introduction: Fluoroscopy reduction strategies during catheter ablation are increasingly adopted to minimize radiation exposure. However, it remains uncertain if reduced-fluoroscopy approaches maintain procedural efficacy and safety. Objectives: This study aimed to evaluate the efficacy and safety of zero- or near-zero fluoroscopy ablation compared with conventional fluoroscopy for atrial fibrillation. Methods: PubMed, Embase, Cochrane Central, and ClinicalTrials.gov were systematically searched through October 2025 for randomized controlled trials (RCTs) comparing reduced-fluoroscopy versus conventional ablation in atrial arrhythmias. To minimize clinical heterogeneity, only trials with ≤10-min fluoroscopy in the intervention arm were included. Subgroup analyses stratified trials by Energy and Map type. Analysis used risk ratio (RR) with 95% confidence intervals (CI) for dichotomous outcomes and mean differences (MD) for continuous outcomes were estimated using a random-effects model with the Restricted Maximum Likelihood estimator. Results and Conclusions: Seven randomized controlled trials comprising 1,170 patients were included, with 583 assigned to zero/near-zero fluoroscopy (ZNF) and 587 to conventional fluoroscopy (CF). Acute procedural success was identical between groups, with no difference observed (RR 1.00, 95% CI 0.99–1.01; p = 1.00; I² = 0%). Complication rates were also comparable (34/583 vs 34/587), with no significant difference between strategies (RR 1.03, 95% CI 0.65–1.62; p = 0.91; I² = 0%). Procedure time did not differ significantly between groups (MD −0.65 minutes, 95% CI −4.82 to 3.53; p = 0.72; I² = 25%). Across all predefined subgroup analyses (energy source, mapping strategy, and fluoroscopy duration), no evidence of effect modification was observed. Sensitivity analyses using a leave-one-out approach confirmed the robustness of all findings, with stable effect estimates and no relevant heterogeneity. ZNF ablation demonstrated equivalent efficacy, safety, and procedural efficiency compared with CF in atrial fibrillation. Given the well-established risks of ionizing radiation and occupational burden associated with lead apron use, these findings support the adoption of fluoroscopy-minimizing strategies as a contemporary standard in AF ablation workflows.

Background/Introduction: Supraventricular tachycardias (SVTs), including atrioventricular nodal and atrioventricular reentrant tachycardias, are commonly treated with catheter ablation, a highly effective strategy. Fluoroscopy has traditionally been essential for catheter guidance; however, cumulative radiation exposure poses relevant risks to both patients and operators, including increased malignancy risk and occupational hazards Objectives: To evaluate the efficacy and safety of zero- or near-zero fluoroscopy compared with conventional fluoroscopy-guided catheter ablation in patients with supraventricular tachycardias. Methods: PubMed, Embase, Cochrane Central, and ClinicalTrials.gov were systematically searched through October 2025 for randomized controlled trials (RCTs) comparing reduced-fluoroscopy versus conventional ablation in atrial arrhythmias. To minimize clinical heterogeneity, only trials with ≤10-min fluoroscopy in the intervention arm were included. Subgroup analyses stratified trials by Energy and Map type. Analysis used risk ratio (RR) with 95% confidence intervals (CI) for dichotomous outcomes and mean differences (MD) for continuous outcomes were estimated using a random-effects model with the Restricted Maximum Likelihood estimator. Results and Conclusions: Nine randomized controlled trials comprising 903 patients undergoing catheter ablation for supraventricular tachycardias were included, with 583 assigned to zero/near-zero fluoroscopy (ZNF) and 587 to conventional fluoroscopy (CF). Acute procedural success was identical between groups, with no difference observed (RR 1.00, 95% CI 0.99–1.01; p = 0.91; I² = 0%). Complication rates were also comparable (7/448 vs 6/455), with no significant difference between strategies (RR 1.08, 95% CI 0.37–3.22; p = 0.88; I² = 0%). Procedure time did not differ significantly between groups (MD 0.07 minutes, 95% CI −13.72 to 13.86; p = 0.99; I² = 89%). Reduced-fluoroscopy ablation demonstrated equivalent success, safety, and procedure timecompared with conventional fluoroscopy in SVT. Given the known harms of radiation exposureand lead apron use, these findings support the use of reduced fluoroscopy techniques as a preferred ablation strategy.

Background/Introduction: Anthracycline-induced cardiotoxicity remains a major limitation of cancer therapy and may lead to ventricular dysfunction and interruption of oncologic treatment. Universal prophylactic cardioprotection has yielded inconsistent results in randomized trials. Biomarker-guided initiation of neurohormonal blockade following early myocardial injury detection has emerged as a potential individualized strategy. Objectives: To evaluate whether biomarker-guided neurohormonal cardioprotection reduces ventricular dysfunction in patients with evidence of myocardial injury during anthracycline therapy. Methods: We performed a systematic review and meta-analysis of randomized controlled trials evaluating neurohormonal blockade initiated after biomarker-defined myocardial injury during anthracycline therapy. The primary outcome was ventricular dysfunction, defined in each trial by significant decline in global longitudinal strain or reduction in left ventricular ejection fraction. Risk ratios were pooled using a random-effects model. Heterogeneity was assessed using I² statistics, and leave-one-out sensitivity analyses were performed. Results and Conclusions: Three randomized trials including 280 patients were analyzed. Biomarker-guided neurohormonal cardioprotection was associated with a numerically lower risk of ventricular dysfunction; however, the pooled random-effects estimate was imprecise and did not reach statistical significance (RR 0.32, 95% CI 0.02–5.04; I²=78%). Leave-one-out analyses demonstrated instability of the pooled estimate, particularly influenced by the Cardinale trial. Biomarker-guided cardioprotection may represent a promising individualized strategy during anthracycline therapy, but current randomized evidence remains limited by substantial heterogeneity and imprecision. Larger contemporary randomized trials using standardized biomarker and imaging-based definitions are needed before routine implementation can be recommended.

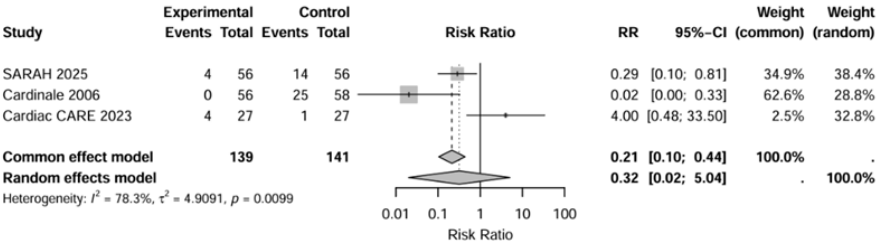

Figure 1. Exploratory random-effects meta-analysis of biomarker-triggered neurohormonal cardioprotection and ventricular dysfunction during anthracycline therapy

CARDIOVASCULAR DISEASE AS A CO-OCCURRING CAUSE OF DEATH IN CANCER PATIENTS IN BRAZIL (2000–2023): A NATIONWIDE MULTIPLE-CAUSE-OF-DEATH ANALYSIS

DANIEL HIGOR DA SILVA BARROS1;

(1) UNIVERSIDADE CATOLICA DE BRASILIA - BRASÍLIA - DF - BRASIL;

Background/Introduction: As cancer survival improves globally, cardiovascular disease (CVD) has emerged as a major competing cause of death. However, nationwide multiple-cause-of-death (MCCOD) analyses in cardio-oncology remain scarce in middle-income countries, limiting understanding of mortality dynamics in these settings. Objectives: To quantify the proportion of cancer deaths with CVD as an associated cause and to analyze temporal trends and regional disparities in Brazil. Methods: Ecological time-series study using the Brazilian Mortality Information System (SIM/DATASUS), applying a MCCOD approach. We included individuals aged 35–74 years (2000–2023). The primary outcome was the proportion of cancer deaths (ICD-10 C00–C97) with CVD (I00–I99) listed as any associated cause. Age-standardized estimates (WHO 2000) were analyzed using joinpoint regression. A pre-specified primary period (2000–2019) and a sensitivity analysis (2020–2023) were defined to account for COVID-19-related disruptions. Analyses were stratified by geographic region. Results and Conclusions: The proportion of cancer deaths with CVD co-occurrence declined significantly from 14.2% (2000) to 12.0% (2019) (AAPC −0.77%/year; 95% CI −1.02 to −0.53; p<0.001), with a transient increase in 2020 (12.8%) and partial recovery by 2023 (12.2%). This decline reflects a structural shift in competing mortality risks rather than a direct improvement in cardiovascular outcomes. Concurrently, the population-level CVD-to-cancer mortality ratio decreased from 2.06 to 1.23, indicating progressive epidemiological convergence. Marked regional heterogeneity revealed a dual epidemiological burden: advanced decline in the South (AAPC −3.1%/year) versus increasing rates in the North (+0.8%/year). Ischemic heart disease and heart failure accounted for nearly half of CVD co-occurrence, consistent with established cardiotoxic mechanisms. Cardiovascular disease is a persistent and structurally integrated component of cancer mortality in Brazil. Despite a declining proportional trend, the coexistence of divergent regional patterns reveals a dual epidemiological burden unique to middle-income settings. These findings redefine the role of CVD in cancer mortality and support the urgent implementation of integrated, regionally tailored cardio-oncology strategies.

CLINICAL IMPACT OF 5-FLUOROURACIL–ASSOCIATED CORONARY VASOSPASM IN GASTROINTESTINAL CANCER: A GLOBAL FEDERATED ANALYSIS

ANA BEATRIZ NEPOMUCENO CUNHA1; GABRIEL MOSTARO FONSECA1; JULIANA CORRÊA DE OLIVEIRA CAIED1; FLAVIA CORTEZ COLOSIMO1; RÔMULO FONSECA DE MORAES1; BRUNA GONÇALVES GUSTINELLI1; ALINE SABRINA HOLANDA TEIXEIRA MORAES1; RIANE RODRIGUES MARTION1; MARCELO CAPITO CASTILHO1; YASMIN TRINDADE MEIRELES1; RODRIGO NORONHA CAMPOS1;

(1) BENEFICENCIA PORTUGUESA - SAO PAULO - SP - BRASIL;

Background/Introduction: Fluoropyrimidine-associated cardiotoxicity is a recognized complication of 5-fluorouracil (5-FU) therapy, with coronary vasospasm (CAS) representing the most common ischemic mechanism. Current cardio-oncology guidelines emphasize the importance of early recognition of 5-FU-related ischemic events because of their association with arrhythmias, hemodynamic instability, treatment interruption, and mortality. However, real-world data evaluating the prognostic impact of CAS in gastrointestinal cancer patients remain limited. Objectives: We aimed to evaluate the association between early CAS-related cardiotoxicity after 5-FU exposure and cardiovascular outcomes, intensive care unit (ICU) admission, and mortality in patients with digestive malignancies. Methods: We conducted a retrospective cohort study using the TriNetX Global Collaborative Network, including data from 173 healthcare organizations worldwide. Adult patients with digestive cancers (ICD-10 C15–C26) treated with 5-FU between January 1, 2016 and December 31, 2025 were identified. Patients were stratified according to the presence or absence of suspected CAS-related cardiotoxicity within 7 days after 5-FU exposure. CAS-related events were defined by ICD-10 codes consistent with acute ischemic presentations (I20, I21, R07) and/or troponin elevation ≥0.04 ng/mL. Propensity score matching was performed for age, sex, and cardiovascular comorbidities. Primary outcomes included 7-day incidence of arrhythmias (ICD-10 I47–I49), cardiac arrest (I46), and ICU admission. One-year all-cause mortality was evaluated as a secondary endpoint. Results and Conclusions: Among 99,845 patients receiving 5-FU for digestive malignancies, 1,357 (1.4%) developed CAS-related cardiotoxicity within 7 days. After propensity matching, patients with CAS-related cardiotoxicity had worse outcomes compared with those without CAS. Arrhythmias were more frequent in the CAS cohort (9.81% vs. 2.20%; RR 4.45; p<0.0001), as was cardiac arrest (0.84% vs. 0.00%; p=0.0009). ICU admission was significantly higher in the CAS cohort (4.79% vs. 0.84%; RR 5.73; p<0.0001). One-year all-cause mortality was also increased (34.27% vs. 28.56%; RR 1.20; p<0.0001). Early CAS-related cardiotoxicity following 5-FU exposure was associated with increased cardiovascular complications, greater healthcare utilization, and higher long-term mortality in patients with digestive cancers. These findings reinforce current recommendations advocating close surveillance during the first week after treatment.

FUNCTIONAL PROFILE AND AUTONOMIC FUNCTION OF PATIENTS UNDERGOING CHEMOTHERAPY AT RISK OF CARDIOTOXICITY: PRELIMINARY RESULTS

FELIPE CARDOZO MODESTO1; SERGIO L. S. M, C CHERMONT,1; FABIANO DE LIMA FREIRE1; FLAVIA CANDOLO PUPO BARBOSA1; CHRISTIANE RODRIGUES ALVES1; WOLNEY DE ANDRADE MARTINS1; MONICA MARIA PENA QUINTÃO1; ANTONIO JOSÉ LAGOETRO JORGE1;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL;

Background/Introduction: Background: Antineoplastic therapies show promising responses in cancer treatment. However, side effects can impair the functional physiological reserve of these patients due to the risk of cardiovascular changes during treatment. Little is known about the autonomic profile of these individuals. Objectives: Objective: To describe previously the autonomic function profile of patients undergoing chemotherapy at risk of cardiotoxicity and their functional frailty Methods: Methods: Patients from a reference oncology hospital (Rio de Janeiro, Brazil), diagnosed with lymphoma and designated for chemotherapy treatment with doxorubicin. They were evaluated before starting treatment. The cross-sectional protocol consisted of functional assessment with: measurement of respiratory muscle strength (RMS), spirometry, handgrip strength (HGS), 6-minute step test (6MST), time-domain heart rate variability (HRV) (SDNN; RMSSD), in addition to the Duke Activity Status Index (DASI) questionnaire and echocardiography. The applied statistics employed the t-test and Pearson correlation, p-value <0.05. Results and Conclusions: Results: Nine patients (5 men) were evaluated, 40±18 years old, BMI 29±3, baseline HR 92.9±14 bpm, BP 132.1±11.2 mmHg, LVEF 68±2.8%, estimated VO2 14.1±1.9 L/min. The functional assessment values were below the predicted values for FPM, dynamometry (27.2±11.7 vs. predicted 44.8±14) with FPM of 60.8±14.9%. In the FMR assessment, although PEmax was below the predicted value (84.4±23.7, predicted 91.1±10.9), it does not characterize an expiratory strength deficit, and PImax was preserved (measured -103.3±50.2, predicted -90.7±8.8). There was a restrictive response in spirometry, with reduced values for FEV1 (2.5±0.8, predicted 3.5±1.1) and FVC (2.9±1.2, predicted 3.7±1.7) with p<0.05, without altering the Tiffeneau index. Regarding the autonomic pattern, the SDNN was 58.3% of the predicted value adjusted for age (21.3 ± 8.5 vs 36.5±11.2 ms), and the RMSSD, 45% of the predicted value (17.2 ± 8.2 vs 37.5±11.5 ms). There was a correlation between FPM and the number of steps (r=0.759; p 0.018); FPM and DASI (r=0.868; p 0.002); DASI and number of steps (r= 0.733 p 0.025). Conclusion: Patients with lymphoma present with pre-treatment functional frailty, marked by muscle weakness, pulmonary restriction, resting tachycardia, and low VO2. Handgrip strength and the DASI questionnaire proved to be good predictors of physical fitness and the autonomic profile shows reduced HRV,

GLOBAL LONGITUDINAL STRAIN AS AN EARLY PREDICTOR OF CHEMOTHERAPY-RELATED CARDIOTOXICITY: A SYSTEMATIC REVIEW AND META-ANALYSIS

MARIA CLARA CHAGAS NEGRÃO DE ALMEIDA BARROS1; ARTUR DIAS PEREZ GRACA1; FERNANDO JOSÉ PEREZ DA SILVA GRAÇA2;

(1) FACULDADE DE CIÊNCIAS MÉDICAS DE SANTOS - UNILUS - SANTOS - SP - BRASIL; (2) UNIVERSIDADE FEDERAL DE RORAIMA - CURSO DE MEDICINA - BOA VISTA - RR - BRASIL;

Background/Introduction: Chemotherapy-related cardiotoxicity remains a major limitation of cancer therapy, often detected only after significant myocardial injury when assessed by left ventricular ejection fraction (LVEF). Global longitudinal strain (GLS) has emerged as a sensitive marker of subclinical myocardial dysfunction, but its predictive value across different populations remains to be fully established. Objectives: To evaluate the predictive performance of early GLS reduction for the development of chemotherapy-related cardiotoxicity. Methods: A systematic review and meta-analysis were conducted according to PRISMA guidelines. Studies assessing GLS by speckle-tracking echocardiography in patients undergoing potentially cardiotoxic chemotherapy were included. Data were extracted to reconstruct 2×2 contingency tables. A random-effects model (DerSimonian–Laird) was used to estimate pooled sensitivity, specificity, and odds ratio (OR). Heterogeneity was assessed using the I² statistic, and publication bias by Egger's test. This systematic review and meta-analysis was conducted according to PRISMA 2020 guidelines and was prospectively registered in the PROSPERO database 2026 - CRD420261342425. Results and Conclusions: Eleven prospective studies (n = 1,366 patients) were included. Early GLS reduction was a strong predictor of cardiotoxicity, with pooled sensitivity of 0.79 (95% CI: 0.74–0.83) and specificity of 0.85 (95% CI: 0.82–0.87). The pooled OR was 18.25 (95% CI: 10.54–31.59), indicating a robust association between early strain impairment and subsequent cardiac dysfunction. No significant heterogeneity (I^2 = 0%) or publication bias (p = 0.45) was observed. The negative predictive value was high (94.6%), supporting its reliability in excluding cardiotoxicity. Conclusion: Early GLS reduction is a robust and clinically actionable predictor of chemotherapy-related cardiotoxicity. Its high negative predictive value supports a reliable rule-out strategy, allowing safer continuation of oncologic therapy in patients with stable strain parameters. Incorporation of GLS into routine surveillance protocols may improve early risk stratification and optimize clinical decision-making in cardio-oncology.

IMPAIRED MUSCLE METABOREFLEX BLUNTS SYMPATHETIC AND PRESSOR RESPONSES TO STATIC HAND GRIP EXERCISE IN LONG-TERM BREAST CANCER SURVIVORS

JOÃO EDUARDO IZAIAS1; BRUNA E ONO1; ARTUR O SALES1; THAIS S RODRIGUES1; GABRIELLY MPS SILVA1; ROBERTA F LIMA1; CAMILA S NUNES1; MATHEUS A BITTENCOURT1; AMANDA G RODRIGUES2; RENATA J MOLL-BERNARDES1; ALLAN ROBSON KLUSER SALES3;

(1) INSTITUTO D'OR DE PESQUISA E ENSINO - RIO DE JANEIRO - RJ - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (3) INSTITUTO D`OR DE PESQUISA E ENSINO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Previous studies have reported blunted increases in blood pressure (BP) during physical exercise in cancer survivors treated with cardiotoxic chemotherapy. However, the sympathetic neural mechanisms underlying this attenuated response remain unknown Objectives: We hypothesized that long-term breast cancer (BC) survivors exhibit impaired muscle metaboreflex function, which would partially explain the reduced sympathetic–cardiovascular responses to exercise Methods: Nineteen BC survivors (age 49±2 years; body mass index [BMI] 27±1 kg/m²) and 14 sex-, age-, and BMI-matched controls (age 48±2 years; BMI 26±1 kg/m²) were studied. Muscle sympathetic nerve activity (MSNA, microneurography), mean arterial pressure (MAP, Finometer), stroke volume, cardiac output, and total peripheral resistance (SV, CO, and TPR; Modelflow), and heart rate (HR, ECG) were continually measured at baseline, during 3 min of static handgrip (HG) at 30% maximal voluntary contraction followed by post-exercise ischemia (PEI) to isolate muscle metaboreflex activation Results and Conclusions: BC survivors were evaluated ~ 9 years post-treatment. Changes in MAP during HG were attenuated in BC survivors versus controls, and this difference persisted during PEI (Δ12.0±2.0 vs. 21.0±2.0 mmHg, P=0.001). Similarly, the MSNA burst frequency response to HG was lower in BC survivors than controls, and the difference remained during PEI (Δ3.0±1.0 vs. 9.0±1.0 bursts/min, P=0.001). SV and CO were reduced during HG in BC survivors (P<0.05) but not during PEI. No group differences were observed in HR or TPR. Conclusion: Collectively, these findings indicate that the attenuated pressor and sympathetic neural responses to exercise in long-term BC survivors are explained, partially, by attenuated muscle metaboreflex control.

RESCUE IMMUNOSUPPRESSION AND CORTICOSTEROID STRATEGIES FOR IMMUNE CHECKPOINT INHIBITOR-ASSOCIATED MYOCARDITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

PEDRO HENRIQUE KADOR MAFFI1; MIGUEL LUCAS SILVA VALENTE1; KEVILYN ASSIS DE ALMEIDA1; ISABELLY DELLA JUSTINA FLORENTINO SILVA1; CLARICE VIUDES DE ABREU1; JOÃO VICTOR BATISTA PIRES1; ODILSON MARCOS SILVESTRE2;

(1) UNIVERSIDADE FEDERAL DO ACRE - RIO BRANCO - AC - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Background/Introduction: Immune checkpoint inhibitor-associated myocarditis (ICI-M) is uncommon but frequently fulminant. Evidence for rescue immunosuppression beyond corticosteroids remains limited. Objectives: To synthesize comparative evidence on corticosteroid intensity/timing and abatacept-based rescue therapy for ICI-M. Methods: A PRISMA-oriented systematic review and exploratory meta-analysis included studies with extractable treatment-outcome data. The primary endpoint was major adverse cardiovascular events (MACE). Secondary endpoints were all-cause death, cardiac death, biomarker rebound/sustained troponin elevation, steroid reinitiation/escalation, and additional immunosuppression. Risk ratios (RR) with 95% confidence intervals (CI) were estimated using Mantel-Haenszel models. Heterogeneity was assessed using Q, I^2 and tau^2. Results and Conclusions: Five full texts were assessed; three provided quantitative comparative data. The main pooled analysis included 2 studies and 217 patients comparing high-dose versus low-dose corticosteroids for MACE. High-dose corticosteroids reduced MACE from 36.1% to 15.3% (15/98 vs 43/119; pooled RR 0.33, 95%CI 0.19-0.56; p<0.001), with no detected heterogeneity (Q=0.20, p=0.65; I^2=0%; tau^2=0). Study-level estimates were consistent: Man_2025, RR 0.27 (95%CI 0.10-0.73; p=0.010), and Zhang_2020, RR 0.36 (95%CI 0.19-0.66; p=0.001). Early corticosteroid initiation within 24 hours was associated with lower MACE than initiation after 72 hours (3/43 vs 37/43; RR 0.08, 95%CI 0.03-0.24; p<0.001). High-dose methylprednisolone was associated with less biomarker rebound/sustained troponin elevation (17/44 vs 56/81; RR 0.56, 95%CI 0.37-0.83; p=0.004) and less steroid reinitiation/escalation (2/48 vs 40/96; RR 0.10, 95%CI 0.03-0.40; p=0.001). Additional immunosuppression was not reduced (28/48 vs 63/98; RR 0.91, 95%CI 0.69-1.20; p=0.498). All-cause mortality numerically favored high-dose steroids (14/46 vs 43/93; RR 0.66, 95%CI 0.40-1.07; p=0.094). In the only direct abatacept comparison, cardiac death did not differ (1/7 vs 2/16; RR 1.14, 95%CI 0.12-10.63; p=0.907), and all-cause death was imprecise (5/7 vs 6/16; RR 1.90, 95%CI 0.87-4.19; p=0.109). Fulminant/steroid-refractory cases were more frequent with abatacept. Early high-dose corticosteroid therapy was associated with lower MACE and improved biochemical control. Abatacept remains promising for fulminant or steroid-refractory ICI-M, but evidence is underpowered.

SACUBITRIL/VALSARTAN AS A NOVEL CARDIOPROTECTIVE STRATEGY IN BREAST CANCER PATIENTS UNDERGOING CHEMOTHERAPY: A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

JOSE ALEJANDRO GASCA1; NELSON EDUARDO MURILLO1; BRUCE GOMEZ1; ANDREA BELTRAN2; LUIS CUEVA3;

(1) UNIVERSIDAD SANTIAGO DE CALI - COLOMBIA; (2) CENTRO DE BIOTECNOLOGÍA GENÓMICA - MEXICO; (3) UNIVERSIDAD NACIONAL DE PIURA - PERU;

Background/Introduction: Cancer therapy–related cardiac dysfunction (CTRCD) remains a major limitation of anthracycline-based chemotherapy in breast cancer. Although sacubitril/valsartan has demonstrated reverse remodeling and biomarker reduction in heart failure, its preventive role in early subclinical myocardial injury during chemotherapy remains uncertain. Objectives: To evaluate the cardioprotective efficacy of sacubitril/valsartan in preventing chemotherapy-related cardiac dysfunction in patients with breast cancer. Methods: A systematic search was conducted through January 9, 2026, to identify randomized controlled trials comparing sacubitril/valsartan versus placebo or standard care in breast cancer patients receiving cardiotoxic chemotherapy. Outcomes included left ventricular ejection fraction (LVEF), global longitudinal strain (GLS), N-terminal pro–B-type natriuretic peptide (NT-proBNP), high-sensitivity cardiac troponin I (hs-cTnI), and high-sensitivity cardiac troponin T (hs-cTnT). Standardized mean differences (SMDs) were pooled using a random-effects model. Heterogeneity was assessed using the I^2 statistic. Results and Conclusions: Three randomized controlled trials, including 365 patients (152 sacubitril/valsartan; 213 control), were analyzed. Sacubitril/valsartan significantly preserved myocardial deformation, with a pooled GLS SMD of −0.64 (95% CI −0.93 to −0.36; P < 0.00001; I^2 = 37%). No significant difference was observed in LVEF (SMD 0.57; 95% CI −0.14 to 1.28; P = 0.11; I^2 = 89%), reflecting substantial heterogeneity and the limited sensitivity of conventional systolic parameters in early cardiotoxicity. Similarly, no significant effects were found for NT-proBNP (SMD −0.88; 95% CI −2.08 to 0.31; P = 0.15; I^2 = 96%), hs-cTnI (SMD −0.06; 95% CI −0.30 to 0.18; P = 0.64; I^2 = 0%), or hs-cTnT (SMD −0.11; 95% CI −0.38 to 0.17; P = 0.45; I^2 = 0%). Sacubitril/valsartan demonstrated a significant protective effect on subclinical myocardial deformation, as evidenced by preserved GLS, without measurable impact on LVEF or circulating cardiac biomarkers. These findings suggest that neurohormonal modulation may attenuate early myocardial injury before overt systolic dysfunction develops. Larger, adequately powered trials with clinical endpoints are warranted to determine whether these mechanistic benefits translate into reduced CTRCD and improved long-term cardiovascular outcomes.

GENOTYPE AND ATRIAL FIBRILLATION IN HYPERTROPHIC CARDIOMYOPATHY: ANALYSIS OF A BRAZILIAN COHORT IN A QUATERNARY CENTER

PAULO RAFAEL GONÇALVES DA SILVA VON ZUBEN1; VINICIUS COUTO MABILIA2; LUIZA ROCHA SILVA1; LORAINNY APARECIDA DE ALENCAR VEIGA1; JULIANO CARDOSO NOVAES3; FABIO FERNANDES3; JOSE EDUARDO KRIEGER3; VAGNER MANDRINI3; LUCIANO NASTARI3; VIVIANE TIEMI HOTTA3; HENRIQUE PESSOTI MENELLI1; MURILO DE OLIVEIRA ANTUNES3;

(1) HOSPITAL SANTA MARCELINA - SAO PAULO - SP - BRASIL; (2) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL; (3) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

BACKGROUND: Hypertrophic cardiomyopathy (HCM) is an autosomal dominant genetic disease characterized by clinical heterogeneity and variable expressivity. Although sarcomeric mutations, especially in MYH7 and MYBPC3, are frequent, the genotype-phenotype correlation remains uncertain. Atrial fibrillation (AF) is the most common sustained arrhythmia in HCM and is associated with worse prognosis. Studies suggest a relationship between genetic variants and AF risk, but results remain conflicting. Objectives: OBJECTIVES: To evaluate the association between genetic profile and occurrence of AF in patients with HCM followed at a Brazilian quaternary referral center. Methods: METHODS: Retrospective, single-center cohort including patients with HCM under specialized follow-up. Individuals were stratified according to the presence of documented AF and genetic testing results. Cases with alternative diagnoses or incomplete data were excluded. Statistical analysis was performed using the chi-square test, with significance defined as p<0.05. Results and Conclusions: RESULTS: Among 741 evaluated patients with HCM, genetic testing was performed in 169 patients. Mean age was 50.8 years (±16.4), and 50.9% were male. Mutations were identified in 140 patients (82.8%), involving 26 distinct genes. The most frequent mutations were MYH7 (27.8%) and MYBPC3 (25.0%). AF occurred in 144 patients (19.4%), of whom 26 had a positive genetic test. No significant association was observed between AF and genetic profile (RR 0.95; 95%CI 0.64–1.39; p=0.78). Only a non-significant trend toward higher prevalence of MYH7 mutations was observed in the AF group (34.6% vs. 26.3%; p=0.41). CONCLUSIONS: In this Brazilian cohort, sarcomeric mutations were predominant, especially MYH7 and MYBPC3. No significant association was demonstrated between genetic profile and AF, reinforcing the multifactorial nature of arrhythmic expression in HCM and the limitations of phenotype prediction based exclusively on genotype. Risk stratification should integrate clinical and structural factors in addition to genetic analysis.

INCREMENTAL VALUE OF THE ACE I/D POLYMORPHISM FOR MAGGIC-BASED MORTALITY RISK STRATIFICATION IN HEART FAILURE PATIENTS

MARLA DARLENE MACHADO VALE1; ÉDINA CAROLINE TERNUS RIBEIRO2; FERNANDA SPERB LUDWIG1; GABRIELA CORRÊA SOUZA3; NADINE OLIVEIRA CLAUSELL1;

(1) UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL; (2) THE GEORGE INSTITUTE FOR GLOBAL HEALTH - IMPERIAL COLLEGE LONDON - UNITED KINGDOM; (3) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: The Meta-Analysis Global Group in Chronic Heart Failure (MAGGIC) score is widely used for mortality prediction in patients with heart failure (HF), despite performance variations across different populations. Genetic factors, including the insertion (I)/deletion (D) polymorphism of the angiotensin-converting enzyme (ACE) gene, have been associated with disease progression and adverse cardiovascular outcomes and may improve prognostic stratification. However, their incremental value when added to established risk models is not yet fully elucidated. Objectives: To evaluate whether the addition of the ACE I/D polymorphism improves mortality risk prediction based on the MAGGIC score in patients with HF. Methods: This longitudinal observational study included outpatients with HF (>18 years; diagnosis ≥3 months). ACE genotyping was performed by polymerase chain reaction followed by agarose gel electrophoresis. Patients were classified according to a dominant genetic model as D-allele carriers (DD+ID) or non-carriers (II), in addition to allele dosage analysis. Clinical data were collected to calculate the MAGGIC score and estimate 1-year mortality risk. The association between the number of D alleles and estimated risk was assessed using Spearman correlation. Exploratory survival analyses were performed using Firth penalized Cox regression, and prognostic discrimination was evaluated by the area under the ROC curve (AUC). Results and Conclusions: Ninety-six patients were included, with a mean age of 55 ± 13 years; 63% were male, and the median left ventricular ejection fraction was 32% (25–40). The genotype distribution was II 12%, ID 40%, and DD 48%. D-allele carriers showed higher estimated 1-year mortality risk according to the MAGGIC score compared with non-carriers [8.4% (5.8–11.1) vs. 5.8% (3.5–7.9)], with a significant positive correlation between the number of D alleles and estimated mortality risk (rho=0.203; p=0.047). In survival modeling, the MAGGIC score remained independently associated with mortality (HR 1.14; 95% CI 1.03–1.26; p=0.007). Incorporating the D allele improved model discrimination (AUC 0.781 vs. 0.803) with adequate model calibration (Brier score = 0.06). These findings suggest a potential contribution of the ACE D allele to a higher clinical risk profile in HF, supporting its role as a complementary marker in prognostic stratification.

INFLUENCE OF EXONIC LOCATION OF DMD GENE MUTATIONS ON LEFT VENTRICULAR EJECTION FRACTION: A CROSS-SECTIONAL STUDY IN A BRAZILIAN DUCHENNE MUSCULAR DYSTROPHY COHORT

MARCOS MORAIS DE MEIS1; YASMIN VITÓRIA VICTORINO2; DAVI WHATELY AMAR2; GABRIEL RANGEL COSTA DA SILVA CARDOSO2; ANA PAULA CASSETTA DOS SANTOS NUCERA2;

(1) HOSPITAL QUINTA D'OR - RIO DE JANEIRO - RJ - BRASIL; (2) UNIRIO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Duchenne muscular dystrophy (DMD) is caused by mutations in the dystrophin gene, and cardiac involvement is the leading cause of death. The dystrophin protein contains functionally distinct domains encoded by different exonic regions, and it has been hypothesized that the location of the mutation along the gene may influence the cardiac phenotype. Mutations affecting proximal regions (exons 1–44) may disrupt the actin-binding domain, whereas distal mutations (exons 45–79) may compromise the dystroglycan-binding complex. However, data on the association between exonic location and left ventricular function remain scarce, particularly in Latin American populations. Objectives: To evaluate whether the exonic location of DMD gene mutations influences left ventricular ejection fraction (LVEF) in a Brazilian DMD cohort. Methods: Cross-sectional, single-center study including 53 genetically confirmed DMD patients followed at a Brazilian university hospital. The most recent LVEF was obtained by echocardiography (Teicholz method). Patients were classified according to the initial exon affected: proximal (exons 1–44; n=28) or distal (exons 45–79; n=25). LVEF was compared between groups using the independent-samples t-test and the Mann-Whitney U test. Linear correlation between the initial exon number and LVEF was assessed by scatter plot with fit line. Results and Conclusions: Mean LVEF was 54.57 ± 12.20% in the proximal group and 49.28 ± 14.45% in the distal group, a numerically lower value in distal mutations (mean difference: −5.29%; 95% CI: −12.64 to 2.06). This difference did not reach statistical significance by either the independent t-test (t=−1.445; p=0.155) or the Mann-Whitney U test (p=0.176). Linear regression of LVEF against the initial exon number showed negligible correlation (R^2=0.010). Despite the absence of statistical significance, the distal group exhibited a trend toward lower LVEF with wider dispersion, including all cases with LVEF below 30%. These findings suggest that exonic location alone, dichotomized at exon 45, does not significantly predict LVEF in this cohort. However, the observed trend toward worse function in distal mutations warrants further investigation in larger, multicenter studies with subgroup analysis by mutation type.

MUCOPOLYSACCHARIDOSIS TYPE IVA: ECHOCARDIOGRAPHIC CHARACTERIZATION AFTER 4 YEARS OF ENZYME REPLACEMENT THERAPY

LUCAS IAN SOUSA QUEIROZ1; EMERSON CÉLIO DA NÓBREGA CASIMIRO1; IMARA CORREIA DE QUEIROZ BARBOSA1; PAULA FRASSINETTI VASCONCELOS DE MEDEIROS1;

(1) UNIVERSIDADE FEDERAL DE CAMPINA GRANDE - UFCG - CAMPINA GRANDE - PB - BRASIL;

Background/Introduction: Mucopolysaccharidosis IVA (MPS IVA) represents a rare genetic disorder which is characterized by deficient enzymatic activity in glycosaminoglycan (GAG) degradation. Multiple organ systems are involved, including the cardiovascular system, although the mechanisms behind its involvement are not completely known. Notably, cardiac manifestations of MPS includes valvular pathology and left ventricular hypertrophy (LVH), pathologies in which the effectiveness of Enzyme Replacement Therapy (ERT) remains poorly substantiated by scientific evidence. Objectives: To delineate echocardiographic changes in MPS IVA patients and their progression after four years having ERT, an observational longitudinal study was undertaken. Methods: This study entailed quantitative analysis of echocardiographic data from a cohort of 10 MPS IVA patients, averaging 28.3 years of age, comprising out of ten people: four males, seven people with identical genotypes, and all of them subjected to ERT. Results and Conclusions: Pre-ERT echocardiograms revealed z-scores ≥ 2 for Left Ventricular Mass (LVM) in 6/10 patients, a trend maintained post-ERT in 5/10 patients. Furthermore, Aortic Root Dilatation (ARD) was identified in 6/10 patients, with no appreciable divergence between pre and post-ERT evaluations. Although ejection fraction remained preserved across the cohort, diastolic dysfunction was prevalent, affecting 6/10 and 7/10 patients pre and post-ERT, respectively. No difference was observed between the sexes with statistical significance in the variables analyzed. Notably, after four years of ERT, left atrial diameter and aortic root diameter exhibited a positive correlation with patient age ($p < 0.05$). Valvular involvement was universal, albeit predominantly mild. The most affected valve in the sample was the aortic valve, and the main involvement was valve insufficiency, with tricuspid predominance (7/10). Despite the study sample having a higher average age compared to similar studies, which is important in the analysis of a progressive disease alongside genotypic homogeneity, we obtained consistent results, such as the predominantly diastolic involvement rather than systolic, and the lack of impact of ERT on aortic root dilatation and left atrial enlargement. Conversely, inconclusive outcomes, such as ERT impact on LVH parameters, may enrich comprehension of the evolving cardiac profile in MPS IVA patients receiving ERT, particularly if ratified with an expanded sample.

PHENOTYPIC AND GENOTYPIC MAPPING OF DILATED CARDIOMYOPATHY IN A BRAZILIAN POPULATION

JULIA MARIA BISPO DOS SANTOS MATTEUZZO1; RAIANA ANDRADE QUINTANILHA BARBOSA1; DILZA BALTEIRO PEREIRA DE CAMPOS1; JACQUELINE SAMPAIO DOS SANTOS MIRANDA2; LUCIANA DA ROCHA FERREIRA LOBBÉ COTTA2; HELENA CRAMER VEIGA REY2; ANTONIO FELICIANO FATORELLI2; MARCELO GERARDIN POIROT LAND1; TAIS HANAE KASAI-BRUNSWICK1; ADRIANA BASTOS CARVALHO1;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Dilated cardiomyopathy (DCM) is an important cause of heart failure and sudden cardiac death, with a well-established genetic basis. However, data integrating phenotypic and genetic findings in Brazilian populations remain limited. Objectives: This study aimed to integrate phenotypic, genetic and family segregation data from Brazilian patients with dilated cardiomyopathy using whole-exome sequencing (WES). Methods: Ninety-five probands recruited from a high-complexity Brazilian heart disease center underwent clinical evaluation, cardiac imaging, WES and family segregation analysis. Variant interpretation followed ACMG recommendations. Results and Conclusions: The population showed male predominance and median age of 53 years. The study population reflected the highly admixed background characteristic of the Brazilian population. Clinical presentation was characterized by advanced heart failure symptoms and severe ventricular dysfunction. Mean left ventricular ejection fraction was 27.9%, indexed left ventricular end-diastolic diameter of 38.2 mm/m² and indexed left ventricular end-diastolic volume of 129.1 ml/m². Genetic yield was higher among probands with family history of DCM compared with apparently sporadic cases. Disease-associated variants were predominantly identified in genes with strong or definitive evidence for DCM, while family segregation analysis substantially improved variant interpretation by enabling the reclassification of two variants from uncertain significance to likely pathogenic (MYH7, c.709C>T; FLNC, c.850+1G>A). This study highlights the classical clinical presentation of DCM in a highly admixed Brazilian population, emphasizing the relevance of genetically diverse populations for improving the interpretation of disease-associated variants and expanding the global representation of cardiovascular genomic data. Furthermore, it reveals severe dysfunction and dilatation in this population. These findings emphasize the importance of integrating cardiac imaging, genetic testing and family history analysis for DCM evaluation in genetically heterogeneous populations.

ADDITIVE EFFECT OF POINT-OF-CARE ULTRASOUND (POCUS) IN THE DIAGNOSIS OF CARDIOVASCULAR DISORDERS IN PATIENTS WITH SICKLE CELL DISEASE

BERNARDO NASCIMENTO LOURENÇO1; ELIZA DE ALMEIDA GRIPP2; ALESSANDRO ZAKHIA DE SEIXAS2; MÁRIO LUIZ RIBEIRO1; EDUARDO AUGUSTO MARTINIANO ALVARES1; SILVIA MARINA DE AMORIM FIGUEIRA2; CLARA DA COSTA MARRUCHO2; MÁRCIO ROBERTO MORAES DE CARVALHO2; JOCEMIR RONALDO LUGON2; ANTONIO JOSE LAGOEIRO JORGE1; MARCIA MARIA SALES DOS SANTOS2; WOLNEY DE ANDRADE MARTINS1;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL; (2) HUAP - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Sickle Cell Disease (SCD) is a genetic disorder with relevant cardiovascular involvement that impacts quality of life and survival. In Brazil, it remains under-recognized, with limited research investment. Accessible tools such as Point-of-Care Ultrasound (POCUS) may play a key role, particularly in low- and middle-income settings with restricted access to comprehensive echocardiography. This highlights the importance of evaluating its role as a complementary tool for the early detection of cardiovascular abnormalities in patients with SCD. Objectives: To evaluate the applicability of POCUS in outpatient individuals with SCD and to determine its incremental diagnostic value when added to the clinical examination for detecting cardiovascular abnormalities. Methods: This cross-sectional diagnostic accuracy study included 32 participants with SCD confirmed by hemoglobin electrophoresis. Imaging data were systematically acquired and independently analyzed by blinded examiners. Clinically relevant cardiac involvement was defined, in the left heart context, as diastolic dysfunction (DD), heart failure with preserved ejection fraction (HFpEF), and early sickle cell cardiomyopathy; and in the right heart context as pulmonary hypertension (PH), cor pulmonale (right ventricular overload/dysfunction), and systemic venous congestion. Agreement between POCUS findings and standard echocardiography was assessed using Cohen's kappa coefficient. Statistical significance was defined as a p-value < 0.05, with 95% confidence intervals. Results and Conclusions: In the context of hemodynamic assessment of the pulmonary circulation, the [LA + TR + IVC] protocol demonstrated a sensitivity of 96.7% and specificity of 100%, yielding a negative likelihood ratio (LR−) of 0.03 and a kappa coefficient of 0.78, supporting its role as an effective rule-out model in potentially decompensated patients. In the outpatient screening setting for chronic left-sided structural heart disease, the [LA + MR] model achieved a sensitivity of 100% and a specificity of 50%, with a kappa coefficient of 0.56 and an LR− approaching zero. As a screening tool, these findings support the safety of downgrading the priority of patients with negative FoCUS results in the queue for standard echocardiography. Therefore, POCUS may assist clinicians in prioritizing patients awaiting comprehensive echocardiographic evaluation, particularly in resource-limited healthcare systems.

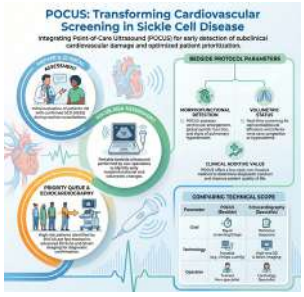

Table 1. Performance metrics for two multi-organ point-of-care ultrasound (FoCUS) protocols in different clinical contexts.

Diagnostic Parameters	Results
Method 1: LA + TR + IVC	
Sensitivity	96.7%
Specificity	100%
Kappa Coefficient (κ)	0.78
Negative Predictive Value (NPV)	100%
Positive Predictive Value (PPV)	96.7%
Method 2: [LA + MR]	
Sensitivity	100%
Specificity	50%
Kappa Coefficient (κ)	0.56
Negative Predictive Value (NPV)	100%
Positive Predictive Value (PPV)	50%

APPROPRIATE USE OF ECHOCARDIOGRAPHY IN A PEDIATRIC EMERGENCY DEPARTMENT: THE VALUE OF JUDICIOUS ECHOCARDIOGRAPHY

MILENA CARMONA GONÇALVES1; KAREN SAORI SHIRAISHI SAWAMURA1; ALESSANDRO CAVALCANTI LIANZA1; MILENA DE PAULIS1; ADRIANA VENTURINI RECHE1; GLAUCIA MARIA PENHA TAVARES1; ANA CLARA TUDE RODRIGUES1; MARCELO LUIZ CAMPOS VIEIRA1; CLAUDIO HENRIQUE FISCHER1; SAMIRA SAADY MORHY1;

(1) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL;

Background/Introduction: Transthoracic echocardiography (TTE) is an essential tool in the management of critically ill patients and is widely used in pediatric emergency departments (ED). However, the expanding use of TTE, particularly when indiscriminate, may lead to inefficient resource utilization and increased healthcare costs without proportional clinical benefit. In this context, robust evidence regarding the appropriateness and clinical impact of echocardiographic examinations in emergency care is critically needed Objectives: To evaluate the appropriateness of emergency TTE indications in pediatric patients according to appropriate use criteria (AUC) and to examine the association between appropriateness classification and clinical impact on patient management. Methods: This prospective observational study included pediatric patients who underwent emergency TTE in a tertiary pediatric ED between November 2019 and April 2023. Echocardiographic indications were independently classified as Appropriate, May Be Appropriate, or Rarely Appropriate by a pediatric echocardiographer and an emergency pediatrician, based on pediatric AUC. Clinical impact was defined as any change in patient management attributable to echocardiographic findings, including medication changes, additional diagnostic testing, hospital admission, or ED discharge. Interobserver agreement was assessed using Cohen's kappa coefficient. Results and Conclusions: A total of 90 emergency TTE were analyzed. The median age was 39 months, with a balanced sex distribution. Overall, 24 examinations (26.7%) resulted in a change in clinical management, most commonly hospital admission or discharge from the ED. Clinical impact was predominantly observed in patients presenting with prolonged fever without an identifiable source or with systemic inflammatory conditions, particularly suspected Kawasaki disease. Echocardiographers classified 23.3% of examinations as Appropriate, whereas emergency pediatricians classified only 7.8% as Appropriate. Conclusion: In a pediatric ED setting, most TTE were not aligned with AUC and did not significantly impact clinical management. However, when appropriately indicated, TTE frequently influenced critical decisions, particularly patient disposition. These findings highlight the importance of promoting rational, criteria-based use of echocardiography in pediatric emergency care. Integration of AUC into emergency decision-making pathways may improve diagnostic efficiency and reduce unnecessary imaging without compromising patient safety

COMPARISON BETWEEN QUALITATIVE VISUAL ASSESSMENT (EYEBALLING) VIA POINT-OF-CARE ULTRASOUND (POCUS) AND QUANTITATIVE LINEAR MEASUREMENT ON STANDARD ECHOCARDIOGRAPHY FOR THE DIAGNOSIS OF LEFT ATRIAL ENLARGEMENT IN PATIENTS WITH SICKLE CELL DISEASE

BERNARDO NASCIMENTO LOURENÇO1; ELIZA DE ALMEIDA GRIPP2; ALESSANDRO ZAKHIA DE SEIXAS2; EDUARDO AUGUSTO MARTINIANO ALVARES1; MÁRIO LUIZ RIBEIRO1; JOCEMIR RONALDO LUGON2; MÁRCIO ROBERTO MORAES DE CARVALHO1; CLARA DA COSTA MARRUCHO2; SILVIA MARINA DE AMORIM FIGUEIRA2; ANTONIO JOSE LAGOEIRO JORGE1; MARCIA MARIA SALES DOS SANTOS2; WOLNEY DE ANDRADE MARTINS1;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL; (2) HUAP - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Sickle Cell Disease (SCD) is a genetic disorder with relevant cardiovascular involvement that significantly impacts quality of life and survival. In Brazil, cardiovascular complications in this population often remain under-recognized. Accessible tools such as Point-of-Care Ultrasound (POCUS) may play a key role, particularly in low- and middle-income settings with restricted access to comprehensive echocardiography. This highlights the importance of evaluating POCUS as a complementary triage tool for the early detection of structural cardiovascular abnormalities in patients with SCD. Objectives: To evaluate the diagnostic accuracy of qualitative visual assessment (eyeballing) using POCUS to estimate left atrial (LA) enlargement in outpatients with SCD, comparing it to the standard echocardiography (SE) quantitative linear measurement. Methods: This cross-sectional diagnostic accuracy study included 32 participants with SCD confirmed by hemoglobin electrophoresis. Imaging data were systematically acquired using Phillips Lumify S4-1 and independently analyzed by blinded examiners. The reference for LA enlargement was defined by an anteroposterior LA diameter ≥ 4.0 cm in SE. We calculated sensitivity, specificity, predictive values and Cohen's kappa coefficient (κ) for categorical agreement. The Mann-Whitney U test were used to compare qualitative POCUS categorization against continuous diameter values. McNemar's test was applied to assess systematic bias. Statistical significance was defined as a two-sided p-value < 0.05. Results and Conclusions: Among the 32 evaluated patients, SE identified 15 cases (46.8%) of LA enlargement (≥ 4.0 cm). Visual assessment by POCUS demonstrated a sensitivity of 100% (15/15) and a specificity of 52.9% (9/17) for detecting LA enlargement. Kappa was moderate (κ = 0.51). POCUS demonstrated NPV of 100%, compared to a PPV of 65.2%. Furthermore, patients classified with an enlarged LA by POCUS had a significantly higher mean diameter on SE compared to those classified as normal (4.23 cm vs. 3.24 cm; p = 0.0001). However, McNemar's test revealed a significant systematic bias (p = 0.007), indicating that examiners tended to overestimate LA size, resulting in 8 false-positive cases. Qualitative visual assessment of the left atrium using POCUS is a highly sensitive screening tool in patients with Sickle Cell Disease. However, due to its moderate specificity and systematic tendency to overestimate LA size, findings suggesting enlargement should be confirmed by SE.

Table 1. Performance metrics and statistical analysis of visual POCUS vs. linear diameter measurement for detecting left atrial enlargement.

Diagnostic Parameters	Results
POCUS Performance Metrics	
Sensitivity	100%
Specificity	53%
Predictive Values	
Negative Predictive Value (NPV)	100%
Positive Predictive Value (PPV)	65%
Inter-method Agreement	
Cohen's Kappa (κ)	0.51
Mann-Whitney U Test	$p = 0.0001$
Systematic Bias Assessment	
McNemar's Test	$p = 0.007$

Clinically relevant left atrial (LA) enlargement was defined by an anteroposterior LA diameter ≥ 4.0 cm. POCUS: Point-of-Care Ultrasound.

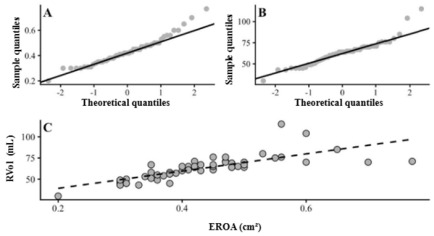
CORRELATION BETWEEN REGURGITANT VOLUME AND EFFECTIVE REGURGITANT ORIFICE AREA IN MITRAL VALVE PROLAPSE-RELATED MITRAL REGURGITATION

GABRIELLI DE MOURA GONÇALVES OLIVEIRA1; PRISCILA LEE1; BRUNA BARROS DE LIMA1; ADRIANA RECHE1; FLÁVIA BERNARDES MORAIS1; AUGUSTO HIROSHI UCHIDA1; ANA CLARA TUDE RODRIGUES1; CLAUDIO HENRIQUE FISCHER1; SAMIRA SAADY MORHY1; MARCELO LUIZ CAMPOS VIEIRA1;

(1) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL;



Background/Introduction: Quantification of mitral regurgitation (MR) in mitral valve prolapse (MVP) is challenging due to the dynamic behavior and eccentric geometry of regurgitant jets. Although effective regurgitant orifice area (EROA) and regurgitant volume (RVol) are physiologically related, the geometric assumptions of the proximal isovelocity surface area (PISA) method may be unreliable in MVP. Objectives: To evaluate the association between EROA and RVol in patients with MVP-related MR and explore potential nonlinear behavior between these parameters. Methods: This retrospective study included 55 adults with primary MR secondary to MVP who underwent transesophageal echocardiography with 2D and 3D acquisitions. EROA was calculated using the PISA method, and RVol was derived from EROA multiplied by the continuous-wave Doppler velocity-time integral, according to American Society of Echocardiography recommendations. Data were obtained from an institutional database linked to a previously approved research project. Due to non-normal distribution (Shapiro-Wilk: EROA p=0.043; RVol p=0.002), Spearman correlation, linear regression, residual analysis, quadratic regression, and Cook's distance analysis were performed. Results and Conclusions: Descriptive data and the linear regression model are detailed in Table 1. A strong positive correlation was observed between EROA and RVol (Spearman's rho=0.869; p<0.001). Linear regression showed EROA as a significant predictor of RVol (β=101.6; 95%CI 77.7-125.5; p<0.001), explaining 57.9% of RVol variability (R^2=0.579) (Figure 1). Residual analysis demonstrated increasing dispersion at higher MR severity, suggesting that jet geometry and dynamic flow characteristics influence RVol independently of orifice area. Addition of a quadratic term significantly improved model fit (R^2=0.830), supporting a nonlinear relationship between EROA and RVol. Sensitivity analysis after exclusion of one potentially influential observation identified by Cook's distance preserved the nonlinear pattern. These findings suggest that simplified geometric assumptions may inadequately reflect volumetric dynamics in MVP-related MR and reinforce the need for an integrated multiparametric approach. Three-dimensional methods may better represent MR severity in anatomically complex scenarios.

Table 1. Echocardiographic characterization and linear correlation parameters (N = 55)

Variable	Mean ± SD	Median (min–max)	p (Shapiro)	Spearman's ρ	p (Spearman)
EROA (cm²)	0.43 ± 0.11	0.42 (0.20–0.77)	0.043	—	—
RV (mL)	62.91 ± 14.21	64.00 (30.00–115.00)	0.002	0.869	< 0.001

Data are presented as mean ± standard deviation or median (min–max). The Shapiro-Wilk test was used to assess normality. The correlation between EROA and RV was evaluated using Spearman's correlation coefficient (ρ).

Figure 1. Assessment of normality and linear correlation between severity parameters

(A) Q-Q plot of residuals for the EROA variable; (B) Q-Q plot of residuals for the VR variable; (C) Scatter plot demonstrating the linear correlation between EROA and VR (R^2 = 0.579).

Background/Introduction: Myocardial ischemia without angina pectoris is called silent ischemia, can be detected by dobutamine stress echocardiography (DSE), and its severity can be estimated using the wall motion score index (WMSI). Patients with extensive ischemia and a high WMSI (above 1.7) are associated with a worse prognosis. Objectives: To evaluate patients with silent ischemia (SI) during DSE, considering the magnitude of the WMSI and the safety profile. Methods: Real-life patients with SI on DSE due to worsening contractility or biphasic response (improvement followed by worsening contractility) were compared from Group 1 (G1), with intermediate WMSI (between 1.1 and 1.7), and Group 2 (G2), with high WMSI (above 1.7). Results and Conclusions: There were 252 patients in G1 and 55 in G2, both homogeneous with respect to age, gender, risk factors for coronary artery disease, and therapy in use. G2 was associated with moderate correlation strength to the presence of biphasic response [52 (20%) vs. 26 (47.3%); p<0.001; Cramer's V: 0.235] and to altered resting contractility [126 (50%) vs. 55 (100%); p<0.001; Cramer's V: 0.390]. The double product (DP = systolic blood pressure x heart rate) at rest in G2 was higher (9914 ± 2117 bpm.mmHg vs 10591 ± 2334; p=0.036), ischemia occurred with lower systolic blood pressure values (160.8 ± 22.4 mmHg vs 153.3 ± 11.1 mmHg; p=0.024) and lower DP (23174 ± 425 vs 21460 ± 4801 bpm.mmHg; p=0.009) also in G2. Isolated ventricular ectopic beats [96 (38.1%) vs 23 (41.8%); p=0.068], paroxysmal supraventricular tachycardia (5.6% vs 3.6%; p= 0.562) and atrial fibrillation (1.6% vs 1.8%; p= 0.902) did not differ between the groups. The arrhythmias reversed spontaneously or after medication. No infarction, ventricular fibrillation, or death occurred. In patients with a positive examination for ischemia, without angina and with high WMSI, the DSE is a safe procedure. On DSE with SI, normal resting contractility is related to a less severe ischemia, while the presence of a biphasic response is related to more extensive ischemia.

Variables	Group 1	Group 2	p
Total sample	252 (100%)	55 (100%)	
Average age in years	64,8 ± 11,7	65,2 ± 12,8	0,633

OVERWEIGHT AND OBESITY ASSOCIATED WITH SUBCLINICAL MYOCARDIAL DYSFUNCTION ASSESSED BY MYOCARDIAL STRAIN: A STUDY IN A BRAZILIAN ADULT POPULATION

BÁRBARA CAVALHEIRO LOCKS1; MURILO FOPPA1; WILSON CAÑON MONTAÑEZ2; EDUARDO GATTI PIANCA1; BRUCE B DUNCAN1; ANGELA B S SANTOS1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL; (2) UNIVERSIDAD DE ANTIOQUIA - COLOMBIA;

Background/Introduction: Obesity has a growing incidence worldwide. Brazilians already have a prevalence of overweight or obesity of approximately 60%, which are well-known cardiovascular risk factors, highlighting heart failure. Although subclinical cardiac dysfunction is well established in obesity, the impact on overweight remains underexplored. Objectives: To evaluate the relationship between overweight and obesity with early cardiac dysfunction assessed by myocardial deformation (strain), and to identify associated independent factors. Methods: A cross-sectional study of a random sample from the ELSA-Brazil cohort, with analysis of left ventricular (LV) and right ventricular (RV) global longitudinal strain (GLS). BMI categorized participants: eutrophic, overweight, and obese. Group comparisons and multiple linear regression models were performed, with statistical significance set at p<0.05. Results and Conclusions: The sample of 1,048 participants comprised 38.4% eutrophic (E), 42.5% overweight (OW), and 19.0% obese (OB) individuals. Overweight and obese individuals exhibited a higher prevalence of hypertension (HTN) and diabetes, along with worse parameters of cardiac remodeling and diastolic dysfunction. Strain values significantly worsened in overweight/obese individuals compared to eutrophic individuals, for both LV GLS (E:−19,1±2,3%, OW:−18,5±2,6%, OB:−18.0±2,7%; p<0.05) and RV GLS (E:−25,5±2.3%, OW:−25,1±2,2%, OB:−24,8±2,6%; p<0.05), with a higher prevalence of subclinical dysfunction among overweight/obese individuals (Figure). Regarding left ventricular ejection fraction (LVEF), a slight reduction was observed in the obese category. In the multivariate analysis, excess weight (overweight/obesity) remained an independent association with worse strain, even after adjusting for age, sex, race, educational level, study center, HTN, diabetes, and LVEF (Table). In addition to BMI, waist circumference and waist-to-hip ratio were also associated with worse ventricular strain, with a stronger association in men and more evident in the LV. Excess weight is independently associated with biventricular subclinical systolic dysfunction in the Brazilian adult population, with impairment already evident in overweight individuals. These findings reinforce the utility of strain as an early biomarker of myocardial function.

Figure: Prevalence of abnormal GLS according to BMI categories

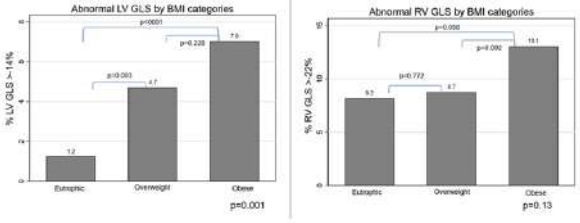

Table: Association between BMI categories and GLS

VIDEOLARYNGOSCOPY FOR TRANSESOPHAGEAL ECHOCARDIOGRAPHY PROBE INSERTION IN PATIENTS UNDERGOING CARDIAC SURGERY: A SYSTEMATIC REVIEW AND META-ANALYSIS.

JOÃO PEDRO CAMPOS LIMA1; KAUÊ ABREU CHAGAS2; KAUANN GARCIA RIDOLPHI2; DIOGO AYD BITTENCOURT3; EDUARDA LORENZINI SAVERGNINI2; ENILTON MONTEIRO MACHADO2;

(1) HOSPITAL SÃO VICENTE DE PAULA - BOM JESUS DO ITABAPOANA - RJ - BRASIL; (2) AFYA CENTRO UNIVERSITÁRIO ITAPERUNA - ITAPERUNA - RJ - BRASIL; (3) IDOMED/ESTACIO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Videolaryngoscopy (VL) has demonstrated utility in facilitating endotracheal intubation, but its role in aiding transesophageal echocardiography (TEE) probe insertion remains unclear. Difficult TEE probe insertion can lead to delays, trauma, and procedural failure. Objectives: This systematic review and meta-analysis aimed to evaluate the efficacy and safety of VL for TEE probe insertion in patients undergoing cardiac surgery. Methods: The MEDLINE, Embase, and Cochrane databases were searched for randomized controlled trials (RCTs) comparing VL-assisted TEE probe insertion with conventional direct laryngoscopy (DL) in adults and children undergoing cardiac surgery. A random-effects model was employed for all analyses. Dichotomous outcomes were analyzed using risk ratios (RR) with 95% confidence intervals (CI). Continuous outcomes were analyzed using mean differences (MD) with 95% CI. Heterogeneity was assessed using the I2 statistic. Meta-analysis was performed using the R Software, version 4.2.3. Results and Conclusions: Eight RCTs comprising 968 patients, 490 in the VL group, were included. The mean age of participants was 54 years for adults and 5.33 years for children. The most common procedure performed was elective coronary artery bypass grafting (CABG). VL-assisted TEE probe insertion was associated with a significantly higher first-attempt success rate compared to DL (RR 1.00;95% CI 1.04, 1.14; P < 0.05; I2 = 0%). Complication rates were lower in the VL group (RR 0.54; 95% CI 0.30, 0.96; P < 0.05; I2 = 54%). Insertion time was not significantly different between the VL and DL groups (MD -6.65 seconds; 95% CI -21.29, 7.99 seconds; P = 0.37; I2 = 97%). However, subgroup analysis in the pediatric population did not demonstrate a significant difference for VL regarding first-attempt success or lower complications. In this meta-analysis, VL was associated with a significant improvement in the first-attempt success rate and reduction in overall complications during TEE probe insertion in patients undergoing cardiac surgery, particularly in the adult population. While insertion time was not significantly different, the benefits of VL suggest it is a valuable technique for facilitating TEE probe placement.

Background/Introduction: Parasite persistence sustains myocardial inflammation and drives progression to Chagas cardiomyopathy. Etiologic therapy with benznidazole reduces parasitic burden and may attenuate myocardial injury, but early treatment response remains difficult to quantify using conventional measures. Objectives: To evaluate the impact of benznidazole therapy on myocardial inflammation using cardiac magnetic resonance (CMR) tissue characterization. Methods: In this prospective observational study, patients with chronic Chagas disease eligible for antiparasitic therapy underwent CMR with T1 and T2 mapping and extracellular volume fraction (ECV) quantification at baseline and 6 months after treatment. Treatment-related changes (ΔT1, ΔT2, ΔECV) were integrated using principal component analysis (PCA) to derive a composite myocardial response index (PC1). Patients were stratified into three groups according to PC1 scores: greatest, intermediate, and minimal/no response (Figure 1). Results and Conclusions: Results: Among 76 patients initiating therapy, 70 completed treatment and were included (age 57 ± 9 years; 63% women). Most patients were in the indeterminate (63%) or mild cardiac form (24%). Baseline ventricular size and systolic function were preserved. At 6 months, T1 and ECV decreased significantly (both $p < 0.05$), whereas T2 remained unchanged. PCA demonstrated marked heterogeneity in treatment response, with approximately one-third of patients showing minimal improvement or worsening tissue abnormalities. Greater reductions in T1 and ECV were observed in patients with higher baseline values. Conclusions: In chronic Chagas disease, benznidazole therapy is associated with measurable improvements in myocardial tissue characteristics by CMR. Integration of multiparametric imaging using PCA reveals substantial heterogeneity in treatment response, supporting the role of CMR as a sensitive tool for detecting early myocardial changes following therapy.

Figure 1

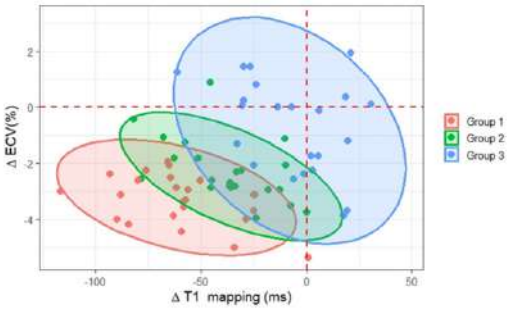

Figure 1. Distribution of treatment-related changes in myocardial tissue parameters. Scatter plot of ΔT1 (ms) versus ΔECV (%) following benznidazole therapy, with patients stratified according to the principal component–derived response groups. Ellipses represent the distribution of each group: Group 1 (greatest response), Group 2 (intermediate response), and Group 3 (minimal or no response). Dashed lines indicate the null change (Δ = 0) for each parameter. Greater reductions in both T1 and ECV are observed in Group 1, whereas Group 3 shows minimal change or worsening, highlighting heterogeneity in myocardial response to therapy.

Background/Introduction: Acute myocarditis has a heterogeneous clinical course, ranging from complete recovery to heart failure, ventricular arrhythmias, recurrent disease, transplantation, and death. Although left ventricular ejection fraction and late gadolinium enhancement are widely used for risk assessment, they may fail to identify subtle myocardial dysfunction. Cardiac magnetic resonance-derived left ventricular global longitudinal strain has emerged as a potentially more sensitive prognostic marker. Objectives: To evaluate the prognostic value of CMR-derived left ventricular global longitudinal strain in adult patients with acute myocarditis. Methods: A systematic review was conducted according to PRISMA principles. PubMed, Embase, and the Cochrane Library were searched in May 2026. Observational studies assessing CMR-derived left ventricular global longitudinal strain or left ventricular longitudinal strain in adults with acute myocarditis and reporting clinical or functional outcomes were included. Diagnostic-only studies, echocardiographic strain studies, pediatric cohorts, wrong populations, and non-original publications were excluded. Results and Conclusions: The search identified 732 records, and 7 observational studies were included. Five studies evaluated composite adverse cardiovascular outcomes, comprising 1,106 patients. Adverse events occurred in 169 patients overall: 29/162, 74/455, 24/256, 26/100, and 16/133 across the five cohorts. Across these studies, impaired CMR-derived left ventricular global longitudinal strain was consistently associated with poorer outcomes. In multiple cohorts, left ventricular global longitudinal strain remained independently associated with adverse events after adjustment for conventional markers, including left ventricular ejection fraction and late gadolinium enhancement. One additional study including 141 patients showed that left ventricular global longitudinal strain independently predicted ventricular arrhythmic events, which occurred in 17 patients. Another study including 69 patients demonstrated that baseline left ventricular longitudinal strain independently predicted functional recovery during follow-up. Overall, current evidence supports CMR-derived left ventricular global longitudinal strain as a clinically relevant prognostic marker in acute myocarditis, with potential incremental value beyond conventional CMR parameters. Further prospective studies are needed to validate standardized cutoff values and determine its role in guiding follow-up strategies.

COST-EFFECTIVENESS AND CLINICAL IMPACT OF ULTRA-HIGH-RESOLUTION CORONARY CT PRIOR TO INVASIVE CORONARY ANGIOGRAPHY: INSIGHTS FROM THE CORE PRECISION STUDY

BRUNA ROMANELLI SCARPA MATUCK1; AYSA OSTOVANEH2; JEFFREY TROST2; MAKOTO ORII3; GILBERTO SZARF4; PEDRO A LEMOS4; HOOMAN BAHKSHI2; MATTHEW MATHESON2; CHRISTOPHER COX2; CARLOS VICENTE SERRANO JR1; JOAO A C LIMA2; ARMIN A ZADEH2;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) JOHNS HOPKINS - UNITED STATES; (3) IWATE MEDICAL UNIVERSITY - JAPAN; (4) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL;

Background/Introduction: Invasive coronary angiography (ICA) is widely used in patients with suspected coronary artery disease (CAD), but a significant proportion of procedures ultimately reveal non-obstructive findings. Ultra-high-resolution coronary computed tomography (UHRCT) may reduce unnecessary ICAs by serving as a noninvasive gatekeeper. Objectives: To evaluate the cost-effectiveness and clinical impact of a UHRCT-first strategy in patients referred for ICA due to suspected CAD using data from CORE PRECISION multicenter trial. Methods: A decision-tree model compared two strategies in 167 high-risk patients who underwent both UHR-CT and ICA: (1) direct ICA for all patients, and (2) UHRCT-first, in which all patients underwent UHR-CT, with ICA hypothetically performed only when ≥70% stenosis was identified. ICA served as the reference standard. Costs were assessed from a U.S. healthcare payer perspective and standardized to 2025 USD using Medicare and Healthcare Cost and Utilization Project (HCUP) sources. The primary outcome was the incremental cost-effectiveness ratio (ICER), defined as the cost per additional correct diagnosis. Secondary outcomes included total costs and ICA utilization. Nonparametric bootstrap resampling was used to estimate uncertainty. Results and Conclusions: Among 167 participants (121 males, 66 ±11 years), direct ICA was associated with a total 30-day cost of $2,380,000 ($14,251 per patient). The UHR-CT-first strategy reduced total cost to $2,107,500 ($12,620 per patient), resulting in an incremental cost difference of −$272,500 (−$1,631 per patient) (Fig 1B). Under the UHR-CT-first strategy, ICA utilization decreased from 100% (167/167) to 77% (129/167), avoiding 38 invasive procedures. However, 15 obstructive cases were not identified as ≥70% stenosis by UHRCT. Of these 15 patients, only 4 underwent coronary revascularization after ICA. The ICER was $18,167 per one additional correct diagnosis gained with the direct ICA strategy. In this 30-day cost-effectiveness analysis, a UHR-CT-first strategy reduced overall healthcare costs and the use of invasive coronary angiography compared with performing direct ICA in all patients. Although direct ICA provided greater diagnostic accuracy, it was associated with higher costs. These findings demonstrate a trade-off between diagnostic performance and cost and support the potential role of UHR-CT as a cost-effective initial triage strategy.

IMPACT OF CORONARY CALCIUM SCORE ON THE DIAGNOSTIC ACCURACY OF ULTRA-HIGH-RESOLUTION CT FOR DETECTING OBSTRUCTIVE CORONARY ARTERY DISEASE IN THE CORE PRECISION MULTICENTER STUDY

BRUNA ROMANELLI SCARPA MATUCK1; AYSA OSTOVANEH2; JEFFREY TROST2; MAKOTO ORII3; GILBERTO SZARF4; HOOMAN BAHKSHI2; MATTHEW MATHESON2; PEDRO A LEMOS4; CHRISTOPHER COX2; CARLOS VICENTE SERRANO JR1; JOAO A C LIMA2; ARMIN A ZADEH2;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) JOHNS HOPKINS - UNITED STATES; (3) IWATE MEDICAL UNIVERSITY - JAPAN; (4) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL;

Background/Introduction: Dense coronary calcification limits the use of conventional coronary CT angiography due to blooming artifacts that obscure the lumen and reduce its diagnostic accuracy. Ultra–high–resolution CT (UHR-CT), with improved spatial resolution, may mitigate this limitation and allow a more reliable assessment even in patients with high calcium score levels. Objectives: To investigate the influence of coronary artery calcium score (CACS) in the diagnostic accuracy of UHR-CT for detecting hemodynamically significant coronary artery disease (CAD) at patient level using quantitative flow ratio (QFR) as the reference standard, and to explore whether a clinically meaningful CACS threshold exists beyond which UHR-CT accuracy declines. Methods: In the CORE Precision study, participants with suspected obstructive CAD underwent non-contrast calcium scoring and UHR-CT prior to invasive coronary angiography. UHR-CT images were analyzed and stenosis ≥70% were deemed obstructive. Functional significance (reference standard) was defined by an abnormal QFR. CACS was analyzed both categorically (0–99, 100–399, 400–999, ≥1000) and as a continuous variable using a moving-threshold approach. Diagnostic accuracy was calculated across increasing CACS cutoffs, restricting analyses to thresholds where each subgroup comprised ≥10% of the cohort to ensure stability. Results and Conclusions: A total of 118 participants (mean age 67±11 years, 75% male) were included. The mean calcium score was 1,004 (± 1,108). The global diagnostic accuracy of UHR-CT was 80.3%. Diagnostic accuracy declined progressively across increasing CACS categories, measuring 90.9% for CACS 0–99, 88.5% for CACS 100–399, 83.8% for CACS 400–999, and 76.7% for CACS ≥1,000. Performance attenuation at very high CACS values was primarily driven by reduced specificity, while sensitivity remained preserved. Detailed diagnostic performance metrics and confidence intervals are presented in Figure 1A. In the continuous analysis, no abrupt cutoff point was identified. The accuracy remained stable, especially in patients with CACS <1,000, with a gradual decline with increasing calcium burden (Figure 1B). The histograms in Figure 1B illustrate correctly and incorrectly classified cases across CACS ranges. UHR-CT maintains robust diagnostic accuracy across a wide range of coronary calcium scores, particularly in patients with CACS <1000, a group previously considered unsuitable for the test, suggesting that UHR-CT may represent a noninvasive diagnostic alternative in this group.

A

CACS Range (n)	Accuracy (95% CI)	Sensitivity (95% CI)	Specificity (95% CI)
0-99 (11)	90.9 (58.7-99.8)	85.7 (42.1-99.6)	100.0 (39.8-100.0)
100-399 (26)	88.5 (69.8-97.6)	92.9 (66.1-99.8)	83.3 (51.6-97.9)
400-999 (37)	83.8 (68.0-93.8)	92.3 (74.9-99.1)	63.6 (30.8-89.1)
≥1000 (44)	76.7 (61.4-88.2)	88.2 (72.5-96.7)	33.3 (7.5-70.1)

Figure 1A. Patient-level diagnostic accuracy, sensitivity, and specificity of UHR-CT across CACS categories (reference standard: QFR ≤0.80). Values shown as % (95% CI). N= number of cases in each category.

B

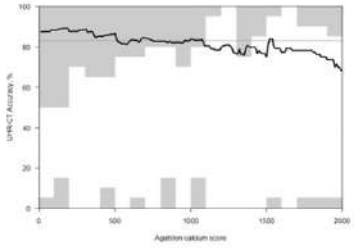

Figure 1B . Distribution of UHR-CT diagnostic accuracy according to CACS.
Solid black line shows the moving average of diagnostic accuracy calculated using a sliding CACS window of x ± 500 Agatston units. Gray horizontal line indicates the overall patient-level diagnostic accuracy for the cohort.
Upper histogram represents correctly classified cases (true positives and true negatives relative to QFR ≤0.80), and the lower histogram represents incorrectly classified cases (false positives and false negatives).

NON-CONTRAST-ENHANCED MAGNETIC RESONANCE ANGIOGRAPHY VERSUS CONTRAST-ENHANCED MULTISLICE COMPUTED TOMOGRAPHY FOR PRE-PROCEDURAL ASSESSMENT IN TRANSCATHETER AORTIC VALVE IMPLANTATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

IGOR RAFAEL SANTANDER1; VICENTE CASTOR BRITO2; BARBARA REIS SILVA3; JUAN PERES OLIVEIRA4; AUGUSTO MONTEIRO CASTRO XAVIER CARVALHO5; DÉBORA MARQUES MIRANDA SANTANDER1; CAROLINE OLIVEIRA FISCHER-BACCA4;

(1) CARDIO LOGICA PB - JOÃO PESSOA - PB - BRASIL; (2) UNIVERSIDADE FEDERAL DE CAMPINA GRANDE - UFCG - CAMPINA GRANDE - PB - BRASIL; (3) PONTIFICIA UNIVERSIDADE CATOLICA DE GOIAS - GOIÂNIA - GO - BRASIL; (4) UNIDAVI - CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL; (5) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL;

Background/Introduction: Accurate aortic valve assessment is essential for optimal planning of transcatheter aortic valve implantation (TAVI). Contrast-enhanced multislice computed tomography (CTA) is the current reference standard; however, its use may be limited in patients with renal dysfunction. Non-contrast-enhanced magnetic resonance angiography (MRA) has emerged as a potential alternative, but evidence comparing both modalities remains inconsistent. Objectives: To systematically evaluate and compare the accuracy of non-contrast-enhanced MRA and contrast-enhanced CTA for aortic valve assessment prior to TAVI. Methods: A systematic search of PubMed, Embase, and Cochrane databases was performed to identify studies comparing non-contrast-enhanced MRA with contrast-enhanced CTA in patients with severe aortic stenosis undergoing TAVI evaluation. Pooled mean differences (MD) were calculated using a random-effects model. Statistical significance was set at $p<0.05$. Heterogeneity was assessed using the I^2 statistic. Results and Conclusions: Nine studies were included, comprising 318 patients (50.6% male) with a mean age of 77.1±6.9 years. No significant differences were observed between MRA and CTA in aortic annular measurements. Aortic annulus area was comparable between modalities (MD −3.96; 95% CI −15.44 to 7.52; p=0.49; I^2=0%). Similarly, aortic annulus perimeter (MD −0.44; 95% CI −1.77 to 0.89; p=0.51; I^2=0%) and diameter (MD −0.11; 95% CI −0.72 to 0.50; p=0.71; I^2=0%) showed no significant differences. Conclusion: In this meta-analysis with no observed heterogeneity between groups, non-contrast-enhanced MRA demonstrated comparable accuracy to contrast-enhanced CTA for pre-procedural aortic valve assessment in TAVI candidates. These findings support MRA as a feasible alternative imaging modality, particularly in patients with contraindications to iodinated contrast.

ULTRA-HIGH-RESOLUTION CT VERSUS INVASIVE ANGIOGRAPHY FOR OBSTRUCTIVE CORONARY ARTERY DISEASE: REAL-WORLD AND CORE LABORATORY DIAGNOSTIC PERFORMANCE IN A MULTICENTER STUDY

BRUNA ROMANELLI SCARPA MATUCK1; AYSA OSTOVANEH2; JEFFREY TROST3; MAKOTO ORII4; GILBERTO SZARF5; HOOMAN BAHKSHI2; MATTHEW MATHESON2; PEDRO A LEMOS5; CHRISTOPHER COX2; CARLOS VICENTE SERRANO JR1; JOAO A C LIMA2; ARMIN A ZADEH2;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) JOHNS HOPKINS - UNITED STATES; (3) JOHSN HOPKINS - UNITED STATES; (4) IWATE MEDICAL UNIVERSITY - JAPAN; (5) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL;

Background/Introduction: Imaging studies interpretation in clinical practice may differ substantially from centralized Core Laboratory assessment, particularly in complex patients with severe calcification or stents. In the CORE PRECISION study, ultra–high-resolution computed tomography (UHR-CT) and invasive coronary angiography (ICA) demonstrated similar diagnostic performance under standardized Core Lab conditions, although statistical non-inferiority was not formally met. Whether real-world interpretation narrows or widens this performance gap remains clinically relevant. Objectives: To compare the diagnostic performance of UHR-CT and ICA to detect hemodynamically significant stenosis according to local versus centralized core lab assessment. Methods: In a prospective multicenter study conducted in Brazil, Japan, and the United States, patients with a calcium score ≥400, known coronary stenosis ≥ 50% or stents underwent UHR-CT prior to ICA due to suspected obstructive coronary artery disease (CAD). UHR-CT and ICA images were analyzed locally at each site and by blinded and centralized Core Labs. Stenosis ≥70% on UHR-CT or ICA were deemed obstructive, and functional significance (reference standard) was defined by an abnormal quantitative flow ratio. The diagnostic accuracy of both tests for detecting significant stenosis was calculated based on both Core Lab and site-level assessments. Results and Conclusions: Among the 173 patients (mean age 65.2 years, 72% male), obstructive CAD was present in 115 (66%). The mean calcium score in patients without stents (n=115) was 1,004 (± 1,108). In real-world site-level readings, ICA accuracy decreased from 83.2% to 74.0% (p for difference=0.009), whereas UHR-CT showed a more modest decline, from 80.3% to 74.0% (p for difference=0.04). The reduction in performance was more pronounced for ICA specificity, resulting in convergence of diagnostic accuracy between modalities in routine practice (Fig 1A). Intercontinental variability further highlighted differences between controlled Core Lab conditions and real-world interpretation (Fig 1B). In real-world practice, UHR-CT has the same diagnostic accuracy as ICA in detecting patients with significant CAD, even among patients with severe coronary calcification or stents. With Core Lab adjudication, the accuracy gain was greater for ICA than for UHR-CT, suggesting that variability in routine ICA interpretation may influence comparative effectiveness more than variability in CT interpretation.

ABDOMINAL CIRCUMFERENCE AND MYOCARDIAL PERFUSION IMAGING FINDINGS: A RETROSPECTIVE HOSPITAL-BASED COHORT ANALYSIS

WLAMIR BATISTA RIBEIRO1; CAROLINA CHRISTIANINI MIZZACI GUILHEN1; RAFAELA PENALVA1; CARLOS HENRIQUE BITTENCOURT VIEIRA1; SANDRO PINELLI FELICIONI1; GUSTAVO FREITAS CARDOSO FAGUNDES1; LUISA MORAIS TEJERIZO2; CAIO HENRIQUE DE OLIVEIRA ABRANTES1; ORNELLA PAOLA GAMBARINI1; YAN MOTA ARAUJO1; LEE MARWYNE DA SILVA BARROS1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (2) HOSPITAL MUNICIPAL ANTÔNIO GÍGLIO - OSASCO - SP - BRASIL;

Background/Introduction: Central adiposity is an established cardiometabolic risk marker; however, its association with myocardial perfusion abnormalities in patients referred for myocardial perfusion imaging (MPI) remains incompletely defined. Objectives: To evaluate the association between abdominal circumference (AC) and MPI findings after adjustment for demographic variables. Methods: This retrospective study included 805 patients with valid AC measurements. Shapiro-Wilk, Mann-Whitney U, chi-square, and multivariable logistic regression analyses adjusted for age and sex were performed. Results and Conclusions: Mean age was 67.2 ± 10.9 years, and 53.7% were male. Mean AC was 98.7 ± 13.7 cm, with elevated AC observed in 56.4% of patients. Myocardial ischemia was identified in 18.8%, fixed perfusion defects in 33.5%, and ventricular dysfunction in 21.6%. Patients with ischemia had higher AC values compared with those without ischemia (100.5 vs. 98.2 cm; p=0.031, Mann-Whitney test). However, AC was not independently associated with ischemia after multivariable adjustment (OR per 10 cm increase = 1.08; 95% CI 0.95–1.23; p=0.251). Male sex was the strongest predictor of ischemia (OR=1.82; p=0.002). Binary categorization of AC also showed no significant association with ischemia (p=1.0). Elevated AC was highly prevalent but was not independently associated with myocardial ischemia after adjustment for age and sex. Male sex emerged as the predominant predictor, suggesting that abdominal adiposity may represent part of a broader cardiometabolic risk profile with limited isolated discriminatory value in this hospital-based population.

Background/Introduction: Background: Functional stress testing identifies inducible ischemia but does not exclude underlying atherosclerosis or future risk. Coronary artery calcium (CAC) quantifies atherosclerotic burden and may provide incremental prognostic value. Its role in symptomatic patients with negative stress tests remains uncertain. We evaluated the prognostic value of CAC in this setting. Objectives: Objective: To evaluate the prognostic value of coronary artery calcium (CAC) in symptomatic adults with negative functional stress tests, and to determine its association with residual cardiovascular risk and adverse clinical outcomes. Methods: Methods: Systematic review and single-arm meta-analysis including adults (≥18 years) with negative stress tests (SPECT, stress echocardiography, PET, or CMR). Random-effects models were used to estimate pooled proportions with 95% confidence intervals (CIs). Heterogeneity was assessed using Cochran's Q and I². Results and Conclusions: Results: Six studies (N = 7,269; mean age 61.3 years; 43% male) were included. Despite negative stress tests, increasing CAC burden was consistently associated with worse cardiovascular outcomes. The prevalence of anatomically significant coronary artery disease (≥50% stenosis) increased from 0% (CAC=0) to 2.8% for CAC 1–399, 48.9% (~1 in 2) for CAC ≥400, and 71.4% (~3 in 4) for CAC ≥1000. Coronary revascularization increased from 0.04% for CAC=0 to 24.5% (~1 in 4) for CAC ≥400 and 38.0% (~1 in 3) for CAC ≥1000. Myocardial infarction increased from 0.77% for CAC=0 to 3.46% for CAC ≥400. All-cause mortality also increased with CAC burden, reaching 5.77% for CAC ≥400, Figure. Conclusion: In symptomatic patients with negative stress tests, CAC reveals a marked gradient of residual risk not captured by ischemia assessment. These findings support its complementary role in risk stratification and potential to guide further evaluation and preventive strategies.

Background/Introduction: Childhood obesity is associated with early vascular and hemodynamic alterations, which may represent subclinical manifestations of increased cardiometabolic risk. In this context, Effective Arterial Elastance (Ea) has emerged as an integrative marker of global arterial load and ventricular–arterial coupling, providing a more comprehensive assessment of cardiovascular hemodynamics. Objectives: To compare Ea and arterial stiffness indices between healthy children (CTRL) and children with obesity (OB). Methods: This was a cross-sectional analytical observational study including 70 children allocated into a healthy control group (n = 35) and an obesity group (n = 35), matched for age (CTRL 10.60 ± 1.95 vs. OB 10.71 ± 1.94 years) and sex. The Mobil-O-Graph (IEM, Stolberg, Germany) was used to noninvasively estimate central and peripheral blood pressures, hemodynamic parameters, and pulse wave velocity (PWV) based on brachial blood pressure measurements. Effective arterial elastance (Ea) was estimated as the ratio of peripheral mean arterial pressure (MAP) to stroke volume (SV). Variables were compared using the unpaired Student's t-test or the Mann–Whitney test, as appropriate, with $p < 0.05$ considered statistically significant. Results and Conclusions: Body weight (65.92±13.98 kg), height (1.51±0,11m), and body mass index (28.36±3.46 kg/cm2) were significantly higher in the OB group in relation to CTRL group (34.56±8.89 kg; 1.41±0,12m; 16.85±1,86 kg/cm2 respectively). Ea and PWV were significantly higher in the OB group (1.81±0.36 mmHg/mL and 4.64±0.37 m/s, respectively) compared to the CTRL group (1.63 ± 0.21 mmHg/mL and 4.41±0.72 m/s). Central and peripheral blood pressures were also significantly higher in the OB group (37.12% normotensive, 25.7% elevated blood pressure, 34.2% stage 1 hypertension, and 2.8% stage 2 hypertension). Children with obesity exhibit increased Ea, PWV, and blood arterial pressure, reflecting higher global arterial load and arterial stiffness early in life. These findings suggest the presence of subclinical hemodynamic alterations with potential cardiovascular impact, highlighting the importance of early identification and intervention in this population.

20246

ASSOCIATION BETWEEN EXTREME TEMPERATURES AND CARDIOVASCULAR MORTALITY: A TIME-SERIES STUDY IN THE METROPOLITAN REGION OF CURITIBA, BRAZIL

GABRIELA LENGLER SILVA1; MARIA EDUARDA RENDAKI1; DAVID SAUERMAN1; ANA KARYN EHRENFRIED FREITAS2;

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (2) HOSPITAL DE CLINICAS DO PARANA - CURITIBA - PR - BRASIL;

Background/Introduction: Climate change represents a major challenge for global public health, impacting both morbidity and mortality. The cardiovascular system is particularly vulnerable to thermal extremes, which exacerbate preexisting risks and may trigger acute events. Maintaining thermal homeostasis (36.5–37.5 °C) requires adaptive responses that, under environmental stress, impose physiological overload. Heat exposure promotes dehydration and reduced plasma volume, increasing blood viscosity. Conversely, cold exposure induces peripheral vasoconstriction, sympathetic activation, and elevated blood pressure, increasing hemodynamic load and the risk of ischemic events. Objectives: To analyze the association between climate variability and cardiovascular mortality in the Metropolitan Region of Curitiba (PR) from 2016 to 2023, characterize the sociodemographic profile of deaths, and identify patterns associated with temperature extremes. Methods: An ecological time-series study was conducted using cardiovascular mortality data (ICD-10) from SIM/DATASUS. Climate variables were extracted from INMET (station A807). The analysis employed Distributed Lag Non-linear Models (DLNM) to assess non-linear relationships and delayed effects (lags). Natural cubic splines modeled the dose–response relationship. Based on the literature, lags of 0–3 days for heat and 0–21 days for cold and thermal amplitude were considered. All analyses were performed using R software. Results and Conclusions: A total of 39,695 deaths were analyzed (13.58/day), predominantly in individuals aged ≥65 years (72.8%) and males (51.2%). Low temperatures were significantly associated with increased cardiovascular mortality. Compared to the median temperature (14.5 °C), temperatures at the 1st percentile (6.5 °C) increased risk by 57% (RR = 1.57; 95% CI: 1.29–1.91; $p < 0.001$), with cumulative effects over 21 days. No significant association was observed for high temperatures (33 °C; RR = 1.04; $p = 0.324$) or thermal amplitude. CONCLUSION: In the Metropolitan Region of Curitiba, cardiovascular mortality was associated with cold exposure, with a significant cumulative effect. No association was observed for heat or thermal amplitude, highlighting the influence of the local climate. These findings reinforce the need for public health policies addressing cold-related risks, particularly in vulnerable elderly populations.

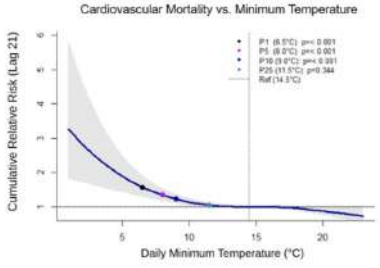

Figure 1: Cumulative relative risk of cardiovascular mortality associated with daily minimum temperatures. The non-linear exposure-response curve (Lag 0–21 days) demonstrates a statistically significant increase in mortality risk at extreme cold percentiles (P10 9.0°C; $p < 0.001$) when compared to the optimal reference temperature of 14.5°C.

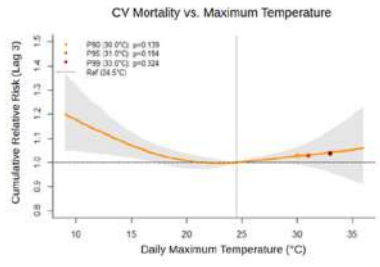

Figure 2: Cumulative relative risk of cardiovascular mortality associated with daily maximum temperatures. The exposure-response curve over a short-term 3-day lag period demonstrates no statistically significant increase in mortality risk during extreme heat events. Risk estimates at the highest temperature percentiles (P99 = 33.0°C) yielded p-values > 0.1 when compared to the 24.5°C reference threshold.

(1) FUNDAÇÃO DE AMPARO A PESQUISA DO ESTAODO DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Dyslipidemia, especially high LDL cholesterol, is a risk factor for cardiovascular diseases. Cardiovascular risk (CVR), estimated by scores such as Framingham, allows the identification of individuals more susceptible to cardiovascular events. In Brazil, there are gaps regarding the distribution of LDL and CVR related to regional inequalities in the macro-regions. Objectives: To analyze the association between high LDL and CVR in Brazilian adults according to sex and the country's macro-regions. Methods: A cross-sectional study using data from the National Health Survey (PNS) between 2014 and 2015, including 8,952 adults. Prevalences (%) and 95% confidence intervals (95% CI) for high LDL were estimated and stratified by sex and the 5 Brazilian macro-regions according to the Framingham risk score. High LDL was considered as levels ≥130 mg/dL. The CVR score was classified into low, intermediate, and high. Differences were evaluated using Pearson's chi-square test (p≤0,05). To verify the associations, logistic regression models were used to estimate Odds Ratios (OR) adjusted for age and race/skin color, with 95% CIs. Results and Conclusions: In women, a statistically significant association was observed between high LDL and cardiovascular risk in the Northeast and Southeast (p≤0,05). In the Northeast, the prevalence of high LDL was 4.2% (95% CI: 3.4–5.2) in low CVR, 8.0% (95% CI: 6.9–9.2) in intermediate, and 5.0% (95% CI: 4.2–5.8) in high risk, with high risk being associated with a greater chance of elevated LDL (OR 1.69; 95% CI: 1.08–2.63). In the Southeast, prevalences were 6.2% (95% CI: 5.4–7.1) in low risk, 8.6% (95% CI: 7.7–9.7) in intermediate, and 4.4% (95% CI: 3.8–5.2) in high risk, with a greater chance of elevated LDL among high-risk women (OR 3.11; 95% CI: 1.40–6.90). In men, a significant association between elevated LDL and cardiovascular risk was observed only in the Northeast (p≤0,05), with an elevated LDL prevalence of 3.7% (95% CI: 2.6–5.1) in low risk, 3.9% (95% CI: 2.9–5.1) in intermediate, and 3.4% (95% CI: 2.5–4.6) in high risk. In this region, high CVR was associated with a greater chance of elevated LDL (OR 2.19; 95% CI: 1.11–4.32)(p≤0,05). The association between elevated LDL and CVR was significantly observed only in the Northeast for both men and women, and in the Southeast for women, highlighting regional inequalities. This reinforces the need for cardiovascular health surveillance strategies with a territorial approach that is sensitive to regional and sex differences.

ASSOCIATION BETWEEN NON-ALCOHOLIC FATTY LIVER DISEASE AND SUBCLINICAL ATHEROSCLEROSIS: A SYSTEMATIC REVIEW

CAROLINE TABOSA KAMAR KHANJAR1; LETÍCIA HANNA MOURA DA SILVA GATTAS GRACIOLLI2; BEATRIZ DE OLIVEIRA2;

(1) UNIVERSIDADE DE TAUBATE - TAUBATÉ - SP - BRASIL; (2) FACULDADE DE MEDICINA DE JUNDIAI - JUNDIAÍ - SP - BRASIL;

Background/Introduction: Non-alcoholic fatty liver disease (NAFLD), recently redefined under the spectrum of metabolic dysfunction-associated steatotic liver disease (MASLD), has emerged as one of the most prevalent chronic liver disorders worldwide. Beyond hepatic complications, growing evidence suggests that NAFLD represents a systemic metabolic condition strongly associated with cardiovascular disease, currently recognized as the leading cause of mortality among affected individuals. Subclinical atherosclerosis, characterized by early vascular alterations preceding overt cardiovascular events, may provide important insight into the cardiovascular burden associated with NAFLD. Objectives: To systematically evaluate the association between non-alcoholic fatty liver disease and markers of subclinical atherosclerosis in adult patients. Methods: A systematic review was conducted according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. The databases PubMed/MEDLINE, Embase, Scopus, and Cochrane Library were searched from inception until March 2026 using the descriptors: "non-alcoholic fatty liver disease", "NAFLD", "MASLD", "subclinical atherosclerosis", "carotid intima-media thickness", "coronary artery calcium", and "endothelial dysfunction". Observational studies evaluating adult patients with NAFLD and at least one marker of subclinical atherosclerosis were included. Studies involving significant alcohol consumption, viral hepatitis, pediatric populations, or insufficient cardiovascular assessment were excluded. Two independent reviewers performed study selection and data extraction. Results and Conclusions: The included studies consistently demonstrated a significant association between NAFLD and increased markers of subclinical atherosclerosis. Patients with NAFLD showed higher carotid intima-media thickness values, increased prevalence of carotid plaques, elevated coronary artery calcium scores, and greater arterial stiffness when compared to controls without hepatic steatosis. The association persisted even after adjustment for traditional cardiovascular risk factors in several studies, suggesting an independent contribution of NAFLD to atherosclerotic progression. Furthermore, more advanced hepatic fibrosis appeared to correlate with worse vascular outcomes and higher cardiovascular risk profiles.

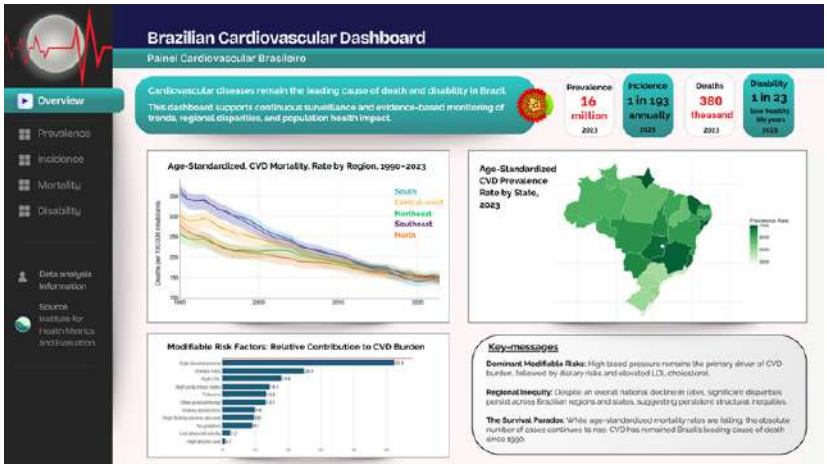
CARDIOMETABOLIC BENEFITS AND FAT FREE MASS PRESERVATION FOLLOWING A 12 WEEK MIXED-MACRONUTRIENT CALORIC RESTRICTION DIET IN HEALTHY WOMEN WITH OBESITY

HAYLEY M O'NEILL1; ANDREW P HILL2; NUALA M BYRNE2;

(1) BOND UNIVERSITY - AUSTRALIA; (2) UNIVERSITY OF TASMANIA - AUSTRALIA;



Background/Introduction: Caloric/energy restriction (ER) is an established strategy for reducing cardiovascular risk through weight loss; however, most trials demonstrate isolated benefits in single domains, and diet-only interventions frequently result in concurrent fat free mass loss of approximately 25% of total weight lost. The simultaneous impact of ER on fasting lipid, insulin, glucose profiles, blood pressure, and body composition within a single rigorously designed randomised controlled trial remains incompletely characterised. Objectives: Fifty-three women with obesity were randomised to 12 weeks of either: [1] continuous (CON), or [2] intermittent (INT) ER completed as 6×2-week blocks of ER alternating with 5×2-week blocks of energy balance (22 weeks total). Fifth-two participants completed a 4-week baseline phase and commenced the intervention (CON: N=24, 40.9±6.8 y, 96.9±12.4 kg, 35.4±3.8 kg.m 2; INT: N=28, 39.6±7.0 y, 98.9±11.8 kg, 35.7±3.5 kg.m-2). During ER, energy intake was equivalent to 67% of weight maintenance requirements in both groups. Macronutrient composition was matched across energy restricted diets (25–30% fat, 15–20% protein, 50–60% carbohydrate). Participants remained sedentary with no prescribed exercise. The primary outcome was weight loss; secondary outcomes included fasting lipids, glycaemic indices, ambulatory blood pressure, and body composition. Methods: For the N=17 CON and N=18 INT who completed the 12-week ER intervention and a 4-week post-intervention energy balance period, weight loss was greater for INT (8.5±1.8 vs 10.4±4.1 kg; P=0.02). Both groups demonstrated significant improvements in cardiometabolic domains: HOMA-IR but not lipids or blood pressure. Critically, fat free mass was preserved in both groups (mean change: -1.3±1.6 vs -0.7±1.0) with fat mass accounting for ≥ 84% to 94% of total weight lost, respectively; substantially exceeding the ~75% fat-fraction typically reported in diet-only ER trials. Results and Conclusions: A structured mixed-macronutrient ER intervention produced simultaneous improvements in HOMA-IR and body compostion over 12-weeks without prescribed exercise. Preservation of fat free mass despite 8.9-10.3% weight loss challenges view that exercise is essential for fat free mass maintenance during early dietary weight loss in women with obesity. Both continuous and intermittent energy restriction, without extreme macronutrient manipulation, yielded meaningful health benefits when adherence is supported, informing cardiovascular risk reduction strategy design.

CARDIOVASCULAR HEALTH DASHBOARD IN BRAZIL: ESTIMATES FROM GLOBAL BURDEN OF DISEASE STUDY DATA (1990–2023)

RAFAELA RIBEIRO LUCAS1; ALINE MARCADENTI2; EMILIO H. MORIGUCHI1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL; (2) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL;

Background/Introduction: The increasing burden of cardiovascular disease, combined with the expansion of health data, challenges health systems due to fragmented sources and limited integration. Converting large-scale epidemiological data into actionable insights remains complex, highlighting the role of interactive dashboards and visual analytics in integrating and communicating patterns of disease burden and inequalities. Objectives: To develop an interactive dashboard for monitoring the burden of cardiovascular disease in Brazil using the Global Burden of Disease (GBD) study data. Methods: Methodological study based on secondary data from the GBD study (Institute for Health Metrics and Evaluation - IHME), covering 1990–2023. Four key metrics were selected: prevalence, incidence, mortality, and DALYs. Development included: (I) metric selection; (II) data import (CSV); (III) data cleaning and structuring in RStudio; and (IV) dashboard development in Microsoft Power BI. Four analytical panels (overview, prevalence, incidence, mortality, and disability) were created, comprising 13 interactive visualizations, including temporal trends, sex- and age-stratified analyses, regional and state comparisons, and DALY (Disability-Adjusted Life Years) decomposition into Premature mortality (YLL) and YLDs (Years Lived with Disability). The data analysis for the dashboard was performed using RStudio (version 3.11.1), and the dashboard was developed in Microsoft Power Business Intelligence (version 2.124.2028.0). Results and Conclusions: Age-standardized rates (per 100,000) decreased from 1990 to 2023: mortality (325.16 to 146.97), incidence (743.62 to 517.33), prevalence (7,613.42 to 6,369.14), and DALYs (7,302.92 to 3,503.29), despite an increase in absolute case numbers. YLL declined, while YLD remained stable, indicating improved survival with persistent morbidity. Higher CVD prevalence and mortality rates were observed in the North and Northeast regions. The dashboard enables multidimensional exploration, supporting the identification of patterns and inequalities. This tool has the potential to support evidence-based decision-making and cardiovascular health planning. This platform is available to clinicians, hospital managers, funders, industry, and the general public, and can be accessed at the following link: https://app.powerbi.com/view?r=eyJrIjoiOWQ1ZmViODgtODEzYS00ZDdmLWFhODYtMjlmMmI3MjM0OWRlIiwidCI6IjM5ZDExMjExLWY2MTktNDlmNy04ZjZkLTJmZWQ4NzkwNjc2ZSJ9. CARDIOVASCULAR OUTCOMES AFTER LIVER TRANSPLANTATION AT A REFERENCE CENTER IN BRAZIL

FLÁVIO MARQUES ANDREON1; ANNA BEATRIZ VASCONCELOS SARLAS2; LETÍCIA RODRIGUES DE FREITAS3; MARIA EDUARDA COTTINI VILLELA2; LUCAS MAGALHÃES DOS REIS2;

(1) HOSPITAL DE CLÍNICAS DE ITAJUBÁ - ITAJUBÁ - MG - BRASIL; (2) FACULDADE DE MEDICINA DE ITAJUBÁ - ITAJUBÁ - MG - BRASIL; (3) FACULDADE DE MEDICINA DE ITAJUBÁ - ITAJUB´Á - MG - BRASIL;

Background/Introduction: Liver transplantation aims to improve survival in patients with irreversible hepatic disease; however, the procedure and postoperative period involve complex hemodynamic and metabolic changes. In the long term, normalization of the hyperdynamic circulation and the use of immunosuppressive agents may lead to the development of cardiovascular risk factors, which represent one of the leading causes of morbidity and mortality in this population. The objective of this study was to correlate cardiovascular outcomes with the development or reduction of comorbidities in liver transplant recipients. Objectives: This is a cross-sectional, retrospective, and descriptive study conducted through the analysis of medical records of 35 patients who underwent liver transplantation between 2017 and 2021 at a Reference Center in Brazil. Demographic data, MELD score, and clinical variables were collected for both pre and post-transplant periods, including Systemic Arterial Hypertension (SAH), Diabetes Mellitus (DM), Chronic Kidney Disease (CKD), Dyslipidemia, and Non-Alcoholic Steatohepatitis (NASH), as well as immunosuppression regimens. Statistical analysis employed binary logistic regression and 95% confidence intervals, with statistical significance set at p <= 0.05. Methods: The sample had a mean MELD score between 10 and 19. Prior to transplantation, the most prevalent comorbidity was Diabetes Mellitus (48.57%). In the post-transplant period, a statistically significant increase in the prevalence of SAH was observed, rising from 42.86% (pre-transplant) to 65.71% (post-transplant) (p = 0.025). Conversely, there was a significant reduction in NASH cases, from 14.29% to 0% (p = 0.027). No statistically significant changes were found for DM, CKD, or Dyslipidemia. The overall mortality rate was 42.86% (15/35); the majority of late deaths (53.33% of late-mortality cases) were of non-cardiac etiology, and no significant correlation was found between the variables studied and late cardiac death. Logistic regression analysis indicated that the use of the immunosuppressant Mycophenolate had a protective effect, reducing the probability of death. Results and Conclusions: Patients who underwent liver transplantation presented a high rate of cardiovascular complications during follow-up, with a notable increase in the prevalence of Systemic Arterial Hypertension. NASH did not recur or develop de novo in the analyzed sample. The use of Mycophenolate was identified as a protective factor for patient survival.

Table 2. Distribution of patients undergoing liver transplantation according to pre- and post-transplant comorbidities.

Variables	Occurred	Sample	%	95% CI	p-value
SAH	15	35	42.46%	0.1% to 45.6%	0.025
SAH post	23	35	65.71%		
DM	17	35	48.6%	–	0.406
DM post	16	35	45.7%		
CKD	2	35	5.71%	–	0.130*
CKD post	6	35	17.14%		
Dyslipidemia	6	35	17.14%	–	0.379
Dyslipidemia post	7	35	20.00%		
NASH	5	35	14.29%	2.7% to 25.9%	0.027*
NASH post	0	35	0%		
Metabolic syndrome	3	35	8.57%	–	0.5*
Metabolic syndrome post	3	35	8.57%		

SAH: Systemic Arterial Hypertension; DM: Diabetes Mellitus; CKD: Chronic Kidney Disease; NASH: Non-Alcoholic Steatohepatitis; CI: Confidence Interval. *Fisher's exact test.

Table 3. Distribution of patients undergoing liver transplantation according to the number and type of death.

CARDIOVASCULAR OUTCOMES OF TIRZEPATIDE VERSUS SEMAGLUTIDE IN PATIENTS WITH OVERWEIGHT AND OBESITY: A MULTINATIONAL RETROSPECTIVE COHORT STUDY

LARISSA MOREIRA ATTA COLLET1; LUCAS TRAMUJAS1; ALLEH NOGUEIRA2; RACHEL H. V. MACHADO1; ERLON OLIVEIRA ABREU-SILVA1; PEDRO G. M. DE BARROS E SILVA1; ALEXANDRE BIASI CAVALCANTI1; ALINE MARCADENTI1;

(1) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL; (2) PROGRAMA DE POS GRADUAÇÃO EM CARDIOLOGIA, UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: Obesity is a chronic, multifactorial condition with a significantly increasing the risk of cardiovascular disease. Glucagon-like peptide-1 (GLP-1) and dual glucose-dependent insulinotropic polypeptide (GIP)/GLP-1 receptor agonists have emerged as transformative therapies for weight loss and cardiometabolic management. However, while clinical trials have demonstrated the efficacy of these agents individually, head-to-head real-world evidence comparing their effectiveness on cardiovascular adverse events remains limited. Objectives: This study aims to compare the risk of major adverse cardiovascular events (MACE) between Tirzepatide and Semaglutide using a large “real-world” evidence database with a diverse population of patients with overweight and obesity. Methods: We conducted a retrospective cohort study using TriNetX data from 113 healthcare organizations. We included patients ≥ 18 years with overweight/obesity (BMI ≥ 27 kg/m² or ICD-10 codes E66.01, E66.8, E66.9, Z68.3, Z68.4). The index date was the first prescription of Tirzepatide or Semaglutide, requiring at least 30 days of follow-up post-initiation. We excluded patients with prior bariatric surgery, acute pancreatitis, pregnancy, or previous MACE. The primary outcome was MACE (the composite of all-cause mortality, myocardial infarction, and ischemic stroke). A landmark analysis (days 90–365) and exploratory analyses for baseline type 2 diabetes were performed. Results and Conclusions: Propensity-score matching resulted in 91,219 patients in each cohort, with a mean age of 51 years. The mean follow-up was 229 ± 132 days in the Tizerpartide group and 283 ± 120 days in the Semaglutide group. Tizerpartide was associated with a significantly lower risk of MACE (HR 0,81: 95% CI 0.74-0.90 p<0,001), all-cause mortality (HR 0.78: 95% CI 0.64-0.94; p=0.001), myocardial infarction (HR 0,82: 95% CI 0.70-0.96 p=0,01) and stroke (HR 0,78: 95% CI 0.67-0.92 p=0,03) when compared to Semaglutide. Landmark analysis results were consistent with the primary findings. Subgroup analysis showed no significant interaction between baseline type 2 diabetes and the primary outcome (p-interaction > 0.05). In this large real-world cohort, Tirzepatide was associated with a significantly lower risk of MACE, all-cause mortality, myocardial infarction, and stroke compared to Semaglutide among patients with overweight and obesity. These findings suggest that dual GIP/GLP-1 receptor agonism may offer superior cardiovascular protection in this population.

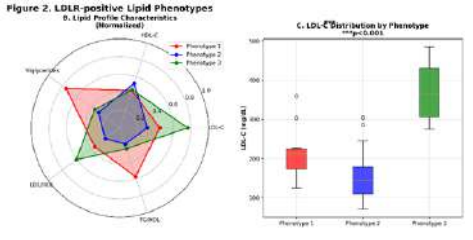
CLINICAL PHENOTYPES IN FAMILIAL HYPERCHOLESTEROLEMIA: IDENTIFICATION THROUGH CLUSTERING INTEGRATING GENETIC STRATIFICATION AND DUTCH MEDPED CRITERIA



ROSA MARIA DE OLIVEIRA GALVÃO DA ROSA COSTA1; JOÃO VICTOR SAVOLDI1; PABLO EDUARDO CAMPERONI LUCIANO1; RIELLI GOMES FALCÃO1; IAGO MOURA AGUIAR1; LORENNA OLIVEIRA MENEZES1; PAULO ROBERTO NUNES FILHO1; LUISA LATADO BRAGA1; VICTOR FERRO E SILVA COLARES1; MAÍSA MARQUES DO VALE1; RAFAELA ANDRADE PENALVA FREITAS1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Background/Introduction: Familial hypercholesterolemia (FH) is a genetic dyslipidemia associated with elevated and premature cardiovascular risk. Despite advances in genetic diagnosis, substantial phenotypic variability exists among affected individuals, posing a significant challenge to treatment personalization. Artificial intelligence-based strategies, particularly consensus clustering, have emerged as promising tools for identifying clinically relevant subgroups and supporting more precise therapeutic decision-making in hereditary dyslipidemias. Objectives: To identify distinct clinical phenotypes among genetically confirmed FH patients through the integration of genetic and clinical data using machine learning techniques, aiming to provide a foundation for individualized therapeutic strategies in preventive cardiology. Methods: Observational study including 164 genetically confirmed FH patients from a tertiary care registry in Brazil. Patients were stratified by genetic profile (variants in LDLR, PCSK9, or genetically negative) prior to consensus clustering. Derived lipid variables (LDL/HDL ratio, TG/HDL ratio, and non-HDL cholesterol) and clinical variables (Dutch MEDPED score, premature cardiovascular events, and physical manifestations) were used. Cluster robustness was assessed through bootstrap validation (500 iterations, 10 seeds), leave-one-out validation, sensitivity threshold analysis, and false discovery rate correction for multiple comparisons. Results and Conclusions: Three distinct clinical phenotypes were identified: hypertriglyceridemia (n=10; 10% with CV events), classic FH (n=40; 17.5% with CV events), and extreme phenotype (n=4; 50% with xanthomas) (Figure 1). Integration of Dutch MEDPED criteria with genetic stratification yielded a silhouette score of 0.731 — representing a 41.4% improvement over approaches based solely on genetic-lipid data (Figure 2). Patients carrying LDLR variants demonstrated high diagnostic certainty (97.4%), with explicable discordances observed in genetically negative severe phenotypes (7.3% of the cohort). Genetic stratification prior to clustering proved to be a methodologically robust approach for identifying clinically relevant lipid phenotypes in FH. These findings establish a methodological framework for precision medicine in hereditary dyslipidemias and support the development of phenotype-guided therapeutic protocols in preventive cardiology.

Background/Introduction: Statins are a cornerstone therapy for cardiovascular risk reduction in patients with type 2 diabetes mellitus (T2DM). While their lipid-lowering effects are well established, comparative data on their impact on systemic inflammatory markers remain limited. Objectives: To evaluate and compare the effects atorvastatin and rosuvastatin on inflammatory and lipid markers in patients with T2DM. Methods: We conducted a systematic review and meta-analysis of randomised controlled trials comparing atorvastatin and rosuvastatin at moderate to high doses in patients with T2DM. PubMed, Embase, and Cochrane library were searched. Analyses were performed at the study-arm level, yielding up to 12 comparisons. For outcomes with substantial baseline variability, pooled ratios of means (ROM) were calculated, while pooled mean differences (MD) were used for outcomes reported in uniform units. The primary outcomes were high-sensitivity C-reactive protein (hsCRP), low-density lipoprotein cholesterol (LDL-C), total cholesterol, and triglycerides. Subgroup analyses were conducted according to statin type and dose intensity. Random-effects models were applied, and heterogeneity was assessed using the I² statistic. Statistical analysis was performed using R (RStudio version 2026.01.0, Build 392). Results and Conclusions: Five randomized clinical trials including 752 participants with treatment durations ranging from 8 weeks to 6 months were included. Overall, statin therapy significantly reduced hsCRP levels (ROM 0.67; 95% CI 0.60–0.75; p<0.0001), corresponding to a 32.6% reduction from baseline (Figure 1). LDL-C (MD −43.31 mg/dL; 95% CI −55.52 to −31.09; p<0.0001), total cholesterol (MD −38.41 mg/dL; 95% CI −47.54 to −29.28; p<0.0001), and triglycerides (ROM 0.88; 95% CI 0.82–0.94; p<0.001) were also significantly reduced (Figure 2). No significant differences were observed between atorvastatin and rosuvastatin or across dose-intensity subgroups for any outcome. In patients with T2DM, atorvastatin and rosuvastatin provide comparable and significant reductions in inflammatory and lipid markers, with no evidence of superiority of one statin over the other. These findings support the use of either agent to address both dyslipidaemia and systemic inflammation in this high cardiovascular risk population. Further trials with standardised dosing, longer follow-up, and clinical cardiovascular endpoints are warranted.

COMPARING RIVAROXABAN, COLCHICINE AND ASPIRIN IN PATIENTS WITH STABLE CORONARY ARTERY DISEASE: A NETWORKING META-ANALYSIS

LUCAS RODRIGUES ORTIZ SALGADO NASCIMENTO1; BRUNO BRANCO RIGHETTO1; CAMILA GAGLIANONE FERREIRA2; LETICIA PEIXOTO FERREIRA GOMES3; FERNANDA MANFROI GUIMARÃES1; MARCELA VASCONCELOS MONTENEGRO4; ANA KARYN EHRENFRIED FREITAS1;

(1) UNIVERSIDADE POSITIVO - CURITIBA - PR - BRASIL; (2) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (3) UNIVERSIDADE CATOLICA DE PERNAMBUCO - RECIFE - PE - BRASIL; (4) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL;

Background/Introduction: Despite advances in medical therapy, patients with established coronary artery disease (CAD) continue to experience a significant burden of recurrent ischemic events, highlighting the presence of persistent “residual risk”. Colchicine (COL), a well-known anti-inflammatory agent, exerts its cardiovascular effects primarily through inhibition of inflammatory mechanisms that are central to the initiation, progression and destabilisation of atherosclerotic plaques. In parallel, rivaroxaban (RXA), an oral direct factor Xa inhibitor, targets the thrombotic arm of atherosclerosis by attenuating thrombin generation, thereby reducing fibrin formation and platelet activation. Although both COL and RXA have independently shown efficacy in reducing cardiovascular events, they target distinct yet interrelated mechanisms: vascular inflammation and thrombosis. The absence of direct head-to-head comparisons creates uncertainty regarding their relative efficacy. Objectives: Compare the efficacy and safety of COL versus RXA, based regimens in the prevention of recurrent cardiovascular events in patients with CAD. Methods: Systematic review and meta-analysis performed according to PRISMA guidelines. PubMed, Cochrane, and Embase were systematically searched for randomised clinical trials of patients with stable CAD, to compare with RXA, RXA plus Aspirin, RXA plus Clopidogrel and COL for event prevention. Primary outcomes were MACE, myocardial infarction and death from any cause, secondary outcomes were: cardiovascular death, stroke and heart failure. We estimated summary risk ratio (RR) using pairwise and network meta-analysis with random effects, with 95% confidence intervals (CI) for each strategy. All analyses were performed using the software R (version 4.5.3). Results and Conclusions: Seven studies comprising 38,821 patients with coronary artery disease were included. In the network comparison, COL alone reduced the risk of MACE (RR 0.49; 95% CI 0.28-0.87; p=0.02) and MI (RR 0.45; 95% CI 0.22-0.93; p=0.03) compared to control, both driven exclusively by direct evidence. The remaining comparisons MACE nor MI, including COL vs RXA, control vs RXA, and control vs RXA plus ASA were not statistically significant . Heterogeneity for these contrasts were substantial (I^2 = 81% and I^2 = 84.7%, respectively). CONCLUSION: In patients with CAD, COL was associated with lower rates of myocardial infarction and MACE, while RXA demonstrated no significant benefit compared with standard therapy.

EFFICACY AND SAFETY OF EVINACUMAB IN PATIENTS WITH FAMILIAL HYPERCHOLESTEROLEMIA: A SYSTEMATIC REVIEW AND SINGLE-ARM META-ANALYSIS

ARTUR MAIA CASTRO MIRANDA1; THEODORA CRISTINA CRUZ ASSIS2; ANISIO UCHOA LEITE SANTANA3; FLÁVIA BERNARDES MORAIS4; NATANAEL PAULA PORTILHO5;

(1) SEM VÍNCULO INSTITUCIONAL - BELO HORIZONTE - MG - BRASIL; (2) UNICAMP - CAMPINAS - MT - BRASIL; (3) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (4) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL; (5) CORPO DE BOMBEIROS MILITAR DO DISTRITO FEDERAL - BRASILIA - DF - BRASIL;

Background/Introduction: Familial hypercholesterolemia [FH] is a genetic disorder related to impaired or absent low-density lipoprotein [LDL]-receptor activity. Given its impact on both homozygous and heterozygous presentations, evinacumab has emerged as a novel lipid-lowering and monoclonal antibody against angiopoietin-like 3 [ANGPTL3], focusing on this population. Early clinical studies have demonstrated the drug’s effectiveness, but an updated comprehensive synthesis of available data is lacking. Objectives: To assess the efficacy and safety of evinacumab in patients with FH. Methods: We performed a single-arm meta-analysis of studies reporting efficacy and safety outcomes of evinacumab, according to the PRISMA statement. PubMed, Embase, and Cochrane were searched through April/2026. Studies evaluating evinacumab at dosages of 15mg/kg and 5mg/kg every 4 weeks were eligible for inclusion. Primary outcomes included percentage changes from baseline up to 24 weeks and absolute changes from baseline up to 48 weeks of follow-up for LDL, non-high-density lipoprotein [non-HDL], and lipoprotein(a) [Lp(a)]. Additionally, percentage changes were reported for apoprotein [Apo] B, and total cholesterol [TC] at 24 weeks. Random effects models were used to pool event rates and mean differences [MDs] with 95% confidence intervals [CIs] using R software [version 4.4.1]. Heterogeneity was assessed using I^2 statistics. Results and Conclusions: We included 197 patients (47% male; mean age 40 ±19 years) from 7 studies, of which 2 were RCTs. Evinacumab demonstrated reductions in lipid biomarkers, including LDL (MD -51.04%; 95% CI -58.21 to -43.86; I^2 = 77.1% / MD -144.17 mg/dL; 95% CI -158.74 to -129.60; I^2 = 12.2%), non-HDL (MD -45.53%; 95% CI -53.83 to -37.23; I^2 = 75.5% / MD -146.24 mg/dL; 95% CI -166.11 to -126.38; I^2 = 0.0%), and Lp(a) (MD -18.38%; 95% CI -29.33 to -7.42; I^2 = 97.7% / MD -12.18 mg/dL; 95% CI -26.96 to 2.60; I^2 = 78.6%). Additional changes were observed in ApoB (MD -38.83%; 95% CI -45.93 to -31.73; I^2 = 78.4%), and TC (MD -46.17%; 95% CI -54.84 to -37.50; I^2 = 85.3%). Evinacumab reported safety outcomes, including any adverse events [AEs] (69%; 95% CI 62.8 to 74.6; I^2 = 2.4%), serious AEs (7.3%; 95% CI 4.6 to 11.4; I^2 = 0%), treatment-emergent AEs leading to discontinuation (2.2%; 95% CI 0.9 to 5.5; I^2 = 0%) and death (1.8%; 95% CI 0.7 to 4.8; I^2 = 0%). In summary, evinacumab demonstrated a favorable efficacy and safety profile in patients with FH, with a sustained reduction in lipid profile over long term follow-up.

Efficacy endpoints. LDL-C, non-HDL, Lp(a) outcomes of evinacumab in patients with familial hypercholesterolemia. **A** Forest plot of absolute LDL-C mean change up to maximum follow-up. **B** Forest plot of percentage LDL-C mean change up to 24 weeks. **C** Forest plot of percentage non-HDL change up to 24 weeks. D Forest plot of percentage Lp(a) mean change up to 24 weeks. Abbreviations: max: maximum; %: percentage; CI: confidence interval; SD: standard deviation; MD: mean difference.

Safety of evinacumab in patients with familial hypercholesterolemia. **A** Forest plot of any adverse events. **B** Forest plot of serious adverse events. Abbreviations: %: percentage; CI: confidence interval.

FACTORS ASSOCIATED WITH LOW HDL CHOLESTEROL IN BRAZILIAN ADULTS: EVIDENCE FROM THE NATIONAL HEALTH SURVEY (2014-2015)

ELTON JUNIO SADY PRAES1; ANA CAROLINA MICHELETTI GOMIDE NOGUEIRA DE SÁ1; TÉRCIA MOREIRA RIBEIRO DA SILVA1; MARCELLA RIBEIRO DA CUNHA PEIXOTO1; RAISSA MOURÃO MARQUES DA SILVA1; GABRIEL SOARES DAMACENO1; MARIANA PIMENTA SOUZA MELO SATIRO1; LUIZ FELIPE SANTIAGO CAMPOLINA VIANA1; FILIPPE LIMA CAVALCANTE1; MARIA VITÓRIA LUIZ DA SILVA1; LUDMILA COSTA FARIA1; DEBORAH CARVALHO MALTA1;

(1) ESCOLA DE ENFERMAGEM DA UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Dyslipidemia refers to alterations in blood lipid levels, and reduced high-density lipoprotein (HDL) is a risk factor for atherosclerotic diseases. Given the high burden of cardiovascular diseases in Brazil, investigating factors associated with low HDL is relevant. Objectives: To analyze factors associated with low HDL cholesterol in Brazilian adults. Methods: A cross-sectional study was conducted using data from 8,952 adults from the National Health Survey (2014–2015). The outcome variable was low HDL, defined as ≤40 mg/dL. Explanatory variables included sociodemographic characteristics (sex, age group [18–29, 30–44, 45–59, ≥60 years], education level, race/skin color, and Brazilian regions), anthropometric measures (body mass index), lifestyle factors (binge drinking, smoking, and sufficient leisure-time physical activity), noncommunicable chronic diseases (diabetes, hypertension, chronic kidney disease, and self-reported anemia), and self-rated health. Associations were assessed using Poisson regression with robust variance, estimating adjusted prevalence ratios (PR) and 95% confidence intervals (95% CI). Variables with p≤0.05 were considered statistically significant. Results and Conclusions: Factors associated with low HDL included male sex (PR 2.00; 95% CI: 1.84–2.16), education level of complete primary or incomplete secondary (PR 1.23; 95% CI: 1.10–1.37), overweight (PR 1.46; 95% CI: 1.33–1.61), obesity (PR 1.72; 95% CI: 1.54–1.91), diabetes (PR 1.18; 95% CI: 1.06–1.32), chronic kidney disease (PR 1.22; 95% CI: 1.06–1.41), and hypertension (PR 1.18; 95% CI: 1.08–1.29). Protective factors included age ≥60 years (PR 0.84; 95% CI: 0.72–0.97), Black race/skin color (PR 0.85; 95% CI: 0.72–0.99), higher education (PR 0.91; 95% CI: 0.83–1.00), residence in the Southeast (PR 0.79; 95% CI: 0.72–0.88), South (PR 0.65; 95% CI: 0.57–0.73), and Central-West (PR 0.87; 95% CI: 0.79–0.97) regions, and binge drinking (PR 0.72; 95% CI: 0.63–0.82). In conclusion, low HDL cholesterol was associated with sociodemographic factors, unhealthy lifestyle behaviors, and noncommunicable chronic diseases.

GLP-1 RECEPTOR AGONISTS AND CARDIOVASCULAR OUTCOMES IN PATIENTS WITH OBESITY AND ESTABLISHED CARDIOVASCULAR DISEASE: A NARRATIVE REVIEW OF RANDOMIZED CONTROLLED TRIALS

JARDESON LIMA DA CRUZ JUNIOR1;

(1) INSTITUTO DO CORACAO EDSON SAAD/UFRJ - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: GLP-1 receptor agonists (GLP-1 RAs) have transformed cardiometabolic pharmacotherapy, demonstrating cardioprotective effects that extend well beyond glucose lowering. A decade of dedicated cardiovascular outcomes trials (CVOTs) now covers patients with type 2 diabetes (T2DM), obesity without diabetes, heart failure, and chronic kidney disease. Objectives: We aimed to synthesize the randomized controlled trial evidence on cardiovascular outcomes — including major adverse cardiovascular events (MACE), heart failure hospitalizations, cardiovascular mortality, and renal endpoints — across the GLP-1 RA class, encompassing liraglutide, subcutaneous and oral semaglutide, albiglutide, dulaglutide, lixisenatide, exenatide, tirzepatide, orforglipron, and cagrisema, and to evaluate whether cardiovascular efficacy represents a class effect or reflects molecular heterogeneity within the class. Methods: We performed a narrative review of phase 3 randomized trials and dedicated CVOTs identified through searches of PubMed/MEDLINE, Embase, Cochrane CENTRAL, and ClinicalTrials.gov, without date restriction, with final searches in March 2026. Two reviewers independently screened titles and abstracts; we manually searched reference lists to identify additional studies. Results and Conclusions: We identified ten CVOTs enrolling more than 97,000 participants. A clinically meaningful structural dichotomy emerged: agents with homology to native human GLP-1 — liraglutide (HR 0.87), subcutaneous semaglutide (HR 0.74), albiglutide (HR 0.78), dulaglutide (HR 0.88), and oral semaglutide (SOUL, NEJM 2025; HR 0.86) — consistently achieved MACE superiority over placebo, while exendin-4-based agents (lixisenatide and exenatide) did not. The SELECT trial demonstrated cardiovascular superiority of semaglutide 2.4 mg in 17,604 obese patients without T2DM (HR 0.80; p<0.001) — the first such result in a non-diabetic population — with benefits independent of glycaemic control and weight loss. Across trials, semaglutide reduced heart failure hospitalizations by 31% (HR 0.69) in patients with preserved ejection fraction, renal composite endpoints by 22–24%, and all-cause mortality by 14–19%. GLP-1 RAs with human GLP-1 structural homology consistently reduce MACE, heart failure hospitalizations, cardiovascular mortality, and renal progression, independently of glycaemic control. SELECT and SOUL establish obesity and oral administration as sufficient indications for GLP-1 RA cardioprotection — a paradigm shift that reshapes preventive cardiology.

HEART RATE VARIABILITY AND CARDIOVASCULAR HEALTH: AN UMBRELLA REVIEW

SARAH GAUCI1; DEBORAH N ASHTREE1; ELIZABETH GAMAGE1; EMMA TODD1; RUBEN FERNANDEZ-RODRIGUEZ1; HAJARA ASLAM1; AMELIA MCGUINNESS1; WOLFGANG MARX1; KEGAN MONEGHETTI2; MICHAEL BERK1; FELICE JACKA1; ADRIENNE O'NEIL1;

(1) DEAKIN INSTITUTE FOR MENTAL AND PHYSICAL HEALTH AND CLINICAL TRANSLATION, SCHOOL OF MEDICINE, DEAKIN UNIVERSITY - AUSTRALIA; (2) CARDIOMETABOLIC HEALTH AND EXERCISE PHYSIOLOGY, BAKER HEART AND DIABETES INSTITUTE - AUSTRALIA;

Background/Introduction: Heart rate variability (HRV) refers to the variation in the time interval between heartbeats and is a marker of autonomic nervous system function, capturing the balance between sympathetic and parasympathetic activity. Substantial evidence has linked HRV with both physical and mental health outcomes. Objectives: To our knowledge, no umbrella review has comprehensively synthesised evidence on the bidirectional relationship between HRV and cardiovascular health. This study aimed to collate and evaluate evidence from meta-analyses examining associations between HRV and cardiovascular outcomes. Methods: We conducted a systematic umbrella review of published meta-analyses, adhering to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Databases searched included Embase, Scopus, Web of Science, and the Cochrane Database of Systematic Reviews. Eligible studies were meta-analyses comprising adults aged 18 years and over that examined HRV as either an exposure or outcome in relation to cardiovascular health. Abstract screening was conducted in duplicate. Full-text screening and data extraction were conducted using the artificial intelligence software Elicit. Extracted data and screening decisions were validated by one reviewer. The methodological quality of included systematic reviews and meta-analyses was assessed using AMSTAR 2. Results and Conclusions: The search identified 11 studies meeting the inclusion criteria (n = >50 000 participants). Lower HRV was consistently associated with an increased risk of cardiac mortality and cardiovascular events across diverse populations, including individuals without prior cardiovascular disease, those with established cardiovascular disease, and those with other comorbid health conditions. However, substantial heterogeneity was observed across studies, reflecting differences in measuring HRV, patient populations, and analytic approaches. No universally accepted clinical threshold for HRV has been established, and assessment methods vary. Overall, reduced HRV appears to be a promising marker of cardiovascular risk, although greater standardisation in measurement is needed.

HIGH-SENSITIVITY C-REACTIVE PROTEIN (HS-CRP) LEVELS IN PATIENTS WITH AND WITHOUT OBESITY FOLLOWED AT A CARDIOMETABOLIC OUTPATIENT CLINIC: A CROSS-SECTIONAL OBSERVATIONAL STUDY

RIELLI GOMES FALCAO1; ROSA MARIA DE OLIVEIRA GALVAO DA COSTA1; IAGO MOURA AGUIAR1; JOAO VICTOR SALVOLDI1; PABLO EDUARDO CAMPERONI LUCIANO1; LORENNA OLIVEIRA MENEZES1; PAULO ROBERTO NUNES FILHO1; LUISA LATADO BRAGA1; VICTOR FERRO E SILVA COLARES1; MAISA MARQUES DO VALE1; RAFAELA ANDRADE PENALVA FREITAS1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Background/Introduction: Chronic inflammation plays a key role in atherosclerosis and residual cardiovascular risk. High-sensitivity C-reactive protein (hs-CRP) is a validated inflammatory biomarker, including in patients with adequate LDL-cholesterol control. Obesity is a heterogeneous condition, and different adiposity phenotypes may be associated with variable inflammatory responses. Thus, hs-CRP may contribute to a more individualized cardiovascular risk assessment. Objectives: To evaluate the association between elevated hs-CRP levels (≥2 mg/L) and obesity defined as body mass index (BMI) ≥30 kg/m² in patients followed at a tertiary cardiometabolic outpatient clinic. Methods: Cross-sectional observational study based on electronic medical records from a specialized cardiometabolic clinic. Eligible patients had established atherosclerotic disease, chronic kidney disease, dyslipidemia, diabetes mellitus, and/or obesity. Participants were classified into two groups according to BMI (<30 vs. ≥30 kg/m²) and high-sensitivity C-reactive protein was analyzed categorically (≤2 vs. >2 mg/dL). Categorical variables were compared using the chi-square test. Odds ratios (OR) with 95% confidence intervals (95% CI) were calculated, adopting p<0.05 as statistically significant. Results and Conclusions: A total of 969 patients were included; 19.8% (n=192) had obesity, and 54.7% were women. In the BMI ≥30 kg/m² group, median age was 65 years (IQR 56–74) and median BMI was 33.95 kg/m² (IQR 31.6–36.8). Obese patients more frequently presented diabetes mellitus (50.0% vs. 39.5%; p=0.010) and systemic arterial hypertension (83.3% vs. 73.8%; p=0.007). No significant differences were found regarding cerebrovascular disease or coronary artery disease. Median hs-CRP levels were lower in obese versus non-obese patients (1.4 vs. 1.8 mg/L). Elevated hs-CRP (≥2 mg/dL) occurred in 41.1% of obese and 47.0% of non-obese individuals, without significant association (OR 0.79; 95% CI 0.57–1.09; p=0.17). In this high cardiovascular risk population, obesity was not associated with higher hs-CRP levels. These findings suggest a complex and non-linear relationship between adiposity and systemic inflammation, supporting individualized cardiovascular risk assessment.

IMPACT OF PHYSICAL CONDITIONING, SLEEP PATTERNS, AND BMI ON STRESS LEVELS AMONG MEDICAL UNDERGRADUATES: A CROSS-SECTIONAL ANALYSIS

MATEUS ABRANCHES LOURES GISTO1; IANN PECENE GONÇALVES1; ZAQUELINE FERNANDES GUERRA1;

(1) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL;

Background/Introduction: The prevalence of psychological distress among medical students is a major concern, given the established link between chronic stress and impaired quality of life. As underscored by the WHO, lifestyle habits such as regular exercise, restorative sleep, and healthy weight maintenance serve as critical buffers for both mental and cardiovascular well-being. Despite these known benefits, evidence suggests that many students fail to meet the physical activity benchmarks. Objectives: This cross-sectional study investigates how physical exertion, sleep duration, and Body Mass Index (BMI) correlate with the stress profiles of individuals undergoing medical training. Methods: A cross-sectional study was conducted with medical students (1st to 12th periods) at a higher education institution in Juiz de Fora, MG, Brazil. Inclusion criteria: age ≥18 years, currently enrolled, and no physical limitations. Sociodemographic data, BMI, sleep duration, physical activity (IPAQ-short version), stress (DASS-21), and substance use (WHO-ASSIST) were collected via self-administered questionnaires (October-December/2023). Statistical analyses (SPSS v20.0) included linear and logistic regression to evaluate associations between variables, with a significance level of α=5%. The study was approved by the Ethics Committee (CAAE: 70685023.7.0000.5103). Results and Conclusions: In a sample of 396 medical students (66.4% female; mean age 22.0 ± 3.5 years), analysis revealed that highly active students presented stress scores 12.5% lower (β=-3,1; p=0,021) compared to sedentary individuals, while active individuals showed no significant difference (β=-0,8; p=0,535). Females presented higher scores than males, scoring 8.129 points higher on the stress scale (β=-8,1; p<0,001), highlighting marked vulnerability. Each additional hour of sleep reduced stress by 1.636 (β=-1,6; p=0,001), reinforcing its importance as a protective factor. Higher BMI levels were identified as an aggravating factor, with each additional unit resulting in a 0.29-point increase in the stress score (β=0,3; p=0,032). Variables such as study hours and course period did not significantly influence stress levels (p>0,05). Vigorous physical activity, sufficient sleep, and maintaining a BMI within healthy parameters are significantly associated with reduced stress levels in the medical student population, potentially offering a protective effect on cardiovascular health.

INCREMENTAL VALUE OF CORONARY ARTERY CALCIUM ADDED TO THE POOLED COHORT EQUATIONS FOR CARDIOVASCULAR EVENT PREDICTION IN PRIMARY PREVENTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

HILLARY HILLARY SANTOS1; RAFAEL CARRARO DE REZENDE REZENDE2; ESTHER MORAIS DA SILVA SILVA3; EMMYLAINE MENDES DE SOUSA SOUSA1; FERNANDA FALCÃO VEIGA FALCÃO3; PAMELLA JEMYMMA FREITAS DA SILVA JEMYMMA1; MARCELO DANTAS TAVARES DE MELO TAVARES1;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (2) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL; (3) FACULDADE DE MEDICINA NOVA ESPERANCA - JOÃO PESSOA - PB - BRASIL;

Background/Introduction: Pooled Cohort Equations (PCE) are widely used to estimate 10-year cardiovascular risk; however, they present limitations in the discrimination and reclassification of individuals. In this context, coronary artery calcium (CAC), a marker of subclinical atherosclerosis, has demonstrated potential to improve cardiovascular events (CEs) prediction. Objectives: To evaluate whether the addition of CAC to PCE improves CEs prediction in individuals undergoing primary prevention (PP) compared with PCE alone. Methods: Research was conducted in the MEDLINE and Google Scholar databases from April to May 2026, using the entry terms “PCE”, “CAC”, and “incremental value”, as well as their MeSH variations. Observational studies published from 2013 onwards, including adult patients without a prior history of CEs, and comparing PCE to PCE + CAC (in Agatston units), were included. Studies with missing data or not meeting the inclusion criteria were excluded. The outcome analyzed was cardiovascular risk discrimination (CRD), evaluated through the difference in C-statistics (ΔC-statistic), by adding CAC to PCE. The PRISMA 2020 statement was used to guide the reporting of this review. Zotero software was used for reference management, and Rayyan software was used for screening studies. Meta-analysis was performed using RStudio software. Results and Conclusions: Initial research revealed 379 studies, of which 11 were first excluded due to duplicates on Zotero, and 361 were then excluded in subsequent abstract and full-text screening on Rayyan. Seven studies were selected for review, but only three met the criteria to be included in the quantitative synthesis, comprising 61001 patients. Zafrir et al. reported an increase from 0.615 to 0.696 (IC95% 0.642-0.749) in CRD; Kermanshahchi et al., from 0.797 to 0.805 (IC95% 0.826-0.784); and Blaha et al, from 0.780 to 0.800 (IC95% 0.790-0.820). Overall ΔC-statistic demonstrated an improvement in CRD of ≅ 0.01, with IC95% near the null effect. Four other studies not included in meta-analysis showed an increase in CRD when CAC was added to PCE (ΔC-statistics of 0.024, 0.012, 0.015, and 0.018), with Razavi et al. (p < 0.001) and Akintoye et al. (p = 0.01) showing statistical significance. In conclusion, the addition of CAC to PCE was associated with a small, but consistent improvement in CRD across included studies. These findings support the potential incremental prognostic value of CAC in PP populations.

INFLUENCE OF SMOKING ON THE BENEFICIAL EFFECT OF STATINS ON ENDOTHELIAL FUNCTION

CAROLINE LYRA MOREIRA1; MATHEUS WANDERKOKE GONÇALVES NADER1; CELIO SANTOS CARVALHO1; ALICE ANDRADE PADILHA1; JULIANA DE MELLO GUIMARÃES1; MICHELLE RABELLO DA CUNHA1; WILLE OIGMAN1; MARIO FRTISCH TOROS NEVES1;

(1) HOSPITAL UNIVERSITARIO PEDRO ERNESTO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Smoking is an important modifiable risk factor for cardiovascular diseases. In the context of cardiovascular prevention, statins are well-known and widely used drugs; however, the relationship between smoking and statin efficacy remains unclear. Objectives: To evaluate the influence of smoking on the effects of statins on vascular function. Methods: This prospective study was conducted in two visits: baseline (V1) and after 12 weeks of atorvastatin use (V12), at doses of 20 or 40 mg according to cardiovascular risk. Non-diabetic patients of both sexes, aged 40 to 70 years, were included. Clinical and laboratory assessments were performed, along with pulse wave analysis by oscillometry using the Mobil-O-Graph® device and endothelial function assessment by flow-mediated dilation (FMD) of the brachial artery using ultrasound (Philips Affinity70®). Patients (n=38) were divided according to smoking status: 17 non-smokers (NS) and 21 smokers (S). Results and Conclusions: The groups were similar regarding mean age (54±7 vs 54±7 years, p=0.758), BMI (29.3±4.5 vs 30.2±4.9 kg/m², p=0.629), systolic blood pressure (126±12 vs 122±19 mmHg, p=0.154), and diastolic blood pressure (87±8 vs 82±14 mmHg, p=1.286). After 12 weeks of atorvastatin use, the NS group showed a significant improvement in endothelial function, with increased FMD (4.8±1.8 vs 6.5±2.9%, p=0.034), whereas the S group showed a smaller, non-significant increase (2.9±2.1 vs 4.3±2.2%, p=0.502). Similarly, central systolic blood pressure significantly decreased in the NS group (120±12 vs 112±10 mmHg, p=0.043), but not in the S group (118±12 vs 118±4 mmHg, p=0.880). Pulse wave velocity (PWV) decreased more in the NS group (8.7±3.6 vs 7.4±1.1 m/s, p=0.236) compared to the S group (8.8±4.2 vs 7.8±1.0 m/s, p=0.335), although neither reached statistical significance. In conclusion, Atorvastatin improved endothelial function and reduced central blood pressure in non-smokers, with no significant effect in smokers. These findings suggest that smoking ma

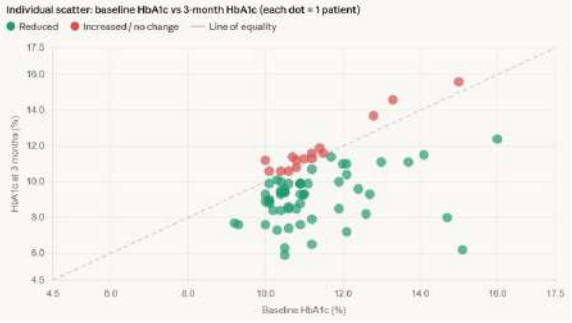
INTENSIVE GLYCEMIC FOLLOW-UP AND DIABETES REEDUCATION IN A PUBLIC CARDIO-METABOLIC OUTPATIENT CLINIC: REAL-WORLD EVIDENCE FROM THE AGIR PROGRAM



CATHERINE MENEZES COSTA1; FERNANDA ANICETO PEREIRA RABELO1; GUSTAVO FREITAS CARDOSO FAGUNDES1; DANIEL BRANCO ARAUJO1; DANIEL MAGNONI1; PAMELA NOGUEIRA CAVALCANTE1; KLEBER GOMES FRANCHINI1; GIULLIA SARABANDO CURY CORDEIRO PEREZ1; HENRI PAULO ZATZ1; FERNANDA LADEIA ABAD1; NEUSA ELI RODRIGUES PORTELA1; RAFAELA ANDRADE PENALVA FREITAS1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Background/Introduction: Type 2 diabetes mellitus (T2DM) affects 16.6 million adults in Brazil, with nearly 50% undiagnosed and high rates of poor glycemic control despite treatment. Patients with glycated hemoglobina (HbA1c) above 10% face substantially elevated risks of cardiovascular and microvascular complications, evidence suggests that each 1% absolute reduction in HbA1c is associated with a reduction of 14% in myocardial infarction risk and 37% in microvascular complications. Objectives: The AGIR Program (Acompanhamento Glicêmico Intensivo e Reeducação) was designed with the goal of reducing HbA1c in low-income, high-complexity patients in a public cardiology outpatient setting in São Paulo - Brazil, through a low-cost hybrid care model. Methods: Prospective observational cohort of consecutively enrolled patients in the AGIR Program (August–December 2025). Inclusion criteria: confirmed T2DM, HbA1c > 10% at baseline, age ≥ 18 years and classic hyperglycemia symptoms. The AGIR intervention consisted of: (1) monthly structured telephone contacts in months 1–2, including remote capillary glucose monitoring and diabetes education; and (2) a structured 30-minute in-person consultation at 3 months. HbA1c was measured at baseline and at 3 months. Statistical analysis: paired Wilcoxon signed-rank test (primary, given non-normal baseline distribution confirmed by Shapiro-Wilk W = 0.841, p < 0.001) and paired t-test (sensitivity analysis). Effect size: Cohen's d. Significance level: p < 0.05. Software: Python/SciPy. Results and Conclusions: Seventy patients with complete paired HbA1c data were analyzed. The mean baseline HbA1c was 11.26% (SD ± 1.38%; range 9.2–16.0%). In 3 months follow-up, mean HbA1c fell to 9.68% (SD ± 1.83%), yielding a mean absolute reduction of 1.58 percentage points (median −1.15 pp; range −8.9 to +1.3 pp). This reduction was highly statistically significant (Wilcoxon W = 175.0, p < 0.001; paired t = 7.235, p < 0.001) and reached a large effect size (Cohen's d = −0.865), a magnitude rarely reported in real-world public health interventions. Nearly 80% of patients responded positively, demonstrating the program's effectiveness across a heterogeneous, vulnerable population. These results were achieved through a low-cost, telephone-based hybrid model readily scalable within public health infrastructure provide. Real-world findings from this study provide strong preliminary evidence supporting the integration of structured telemedicine into intensive glycemic management in public cardio-metabolic outpatient care.

Parameter	Baseline HbA1c	3-Month HbA1c	Change (Δ)
N	71	70	70 paired
Mean ± SD	11.26 ± 1.38%	9.68 ± 1.83%	−1.58 ± 1.83 pp

Background/Introduction: Lipoprotein(a) [Lp(a)] is a genetically determined risk factor for atherosclerotic cardiovascular disease, but its prognostic role in peripheral artery disease (PAD) remains uncertain. Evidence linking elevated Lp(a) to cardiovascular and limb outcomes in PAD is inconsistent, with heterogeneous thresholds and study designs. Objectives: OBJECTIVE: To evaluate the association between elevated Lp(a) levels and the risk of cardiovascular and limb outcomes in patients with peripheral artery disease. Methods: METHODS: We conducted a systematic review and meta-analysis of randomized and non-randomized studies evaluating the association between Lp(a) levels and outcomes in adults with peripheral artery disease. Searches were performed in PubMed, Web of Science, and Cochrane databases. Elevated Lp(a) was defined according to study-specific thresholds or categories. Primary outcomes included major adverse limb events (MALE), major adverse cardiovascular events (MACE), all-cause mortality, and cardiovascular mortality. Pooled hazard ratios (HRs) were estimated using random-effects models (REML). Heterogeneity was assessed using the I^2 statistic, and subgroup analyses were performed according to elevated Lp(a), in mg/dl, thresholds. Sensitivity analyses were conducted using leave-one-out approaches. Results and Conclusions: Seven studies (n = 40,395) were included, with 18,448 were male. Mean age ranged from 68 to 75.1 years. Elevated Lp(a) levels was not associated with all-cause mortality (HR 1.48, 95% CI 0.01–179.38; I^2 = 96.6%), cardiovascular mortality (HR 2.04, 95% CI 0.44–9.50; I^2 = 85.6%), MACE (HR 1.55, 95% CI 0.13–18.82; I^2 = 82.0%), or MALE (HR 2.36, 95% CI 0.46–12.12; I^2 = 96.6%). Continuous analyses also showed no associations for MACE (HR 1.04, 95% CI 0.62–1.74; I^2 = 71.3%) or MALE (HR 1.02, 95% CI 0.70–1.49; I^2 = 90.9%). Heterogeneity was high but decreased for cardiovascular mortality after excluding Tomoi et al. (I^2 = 0%) and for MALE after excluding McClintick et al. (I^2 = 12.6%) CONCLUSION: In this meta-analysis, elevated Lp(a) levels compared with lower levels were not significantly associated with cardiovascular or limb outcomes in patients with peripheral artery disease, with wide intervals, highlighting the need for further large studies to clarify its prognostic role in this population.

MAPPING CARDIOVASCULAR RISK IN OLDER BRAZILIANS: HYPERTENSION AND DIABETES — A POPULATION-BASED ANALYSIS OF REGIONAL DISPARITIES

RAFAELA RIBEIRO LUCAS1; PATRICIA K ZIEGELMANN1; EMILIO H. MORIGUCHI1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: Population aging represents a major global transition that has profoundly influenced the epidemiology of cardiovascular disease. This shift is closely associated with the rising burden of cardiometabolic risk factors, such as type 2 diabetes mellitus (T2DM) and systemic arterial hypertension (SAH). Despite the increasing prevalence of these conditions in adults, little is known about the predictors and their impact on older people. Objectives: The objective of this study was to investigate the prognostic factors, such as age, sex, and geographical context, associated with the prevalence of T2DM and SAH in noninstitutionalized older people in Brazil. Methods: This study used data from the 2013 and 2019 editions of the Brazilian National Health Survey (PNS), a nationally representative household survey. The prevalence of self-reported SAH and T2DM among individuals aged 60 years and older, and their prevalence ratio (PR) were estimated via a Poisson regression model with robust variance adjusted by age group, sex, and Brazilian geographic region, and considering the complexity of the sampling plan. Results and Conclusions: A total of 11,177 participants were included in 2013, and 22,728 were included in 2019. In 2013, the prevalence of self-reported hypertension was 51.2% (95% CI: 50.2-52.3) and 56.4% in 2019 (95% CI: 56.0-56.8), with regional differences: 44.2% in the North and 54.1% in the South. The increase was significant only in the northeast (PRa=1.23; 95% CI: 1.15-1.31; p<0.001) and Midwest (PRa=1.12; 95% CI: 1.01-1.22; p<0.001) regions when adjusted for age and sex. In 2019, the prevalence of SAH varied between 48.3% in the north region and 57% in the south region. With respect to T2DM, in 2013, the prevalence of self-reported diabetes was 19.1 (95% CI: 17.9-20.4), and in 2019 it increased to 20.8 (95% CI: 20.2-21.5). The lowest prevalence is consistently observed in the North, and the highest prevalence is in the Midwest. All the regions showed a significant increase in the prevalence of T2DM. The rising prevalence of hypertension and T2DM among older adults indicates an expanding burden of cardiovascular risk in Brazil, disproportionately affecting certain regions. Addressing these disparities is essential to prevent future cardiovascular events and reduce inequities in aging populations.

PHYSICAL ACTIVITY AND CARDIOVASCULAR RISK ASSESSED BY THE FRAMINGHAM RISK SCORE IN BRAZILIAN ADULTS: ANALYSIS OF THE NATIONAL HEALTH SURVEY LABORATORY (2014-2015)

ELTON JUNIO SADY PRATES1; ANA CAROLINA MICHELETTI GOMIDE NOGUEIRA DE SÁ1; MARIANA PIMENTA SOUZA MELO SATIRO1; LUIZ FELIPE SANTIAGO CAMPOLINA VIANA1; FILIPPE LIMA CAVALCANTE1; GABRIEL SOARES DAMACENO1; PATRÍCIA VIEIRA DE LUCA2; DEBORAH CARVALHO MALTA1;

(1) ESCOLA DE ENFERMAGEM DA UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) FÓRUM INTERSETORIAL DE CCNTS NO BRASIL - SÃO PAULO - SP - BRASIL;

Background/Introduction: Physical inactivity is associated with the development of cardiovascular diseases (CVD). Cardiovascular risk (CVR) can be assessed using the Framingham Risk Score (FRS), which incorporates clinical and laboratory variables. Given the magnitude of CVD, investigating the association between physical activity (PA) and CVR is relevant. Objectives: To analyze the association between PA and the FRS and its components in Brazilian adults. Methods: A cross-sectional study was conducted using data from 8,941 adults from the National Health Survey Laboratory (2014–2015). The FRS was calculated separately for men and women, considering both the overall score and its components: age, total cholesterol (TC), high-density lipoprotein (HDL), systolic blood pressure (SBP) (treated and untreated), smoking, and diabetes. The outcome variable was PA, stratified by sex and classified as low or ideal. An ideal level was defined as 150 minutes of light/moderate intensity per week or 75 minutes of vigorous intensity. The explanatory variables were the FRS categories (low, intermediate, high) and its components. Socioeconomic variables were used to characterize the population. Associations between PA and the FRS and its components were assessed using logistic regression models, estimating age-adjusted odds ratios (OR) with 95% confidence intervals (95% CI). Variables with p≤0.05 were considered statistically significant. Results and Conclusions: Ideal PA was associated with lower odds of intermediate and high CVR in men (OR 0.34; 95% CI: 0.26–0.43 and OR 0.28; 95% CI: 0.21–0.37) and in women (OR 0.68; 95% CI: 0.54–0.85 and OR 0.53; 95% CI: 0.36–0.76). Both sexes showed lower odds of smoking (men: OR 0.66; 95% CI: 0.49–0.90; women: OR 0.39; 95% CI: 0.27–0.57). In men, PA decreased progressively after age 30 and was associated with lower odds of untreated SBP ≥160 mmHg (OR 0.50; 95% CI: 0.26–0.96). In women, ideal PA was positively associated with HDL ≥60 mg/dL (OR 1.70; 95% CI: 1.12–2.43) and with lower odds of untreated SBP at 130–139 mmHg (OR 0.65; 95% CI: 0.44–0.98) and 150–159 mmHg (OR 0.33; 95% CI: 0.12–0.93), as well as treated SBP at 130–139 mmHg (OR 0.49; 95% CI: 0.25–0.96) and 140–149 mmHg (OR 0.37; 95% CI: 0.18–0.80). Lower PA levels were observed among women aged ≥75 years (OR 0.46; 95% CI: 0.26–0.79). Overall, physical activity in Brazilian adults was associated with lower odds of intermediate and high cardiovascular risk in both sexes.

PREVALENCE OF HDL CHOLESTEROL IN BRAZILIAN ADULTS ACCORDING TO THE NATIONAL HEALTH SURVEY

GABRIEL SOARES DAMACENO1; TÉRCIA MOREIRA RIBEIRO DA SILVA2; ELTON ELTON JUNIO SADY PRATES2; MARCELLA RIBEIRO DA CUNHA PEIXOTO2; RAISSA MOURÃO MARQUES DA SILVA2; DEBORAH DEBORAH CARVALHO MALTA2; LUIZ LUIZ FILIPE SANTIAGO FELIPE SANTIAGO CAMPOLINA VIANA2; MARIANA PIMENTA SOUZA MELO SATIRO2; FILIPPE FILIPPE LIMA CAVALCANTE2; LUANA MARIA DELFINO2; JULIA FERREIRA COSTA2; ANA CAROLINA MICHELETTI GOMIDE NOGUEIRA DE SÁ2;

(1) FUNDAÇÃO DE AMPARO A PESQUISA DO ESTADO DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Dyslipidemia corresponds to alterations in blood lipid levels. With the increase in chronic non-communicable diseases (NCDs), such as obesity, diabetes, and metabolic syndrome, the prevalence of low high-density lipoprotein (HDL) tends to grow. Considering its role as an important cardiovascular risk marker, it is essential to investigate, through laboratory tests, the prevalence of low HDL in the Brazilian adult population. Objectives: To analyze the prevalence of low HDL cholesterol in Brazilian adults Methods: A cross-sectional study using laboratory data from 8,952 adults from the National Health Survey (PNS) between 2014 and 2015. The outcome variable was low HDL-cholesterol, considering ≤ 40 mg/dL as low and >40 mg/dL as the ideal value. Explanatory variables were: Sex (male and female); Age group in years (18 to 29, 30 to 44, 45 to 59, and 60 or older); Education (illiterate and incomplete elementary school, complete elementary school and incomplete high school, complete high school or more); Race/skin color (White and others, corresponding to Asian and Indigenous; Black and Brown); Regions of Brazil (North, Northeast, Southeast, South, and Midwest); anthropometric variables: body mass index (BMI), heavy alcohol consumption, smoking, NCDs, and self-rated health. Prevalences and 95% confidence intervals (95% CI) were estimated, and differences were evaluated using Pearson's χ^2 test (p≤ 0,05) Results and Conclusions: The prevalence of low HDL in Brazil was 34.81% (95% CI: 33.46–36.18), being higher in men (46.11%; 95% CI: 43.90-48.33), individuals with low education (42.18%; 95% CI: 38.53-45.92), Black race/skin color (36.97%; 95% CI: 35.08-38.89), smokers (39.82%; 95% CI: 36.09-43.67), individuals with obesity (42.99%; 95% CI: 39.99-46.04), diabetes (45.03%; 95% CI: 40.85-49.28), chronic kidney disease (41.74%; 95% CI: 36.71-46.95), hypertension (40.66%; 95% CI: 37.96-43.41), and worse self-rated health (38.76%; 95% CI: 34.17-43.56). Regarding the regions of Brazil, the lowest prevalences occurred in the South (28.75%; 95% CI: 25.90-31.78) and Southeast (33.53%; 95% CI: 30.98-36.18), and the highest in the North (39.88%; 95% CI: 37.66-42.14) and Northeast (38.37%; 95% CI: 36.54-40.23) (p≤ 0,05). Low HDL cholesterol affects 1 in 3 Brazilian adults and is associated with sociodemographic factors, unhealthy lifestyles (smoking), the presence of overweight and obesity, and NCDs.

PROBIOTIC BLEND IMPROVES TRIGLYCERIDE LEVELS BUT DOES NOT AFFECT TMAO CONCENTRATIONS IN PATIENTS UNDERGOING CORONARY ARTERY BYPASS GRAFTING SURGERY

MARCOS ANTONIO CANTERO1; MARIANA GALEGO CANTERO2; MARCOS EDUARDO PORTUGAL RODRIGUES2; ANA CLARA SCHREIBER2; ISABELLA KLOSTER DE PAULA2; EDUARDA CAROLINE MATTOS DE ALMEIDA2;

(1) UNIVERSIDADE FEDERAL DA GRANDE DOURADOS - DOURADOS - MS - BRASIL; (2) UNIVERSIDADE ESTADUAL DO OESTE DO PARANÁ - CASCAVEL - PR - BRASIL;

Background/Introduction: Cardiovascular disease (CVD) remains one of the leading causes of mortality worldwide. Among nutrient-derived metabolites, trimethylamine N-oxide (TMAO) has been associated with adverse cardiovascular outcomes. Evidence demonstrates a direct association between elevated circulating TMAO concentrations and an increased risk of major adverse cardiovascular and cerebrovascular events, suggesting a contributory role in CVD pathophysiology. Although the mechanistic basis of this relationship remains incompletely understood, modulation of the gut microbiota has been proposed as a potential strategy to influence TMAO-related pathways. Therefore, this study investigated the effects of a commercially available probiotic blend on circulating TMAO concentrations and lipid parameters in patients undergoing CABG, testing the hypothesis that probiotic supplementation could favorably modulate TMAO levels and improve postoperative lipid profiles. Objectives: To evaluate the effects of a probiotic blend on circulating TMAO and cardiometabolic outcomes in patients undergoing coronary artery bypass grafting (CABG). Methods: In this randomized, placebo-controlled, triple-blind trial, adults undergoing CABG received a probiotic blend or placebo for 90 days. Outcomes were assessed at baseline, 30, and 90 days and analyzed using intention-to-treat linear mixed-effects models. Results and Conclusions: Longitudinal analyses based on linear mixed-effects models showed no significant time × group interaction for circulating TMAO, indicating that probiotic supplementation did not meaningfully alter this metabolite over the follow-up period. In contrast, triglyceride concentrations exhibited a significant time × group interaction, with a progressive reduction observed in the probiotic group and minimal temporal variation in the placebo group. C-reactive protein decreased markedly in both groups, without differential effect between arms, while HDL cholesterol, waist circumference, and left ventricular ejection fraction showed significant time effects without evidence of differential trajectories. In conclusion, probiotic supplementation did not significantly modify TMAO levels in CABG patients but was associated with a distinct longitudinal reduction in triglycerides, supporting a potential adjuvant role in postoperative lipid metabolism and warranting further investigation.

PROGNOSTIC AND INCREMENTAL PREDICTIVE VALUE OF CIRCULATING BIOMARKERS FOR CARDIOVASCULAR RISK IN ASYMPTOMATIC ADULTS: A SYSTEMATIC REVIEW

BRUNA FELISBERTO DOS SANTOS1; EMANUELLE APARECIDA DE AGUIAR FAUSTO1; JULIANA LUIZA PAULA DE ARAÚJO1; LAURA SETRAGNI FREITAS1; LUANA LINS SILVA TÉRCIO1; RENÊH DANTAS DE SÁ1; VANDERLÉIA MATOS DA SILVA1; TARCÍSIO TAYLON DE AGUIAR FAUSTO2;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (2) UNICAMP - CAMPINAS - MT - BRASIL;

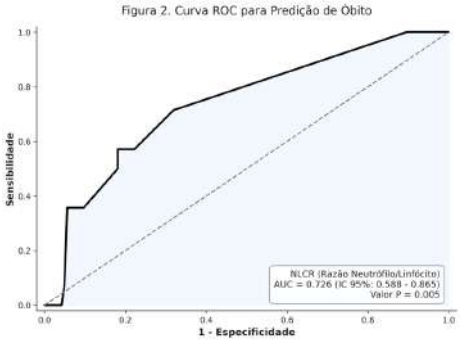
Background/Introduction: Cardiovascular diseases (CVD) remain the leading cause of global morbidity and mortality, reinforcing the importance of risk stratification (RS) in asymptomatic adults (AA) for guiding primary prevention. Traditional clinical scores are widely used but have limited predictive (PD) capacity and do not fully capture disease pathophysiology. In this context, circulating biomarkers (CB), reflecting inflammation, myocardial injury, and endothelial dysfunction, have shown association with major adverse cardiovascular events (MACE). However, it remains unclear whether CB, beyond prognostic value, significantly improve risk prediction when added to traditional models. Objectives: This study aims critically evaluate the available evidence on the prognostic value and the potential incremental PD value of CB in CV risk stratification for AA, highlighting their applicability in clinical practice. Methods: The literature search was performed in PubMed/MEDLINE, Embase, and SciELO databases using the descriptors “cardiovascular risk”, “novel biomarkers”, and “asymptomatic adults” combined with Boolean operators. Of the 807 initial records, 43 were selected for full-text review, and 15 studies published within the last 10 years were ultimately included for data extraction, following PRISMA guidelines. Results and Conclusions: The analysis demonstrated that the TyG Index is associated with increased CV risk, including MACE incidence and higher estimated risk in hypertensive populations. Its PD improves when combined with central obesity parameters, suggesting incremental value over isolated metabolic CB. High-sensitivity cardiac troponins (hs-cTnI and hs-cTnT) showed strong independent associations with coronary events and CV mortality, improving risk discrimination and reclassification beyond traditional models. NT-proBNP emerged as a robust independent predictor of MACE, improving risk stratification when added to clinical models. sST2 showed prognostic value, with longitudinal increases associated with higher MACE rates and superior PD compared to natriuretic peptides in some populations, particularly in higher-risk groups. Additionally, multimarker approaches incorporating proteomic panels and genetic scores improved discrimination (AUC up to 0.803) and risk reclassification, supporting their role in precision cardiology and individualized risk assessment. Despite these findings, heterogeneity, limited validation, and high costs remain barriers to clinical implementation in routine practice.

Biomarker Predictive Value Summary

Biomarker	Studies	Predictive value
TyG index	Xue Xia 2024; Piskorz 2024	Associated with ASCVD; better with obesity markers; linked to higher risk in hypertension
hs-cTnI / hs-cTnT	Iribarren 2016; Wu 2022; Raymondi 2019	Strong predictor of coronary events; improves risk classification; detects subclinical injury
NT-proBNP	Wu 2022; Ballo 2016	Predicts CV events and heart failure; improves risk stratification
sST2	Watson 2020; Harmon 2021	↑ MACE risk (~8% per unit); may outperform BNP; independent predictor
hs-CRP	Kurt 2025; Li 2025	Predicts CV risk; additive effect with metabolic markers
Proteomic panels	Hoogeveen 2020; Royer 2024; Sun 2023; Madizi 2024	Improve AUC (up to 0.803); improve reclassification

19693

PROGNOSTIC VALUE OF THE NEUTROPHIL-TO-LYMPHOCYTE RATIO AND C-REACTIVE PROTEIN IN CARDIAC PATIENTS HOSPITALIZED FOR COMMUNITY-ACQUIRED PNEUMONIA



JOÃO RICARDO CAMBRUZZI ZIMMER1; GUILHERME CRISTIANETTI FRISON2; RENATO SELIGMAN2;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (2) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: Community-Acquired Pneumonia (CAP) acts as a potent trigger for decompensation in patients with prior cardiovascular disease. In this subgroup, risk stratification is challenging. Traditional scores such as CURB-65 and markers like C-Reactive Protein (CRP) may have reduced accuracy in cardiac patients due to factors such as intrinsic renal dysfunction and chronic low-grade inflammation. The Neutrophil-to-Lymphocyte Ratio (NLR) emerges as a promising and integrated index, combining the neutrophilia of the innate immune response and the lymphopenia of sympathetic neurohormonal stress. Objectives: To evaluate the prognostic value of NLR as an independent predictor of in-hospital mortality in cardiac patients admitted for CAP, comparing its accuracy with isolated CRP and the CURB-65 clinical score. Methods: A single-center retrospective cohort study involving 158 patients with underlying cardiovascular disease (Heart Failure, Acute Myocardial Infarction, or Essential Hypertension) admitted for CAP. The primary outcome was in-hospital mortality. Statistical analysis included non-parametric tests for continuous variables and multiple logistic regression adjusted for confounding variables (age, sex) and comorbidities (COPD, neoplasms, diabetes). Results and Conclusions: The cohort was characterized by advanced age (68.4% elderly) and an overall mortality rate of 8.9%. Median NLR was significantly higher in non-survivors compared to survivors (13.13 vs. 5.86; p=0.005). In contrast, CRP (p=0.126) and the CURB-65 score (p=0.112) failed to discriminate the outcome. In the multivariable analysis, NLR remained an independent predictor of mortality, as did female sex. In conclusion, NLR is a superior prognostic tool to CRP and CURB-65 in this setting. As a universally available, low-cost biomarker, it more accurately captures integrated systemic stress and should be incorporated into the admission assessment to allow for earlier interventions in this vulnerable population.

(1) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL; (3) UNIVERSIDADE CHRISTUS - AFGHANISTAN;

Background/Introduction: Sleep is an essential physiological state for the regulation of metabolic, hormonal, and cardiovascular functions, playing a fundamental role in childhood growth. However, reduced sleep duration has become increasingly prevalent in the pediatric population. Consequently, there is an increased risk for the development of cardiovascular diseases, such as arrhythmias and elevated blood pressure (BP), representing an important health concern. Objectives: To analyze the evidence regarding the association between sleep deprivation and cardiovascular risk in the pediatric population, evaluating the impact of sleep duration and quality on the cardiometabolic profile. Methods: A systematic review guided by PRISMA 2020 was conducted using searches in the PubMed, SciELO, and EMBASE databases. The descriptors “sleep deprivation,” “pediatrics,” “children,” “obesity,” “hypertension,” and “heart rate” were combined using Boolean operators (AND/OR). Articles published within the last 10 years involving pediatric populations and evaluating the association between sleep deprivation and cardiovascular risk were included. Study selection was performed using the Rayyan platform. Of the 90 studies identified, 11 were selected for analysis. Results and Conclusions: The analysis of 11 studies resulted in a sample of 38,455 children and adolescents. In the ABCD study (n = 3,498), only 18.4% of overweight participants achieved an adequate body mass index (BMI) during follow-up, a difficulty associated with poor sleep hygiene and excessive screen time. A Canadian analysis (n = 4,169) identified sleep as a protective factor against obesity and hypertension ($p < 0.02$). In the hemodynamic spectrum, the IDEFICS cohort (n = 16,228) associated sleep restriction with elevated blood pressure levels, particularly in individuals with irregular sleep routines. Finally, the clinical relevance extends into adulthood, as demonstrated by the Add Health study (n = 4,151), in which late sleep schedules and the absence of regular sleep patterns during adolescence significantly increased cardiovascular risk at 30 years of age (OR 2.32). The analyzed evidence demonstrates that sleep deprivation, irregular sleep patterns, and delayed sleep are associated with obesity, elevated blood pressure, and metabolic dysfunctions in the pediatric population, contributing to increased cardiovascular risk.

SAGITTAL ABDOMINAL DIAMETER VERSUS WAIST CIRCUMFERENCE IN CARDIOVASCULAR RISK PREDICTION AMONG OVERWEIGHT AND OBESE ADULTS

JHAYME FARIAS CARTAXO LOPES1; IVSON CARTAXO BRAGA1; HERBERT DOS REIS CABRAL1; OHANNA NURIA NUNES PEREIRA INACIO1; PABLO HENRIQUE GUEDES SILVA1; GABRYELLE GUEDES DANTAS DA NÓBREGA1; PEDRO PAULO ALVES VIEIRA1; ANA BEATRIZ DUTRA GAMA1; MARIA EDUARDA DE ALENCAR TAVARES NORÕES1; LUCAS ALBUERNE DINIZ BEZERRA1; ANA LUIZA MAURÍCIO LEITE BARREIROS1; ALEXANDRA ISIS SOARES DE LIMA DANTAS1;

(1) FAMENE - JOÃO PESSOA - PB - BRASIL;

Background/Introduction: Visceral adiposity is a key determinant of cardiovascular risk, and traditional anthropometric measures such as body mass index (BMI) and waist circumference (WC) have limitations in accurately estimating this compartment. The sagittal abdominal diameter (SAD) has been proposed as a more specific marker of visceral fat and may improve cardiovascular risk stratification. Objectives: To compare the association of sagittal abdominal diameter and waist circumference with cardiovascular risk scores (Framingham, ASCVD, and PREVENT) in overweight and obese adults. Methods: Cross-sectional analytical study including 36 adults (BMI ³25 kg/m²) in primary prevention. Anthropometric measures (SAD, WC, BMI) were obtained, and cardiovascular risk scores were calculated. Associations were assessed using Spearman correlation, and dependent correlations were compared using Zou's method (95% CI). Results and Conclusions: SAD showed weak positive correlations with ASCVD (r=0.23), PREVENT (r=0.26), and Framingham (r=0.23), while WC showed correlations close to zero. Comparisons favored SAD over BMI for ASCVD (Dr=0.52; 95% CI: 0.14–0.72) and PREVENT (Dr=0.47; 95% CI: 0.09–0.70), with similar trends for Framingham. However, confidence intervals for comparisons with WC included the null value. Overall, associations were weak. SAD demonstrated a more consistent pattern of association with cardiovascular risk scores, suggesting potential as a marker of visceral adiposity, although no clear statistical superiority was established.

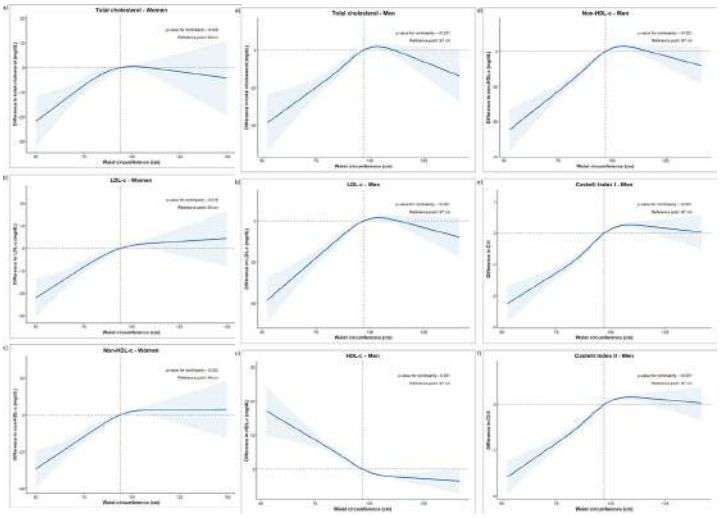
TIRZEPATIDE AND CARDIOVASCULAR RISK REDUCTION IN TYPE 2 DIABETES AND OBESITY: A META-ANALYSIS

RAFAEL FORTES LOCATELI1; CAMILA SALES FAGUNDES2; PEDRO HENRIQUE TAVARES FOGAÇA2; DIEGO CHEMELLO2; MATEUS DINIZ MARQUES2;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL; (2) UNIVERSIDADE FEDERAL DE SANTA MARIA - SANTA MARIA - RS - BRASIL;

Background/Introduction: Type 2 diabetes mellitus (T2DM) and obesity increase cardiovascular disease risk. Tirzepatide, a dual GIP/GLP-1 receptor agonist, has demonstrated superior metabolic effects. Objectives: Evaluate the effects of Tirzepatide on cardiovascular risk markers and adverse events in patients with T2DM or obesity. Methods: We searched PubMed, Embase, and the Cochrane Library up to March 2025 for randomized controlled trials. A random-effects meta-analysis was conducted using mean differences (MD) or odds ratios (OR) with 95% confidence intervals (CI). Heterogeneity was assessed with the I² statistic. The study protocol was registered in PROSPERO (registration number CRD420251007910). Results and Conclusions: Results: Four trials comprising 5,143 patients were included. Tirzepatide reduced systolic blood pressure compared to placebo or insulin across all doses (MD: -5.52 mmHg; 95% CI: -6.27 to -4.78; p<0.00001), with consistent reductions at 5 mg (MD: -5.15 mmHg; p<0.00001), 10 mg (MD: -6.37 mmHg; p<0.0001), and 15 mg (MD: -5.8 mmHg; p<0.00001). Diastolic blood pressure also decreased with 5 mg (MD: -2.85 mmHg; p=0.02) and 15 mg (MD: -2.53 mmHg; p=0.005), and in pooled analysis (MD: -1.77 mmHg; p<0.00001). Tirzepatide reduced body mass index (pooled MD: -5.27 kg/m²; 95% CI: -5.89 to -4.66; p<0.00001), with greater reductions at higher doses. Fasting serum glucose decreased significantly at 15 mg (MD: -9.31 mg/dL; p<0.00001) and in pooled analysis (MD: -6.59 mg/dL; p=0.0004). Low densisty lipoprotein cholesterol (LDL-c) levels also declined (pooled MD: -7.51 mg/dL; p=0.0002), with the 15 mg dose showing the largest reduction (MD: -12.48 mg/dL; p<0.0001). HDL increased in pooled analysis (MD: 1.42 mg/dL; p=0.03). Conclusion: Tirzepatide demonstrated significant improvements in multiple cardiovascular risk markers in patients with T2DM or obesity, including reductions in blood pressure, body mass index, fasting serum glucose and LDL. These findings support the role of Tirzeptide as a promising therapeutic strategy for cardiovascular risk reduction in the studied population. However, placebo-controlled outcome trials are needed to definitively establish its independent cardiovascular benefit.



20381

WAIST CIRCUMFERENCE AND ATHEROGENIC LIPID PROFILE IN BRAZIL: EVIDENCE OF SEX-SPECIFIC NONLINEAR ASSOCIATIONS

DANIEL FERREIRA DA SILVA1; ELIZABETE ALEXANDRE DOS SANTOS1; GABRIELA SEGALLA MARONI1; DIRCE MARIA LOBO MARCHIONI1;

(1) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Background/Introduction: Waist circumference (WC) is an important marker of abdominal adiposity and cardiovascular risk. Although increases in abdominal adiposity are classically associated with progressive worsening of the lipid profile, evidence suggests that this relationship may present different effect magnitudes across the distribution of WC, with possible thresholds and nonlinear patterns, particularly according to sex. However, population-based studies evaluating these nonlinear associations in the Brazilian population remain scarce. Objectives: To evaluate sex-specific nonlinear associations between WC and lipid biomarkers of cardiovascular risk in Brazilian adults. Methods: This cross-sectional study used data collected between 2014 and 2015 from the laboratory subsample of the 2013 Brazilian National Health Survey (PNS). A total of 8,405 adults with valid waist circumference (WC) and lipid profile data were included. Total cholesterol (TC), high-density lipoprotein cholesterol (HDL-c), low-density lipoprotein cholesterol (LDL-c), non-high-density lipoprotein cholesterol (non-HDL-c), and Castelli Index I (CI-I) and II (CI-II) were evaluated. Analyses accounted for the complex sampling design. Restricted cubic splines and segmented linear regression were used to investigate nonlinear associations. Models were adjusted for sociodemographic and behavioral variables. Results were expressed as beta coefficients (β), 95% confidence intervals (95%CI), and p-values. Analyses were performed using R version 4.4.2. The 2013 PNS was approved by the National Research Ethics Commission (CONEP) of the Brazilian National Health Council (approval number 328,159). Results and Conclusions: Among women, nonlinear associations were observed between WC and TC (p=0.006), LDL-c (p=0.016), and non-HDL-c (p=0.002), with slope changes around 94 cm (figure 1). Below this point, each 10-cm increase in WC was associated with increases of 4.5 mg/dL in TC, 4.8 mg/dL in LDL-c, and 6.8 mg/dL in non-HDL-c (all p<0.001). Among men, all biomarkers showed nonlinear behavior, with an inflection point around 97 cm (figure 2). Below this value, each 10-cm increase in WC was associated with higher TC (+9.9 mg/dL), LDL-c (+10.2 mg/dL), non-HDL-c (+15.3 mg/dL), CI-I (+0.61), and CI-II (+0.42), as well as lower HDL-c (-4.1 mg/dL) (all p<0.001). Above the inflection points, attenuation of the associations was observed. These findings indicate that abdominal adiposity is associated with a worse lipid profile in a heterogeneous manner according to sex and WC level.

Background/Introduction: Kawasaki disease (KD) represents the leading cause of acquired heart disease in childhood in developed countries, often resulting in coronary aneurysms that may require Coronary Artery Bypass Grafting (CABG). Despite the severity of that complication, there is still no definitive consensus on the choice of surgical conduit, as most revascularization guidelines are based on the adult population Objectives: Evaluate long-term coronary graft patency and prevalence of affected vessels in KD undergoing CABG. Methods: A systematic review and meta-analysis of observational studies evaluating patients with Kawasaki disease undergoing CABG was performed. Studies reporting graft type, graft patency, or angiographic distribution of coronary involvement were included. Case series, reviews and non-original studies were excluded. The defined primary outcomes were arterial and saphenous vein graft patency and the number of vessels involved. Pooled analyses were conducted using random-effects models, continuous outcomes were summarized as pooled means and prevalence outcomes were estimated using generalized linear mixed models, both with 95% confidence intervals. Statistical heterogeneity was assessed using I2. Analyses were performed using the software R (version 4.5.3). Results and Conclusions: Arterial grafts showed higher patency compared to saphenous vein grafts (mean difference 34.9%; 95% CI 20.7-49.1; I2=96.9%). Arterial patency was 84.35% (95% CI 77.15-92.22) at 10 years and 87.00% (95% CI 35.12-64.70) at 20 years, whereas SVG patency was 47.48% (95% CI 35.12-64.18; I2=96.8%). Single-, double-, and triple-vessel disease were observed 34.28% (95% CI 12.92-64.70), 62.33% (95% CI 27.89-87.62), and 14.67% (95% CI 7.47-26.80), respectively. Giant aneurysms were most frequent in the right coronary artery (70.44%), followed by the left anterior descending (60.61%), left main (41.85%) and left circumflex (23.45%). CONCLUSION: In Kawasaki disease patients undergoing CABG, arterial grafts demonstrate superior long-term patency compared to saphenous vein grafts, supporting their preferential use. Coronary disease was found to be frequently multivessel, with giant aneurysms predominantly affecting the right coronary and left anterior descending arteries. However, the observational nature of current evidence, along with the high heterogeneity identified, highlights the need for prospective studies to better establish these findings.

DOES BODY MASS INDEX INFLUENCE OUTCOMES AFTER CARDIAC SURGERY? A SINGLE-CENTER REGISTRY

LUCIA DE LA COSTA1; JESICA ARANDA1; CAROLINA FLAMINI1; JULIAN CARDINALE1; FLORENCIA GARDINO1; YANELA BERTELLO1; MAILEN DEZIO1; MANUEL GENERO1; SEBASTIÁN GARCIA-ZAMORA1;

(1) SANATORIO DELTA, ROSARIO - ARGENTINA;

Background/Introduction: The prevalence of obesity has increased over recent decades and is associated with higher cardiovascular risk. In cardiac surgery, excess body weight may influence perioperative management and increase the risk of complications. However, some studies have suggested lower morbidity and mortality in obese patients, a phenomenon known as the “obesity paradox”. Objectives: To evaluate the association between overweight and obesity and postoperative complications and mortality in patients undergoing cardiac surgery. Methods: A retrospective, single-center registry was conducted between February 2019 and January 2026, including adult patients (≥18 years) who underwent cardiac surgery in a high-complexity private institution. Overweight was defined as body mass index (BMI) 25–29.9 kg/m² and obesity as BMI ≥30 kg/m². Results and Conclusions: A total of 229 patients were included, 36.2% were female; the median age was 70 years (interquartile range [IQR] 67–73). Overall, 18.3% of patients had normal weight, 50.7% were overweight, and 31.0% were obese. A total of 81.2% had hypertension, 35.3% diabetes, and 55% dyslipidemia. Baseline characteristics of the population are summarized in Table 1. A total of 86.4% of procedures were elective, 11.7% were urgent, and 1.7% were emergent. Among coronary surgeries, 15.7% were off-pump. Median hospital stay was 7 days (IQR 5–11). Procedures are shown in Figure 1. Regarding postoperative complications, 5.7% required reintubation, 3.4% experienced perioperative myocardial infarction, 5.2% cardiac arrest, 4.3% transient ischemic attack or stroke, 0.8% required dialysis, 3.4% respiratory distress, 3% respiratory infection, 5.2% sternal wound infection, and 1.3% saphenectomy site infection. Additionally, 6.1% required sternal reopening and 3.5% reoperation. Cardiac mortality was 6.6%; 4.8% in normal weight, 6.0% in overweight, and 8.5% in obesity (p=0.709). Overall, 30.6% of patients presented at least one of the previously described complications. The proportion of patients who developed at least one complication was higher in those with overweight or obesity: 16.7% in normal-weight individuals, 31.9% in overweight, and 36.6% in obesity (p=0.030). Our data suggest that overweight and obesity are associated with increased postoperative complications, along with a trend toward higher mortality with increasing BMI. Further studies are needed to better clarify this association in cardiac surgery.

Figure 1. Surgical procedures performed.

CABG = Coronary Artery Bypass Grafting.

Table 1. Baseline Characteristics of the Registry Participants.

Characteristics	Total (n=229)
Male	63.7%
Female	36.2%
Mean age, years	70 (67–73)
Body Mass Index (kg/m²)	28.8 ± 5.9
– Normal weight	18.3%
– Overweight	50.7%
– Obesity	31.0%
Hypertension	81.2%
Type 2 diabetes	35.3%
Current smoker	17.0%
Former smoker	42.3%
Dyslipidemia	55.0%
Hyperuricemia	2.1%
Prior heart failure	31.8%
Prior myocardial infarction	17.9%
Prior cardiac surgery	1.7%
Prior coronary angioplasty	1.2%
Prior atrial fibrillation	7%

IMPACT OF CARDIOPULMONARY BYPASS ON POSTOPERATIVE OUTCOMES IN CORONARY ARTERY BYPASS GRAFTING

RAYSSA KELY SILVA DE SOUZA1; ELLEN VITÓRIA BARBOSA DA SILVA1; MICAELE FARIAS NASCIMENTO1; DANYELLE NÓBREGA DE FARIAS1; CAMILA ABRANTES CORDEIRO MORAIS1; THIAGO BEZERRA WANDERLEY E LIMA1; RAFAELA FIGUEIRÊDO FERNANDES SOARES1; DYEGO ANDERSON ALVES DE FARIAS1;

(1) FAMENE - JOÃO PESSOA - PB - BRASIL;

Background/Introduction: Cardiopulmonary bypass (CPB) facilitates the performance of complex cardiac procedures; however, it has been associated with increased postoperative morbidity due to systemic inflammatory response, hemodynamic alterations, and organ dysfunction when compared to off-pump techniques. Objectives: To compare postoperative outcomes in patients undergoing coronary artery bypass grafting (CABG) with and without CPB. Methods: This retrospective observational study analyzed 72 adult patients who underwent CABG and were admitted to the ICU between August and December 2024. Patients were stratified according to CPB use. Outcomes included mechanical ventilation duration, ICU length of stay, postoperative complications, and hospital mortality. Non-parametric tests were used for group comparisons, with statistical significance set at $p<0.05$. Results and Conclusions: Patients in the CPB group had longer ICU length of stay (median 5 vs 3 days; $p=0.002$) and mechanical ventilation duration (median 1.0 vs 0.25 days; $p<0.001$). They also showed higher rates of arrhythmias (47.2% vs 19.4%; $p=0.024$) and infections (30.6% vs 5.6%; $p=0.014$). Hospital mortality did not differ significantly between groups. CPB use in CABG is associated with increased postoperative morbidity and delayed recovery, despite similar mortality rates. These findings support careful selection of surgical technique to optimize patient outcomes.

IMPACT OF IMMUNOMODULATORY THERAPIES TARGETING ON ATHEROSCLEROTIC PLAQUE PROGRESSION AND CARDIOVASCULAR OUTCOMES

RODRIGO RUFINO PEREIRA SILVA1; RAMILLY LUCENA ROLIM1;

(1) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL;

Background/Introduction: Atherosclerosis is fundamentally a chronic inflammatory disease, and patients frequently experience recurrent ischemic events due to residual inflammatory risk despite optimal lipid-lowering therapies. This residual risk is heavily mediated by the NLRP3 inflammasome, which triggers the cleavage of interleukin-1β (IL-1β) and subsequently stimulates the production of interleukin-6 (IL-6), a crucial cytokine in the inflammatory cascade. Objectives: This study aims to evaluate the impact of therapies targeting the NLRP3/IL-1β/IL-6 inflammatory pathway on cardiovascular outcomes and inflammatory biomarkers in patients with atherosclerosis. Methods: To evaluate interventions targeting this axis, researchers conducted a systematic review of databases including PubMed and Cochrane Library for studies published up to 2026, focusing on clinical trials and cohorts that assessed cardiovascular outcomes and inflammatory biomarkers. Results and Conclusions: The analysis highlighted that IL-1β inhibitors, specifically canakinumab, significantly reduced the composite endpoint of non-fatal infarction, stroke, or cardiovascular death by 15% while notably lowering high-sensitivity C-reactive protein (hs-CRP) levels. However, other agents like the IL-1 receptor antagonist anakinra showed only transient effects, suggesting insufficient efficacy for chronic atherosclerosis management. Conversely, direct IL-6 inhibitors demonstrated profound biological potency; ziltivekimab produced dose-dependent hs-CRP reductions of up to 92% while maintaining a favorable lipid profile, thereby avoiding the metabolic complications often seen with tocilizumab. Mechanistically, modulating this pathway reduces leukocyte recruitment, suppresses endothelial adhesion molecules, and promotes the structural stabilization of atherosclerotic plaques. Crucially, analyses revealed that achieving IL-6 levels below 1.65 ng/L is associated with a 32% reduction in major cardiovascular events, positioning IL-6 as a highly potent therapeutic target. CONCLUSION. Despite these clinical gains, implementing these biological therapies requires caution due to high costs and the increased risk of fatal infections caused by the dampening of acute inflammatory responses. While cost-effective alternatives like colchicine remain viable, the successful application of targeted IL-1β and IL-6 immunomodulation heavily depends on the rigorous stratification of patients using hs-CRP biomarkers and careful clinical monitoring to safely mitigate residual cardiovascular risk.

Background/Introduction: Kawasaki disease (KD) is characterized as a febrile systemic vasculitis that, in severe cases, progresses to giants coronary aneurysms and arterial stenoses, often requiring high-complexity interventions to restore myocardial flow. Although Coronary Artery Bypass Graft Surgery (CABG) is an established management strategy for critical cases, there remains a gap in consolidated evidence regarding graft durability and the incidence of cardiac events over time in this population. Objectives: To evaluate the survival rate, the occurrence of cardiovascular events and prevalence of new coronary interventions after CABG in patients with KD Methods: A systematic review and meta-analysis of observational studies was conducted to evaluate clinical outcomes after CABG in patients with Kawasaki disease. Eligible studies included patients undergoing surgical myocardial revascularization with reported follow-up data. Case series, reviews, and non-original studies were excluded. The main outcomes were 10-year cardiac event-free survival, and prevalence of new coronary interventions. Pooled analyses were performed using random-effects models. Time-related outcomes were summarized as pooled means and prevalence outcomes were estimated using generalized linear mixed models, both with 95% confidence intervals. Heterogeneity was evaluated with I2. Analyses were performed using the software R (version 4.5.3). Results and Conclusions: A total of studies including patients with Kawasaki disease undergoing CABG were analyzed. The pooled 10-year cardiac event-free survival rate was 78.59% (95%CI 71.81-86.01), with high heterogeneity across studies (I2=93.5%) (Figure 1B). The 10-year overall survival rate was high, with a pooled estimate of 97.62% (95% CI 97.16-98.08) and no significant heterogeneity (I2=0%) (Figure 2). The prevalence of new coronary interventions after CABG was 11.14% (95% CI 4.83-23.64), with substantial heterogeneity among studies (I2=75.9%) (Figure 1A). CONCLUSION: Patients with Kawasaki disease undergoing CABG demonstrate excellent long-term survival. However, reduced event-free survival and the need for repeat interventions reflect a sustained cardiovascular burden. These findings support tailored management and structured long-term follow-up. Nevertheless, these results must be interpreted with caution due to a considerable heterogeneity among the current literature.

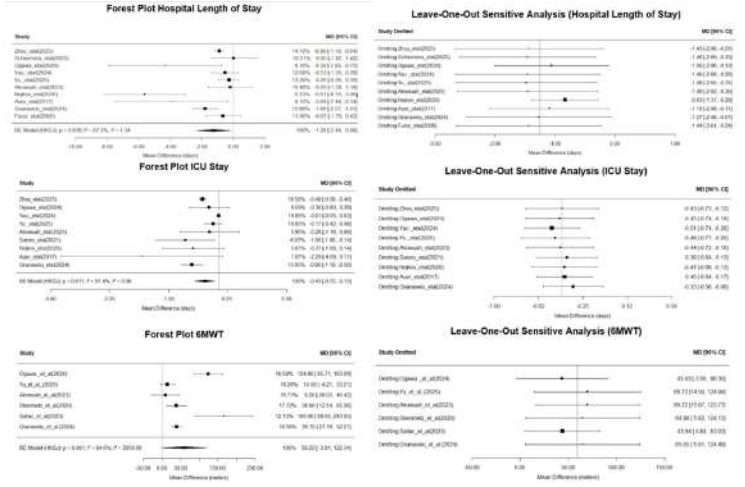
POST-REVASCULARIZATION MYOCARDIAL INJURY WITH CARDIOPULMONARY BYPASS: THE DOSE–RESPONSE GRADIENT OF TROPONIN T AS A PREDICTOR OF ACUTE KIDNEY INJURY AND 30-DAY MORTALITY

CYNTHIA SPERANDIO1; MAURÍCIO DE NASSAU MACHADO1; RAPHAEL FERNANDES CARDOSO VIANNA ALVES1; JÚLIA DE OLIVEIRA MACHADO1; LUDMILA SOUZA DA CUNHA1; RENATO DE FARIAS VIGOLO1; GUILHERME CUSTODIO GERMANO1; PAULO GONCALVES MARTIN1; LAURA DE OLIVEIRA MACHADO1; ATTILIO CARETTA BASTREGHI2;

(1) FAMERP - FACULDADE DE MEDICINA DE SÃO JOSÉ DO RIO PRETO - SÃO JOSÉ DO RIO PRETO - SP - BRASIL; (2) FUNDAÇÃO PADRE ALBINO - CATANDUVA - SP - BRASIL;

Background/Introduction: Perioperative myocardial injury, detected by elevation of high-sensitivity cardiac troponin T (hs-cTnT), is common after coronary artery bypass grafting (CABG) with cardiopulmonary bypass (CPB). Although extreme elevations suggest a poor prognosis, the epidemiological distribution of these patients and the independent contribution of each elevation stratum to renal and mortality outcomes require further characterization. Objectives: To assess the distribution of myocardial injury severity and its independent impact on acute kidney injury (AKI) and 30-day mortality, correlating the frequency of each stratum with the observed risk. Methods: This retrospective cohort study included 1,467 adult patients undergoing isolated CABG with CPB. Postoperative peak hs-cTnT levels were stratified according to multiples of the upper reference limit (URL): <10×, 10–20×, 20–40×, 40–100×, and ≥100× URL. Multivariable logistic regression was performed adjusting for age, baseline renal function (CKD-EPI 2021), CPB duration, and use of intra-aortic balloon pump (IABP). Results and Conclusions: Results: Most of the cohort presented with moderate levels of myocardial injury: <10× (n=176; 12%), 10–20× (n=565; 38.5%), and 20–40× (n=450; 30.7%). Higher levels were less frequent: 40–100× (n=200; 13.6%) and ≥100× (n=76; 5.2%). Despite its low prevalence (5.2%), the ≥100× URL group exhibited the highest relative risk. In multivariable analysis, a clear dose–response gradient was observed: (1) AKI (Reference: <10× URL): Risk increased from OR 1.60 (10–20×) to OR 5.11 (≥100×; 95% CI 2.62–9.94; p<0.001). (2) Mortality (Reference: <20× URL): Mortality risk tripled in the 20–40× stratum (OR 3.00; p=0.017) and reached a critical impact in the ≥100× group, with an adjusted OR of 19.71 (95% CI 7.25–53.59; p<0.001). While patients with mild injury (<10×) had zero mortality, the ≥100× group exhibited a 22.4% mortality rate. Age (OR 1.06) and baseline renal function (OR 0.84) remained independent predictors (p<0.05). Conclusion: Although extreme myocardial injury (≥100× URL) occurs in only 5.2% of post-CPB patients, it identifies a highly vulnerable subgroup with nearly a 20-fold increased risk of death. The cohort distribution demonstrates that while most patients experience mild-to-moderate injury, systematic monitoring of hs-cTnT is essential to early identify the high-risk minority requiring aggressive hemodynamic support and nephroprotective strategies.



18082

PREOPERATIVE PREHABILITATION FOR ADULTS UNDERGOING ELECTIVE CARDIAC SURGERY: EFFECTS ON FUNCTIONAL RECOVERY AND POSTOPERATIVE OUTCOMES - A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

RAFAEL BRAGA MACIEL1; THEODORA CRISTINA CRUZ DE ASSIS2; UDOCHUKWU GODSWILL ANOSIKE3; DANIEL BRAGA MACIEL1; PAOLA KEESE MONTANHESI4;

(1) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (2) UNICAMP - CAMPINAS - SP - BRASIL; (3) NNAMDI AZIKIWE UNIVERSITY COLLEGE OF HEALTH SCIENCES - NIGERIA; (4) UNIVERSITY OF TORONTO - CANADA;

Background/Introduction: Cardiovascular disease remains the leading cause of death worldwide, and many patients require cardiac surgery. Cardiac prehabilitation, including exercise, respiratory training, nutritional optimization, and psychological support, has been proposed to improve postoperative outcomes. Although individual studies have shown promising results, a synthesis of available data is lacking. Objectives: To evaluate the impact of cardiac prehabilitation on postoperative outcomes in adults undergoing cardiac surgery. Methods: We performed a systematic review and meta-analysis of studies evaluating the association between prehabilitation strategies and clinical outcomes in adults undergoing elective cardiac surgery. PubMed, Embase, and Cochrane were searched. Outcomes of interest were hospital length of stay (LOS), intensive care unit (ICU) LOS, and 6-minute walk test (6MWT) distance. Random-effects models were used to estimate mean differences (MDs) with 95% confidence intervals (CIs). Leave-one-out (LOO) sensitivity analyses were performed. Analyses were conducted in R version 4.1.0 in accordance with PRISMA guidelines. Results and Conclusions: Thirteen studies, including 1,743 patients, were included. Mean age was 61.29±13.14 years, and 67.95% were male. Prehabilitation was associated with shorter hospital LOS (MD, -1.26 days; 95% CI, -2.44 to -0.08; p=0.04; I²=87.30%) and shorter ICU LOS (MD, -0.43 days; 95% CI, -0.72 to -0.13; p=0.01; I²=91.40%) compared with standard care. For 6MWT, prehabilitation did not improve walking distance compared to usual care (MD, 59.22 m; 95% CI, -3.91 to 122.34; p=0.06; I²=94.61%). Sensitivity analyses confirmed the robustness of our findings. Cardiac prehabilitation was associated with significant reductions in ICU and hospital LOS. These findings suggest that prehabilitation may be a valuable addition to surgical planning for patients undergoing elective cardiac surgery, as it may enhance postoperative recovery and healthcare resource utilization. Limitations include the low certainty of evidence and high heterogeneity across trials, highlighting the need for further research to optimize prehabilitation protocols.

PROSTHESIS–PATIENT MISMATCH AFTER TRANSCATHETER VERSUS SURGICAL AORTIC VALVE REPLACEMENT IN SEVERE AORTIC STENOSIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

CHRISTOPHER AQUINO PEREIRA LIMA1; GIOVANA CLAUSSON BITOLO1; IRVING GABRIEL ARAÚJO BISPO1;

(1) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL;

Background/Introduction: Patient–prosthesis mismatch (PPM) after aortic valve replacement is associated with impaired prosthetic hemodynamic performance and may adversely affect prognosis. Although previous studies suggest a lower rate of severe PPM with transcatheter implantation, the consistency of this benefit compared with surgery remains uncertain. Objectives: To compare transcatheter aortic valve replacement (TAVR) versus surgical aortic valve replacement (SAVR) regarding the incidence of PPM, with emphasis on severe PPM, in adults with severe aortic stenosis undergoing aortic valve replacement. Methods: This systematic review and meta-analysis was registered in PROSPERO (CRD420261336092) and conducted in accordance with PRISMA 2020. PubMed, Cochrane Library, EMBASE, Web of Science, and Scopus were searched. Randomized clinical trials and trial-derived comparative analyses directly comparing TAVR and SAVR and reporting PPM were included. The primary outcome was early post-procedural severe PPM; secondary outcomes were moderate PPM and mean transvalvular gradient. Risk ratios (RRs) were calculated for dichotomous outcomes and mean differences (MDs) for continuous outcomes, both with 95% confidence intervals (95% CIs). Risk of bias was assessed using RoB 2.0, certainty of evidence using GRADE, and sensitivity analyses were performed with a leave-one-out approach. Results and Conclusions: 2,688 identified records, 5 studies were included. TAVR significantly reduced the incidence of severe PPM compared with SAVR (53/731 vs. 121/653; RR, 0.42; 95% CI, 0.25–0.72; I²=57.6%). For moderate PPM, a nonsignificant trend favoring TAVR was observed (96/492 vs. 112/429; RR, 0.76; 95% CI, 0.55–1.06; I²=45.7%). No significant difference was found in mean gradient between the 2 strategies (MD, -0.76 mmHg; 95% CI, -11.78 to 10.25; I²=0%). Leave-one-out analyses confirmed the robustness of the severe PPM result, whereas the moderate PPM estimate was less stable and mean gradient findings remained unchanged. Certainty of evidence was moderate for severe PPM, low for moderate PPM, and very low for mean gradient. In patients with severe aortic stenosis undergoing aortic valve replacement, TAVR was associated with a lower incidence of early severe PPM compared with SAVR. This benefit was not conclusively demonstrated for moderate PPM, and no consistent difference was observed in mean gradient. These findings suggest that the main hemodynamic advantage of TAVR lies in reducing severe prosthesis–patient mismatch.

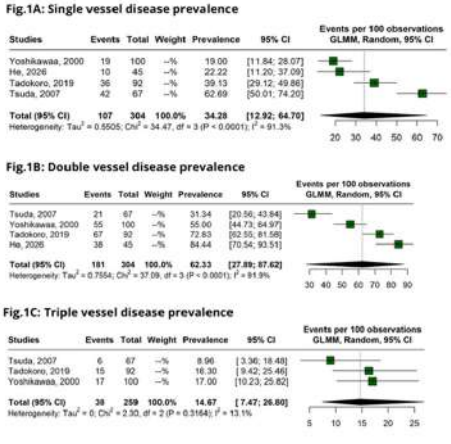
22090

SAPHENOUS VEIN GRAFT REMAINS THE MOST RELIABLE CONDUIT FOR NONSELECTED RIGHT CORONARY TERRITORY REVASCULARIZATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

GABRIEL BASTOS COSTA DE ASSIS1; BRUNO FERRAZ DE OLIVEIRA GOMES1; LAIZA SANTOS PIMENTEL HADDAD1; JOÃO VICTOR CORREIA DE SOUZA1; RENATA MEDINA DOS SANTOS1;

(1) INSTITUTO DO CORACAO EDSON SAAD/UFRJ - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Background: The optimal conduit for right coronary artery (RCA) territory bypass remains controversial. Although the right gastroepiploic artery (RGEA) is an attractive arterial option, its performance appears to depend heavily on target-vessel stenosis and competitive flow. Objectives: We compared RGEA and saphenous vein graft (SVG) for RCA territory revascularization. Methods: Methods: We performed a systematic review and meta-analysis of comparative studies evaluating RGEA versus SVG for RCA territory bypass in patients undergoing coronary artery bypass grafting. The search strategy included major biomedical databases, manual review of key references, and citation tracking. To avoid duplicate populations, only one report per cohort was retained in the primary quantitative analysis, prioritizing the longest available follow-up. The primary endpoint was graft patency. Pooled estimates were calculated using a random-effects model. Results and Conclusions: Results: Twelve comparative studies were identified for qualitative review. Three studies provided extractable patency data for the primary meta-analysis. In the pooled analysis, SVG showed a numerical advantage over RGEA, but the difference did not reach statistical significance (risk ratio 1.19, 95% confidence interval 0.90-1.56; I²=82.6%). Across the available literature, randomized evidence favored SVG, whereas the apparent benefit of RGEA in observational series was largely confined to highly selected patients with severe native RCA stenosis and minimal competitive flow. Conclusions: Current comparative evidence does not demonstrate a statistically significant overall patency advantage of SVG over RGEA, although the direction of effect favors SVG. For routine, nonselected RCA targets, SVG appears to remain the most reliable conduit, whereas RGEA may be best reserved for carefully selected anatomical settings.



19719

THE ANATOMY OF CORONARY ARTERY INVOLVEMENT IN KAWASAKI DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

LUCAS RODRIGUES ORTIZ SALGADO DO NASCIMENTO1; TAREK CASTRO FAYYAT1; MARIANA MAINARDES SILVA2; FERNANDA MANFROI GUIMARÃES1; ANA CLARA DE MATTOS CAMARGO3; SARA CAMARGO GUEIBER2; ANA KARYN EHRENFRIED FREITAS1;

(1) UNIVERISADE POSITIVO - CURTIBA - PR - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARANÁ - CURITIBA - PR - BRASIL; (3) HOSPITAL CRUZ VERMELHA DO PARANÁ - CURITIBA - PR - BRASIL;

Background/Introduction: Kawasaki disease (KD) is a systemic vasculitis that primarily affects small and medium-sized blood vessels. Its main and most serious complication is coronary aneurysm. Knowledge of the anatomy of the affected vessels is an extremely important tool for both prognostic evaluation and as a guide for invasive approaches in these patients. Objectives: To evaluate the prevalence of multi-vessel involvement of Kawasaki disease and the main locations of giant coronary aneurysms. Methods: A systematic review and meta-analysis of observational studies evaluating the anatomical pattern of coronary artery involvement in patients with Kawasaki disease was performed. Studies reporting the number of coronary vessels involved and/or the location of giant coronary aneurysms were included. Case reports, reviews and non-original studies were excluded. The primary outcomes were the prevalence of single-, double-, and triple-vessel disease and main anatomical locations of giant coronary aneurysms. Pooled analyses were conducted using random-effects models, and prevalence estimates were calculated using generalized linear mixed models with 95% confidence intervals. Statistical heterogeneity was assessed with I2. Analyses were performed in R (version 4.5.3). Results and Conclusions: Double vessel disease showed the highest prevalence at 62.33% [95% CI 27.89-87.62; I²=91.9%], but with the greatest heterogeneity among the studies. Single vessel disease and triple vessel disease showed prevalences of 34.28% [CI 12.92-64.70; I²=91.3%] and 14.67% [7.47-26.80; I²=13.1%], respectively. The most prevalent location of giant coronary aneurysm was in the right coronary artery (RCA), with a prevalence of 70.44% [CI 59.87 - 79.9; I²=4.0%], and the least prevalent was in the left circumflex artery (LCX) with 23.45% [CI 14.65-35.36; I²=0.0%], heterogeneity was low in both cases. Involvement of the left anterior descending (LAD) and left main trunk (LMT) was 60.61% [CI 44.36-74.81; I²=64.7%] and 41.85% [CI 33.33 - 50.9; I²=0.0%], respectively. CONCLUSION: The type of vascular involvement in Kawasaki disease shows a higher prevalence of double vessel disease. However, heterogeneity among studies should be noted. The prevalence of giant coronary aneurysms showed a more homogeneous distribution, mainly affecting the right coronary artery (RCA). These findings may aid clinical follow-up and intervention planning, but should be interpreted with caution.

Background/Introduction: The expansion of heart transplantation with donation after circulatory death (DCD) has shifted the focus from feasibility to optimizing safety and reproducibility. The graft retrieval method significantly impacts the severity of primary dysfunction and the early need for advanced support. Specifically, thoracoabdominal normothermic regional perfusion (TA-NRP) and direct procurement with ex situ machine perfusion differ in reperfusion control and ischemia exposure. Given that evidence is largely observational, a synthesis strategy is required to avoid cohort overlap and effect overestimation. Objectives: To compare TA-NRP versus direct procurement with ex situ machine perfusion in DCD heart transplantation regarding severe primary graft dysfunction (PGD) requiring venoarterial extracorporeal membrane oxygenation (VA-ECMO) and selected early outcomes. Methods: A systematic review was conducted with multi-stage screening and standardized extraction. The primary analysis included only non-overlapping cohorts, prioritizing standardized early definitions (up to 30 days or discharge). We performed a random-effects meta-analysis using restricted maximum likelihood with Hartung–Knapp adjustment, estimating relative risk (RR) with a 95% confidence interval (CI). Heterogeneity was assessed by I^2. Sensitivity analysis with an additional study evaluated finding stability. Results and Conclusions: In the primary analysis (2 studies; 580 patients), TA-NRP reduced the risk of severe PGD requiring VA-ECMO (RR 0.37; 95% CI 0.17–0.79; $I^2 \approx 0\%$), suggesting a 63% relative reduction in high-impact events. TA-NRP also reduced treated rejection (RR 0.52; 95% CI 0.46–0.58; $I^2 \approx 0\%$). No consistent difference was found for renal replacement therapy. Sensitivity analysis maintained a favorable direction for VA-ECMO, albeit with higher uncertainty. In this synthesis of non-overlapping cohorts, TA-NRP was associated with a lower need for VA-ECMO and reduced treated rejection. This benefit is relevant for centers of excellence, potentially reducing severe complications and improving post-transplant predictability. While evidence remains observational and limited, these results support the standardization of protocols and prospective multicenter evaluation to confirm the magnitude of benefit and ensure safe, reproducible adoption.

Background/Introduction: ST-segment elevation myocardial infarction (STEMI) requires immediate restoration of coronary blood flow. Primary percutaneous coronary intervention (PCI) is the gold standard treatment; however, thrombus burden can lead to distal embolization and microvascular reperfusion failure. Manual thrombus aspiration was proposed to mitigate these effects and optimize flow, but recent evidence from large-scale trials has generated controversy regarding its clinical efficacy and, notably, its neurological safety. Objectives: To evaluate the impact of manual thrombus aspiration on angiographic and clinical outcomes in (STEMI) patients undergoing primary (PCI), through a systematic review of clinical trials. Methods: This is a systematic review of randomized clinical trials (RCT) conducted under the (PICO) strategy. The search was performed in the PubMed database using the descriptors: "STEMI", "thrombus aspiration", and "primary PCI". Inclusion criteria selected (RCT) that compared manual thrombus aspiration to conventional angioplasty. The analysis was qualitative and descriptive, focusing on microvascular reperfusion parameters (ST-segment resolution and TIMI flow) and hard clinical outcomes (mortality and safety). Results and Conclusions: Four (RCT) were included, totaling more than 18,000 patients. Smaller studies (n≈200) indicated immediate benefit in myocardial reperfusion. However, large-scale multicenter trials demonstrated that thrombus aspiration did not reduce all-cause mortality or reinfarction rates. In one of the main trials, a statistically significant increase in the incidence of stroke (STK) at 30 days was observed in the aspiration group (0.7% vs 0.3%). Conclusions: Manual thrombus aspiration improves immediate angiographic parameters; however, this effect does not translate into relevant clinical benefit. Given the lack of impact on mortality and the elevated risk of (STK), the routine use of this technique is not justified in current clinical practice and should be considered only in selected scenarios.

TRANSCATHETER VERSUS SURGICAL AORTIC VALVE REPLACEMENT IN LOW-RISK ELDERLY PATIENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF VALVE-RELATED COMPLICATIONS AT 5 YEARS

CHRISTOPHER AQUINO PEREIRA LIMA1; GIOVANA CLAUSSON BITOLO1; AYLTON FIGUEIRA JUNIOR1; IRVING GABRIEL ARAÚJO BISPO2;

(1) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE MUNICIPAL DE SAO CAETANO DO SUL - SÃO PAULO - SP - BRASIL;

Background/Introduction: Transcatheter aortic valve implantation (TAVI) has expanded to elderly patients at low surgical risk; however, uncertainty remains regarding prosthesis durability and valve-related complications compared with surgical aortic valve replacement (SAVR) at mid-term follow-up. Objectives: To evaluate aortic valve reintervention, valve thrombosis, and prosthetic valve endocarditis at approximately five years in randomized controlled trials comparing TAVI and SAVR in low-risk elderly patients. Methods: This systematic review and meta-analysis followed PRISMA 2020 and was registered in PROSPERO (CRD420251241177). PubMed, Embase, Cochrane, Web of Science, and Scopus were searched through February 25, 2026. Eligible studies were head-to-head randomized controlled trials enrolling elderly patients (mean age ≥70 years) with severe aortic stenosis at low surgical risk (STS-PROM <4% or EuroSCORE II <4%, or equivalent assessment). Outcomes were assessed at five years. Pooled risk ratios (RR) with 95% confidence intervals (CI) were calculated using a Mantel–Haenszel random-effects model. Heterogeneity was evaluated using I² statistics. Certainty of evidence was assessed using GRADE. Results and Conclusions: Three randomized trials including 2,758 patients (TAVI 1,385; SAVR 1,373) were analyzed. For aortic valve reintervention, the pooled RR was 1.31 (95% CI 0.80–2.16; I² = 0.0%). For valve thrombosis, the pooled RR was 3.60 (95% CI 0.49–26.48; I² = 64.9%). For prosthetic valve endocarditis, the pooled RR was 0.85 (95% CI 0.48–1.50; I² = 0.0%). Statistical significance was not reached for any outcome. Certainty of evidence was ⊕◯◯◯ (Very low) for reintervention, ⊕◯◯◯ (Very low) for valve thrombosis, and ⊕⊕◯◯ (Low) for endocarditis. In low-risk elderly patients followed for approximately five years, randomized evidence did not demonstrate statistically significant differences between TAVI and SAVR for reintervention, valve thrombosis, or endocarditis. Certainty of evidence ranged from very low to low, indicating substantial uncertainty in the comparative estimates within this follow-up period.

Figure 1. Meta-analysis of valve-related outcomes comparing TAVI versus SAVR at approximately 5 years.

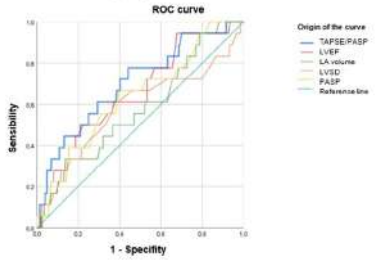
VENTRICULO-ARTERIAL COUPLING INDEX AS A PREDICTOR OF EARLY ADVERSE OUTCOMES IN PATIENTS UNDERGOING MITRAL VALVE SURGERY FOR PRIMARY MITRAL REGURGITATION

CAMILA TELES NOVAIS1; ANA LUIZA DE PAULA DOURADO1; GUSTAVO PEREIRA SANTANA1; NATALIA SANTOS BONFIM1; BRUNA APARECIDA REIS BRITO1; LAILA GABRIELY SOUZA MOTA1; JULIA ANDRADE MOUTINHO1;

(1) HOSPITAL ANA NERY - SALVADOR - BA - BRASIL;



Background/Introduction: Primary mitral regurgitation (MR) may lead to pulmonary hypertension and right ventricular (RV) dysfunction, both associated with worse surgical outcomes. The tricuspid annular plane systolic excursion to pulmonary artery systolic pressure ratio (TAPSE/PASP) reflects RV–pulmonary arterial coupling and may serve as an early prognostic marker beyond conventional parameters. Objectives: To evaluate the prognostic value of the TAPSE/PASP ratio in predicting early postoperative complications in patients undergoing surgery for severe primary MR. Methods: This prospective single-center cohort included 424 adult patients with severe primary MR who underwent mitral valve surgery between July 2023 and April 2025. Preoperative echocardiographic parameters, including TAPSE, PASP, and left ventricular ejection fraction (LVEF), were collected. The primary outcome was a composite of in-hospital death, cardiogenic shock, or prolonged mechanical ventilation (>24 hours). Associations were assessed using univariate logistic regression and receiver operating characteristic (ROC) curve analysis. Results and Conclusions: The TAPSE/PASP ratio was significantly associated with adverse outcomes (RR = 0.02; 95% CI: 0.01–0.26; p < 0.01). ROC analysis identified a cutoff ≤0.48, with an AUC of 0.71 (p < 0.01), sensitivity of 78%, and specificity of 55%. The TAPSE/PASP ratio outperformed conventional markers such as LVEF and PASP in predicting early postoperative risk. These findings suggest that ventriculo-arterial coupling assessment provides incremental prognostic value and may enhance preoperative risk stratification. However, given its moderate accuracy and limited specificity, this parameter should be integrated into a multimodal assessment and validated in larger multicenter studies.

Figure 1. ROC curve of ventriculo-arterial coupling index versus death, cardiogenic shock and prolonged time in mechanical ventilation (>24h)

ROC curve estimating 0.48mm/mmHg as the TAPSE/PASP cutoff point with greater precision for surgical complications and to aid decision-making in clinical practice (area 0.714, *p* 0.001).

Figure 2. ROC curve of ventriculo-arterial coupling index, LVEF, LA volume, LVSD and PASP versus death, cardiogenic shock and prolonged time in mechanical ventilation (>24h)

ROC curve estimating the AUC. Ventriculo-arterial coupling index (AUC 0.714; *p* 0.001), LVEF (AUC 0.555; *p* 0.029), LA volume (AUC 0.578; *p* 0.273), LVSD (AUC 0.582; *p* 0.247) and PASP (AUC 0.639; *p* 0.028).

Background/Introduction: Congenital heart diseases (CHDs) are the most common structural malformations at birth and represent a major cause of neonatal morbidity and mortality. Fetal echocardiography is essential for prenatal diagnosis and therapeutic planning; however, its accuracy depends on the examiner's expertise, which may result in diagnostic variability, particularly in settings with limited access to specialists. In this context, Artificial Intelligence (AI) has emerged as a promising tool for image analysis, with the potential to improve diagnostic accuracy. Nevertheless, it remains unclear whether these technologies can match the performance of specialists, and their accuracy in detecting CHDs in fetal echocardiography is still uncertain. Objectives: To evaluate the diagnostic performance of AI in detecting CHDs compared to specialists. Methods: This systematic review was conducted in accordance with the PRISMA guidelines. Literature searches were performed in PubMed, SciELO, Cochrane Library, and Biblioteca Virtual de Saúde, using the descriptors "artificial intelligence" AND "heart defects, congenital" AND "fetal echocardiography." A total of 17 studies were identified. Full-text articles published in the last five years in English or Portuguese were included. After screening, filtering, and final assessment, three studies were included in the analysis. Results and Conclusions: The synthesis of the included studies demonstrates that AI application in fetal cardiology shows good diagnostic performance. In the prenatal context, AI achieved sensitivity rates of up to 93% for CHD detection in certain scenarios, with a mean area under the curve (AUC) ranging from 0.91 to 0.98. In complex structural anomalies, such as hypoplastic left heart syndrome, sensitivity reached 95%, comparable to specialists and superior to general ultrasonographers (approximately 70%). Studies also indicate that AI reduces screening time by approximately 35% and improves the identification of standard axial views. However, limitations were observed in cases involving anomalous venous connections and complex Doppler flow patterns, where specialist clinical judgment remains essential. AI shows potential as a complementary tool to conventional diagnosis, improving screening accessibility and reducing false negatives. Although it does not replace physicians, it supports clinical decision-making. Its implementation requires ethical standards and integration into real-world workflows to ensure diagnostic safety in fetal cardiology.

DIAGNOSTIC ACCURACY OF FIRST-TRIMESTER FETAL ECHOCARDIOGRAPHY IN DETECTING MAJOR CONGENITAL HEART DEFECTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

ARTUR DIAS PEREZ GRACA1; MARIA CLARA CHAGAS NEGRÃO DE ALMEIDA BARROS1; FERNANDO JOSÉ PEREZ DA SILVA GRACA2;

(1) FACULDADE DE CIÊNCIAS MÉDICAS DE SANTOS - UNILUS - SANTOS - SP - BRASIL; (2) UNIVERSIDADE FEDERAL DE RORAIMA - CURSO DE MEDICINA - BOA VISTA - RR - BRASIL;

Background/Introduction: Early detection of congenital heart disease (CHD) is essential to optimize perinatal outcomes, yet standard diagnosis is typically performed in the second trimester. First-trimester fetal echocardiography has emerged as a potential early diagnostic tool, but its accuracy remains uncertain. Objectives: To evaluate the diagnostic accuracy of first-trimester fetal echocardiography for detecting major CHD. Methods: A systematic review and meta-analysis were conducted according to PRISMA guidelines. Studies evaluating fetal echocardiography between 11 and 14 weeks of gestation were included. Diagnostic data were extracted to construct 2×2 contingency tables. A bivariate random-effects model (Reitsma) was used to estimate pooled sensitivity and specificity. Overall performance was assessed using hierarchical summary receiver operating characteristic (HSROC) analysis. This study was prospectively registered in PROSPERO (CRD420261379243). Results and Conclusions: Results: Seven studies (n = 778 fetuses) were included. The pooled sensitivity was 0.82 (95% CI: 0.68–0.91), and specificity was 0.99 (95% CI: 0.97–1.00). Specificity was highly consistent (I^2 = 0%), while sensitivity showed significant heterogeneity (I^2 = 70.2%). HSROC analysis demonstrated excellent diagnostic performance (AUC = 0.979). The false-positive rate was low (1.4%), supporting high diagnostic reliability for confirming CHD in early gestation. Conclusion: First-trimester fetal echocardiography demonstrates excellent specificity and high diagnostic accuracy, supporting its role as a reliable rule-in diagnostic tool. However, its moderate and heterogeneous sensitivity limits its use as a standalone screening modality. In practical terms, this modality should be interpreted as an early confirmatory (rule-in) strategy rather than a primary screening tool, given its near-perfect specificity and limited sensitivity. These findings suggest a paradigm shift from early screening to early confirmation in prenatal cardiac evaluation.

FETAL CARDIOLOGY IN THE AMAZON: EARLY EXPERIENCE AND CHALLENGES IN IMPLEMENTING A REFERRAL SERVICE IN A RESOURCE-LIMITED SETTING

VICTÓRIA KAROLINNY COELHO CORREA1; ANANDA MACHADO DA SILVA1; GIOVANNA VIEIRA LIBORIO1; JULIA CASTRO RODRIGUES1; THAYLA LAIS LIMA ESTEVAM2; LUCIANE ALVES DA ROCHA AMORIM3;

(1) UNIVERSIDADE FEDERAL DO AMAZONAS - MANAUS - AM - BRASIL; (2) HOSPITAL UNIVERSITÁRIO GETÚLIO VARGAS - UFAM - MANAUS - AM - BRASIL; (3) HOSPITAL UNIVERSITÁRIO GÉTULIO VARGAS - UFAM - MANAUS - AM - BRASIL;

Background/Introduction: Congenital heart disease (CHD) remains one of the leading causes of neonatal morbidity and mortality worldwide, and outcomes are closely tied to how early a diagnosis is made and whether families can actually reach specialized care. In regions like the Brazilian Amazon, a geographically vast and chronically underserved, these conditions are rarely met. Access to fetal echocardiography is scarce, and the quality of prenatal screening varies considerably across the territory. Objectives: To describe referral patterns, diagnostic yield, and the practical challenges encountered in establishing a fetal cardiology service in the Amazon region. Methods: This cross-sectional study included pregnant women referred for fetal echocardiography at a tertiary public hospital in Manaus, Brazil, from March 2023 to March 2024. We analyzed maternal characteristics, indications for referral, and echocardiographic findings, while also documenting system-level obstacles observed throughout service implementation. Results and Conclusions: Seventy-four patients were included. Mean maternal age was 31 years. The majority of referrals were driven by maternal risk factors (54.1%), with diabetes accounting for 87.5% of those cases. Nearly all patients (92.4%) had previously undergone morphological ultrasound — yet only 5% had any suspected cardiac abnormality flagged at that stage. Fetal echocardiography identified cardiac alterations in 8.2% of cases, including structural defects such as ventricular septal defects and functional findings such as myocardial hypertrophy. On the implementation side, several recurring challenges stood out: the low sensitivity of routine prenatal screening for cardiac abnormalities; a referral logic driven more by maternal comorbidities than by fetal findings; a shortage of trained professionals outside the capital; and the geographic and logistical barriers that delay or outright preventing access to specialized care for many families. Fetal echocardiography in this high-risk group yielded a significant diagnostic return, likely due to referral bias. The difference between routine ultrasound flags and actual echo findings highlights limitations in current prenatal cardiac screening. This experience underscores the difficulty of establishing a fetal cardiology service in the Amazon. Improving outcomes requires better sonographer training, smarter referral criteria, and expanded specialized care access, favoring a coordinated regional network over isolated efforts.
