LACTATE KINETICS AND VASOACTIVE-INOTROPIC SCORE AS PREDICTORS OF MORTALITY IN CHILDREN UNDERGOING CARDIAC SURGERY

CAMYLLA SANTOS DE SOUZA1; ANA LUIZA TORQUATO DE AQUINO1; MARCELA TORRES DE MELO CAVALCANTE2; PAULO GONDIM GONÇALVES2; MARIA EDUARDA SAMPAIO CÂMARA2; ALICE PETROLA BEZERRA SAYÃO2; CECÍLIA GABRIELA DANTAS DE SOUZA2; RAFAELA RIOS SABINO2; LORENA GURGEL LEITE VIANA2; ANDREA CONSUELO DE OLIVEIRA TELES1; KLEBIA MAGALHÃES PEREIRA CASTELLO BRANCO1; CANDICE TORRES DE MELO BEZERRA CAVALCANTE1;

(1) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Background/Introduction: Lactate is a well-established biomarker of tissue hypoperfusion in critically ill patients. In pediatric cardiac surgery, postoperative outcomes are influenced by both metabolic disturbances and hemodynamic instability. The vasoactive-inotropic score (VIS) quantifies the intensity of cardiovascular support and may enhance risk stratification when evaluated alongside lactate kinetics. However, the combined prognostic value of lactate and VIS remains incompletely understood. Objectives: To evaluate the association between lactate levels, VIS, and in-hospital mortality in children under 2 years undergoing cardiac surgery, and to determine a lactate cutoff associated with increased mortality. Methods: This retrospective cohort study included children under 2 years of age who underwent cardiac surgery between 2018 and 2024. Lactate levels were measured at the immediate postoperative period (POI), postoperative day 1 (POD1), and postoperative day 2 (POD2). The vasoactive-inotropic score (VIS) was calculated at the same time points. The primary outcome was in-hospital mortality. Continuous variables were expressed as mean ± standard deviation or median (interquartile range), as appropriate, and compared using the Mann–Whitney U test. Multivariable logistic regression adjusted for surgical complexity (RACHS-1) and weight was used to identify independent predictors. ROC curve analysis was performed to evaluate discriminatory ability and determine the optimal lactate cutoff. Results and Conclusions: Non-survivors had consistently higher lactate levels across all time points (3.50 vs 2.42 mmol/L immediately postoperatively, $p<0.001$) and required higher vasoactive support (VIS 18.0 vs 12.5, $p<0.001$). Lactate remained an independent predictor of mortality after adjustment (OR 1.24 per mmol/L increase, $p<0.001$). A lactate threshold of 3.2 mmol/L identified high-risk patients early.Lactate showed better discrimination than VIS alone (AUC 0.69 vs 0.64). A combined model improved prediction (AUC 0.70), suggesting complementary prognostic value. Lactate is a strong early predictor of mortality after pediatric cardiac surgery. VIS provides complementary information on hemodynamic support, and their combined use improves risk stratification. An integrated metabolic-hemodynamic approach may allow earlier identification of high-risk patients and guide postoperative management.

ARTIFICIAL INTELLIGENCE APPLIED TO ELECTROCARDIOGRAM-BASED CARDIOVASCULAR RISK ASSESSMENT: A SYSTEMATIC REVIEW

MARIA CLARA MANTOA PINHEIRO1; LÍVIA FELBERG1; ISADORA CRISTINE REIS SGUIZZATO BOZZI1; ANTONIO LUIZ PINHO RIBEIRO1; GABRIELA MIANA DE MATTOS PAIXÃO1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Cardiovascular diseases are the leading cause of mortality worldwide, underscoring the need for effective risk prediction and early detection. The electrocardiogram (ECG) is a widely available, low-cost diagnostic tool, but its traditional interpretation is limited by subjectivity. Artificial intelligence (AI) has emerged as a tool to extract previously inaccessible prognostic information from ECG signals. Objectives: This systematic review aimed to evaluate original studies applying AI-based models to ECG signals for cardiovascular risk prediction and mortality outcomes. Methods: A systematic review was conducted in accordance with PRISMA guidelines. Four databases were searched for studies published between 2020 and 2025 that used AI models with ECG signals as the sole input to predict cardiovascular risk in adult populations. Primary outcomes included all-cause mortality, cardiovascular death, heart failure (HF), myocardial infarction (MI), stroke, atherosclerotic cardiovascular disease (ASCVD), and major adverse cardiovascular events (MACE). Two reviewers independently performed study selection and data extraction. Data were synthesized narratively. The protocol was registered in PROSPERO. Results and Conclusions: A total of 11 studies were included, most of which were retrospective cohorts. Convolutional neural networks were the predominant architecture (90.9%). Sample sizes ranged from 238 to over 4 million ECGs. Mean age varied from 54 to 65 years, and follow-up ranged from 2 to 34 years. Model interpretability techniques were reported in 9 studies, with saliency maps being the most commonly used method. Reported AUROC values ranged from 0.63 to 0.96 in training datasets, with some models outperforming traditional risk scores. AI-ECG demonstrated the ability to detect subclinical disease and enable early risk stratification, even in individuals with apparently normal ECGs. However, important challenges remain, including limited population diversity, suboptimal interpretability, and lack of prospective validation. In conclusion, the application of AI to ECG analysis represents a promising advancement in personalized cardiovascular risk assessment. Nonetheless, further research is needed to ensure the safety, effectiveness, and equitable clinical integration of these technologies.

ARTIFICIAL INTELLIGENCE IN PUBLIC HEALTH POLICIES: GOVERNANCE AND EFFECTIVENESS IN PUBLIC MANAGEMENT

ITALO COSTA SALES1; LAISA ALLEN GOMES DE SOUSA2; PAULA ZAMBELLI SALGADO BRASIL1;

(1) INSTITUTO BRASILEIRO DE ENSINO, DESENVOLVIMENTO E PESQUISA / IDP-SP - SÃO PAULO - SP - BRASIL; (2) HOSPITAL GETULIO VARGAS - TERESINA - PI - BRASIL;

Background/Introduction: The digital transformation of the state has driven the adoption of data-driven technologies in public administration, particularly in health. Artificial intelligence (AI) emerges as a strategic tool for evidence-based decision-making, epidemiological surveillance, and resource optimization. However, its incorporation involves ethical, institutional, and regulatory challenges, especially in developing countries marked by regional inequalities and fragmented information systems. Objectives: To analyze AI application in public health policies, focusing on governance and governmental effectiveness. Specific objectives include: mapping AI initiatives in public health (2015–2025); comparing domestic and international experiences (United Kingdom and Canada); identifying institutional and ethical barriers; and proposing recommendations for an AI governance ecosystem in public health. Methods: Qualitative and analytical-descriptive research with comparative elements. A systematic bibliographic review followed PRISMA guidelines across Scopus, Web of Science, SciELO, and PubMed (2015–2025). Documentary analysis covered national health digitalization programs and international reports (NHS AI Lab, AI4Health). A multiple-case comparative study examined three variables: institutional maturity of AI governance, systems interoperability, and observed policy effectiveness. Thematic content analysis was applied throughout. Results and Conclusions: AI contributes positively to public health policy effectiveness in epidemiological monitoring, hospital resource optimization, and identification of vulnerable populations, but only when integrated into the full policy cycle. Comparison with the United Kingdom and Canada showed that performance differentials are primarily institutional: consolidated governance frameworks and algorithmic audit mechanisms explain superior outcomes. In the analyzed national context, structural fragmentation, lack of data interoperability, insufficient technical capacity, and the absence of a national AI governance policy are the main limiting factors. An unanticipated finding concerns the risk of reinforcing regional and racial inequalities through biased algorithmic systems. Responsible AI adoption in public health requires simultaneous investment in technology, governance, equity, and institutional culture.

ARTIFICIAL INTELLIGENCE METHODS IN CARDIOVASCULAR HEALTH RISK ASSESSMENT

JOÃO VITOR LEVINDO COELHO NOVAES1; ISADORA SOARES BICALHO GARCIA2; GUSTAVO SANTOS RAINATO3; JOÃO VITOR INNECO ARÊAS3;

(1) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (2) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (3) FACULDADE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Artificial intelligence (AI) has been increasingly applied to cardiovascular risk assessment, offering new opportunities for individualized prediction, early identification of high-risk patients, and clinical decision support. However, the relative performance, interpretability, and implementation readiness of different AI approaches remain heterogeneous across studies. Objectives: To systematically review AI-based methods used for cardiovascular health risk assessment, comparing traditional machine learning, ensemble methods, and deep learning approaches in terms of predictive performance, clinical applicability, interpretability, and implementation requirements. Methods: A systematic search was conducted in MEDLINE/PubMed, Embase, Cochrane Library and SciELO from inception to February 2025. Eligible studies evaluated AI-based models for cardiovascular risk prediction or risk stratification in adult populations and reported at least one measure of model performance, validation, or clinical utility. Two independent reviewers screened studies, extracted data, and assessed methodological quality using PROBAST. Findings were synthesized narratively according to model class, data source, outcome, validation strategy, discrimination, calibration, interpretability, and implementation feasibility. Results and Conclusions: A total of 10 studies met the inclusion criteria. Traditional machine learning methods demonstrated practical utility in structured clinical datasets, particularly when interpretability and ease of implementation were priorities. Ensemble methods, including random forests, gradient boosting, and Random Survival Forests, generally improved the ability to capture non-linear relationships and interactions among predictors, although transparency and calibration reporting were variable. Deep learning models, including neural survival models such as DeepSurv and architectures using imaging, electrocardiographic, or electronic health record data, showed the greatest potential in large-scale, high-dimensional datasets. However, their use was limited by higher computational demands, lower interpretability, inconsistent external validation, and limited evidence of prospective clinical impact. Across model classes, reporting of calibration, fairness, explainability, and decision-curve or clinical utility analyses was inconsistent.

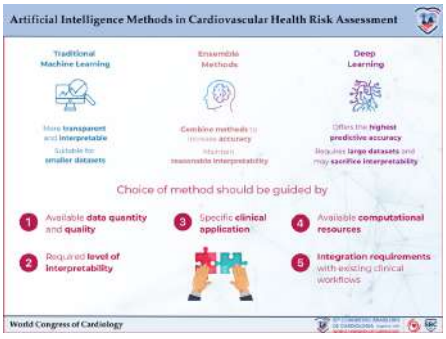

Table 1 – Predictive Performance Metrics for Cardiovascular Risk Assessment Models

Study	Disease type	Best performed method	Performance Metrics	Dataset size	Follow-up period (years)
Aljaaf 2015[57]	HF	Decision Tree	ACC: 86.5%	297	NA
Ambale-Venkatesh 2017[30]	CVD, Stroke and HF	RSF	C-index: 0.80 Brier score: 0.079	6,814	11.2 (10.6-11.7)
Barbieri 2022[64]	CVD	DeepSurv	C-index: 0.771-0.813 Brier score: 0.0176-0.00971	2,164,872	4.75
Blanchard 2022[78]	MACE	DeepConvSurv	C-index: 0.788 AUC: 0.823	5,506	6.0 (3.9-8.7)
Dinesh 2018[70]	CVD	Logistic Regression	ACC: 91.61%	920	NA
Gulshan 2016[18]	Diabetic retinopathy	CNN	AUC: 0.991	11,711	NA

CHAGAS DISEASE AND AI-DERIVED ECG-AGE

ISADORA CRISTINE REIS SGUIZZATO BOZZI1; LOURENÇO RIBEIRO GROSSI ARAÚJO1; MARIA CLARA DE ARAUJO GONTIJO LIMA1; PETRUS EMMANUEL OLIVEIRA GOMES BRANT ABREU1; ANTONIO HORTA RIBEIRO2; ANTONIO LUIZ PINHO RIBEIRO1; GABRIELA MIANA DE MATTOS PAIXÃO1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) UPPSALA UNIVERSITY - SWEDEN;

Background/Introduction: Artificial intelligence-derived electrocardiographic age (ECG-age) has emerged as a biomarker of cardiovascular risk and biological cardiac aging. However, its behavior in diseases that directly affect the cardiac conduction system, such as Chagas disease (ChD), remains poorly understood. Objectives: To assess how Chagas disease affects ECG-age. Methods: This retrospective cross-sectional study included adult patients whose ECGs were analyzed by a nationwide Brazilian telehealth network between 2019 and 2022. ECGs were interpreted by certified cardiologists and classified into standardized diagnostic categories and abnormality severity (normal, minor, and major, based on the Minnesota Code). ECG-age was estimated using a convolutional neural network, and delta-age was defined as ECG-age minus chronological age. Clinical data were self-reported or inferred from the use of condition-specific medications (diabetes mellitus, hypertension, coronary artery disease, ChD, and dyslipidemia). Multivariable linear regression models adjusted for age, sex, and comorbidities were used to evaluate the association between ECG abnormalities and delta-age, and to assess interactions with comorbidities. Results and Conclusions: A total of 2,045,601 ECGs from individual patients were analyzed. Median age was 54.2 years [IQR 40.9–66.3]; 40.8% were male. 21,825 (1.1%) participants reported ChD. Overall, ECG abnormalities were associated with progressively higher delta-age. Interaction analyses indicated effect modification by comorbidities. In contrast with other clinical diseases evaluated, a significant interaction between ECG abnormality severity and Chagas disease was observed, showing that ChD amplified this association. Both minor and major ECG abnormalities were associated with higher delta-age values among individuals with Chagas disease [β = 0.94 (95% CI 0.59-1.28) and β = 1.51 (95% CI 1.19-1.84), respectively]. Marginal effects plot showing delta-age across ECG abnormality categories for individuals with and without ChD and the marginal differences plot are shown in Figures 1 and 2. These findings suggest greater cardiac aging in the presence of structural and conduction system involvement, such as Chagas disease, and the sensitivity of delta-age under those circumstances. This reinforces its potential role as a biomarker even in populations with endemic cardiomyopathies.

CUSTO-BENEFÍCIO DO TELEMONITORAMENTO NA INSUFICIÊNCIA CARDÍACA

ANA LUIZA ASSUMPÇÃO CIMINELLI1; MÔNICA VIEGAS ANDRADE1; NAYARA A JULIÃO1; ALINE DE SOUZA1; KENYA NORONHA1; ANDRÉ S MOTTA-SANTOS1; EDMAR G RIBEIRO1; DEBORAH C MALTA1; ANTONIO L P RIBEIRO1; LILIAN C REZENDE1; LUISA CAMPOS CALDEIRA BRANT1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: A insuficiência cardíaca (IC) é principal causa de internação por doenças cardiovasculares com custos elevados associados às internações. Evidências de ensaio clínico indicam redução de 44% nas reinternações em pacientes sob telemonitoramento adicionado ao cuidado usual, sugerindo potencial para reduzir custos hospitalares. Objectives: Estimar o custo benefício do telemonitoramento para pacientes com IC sob a perspectiva do Sistema Único de Saúde (SUS) e projetar seu impacto econômico para o estado de Minas Gerais (MG). Methods: Análise econômica baseada em ensaio clínico com horizonte de 180 dias, adotando microcusteio pelo SUS. Custos incluíram materiais, equipamentos, remuneração profissional e despesas de telessaúde; valores atualizados para dez/2024. Os benefícios foram estimados a partir da redução de reinternações observada no estudo (26% tratamento vs 46% controle). Avaliou se quatro cenários de valoração de internações: três níveis DRG Brasil (gravidade 1–3) e média do SIH/SUS. DRG Brasil estima valores de internação segundo diagnóstico e complexidade; SIH/SUS reflete a média de valores de internação por repasses federais. O benefício para MG foi projetado a partir da média anual de internações por IC (2022–2024). Realizada análise de sensibilidade probabilística considerando variações na remuneração profissional e preço de equipamentos. Results and Conclusions: Resultados: O custo de implementação estimado foi R$426,00 por paciente. O benefício líquido incremental esperado foi positivo em todos os cenários, variando de R$47,00 por paciente (média SIH/SUS) a R$2.396,00 (DRG Brasil, gravidade 3). Para Minas Gerais (média anual 27.439 internações), o benefício líquido anual projetado variou entre R$1,3 milhões e R$65,7 milhões. Na análise probabilística, os intervalos de credibilidade de 95% incluíram o zero, porém com um perfil assimétrico: perdas potenciais limitadas (R$−490,00 a R$−451,00), e probabilidade de benefício líquido positivo entre 34,1% e 48,1% conforme o cenário. Conclusões: O telemonitoramento para pacientes com IC demonstrou favorecimento econômico sob a perspectiva do SUS em todos os cenários avaliados, apoiando sua adoção e escalonamento no setor público.

DEVELOPMENT, IMPLEMENTATION, AND EVALUATION OF A CLINICAL DECISION SUPPORT SYSTEMS FOR ANTICOAGULATION MANAGEMENT IN PRIMARY CARE

ISABELLA VIANA GOMES SCHETTINI1; LILIAN CRISTINA REZENDE1; LETÍCIA VITORIA RAMOS DA CUNHA1; LARA MATTOS PIRES1; RAFAELA BONFIOLI COSTA1; THÁBATA QUEIROZ VIVAS DE SÁ1; THIAGO BARBABELA DE CASTRO SOARES1; DANYELLE ROMANA ALVES RIOS2; ANTONIO LUIZ PINHO RIBEIRO1; MILENA SORIANO MARCOLINO1;

(1) TELEHEALTH CENTER, UNIVERSITY HOSPITAL, UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) CAMPUS CENTRO OESTE DONA LINDU, UNIVERSIDADE FEDERAL DE SÃO JOÃO DEL-REI - DIVINOPOLIS - MG - BRASIL;

Background/Introduction: Stroke is one of the leading causes of death and disability worldwide, with a growing impact in low- and middle-income countries. In these settings, warfarin remains widely used for the prevention of thromboembolic events, despite its complex management. Clinical decision support systems (CDSS) have emerged as promising strategies to improve care, particularly in primary care. Objectives: To develop and implement a CDSS for anticoagulation management in primary care, and to evaluate its usability and user satisfaction among healthcare professionals. Methods: Four-phase mixed-methods study based on the Medical Research Council framework. Phase 1 consisted of a cross-sectional assessment of primary care units. Phase 2 involved the development of an initial web-based prototype with structured patient data entry and tools for monitoring anticoagulation quality, but without decision-support messages. A formative evaluation was conducted with 514 patients across 4,022 consultations to assess system functionality, usability, and data entry processes. Phase 3 focused on developing individualized decision-support messages. Phase 4 consisted of a pilot implementation during routine outpatient consultations, in which pharmacists used the CDSS. Usability and acceptability were evaluated through semi-structured interviews, and qualitative data were analyzed using thematic analysis. Results and Conclusions: The final CDSS included 210 recommendations targeting anticoagulation indication, dose adjustment, drug–drug interactions, and bleeding management. Internal testing identified minor issues that were corrected, confirming the logical consistency of the algorithms and appropriate recommendation triggering, supporting the CDSS internal validity. The system was adopted by all pharmacists, who reported high usability, intuitive navigation, and perceived usefulness of the graphical tools. The CDSS improved consultation organization, standardized decision-making, and supported follow-up, but faced barriers such as time constraints, competing demands, technical issues, and lack of integration with electronic health records. These findings confirm the feasibility and acceptability of the CDSS in primary care settings with limited resources. Future studies should evaluate its clinical impact and further advance integration, scalability, and sustainability.

EXPLAINABLE DEEP LEARNING PREDICTS 1-YEAR ATRIAL FIBRILLATION RECURRENCE FROM ECG TAKEN AFTER SUCCESSFUL CATHETER ABLATION

GEORGE OBADA1; SHAHEIM OGBOMO-HARMITT1; RICCARDO CAVARRA1; MARIA DEPREZ1; OLEG ASLANIDI1;

(1) KING'S COLLEGE LONDON - UNITED KINGDOM;

Background/Introduction: Atrial fibrillation (AF) recurrence after catheter ablation remains high, affecting 30-50% of patients within 1 year. However, post-procedural risk stratification is limited, and current follow-up does not leverage patient-specific electrophysiology information. Artificial intelligence applied to routine electrocardiograms (ECGs) may provide a scalable approach for post-ablation prognosis, with its interpretability constituting an essential factor in the clinical translation. Objectives: This work aims to develop and evaluate an explainable deep learning (DL) model that uses a single 12-lead ECG taken post-ablation to predict AF recurrence within 1 year. Methods: We analysed 968 patients undergoing AF ablation from the MIMIC-IV dataset (recurrence rate 28%), each represented by a single 12-lead ECG acquired at a mean of 74.5 days post-procedure. DL model was trained on this dataset, with each ECG labelled recurrent or non-recurrent, to predict AF recurrence. The model performance was evaluated using stratified 5-fold cross-validation with out-of-fold predictions, using the standard metrics (area under the receiver operating characteristic curve, ROC AUC). Model interpretability was examined using gradient-based saliency maps at both ECG waveform and individual lead levels. Results and Conclusions: The model achieved an AUC of 0.70 (95% CI 0.665–0.738) for predicting 1-year AF recurrence (Figure 1A), demonstrating robust discrimination from a single ECG. Saliency analysis showed that predictions were driven predominantly by atrial activation and the overall cardiac repolarisation features, with the highest relative importance assigned to the P-wave (~0.29) and TP segment (~0.25) (Figure 2). This suggests that recurrence risk is primarily encoded in atrial substrate, while the elevated TP segment may reflect subtle atrial ectopy or rate-related changes. At the lead level, the most informative leads were III, aVL, aVF, and I (Figure 1B), indicating a non-uniform spatial contribution across the 12-lead ECG. Patient-level visualisations (Figure 2) further showed consistent localisation of model attention to specific ECG features across individuals. A single ECG routinely collected post-ablation contains clinically relevant prognostic information about AF recurrence. Explainable DL highlights atrial substrate and baseline repolarisation dynamics as key drivers of risk, supporting the feasibility of ECG-based post-ablation risk stratification and its potential integration into clinical workflows.

EXTERNAL VALIDATION PERFORMANCE OF DEEP LEARNING ALGORITHMS APPLIED TO SINUS-RHYTHM ELECTROCARDIOGRAMS FOR PREDICTION OF INCIDENT ATRIAL FIBRILLATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

PEDRO HENRIQUE KADOR MAFFI1; MIGUEL LUCAS SILVA VALENTE1; KEVILYN ASSIS DE ALMEIDA1; ISABELLY DELLA JUSTINA FLORENTINO SILVA1; CLARICE VIUDES DE ABREU1; JOÃO VICTOR BATISTA PIRES1; ODILSON MARCOS SILVESTRE2;

(1) UNIVERSIDADE FEDERAL DO ACRE - RIO BRANCO - AC - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Background/Introduction: Artificial intelligence-enabled electrocardiography (AI-ECG) has emerged as a promising strategy for identifying individuals at increased risk of atrial fibrillation (AF) before overt arrhythmia develops. However, the reproducibility and external validation performance of deep learning models across heterogeneous populations and ECG platforms remain uncertain. Objectives: To evaluate the prognostic discrimination and external validation performance of deep learning algorithms applied to sinus-rhythm ECGs for prediction of incident AF. Methods: A systematic review and meta-analysis were conducted according to PRISMA 2020 recommendations. PubMed/MEDLINE, Embase, Scopus, Web of Science, and Cochrane Library were searched for studies evaluating deep learning models applied to sinus-rhythm ECGs for prediction of future AF. The primary outcome was pooled discrimination performance measured by AUROC/C-index. Random-effects meta-analysis with REML and Hartung-Knapp adjustment was performed after logit transformation of AUROC values. Prespecified subgroup analyses included external validation cohorts, 12-lead ECG studies, handheld/single-lead ECG studies, and short-term or occult AF detection studies. Results and Conclusions: Seventeen quantitative estimates from 10 studies involving more than 520,000 participants were included. Seven primary estimates evaluating incident AF were synthesized in the main analysis. The pooled AUROC/C-index for prediction of incident AF was 0.745 (95% CI 0.682–0.799), with substantial heterogeneity (I^2=99.2%; tau^2=0.108; p<0.0001) and a 95% prediction interval of 0.552–0.874. External or independent validation cohorts demonstrated preserved discrimination, with pooled AUROC/C-index of 0.725 (95% CI 0.689–0.758). Studies using 12-lead ECGs yielded pooled AUROC/C-index of 0.767 (95% CI 0.727–0.803). Models targeting short-term, occult, or paroxysmal AF demonstrated higher discrimination (AUROC/C-index 0.839; 95% CI 0.769–0.891), although these represented distinct clinical targets from long-term incident AF prediction. Across studies reporting longitudinal risk estimates, high-risk AI-ECG strata were associated with significantly increased incident AF risk (pooled HR 2.845; 95% CI 1.815–4.459). Deep learning analysis of sinus-rhythm ECGs provides clinically meaningful discrimination for future AF and may enable scalable cardiovascular screening strategies.

20535

FINE-TUNING PRE-TRAINED ECG AND CMR WITH COMPREHENSIVE EVALUATION FOR CARDIOVASCULAR DIAGNOSTICS

DOMINIK ROLF FILLIGER1; NOAH LEUENBERGER2; LUCAS ARAUJO CARVALHO3; SARAH BRÜNINGK1; ARZU ÇÖLTEKIN1; LETICIA FERNANDEZ MOGUEL4; ANDREA ROCHA LORENZO3; ADRIANA BASTOS CARVALHO5; ERITO MARQUES DE SOUZA FILHO6; JORGE LUÍS MACHADO AMARAL7; HELENA CRAMER VEIGA REY3;

(1) 1- UNIVERSITY OF APPLIED SCIENCES NORTHWESTERN SWITZERLAND (FHNW) - SWITZERLAND; (2) UNIVERSITY OF APPLIED SCIENCES NORTHWESTERN SWITZERLAND (FHNW) - SWITZERLAND; (3) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL; (4) 4- ZURICH UNIVERSITY OF APPLIED SCIENCES (ZHAW) - SWITZERLAND; (5) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (6) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (7) UNIVERSIDADE ESTADUAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Cardiovascular diseases (CVDs) are leading cause of death worldwide, accounting for about one-third of global deaths. In this regard, there are various ways to establish a diagnosis of CVDs, including electrocardiograms (ECGs) and imaging test, such as cardiac magnetic resonance imaging (CMR). The growth of artificial intelligence (AI) applications have been contributing to improvements in health area. Objectives: This study investigates how fine-tuning pre-trained ECG and MRI encoders, originally developed on predominantly healthy populations, can improve the identification and representation of pathological cardiac conditions. Methods: This study was approved by ethical committee (CAE 42370821910015272). Three publicly available datasets are used—two ECG (Chapman and PTB-XL) and one CMR (ACDC)—to assess whether fine-tuning yields, clearer disease-related clusters, how demographic information (age, sex) influences the embedding space, and whether these refined representations remain robust when tested on new data. The selected ECG datasets consist of 12-lead recordings sampled at 500Hz with a minimum duration of 10 seconds. Rhythm conditions are especially well represented in the chosen ECG datasets. MRI dataset provides a structural and functional view of the heart, focusing on anatomical characteristics rather than electrical activity. Results and Conclusions: The quantitative results indicate that fine-tuning on pathology-rich datasets substantially increases silhouette scores (Chapman=436.75%, PTB-XL=2120.17%, ACDC increased from -0.117 ± 0.110 to 0.055 ± 0.106) suggesting more coherent clustering of arrhythmias and cardiomyopathies. Qualitative embedding analyses reveal the formation of subclusters for conduction abnormalities while showing limited imprint of demographic factors. Testing with an additional ECG dataset (PTB-XL) demonstrates satisfactory cross-domain alignment, although the small size of the ACDC dataset constrains CMR conclusions. These findings highlight that domain-adaptive fine-tuning can guide large-scale encoders toward clinically meaningful discriminations, without overtly amplifying demographic biases. A flexible, reproducible deep learning framework developed as part of this work facilitates further experimentation, including multimodal fusion and validation on larger, more diverse cohorts. This approach offers a step toward robust transfer learning in cardiovascular imaging, enabling better generalization across patient populations and clinical environments.

GEOGRAPHICAL INEQUALITIES IN CARDIOVASCULAR CARE IN THE BRAZILIAN AMAZON: TELEMEDICINE AS A STRATEGY FOR EQUITY IN REMOTE POPULATIONS — A SYSTEMATIC REVIEW

NAYLLA MICAELLY SOUZA FERNANDES1; MARIA JÚLIA ROCHA DA SILVA OLIVEIRA1; MOISÉS DE SOUSA VELOSO1; REYNALD LIMA2; JULLIA CAMARGO CARDOSO1;

(1) FACULDADE DE ENSINO SUPERIOR DA AMAZONIA REUNIDA - REDENÇÃO - PA - BRASIL; (2) HOSPITAL DE BASE DO DISTRITO FEDERAL - BRASÍLIA - DF - BRASIL;

Background/Introduction: Cardiovascular diseases are the leading cause of global morbidity and mortality, with a disproportionate impact on rural and remote populations. In the Brazilian Amazon, factors such as vast distances, low population density, shortage of specialists, and structural limitations compromise access to diagnosis and treatment, contributing to worse clinical outcomes. Objectives: To analyze the impact of inequalities in access to cardiovascular care and to evaluate the role of telemedicine in expanding healthcare delivery to remote populations. Methods: Systematic review conducted in accordance with PRISMA 2020 guidelines, with searches performed in the PubMed, Scopus, Web of Science, and SciELO databases (2015–2025). MeSH/DeCS descriptors and free-text terms were combined using the Boolean operators AND, OR, and NOT: (“cardiovascular diseases” OR “heart disease”) AND (“telemedicine” OR “telehealth”) AND (“rural population” OR “remote areas”) AND (“health access”). A total of 120 studies were identified, of which 11 were included after eligibility assessment. Studies with primary data on access to cardiovascular care or telemedicine in rural/remote areas were included. Reviews, editorials, duplicates, and studies without relevant outcomes or involving urban populations were excluded. Methodological quality was assessed using the Newcastle-Ottawa Scale, with analysis of effect measures (RR and OR) and p < 0.05. Results and Conclusions: Among the included studies, 73% reported reduced access to specialized services, 64% longer time to diagnosis, and 55% higher incidence of adverse cardiovascular outcomes. In Brazil, more than 80% identified additional structural barriers, particularly in the Amazon region. Telemedicine interventions demonstrated a 22% reduction in the risk of hospitalization (RR = 0.78; 95% CI: 0.68–0.89; p < 0.01) and an 85% increase in access to specialists (OR = 1.85; 95% CI: 1.42–2.41; p < 0.001). Approximately 60% of the studies reported improvements in clinical follow-up. Despite these benefits, limitations related to connectivity, infrastructure, and professional training still restrict large-scale implementation. These findings reinforce telemedicine as an essential strategic tool to reduce inequities in cardiovascular health in remote regions.

HIGH REPERFUSION RATE AND LOW MORTALITY IN A STEMI NETWORK WITH LESS THAN 12 MONTHS OF OPERATION IN A RESOURCE-LIMITED REGION: A PROOF OF CONCEPT FROM NORTHEASTERN BRAZIL

TIAGO CORDEIRO MEDEIROS1; SAMUEL VICTOR SOARES DE CARVALHO1; HIAGO SOUSA BASTOS2; VICTHOR GABRIEL BOAES MARTINS1; JOSE KLEBER DE FIGUEIREDO1; FILIPE SOUSA AMADO1; THALITA PEREIRA VEIGA2; HUGO FERNANDO FURTADO VIEIRA1; SAMYA FERNANDA NOLLETO SOUSA LEITE3; LUCIANA ALBUQUERQUE DE OLIVEIRA1; MARCOS ADRIANO GARCIA CAMPOS1;

(1) UFMA - CAMPUS SAO LUIS - SÃO LUÍS - MA - BRASIL; (2) UNIVERSIDADE CEUMA - IMPERATRIZ - MA - BRASIL; (3) CENTRO UNIVERSITARIO UNINOVAFAPI - TERESINA - PI - BRASIL;

Background/Introduction: In the Brazilian public health system (SUS), national registries report 30-day mortality from ST-elevation myocardial infarction (STEMI) of 11.9% to 15.0% and reperfusion rates of 40% to 67%, with wide regional variability and the worst indicators concentrated in the North and Northeast regions. The feasibility of structured telemedicine-coordinated STEMI networks in this context remains poorly documented. Objectives: To describe the outcomes of a telemedicine-coordinated regional STEMI network during its first 10 months of operation, positioning the findings as a proof of concept for formal evaluation and scalability of the model. Methods: Prospective registry of consecutive STEMI patients admitted between June 2025 and April 2026 across eight emergency units without percutaneous coronary intervention (PCI) capability, integrated with a single 24/7 primary PCI reference center. Platform activation was restricted to suspected STEMI cases; patients without qualifying criteria were not enrolled, characterizing a population defined by system activation. Diagnosis was confirmed remotely by a cardiologist via real-time electrocardiogram analysis. Descriptive analysis without risk adjustment. External benchmarks (VICTIM, RESISST, ACCEPT, EORP STEMI) were used as contextual references, not as adjusted comparisons. Results and Conclusions: A total of 168 patients were included (age 60.7±13.0 years; 73.8% male). Reperfusion rate: 79.8% (primary PCI 70.8%, pharmacoinvasive strategy 1.8%, fibrinolysis alone 7.1%). In-network mortality: 3.0% (5/168), with 2.2% among reperfused and 7.4% among non-reperfused patients. For contextual reference, Brazilian SUS registries reported 30-day mortality of 11.9% to 15.0% and reperfusion rates of 40% to 67% in populations without structured STEMI networks, with regional data from the Northeast derived from the ACCEPT registry. Within less than 12 months of operation, a telemedicine-coordinated STEMI network in a resource-limited region demonstrated operational feasibility, with reperfusion and mortality outcomes that justify formal evaluation in risk-adjusted studies with long-term follow-up. These findings support the hypothesis that telemedicine can enable effective STEMI networks and expand access to reperfusion in low- and middle-income settings.

20809

HIGH REPERFUSION RATE IN A TELEMEDICINE-COORDINATED STEMI NETWORK IN A RESOURCE-LIMITED REGION OF NORTHEASTERN BRAZIL: A 10-MONTH REGISTRY

TIAGO CORDEIRO MEDEIROS1; SAMUEL VICTOR SOARES DE CARVALHO1; HIAGO SOUSA BASTOS2; VICTHOR GABRIEL BOAES MARTINS1; JOSE KLEBER DE FIGUEIREDO1; FILIPE SOUSA AMADO1; THALITA PEREIRA VEIGA2; HUGO LEANDRO FURTADO VIEIRA1; SAMYA FERNANDA NOLLETO SOUSA LEITE3; LUCIANA ALBUQUERQUE DE OLIVEIRA1; MARCOS ADRIANO GARCIA CAMPOS1;

(1) UFMA - CAMPUS SAO LUIS - SÃO LUÍS - MA - BRASIL; (2) UNIVERSIDADE CEUMA - IMPERATRIZ - MA - BRASIL; (3) CENTRO UNIVERSITARIO UNINOVAFAPI - TERESINA - PI - BRASIL;

Background/Introduction: Regional networks for ST-elevation myocardial infarction (STEMI) management remain insufficiently implemented in resource-limited settings. Telemedicine platforms represent a promising strategy for diagnostic integration and care flow activation in contexts with restricted access to percutaneous coronary intervention (PCI). Objectives: To describe the first 10 months of operation of a telemedicine-coordinated regional STEMI network, evaluating reperfusion rates, system delays, and in-network mortality. Methods: Retrospective observational study with prospective registry of consecutive patients admitted between June 2025 and April 2026 across eight emergency units without PCI capability, integrated with a single 24/7 primary PCI reference center. Telemedicine platform activation was restricted to suspected STEMI cases. Diagnosis was confirmed by a remote cardiologist via real-time electrocardiogram analysis. Reperfusion was defined as PCI or fibrinolysis. Results and Conclusions: A total of 168 patients were included (age 60.7±13.0 years; 73.8% male). Comorbidities: hypertension 49.1%, diabetes 30.1%, smoking 11.0%. Reperfusion was performed in 134 patients (79.8%): primary PCI 119 (70.8%), pharmacoinvasive strategy 3 (1.8%), and fibrinolysis alone 12 (7.1%). Median door-to-ECG time was 10 min (IQR 2–33), with 50.3% achieving ≤10 min. Median symptom-to-door time was 134 min (IQR 60–260). Median door-to-transfer time in PCI patients was 133 min (IQR 111–196), with 33.3% within the 120-min target. In-network mortality was 3.0% (5/168): 2.2% among reperfused and 7.4% among non-reperfused patients. Implementation of a telemedicine-coordinated regional STEMI network proved feasible in a resource-limited setting, achieving a reperfusion rate of 79.8% and in-network mortality of 3.0%. Pre-hospital delay and door-to-transfer time represent the main targets for system improvement.

IMPACT OF TELEHEALTH INTERVENTIONS ON ORAL ANTICOAGULATION INDICATION AND MANAGEMENT: A SYSTEMATIC REVIEW AND META-ANALYSIS OF EFFICACY AND SAFETY OUTCOMES

AMANDA ABRANTES ABREU COSTA1; ISABELLA VIANA GOMES SCHETTINI1; ANA CAROLINA DE ALMEIDA BASTOS1; LARA MATTOS PIRES2; LUCAS ROCHA VALLE1; LAURA CARRARA RIBEIRO1; ELIABE SILVA DE ABREU3; GABRIELA TEODORA DE SOUZA SANCHES1; MARIA ANGÉLICA GOMES CARNEIRO1; LUANNA BATISTA FERREIRA1; LUCIANE KOPITTKE1; MILENA SORIANO MARCOLINO1;

(1) TELEHEALTH CENTER, UNIVERSITY HOSPITAL, UNIVERSIDADE FEDERAL DE MINAS GERAIS. - BELO HORIZONTE - MG - BRASIL; (2) TELEHEALTH CENTER, UNIVERSITY HOSPITAL, UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) DEPARTMENT OF MEDICINE, MAYO CLINIC. - UNITED STATES;

Background/Introduction: Anticoagulation is essential for primary and secondary prevention of thromboembolic events in patients with atrial fibrillation. In this context, telehealth has the potential to improve indication, management and access to care. Objectives: To synthesize the safety and efficacy of telehealth strategies in the indication and management of oral anticoagulation in patients with cardiovascular disease. Methods: A systematic review using five databases up to January/2026 was conducted. Eligible studies included randomised clinical trials evaluating the use of telehealth in anticoagulation indication or management versus usual care. Efficacy outcomes included change in the proportion of eligible patients receiving therapy, mortality, thromboembolic events and quality of anticoagulation (time in therapeutic range [TTR] of patients using warfarin), while major bleeding events were the safety outcome. Study selection and data extraction were conducted independently by two reviewers. Inconsistencies were solved by a third. Analyses were conducted in R software (meta, version 8.0-2). Effect measures were relative risk (RR) and mean difference (MD), with 95% confidence intervals. Heterogeneity was assessed using the inconsistency measure (I^2). Results and Conclusions: Our search identified 13,177 studies. After removing duplicates and screening, 49 clinical trials were selected and evaluated (124,572 patients, with 43% men and the average age 68 years-old). Of those, 11 referred to the use of telehealth to indicate anticoagulation, and 38 were about the use of telehealth in the management of oral anticoagulants. Telehealth was associated with an increase in the proportion of eligible patients receiving anticoagulant therapy (Δ= 0.02, 95%-CI [0.01; 0.03], I2 80.2%), and an increase in TTR (MD 5.1, 95%-CI [2.42; 7.78], I2 95.6%) in those using warfarin, when compared to control. No differences were observed regarding thromboembolic events (RR 0.91, 95%-CI [0.79; 1.04], I2 0%), in the mortality risk (RR 0.94, 95%-CI [0.85; 1.03], I2 11.8%) and major bleeding risk (RR 0.92, 95%-CI [0.77; 1.09], I2 13.1%). Telehealth may increase the proportion of patients using oral anticoagulants and the management of these medications, without increasing major bleeding risk or mortality.

INTERPRETABLE XGBOOST WITH MORPHOLOGICAL AND RHYTHM FEATURES FOR ARRHYTHMIA CLASSIFICATION IN SINGLE-LEAD ECG: INTER-PATIENT VALIDATION PER AAMI EC57

ENRICO DE FRANCISCO MAGNANI1; IGOR LUCAS GERALDO IZALINO DE ALMEIDA1; BRENO AUGUSTO MAGALHÃES OLIVEIRA1; BHIANCA LOPES TEIXEIRA1; CAMILA MACIEL CORTES2; RONI ARLEY SILVA DUQUE3; DEBORAH PEREIRA PRADO3; LILIAN PAULA DE SOUZA3; MARIA DO CARMO PEREIRA NUNES3; DENISE MAYUMI TANAKA1; LUCIANO FONSECA LEMOS DE OLIVEIRA1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) HOSPITAL SÃO MARCOS, UBERABA - MG - UBERABA - MG - BRASIL; (3) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Automated beat-level arrhythmia classification from single-lead ECG holds significant clinical potential for wearable cardiac monitoring. However, most published models rely on intra-patient splits that inflate performance metrics and lack the interpretability required by cardiac monitoring software regulations. Objectives: To develop and evaluate an automated machine learning model for beat-level arrhythmia classification from single-lead ECG recordings, aiming to support future implementation in wearable and ambulatory cardiac monitoring systems. Methods: The MIT-BIH Arrhythmia Database (48 recordings, ~100,000 annotated beats) was used. An inter-patient split following the AAMI EC57 protocol was applied (DS1: 22 patients for training; DS2: 22 patients for testing — no overlap). Signals were preprocessed with a zero-phase Butterworth filter (0.5–40 Hz) and resampled to 130 Hz. One-second windows were extracted centered on each R-peak and z-score normalized. Two models were compared: a 5-block 1D Convolutional Neural Network (1D-CNN) trained with class-weighted cross-entropy loss, and an XGBoost classifier trained on 28 features (24 morphological + 4 RR interval features), with SMOTE oversampling applied to minority classes. SHAP values were computed for interpretability analysis. Results and Conclusions: XGBoost achieved F1-macro = 0.54 versus 0.45 for 1D-CNN across four AAMI beat classes (N/S/V/F). For clinically critical ventricular ectopic beats (class V), XGBoost reached F1 = 0.94 compared to 0.78 for 1D-CNN. RR interval features drove a 55% relative improvement in supraventricular classification (F1-S: 0.10 → 0.17). SHAP analysis identified QRS amplitude and morphological asymmetry as the primary discriminators for ventricular beats, and RR interval ratio as the dominant feature for supraventricular premature beats — consistent with established clinical electrophysiology criteria. An interpretable XGBoost model with morphological and rhythm features outperformed 1D-CNN for single-lead ECG arrhythmia classification under rigorous inter-patient conditions. SHAP-based explanations aligned with standard clinical criteria for arrhythmia recognition, supporting regulatory transparency for cardiac monitoring software.

LIFE-COURSE SOCIAL GRADIENTS IN CARDIOVASCULAR AGING: EVIDENCE FROM AI-ESTIMATED ECG AGE IN THE ELSA-BRASIL

ALENICE ALIANE FONSECA1; LIDYANE V CAMELO1; ANTONIO HORTA RIBEIRO2; MARCELO MARTINS PINTO FILHO3; LUISA CAMPOS CALDEIRA BRANT1; LUANA GIATTI1; SANDHI MARIA BARRETO1; ANTONIO LUIZ PINHO RIBEIRO3;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) UPPSALA UNIVERSITY - SWEDEN; (3) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Artificial intelligence applied to 12-lead electrocardiograms (ECGs) enables the estimation of biological age (ECG-age), a biomarker of cardiovascular aging associated with increased risk of cardiovascular events and mortality. Individuals in disadvantaged socioeconomic positions (SEP) and exposed to adverse social conditions tend to experience accelerated aging; however, the relationship between these determinants and ECG-age remains poorly understood. Objectives: To investigate the association between race/skin color, racial discrimination, and socioeconomic position (SEP) across the life course—including accumulation of disadvantage and intergenerational social mobility—and accelerated ECG-age in participants from the ELSA-Brasil cohort. Methods: We included 13,592 participants with valid ECG data from the ELSA-Brasil baseline (2008–2010). The difference between ECG-age and chronological age (Δage) was calculated, and individuals were classified as having accelerated aging (Δage > 8 years) or normal/decelerated aging (Δage ≤ 8 years), based on the model's mean absolute error. Logistic regression models adjusted for age, sex, race/skin color, and study center were used to estimate odds ratios (OR) and 95% confidence intervals (95% CI). Results and Conclusions: The prevalence of accelerated ECG-age was 7.8%. After adjustment, lower maternal education in childhood was associated with higher odds of accelerated ECG-age, particularly among participants whose mothers had incomplete primary education (OR=1.21; 95% CI: 1.02–1.43) or no formal education (OR=1.37; 95% CI: 1.09–1.73). In adulthood, lower educational (high school: OR=1.44; 95% CI: 1.23–1.69; primary education: OR=1.45; 95% CI: 1.14–1.82), lower occupational class (middle: OR=1.32; 95% CI: 1.12–1.55; low: OR=1.52; 95% CI: 1.26–1.83), and routine manual occupations (OR=1.28; 95% CI: 1.06–1.53) were also associated with the outcome. Accumulation of disadvantage (OR=1.47; 95% CI: 1.12–1.92) and unfavorable intergenerational mobility patterns—both educational (downward: OR=1.50; 95% CI: 1.20–1.86; stable low: OR=1.51; 95% CI: 1.27–1.80) and occupational (stable low: OR=1.42; 95% CI: 1.17–1.73)—were associated with accelerated ECG-age. No associations were observed with sex, race/skin color, or racial discrimination. These findings indicate that socioeconomic disadvantage across the life course and unfavorable social trajectories are associated with accelerated cardiovascular aging, highlighting ECG-age as a sensitive marker of social inequalities.

PERFORMANCE OF FULLY AUTOMATED ARTIFICIAL INTELLIGENCE MODELS VERSUS EXPERTS IN THE MEASUREMENT OF EJECTION FRACTION AND STRAIN: AN ACCURACY META-ANALYSIS

PEDRO HENRIQUE KADOR MAFFI1; MIGUEL LUCAS SILVA VALENTE1; KEVILYN ASSIS DE ALMEIDA1; ISABELLY DELLA JUSTINA FLORENTINO SILVA1; DANIEL BATISTA MONTE ALTO DO VALE LORDÃO2; LAYANNE ANNICE SOARES PORTELA2; CLARICE VIUDES DE ABREU1; JOÃO VICTOR BATISTA PIRES1; ODILSON MARCOS SILVESTRE3;

(1) UNIVERSIDADE FEDERAL DO ACRE - RIO BRANCO - AC - BRASIL; (2) CENTRO UNIVERSITÁRIO DE CARATINGA - UNEC - CARATINGA - MG - BRASIL; (3) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Background/Introduction: Echocardiographic assessment of Left Ventricular Ejection Fraction (LVEF) and Global Longitudinal Strain (GLS) is essential in cardiology but is subject to significant interobserver variability and is highly time-consuming. Fully automated Artificial Intelligence (AI) software based on Deep Learning promises to mitigate these issues. However, proving strict clinical non-inferiority to human experts requires rigorous validation, free from publication bias. Objectives: To evaluate the systematic bias (accuracy) and reproducibility of fully automated AI tools in measuring LVEF and GLS compared to the clinical gold standard (expert echocardiographers), while adjusting for potential publication biases in the medical literature. Methods: A systematic review and meta-analysis (PRISMA methodology) of recent clinical trials and external validation cohorts was conducted. Systematic bias was assessed by Bland-Altman mean difference (MD), and reproducibility by the Intraclass Correlation Coefficient (ICC), utilizing random-effects statistical models. Subgroup analysis compared performance across LVEF and GLS. Publication bias was analytically investigated via funnel plot asymmetry and corrected using the non-parametric Duval and Tweedie's trim-and-fill method. Results and Conclusions: In the primary analysis (n=5,140 patients across 5 studies), AI slightly underestimated measurements compared to humans (MD -0.99%; 95% CI: -1.86 to -0.12; p=0.024). This underestimation was primarily driven by LVEF (MD -1.63%), whereas GLS showed no significant systematic bias (MD -0.62%). Overall inter-method reproducibility was high (ICC 0.84) and statistically superior in GLS quantification (ICC 0.90) compared to LVEF biplane volumetry (ICC 0.77). Funnel plot assessment revealed strong literature asymmetry. Following mathematical correction for publication bias via the trim-and-fill method (imputing three theoretical studies), the underestimation bias completely disappeared (Adjusted MD 0.30%; 95% CI: -1.05 to 1.65; p=0.664). We conclude that fully automated AI algorithms are strictly non-inferior to expert echocardiographers, exhibiting exceptional precision in GLS calculation. The initial apparent underestimation reflects a publication failure in the literature (omission of overestimations) rather than a clinical algorithmic flaw.

RETINA: THE WINDOW TO THE HEART. OCULOMICS AND ARTIFICIAL INTELLIGENCE IN THE PREDICTION OF CARDIOVASCULAR DISEASES — A SYSTEMATIC REVIEW

MARIA JULIA ROCHA DA SILVA OLIVEIRA1; ALEXANDRE JORGE DE ANDRADE NEGRI2; NAYLLA MICAELLY SOUZA FERNANDES1; NICOLE COSTA FREITAS3; LEONARDO DO NASCIMENTO DIAS ARAÚJO2; MOISÉS DE SOUSA VELOSO1; DANIELY DOMINGOS MOREIRA1;

(1) FACULDADE DE ENSINO SUPERIOR DA AMAZONIA REUNIDA - REDENÇÃO - PA - BRASIL; (2) AFYA - FACULDADE DE CIENCIAS MEDICAS DA PARAIBA - CABEDELO - PB - BRASIL; (3) UNIVERSIDADE TOCANTINENSE PRESIDENTE ANTONIO CARLOS - ARAGUAÍNA - TO - BRASIL;

Background/Introduction: Cardiovascular diseases require early risk detection strategies. The retina acts as a non- invasive biomarker of these alterations, and artificial intelligence has enhanced its predictive analysis. However, limitations remain that require further investigation. Objectives: To evaluate the potential of artificial intelligence applied to retinal imaging as a tool for early prediction and stratification of cardiovascular risk. Methods: Systematic review conducted in accordance with PRISMA 2020 guidelines, with searches performed in the Virtual Health Library (VHL), including the MEDLINE and LILACS databases, in March 2026. DeCS/MeSH descriptors were used with the AND operator: (“Retina” AND “Cardiovascular Diseases”), (“Retina” AND “Cardiovascular Diseases” AND “Artificial Intelligence”), and their Portuguese equivalents. Observational, diagnostic, or predictive studies involving artificial intelligence applied to retinal data correlated with cardiovascular risk were included. Reviews, editorials, case reports, duplicates, and studies without relevant data or without clear association were excluded. Study selection was conducted in three stages (titles, abstracts, and full texts) by independent reviewers. Methodological quality was assessed using the Newcastle-Ottawa Scale, and the level of evidence was classified according to the Oxford Centre for Evidence-Based Medicine (OCEBM), considering $p < 0.05$ Results and Conclusions: A total of 306 studies were identified, and 10 studies (2011–2023) were included after screening and application of eligibility criteria, with a predominance of cohort designs and the use of techniques such as OCT, OCT-A, and fundus photography. A consistent association was observed between retinal alterations and increased cardiovascular risk, including arteriolar narrowing, vascular tortuosity, and thinning of retinal layers. Quantitative measures indicated an increased risk of cardiovascular events (HR ≈ 1.11; OR ≈ 2.56), while better cardiovascular health was associated with a lower occurrence of retinopathy. Artificial intelligence models demonstrated good predictive performance (AUC ≈ 0.80–0.90), particularly in multimodal approaches. Oculomics combined with artificial intelligence appears promising as a non-invasive tool for early risk stratification. However, limitations such as methodological heterogeneity, lack of standardization, and absence of external validation restrict its immediate clinical application.

PRISMA 2020 flow diagram for new systematic reviews which included searches of databases and registers only

From: Page MJ, McKenzie JE, Bossuyt PM, Boutron I, Hoffmann TC, Mulrow CD, et al. The PRISMA 2020 statement: an updated guideline for reporting systematic reviews. BMJ 2021;372:n71. doi: 10.1136/bmj.n71

Table 1 - Characteristics of studies included in the integrative review on oculomics associated with artificial intelligence algorithms as predictors of cardiovascular diseases.

Article Title	Author/Year	Country	Study Design	Main Finding / Result
Retinal arteriolar tortuosity and cardiovascular risk factors in a multi-ethnic population study of 10-year-old children (SCAMP).	Owen CG et al., 2011	United Kingdom	Cross-sectional observational	Greater arteriolar tortuosity was associated with higher blood pressure, adiposity and adiposity, indicating early cardiovascular risk.
Artificial intelligence-driven retinal age as a single-layer to predict risks of mortality and cardiometabolic diseases.	Yang S et al., 2023	China	Cohort	Retinal nerve fiber layer patterns were associated with a higher risk of mortality and cardiometabolic diseases, with high predictive accuracy using AI.
Prediction of major adverse cardiovascular events from retinal, clinical, and genomic data in individuals with type 2 diabetes.	Mordi IR et al., 2021	India	Cohort	Integration of retinal, clinical and genomic data increased the accuracy of predicting major cardiovascular events in diabetic patients.
Cardiovascular disease diagnosis from DNA scan and retinal images using deep learning	Al-Absi HRH et al., 2022	Qatar	Cohort	Deep learning algorithms identified patterns associated with cardiovascular disease, with high diagnostic performance when imaging data were combined
Prognostic value of retinal vessel fractals and rate of retinal arteries in patients with end-stage chronic kidney disease	Faure C et al., 2021	France	Cohort	Increased wall-to-lumen ratio was associated with worse cardiovascular prognosis, reflecting systemic vascular remodeling.
Photoreceptor layer thinning as biomarker for circulatory premature mortality: UK Biobank cohort study.	Yusufu M et al.,2022	United Kingdom	Observational	Teleradiology expanded access to diagnosis in rural areas
Causal effects between retinal characteristics and cardiometabolic diseases: Mendelian randomization	Cui X et al., 2023	China	Mendelian randomization	Evidence of a causal relationship between retinal changes and cardiovascular diseases.
Association between cardiovascular health and retinopathy in US adults aged 2003-2008	Liu X et al., 2019	United States	Cross-sectional observational	Poorer cardiovascular health was associated with a greater prevalence of retinopathy in the general population
Progression of retinopathy and incidence of cardiovascular disease: CRIC Study	Grunwald JE et al., 2012	United States	Cohort	Progression of retinopathy was associated with a higher incidence of cardiovascular events over time.
Artificial intelligence-based prediction of cardiovascular risk factors from retinal swept-source optical coherence tomography-angiography	Germanese C et al., 2023	France	Cross-sectional observational	An AI model applied to OCT-angiography estimated cardiometabolic risk based on retinal microvasculature.

SIGNAL QUALITY MATTERS: IMPACT OF NOISE ON THE ACCURACY OF AI-DERIVED ECG AGE

ISADORA CRISTINE REIS SGUIZZATO BOZZI1; PABLO HUGO FREITAS ALVES2; RYAM LAEL OLIVEIRA2; GABRIELA MIANA DE MATTOS PAIXÃO1; ANTONIO LUIZ PINHO RIBEIRO1; JERMANA LOPES DE MORAES2;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) UFC - FORTALEZA - CE - BRASIL;

Background/Introduction: The electrocardiogram-derived age (ECG age) by artificial intelligence (AI) is a biological marker associated with cardiovascular risk, predicting higher mortality when the age is ≥8 years above the chronological age and lower mortality when it is ≤8 years below the chronological age. Despite its good performance and extremely relevant clinical findings, it is unknown whether ECG age maintains this performance on noisy ECGs, which are common in daily clinical practice (approximately 2%). Objectives: To evaluate the performance of AI-based ECG age estimation when applied to noisy 12-lead ECG recordings classified as uninterpretable due to technical interference. Methods: We analyzed noisy 12-lead ECGs from a large Brazilian telehealth network that were classified as uninterpretable due to technical interference by expert cardiologists. Only recordings from individuals aged 18 years or older were included. Signal-to-noise ratio (SNR) was calculated using the Noise Automatic Classification Algorithm (NACA) method. The deep neural network model proposed by Lima et al. was employed to predict ECG age. Results and Conclusions: A total of 572 ECGs were included; 57% were from females, with a mean age of 56 years. The mean SNR was 1.8. When applied to these recordings, the model exhibited markedly reduced performance, yielding a mean predicted ECG age of 61 years and a mean absolute error (MAE) of approximately 16 years, twice the error reported in the original study. Furthermore, the Pearson correlation between chronological age and predicted ECG age dropped to 0.30, compared with 0.70 reported by Lima et al., indicating a weaker association than the strong correlation previously reported in the literature. In conclusion, AI-derived ECG age estimation showed a systematic decline in accuracy when applied to low-quality ECGs. Although robust performance has been reported for high-quality recordings, reliability is substantially compromised in noisy ECGs. These findings underscore the critical importance of enforcing minimum signal quality criteria for the deployment of deep learning models in real-world clinical settings.

TEMPORAL CHANGES IN AMI OUTCOMES FOLLOWING IMPLEMENTATION OF A STRUCTURED CHEST PAIN PROTOCOL: BASELINE DATA FOR THE SALVA CORAÇÃO STEMI NETWORK

TIAGO CORDEIRO MEDEIROS1; SAMUEL VICTOR SOARES DE CARVALHO1; HIAGO SOUSA BASTOS2; VICTHOR GABRIEL BOAES MARTINS1; JOSE KLEBER DE FIGUEIREDO1; FILIPE SOUSA AMADO1; THALITA PEREIRA VEIGA2; HUGO LEANDRO FURTADO VIEIRA1; SAMYA FERNANDA NOLLETO SOUSA LEITE3; MARCOS ADRIANO GARCIA CAMPOS1; LUCIANA ALBUQUERQUE DE OLIVEIRA1;

(1) UFMA - CAMPUS SAO LUIS - SÃO LUÍS - MA - BRASIL; (2) UNIVERSIDADE CEUMA - IMPERATRIZ - MA - BRASIL; (3) CENTRO UNIVERSITARIO UNINOVAFAPI - TERESINA - PI - BRASIL;

Background/Introduction: Structured AMI care networks supported by telemedicine have the potential to reduce cardiovascular mortality in resource-limited settings. In August 2024, a structured chest pain protocol was implemented across emergency units in São Luís (MA). Subsequently, in June 2025, a STEMI telemedicine network was launched under the Salva Coração Program, highlighting the need for pre-telemedicine baseline indicators for future impact assessment. Objectives: To describe temporal changes in AMI hospital indicators before and after implementation of a structured chest pain protocol, establishing baseline data for future evaluation of the Salva Coração STEMI telemedicine network. Methods: Ecological before-after study using data from the Brazilian Hospital Information System (SIH/SUS), municipality of São Luís, January 2022–May 2025, using the SIH/SUS category 'Acute myocardial infarction'. Two periods were compared: Phase 0 (pre-protocol: Jan/2022–Jul/2024, 31 months) and Phase 1 (post-protocol: Aug/2024–May/2025, 10 months). Outcomes: in-hospital mortality, hospitalization volume, and mean length of stay. The analysis is subject to uncontrolled temporal confounders and lacks risk adjustment. The SIH/SUS does not allow isolation of STEMI cases, potentially underestimating the impact of STEMI-focused interventions. Results and Conclusions: A total of 3,435 hospitalizations and 294 deaths were recorded. Phase 0: 2,282 hospitalizations, 204 deaths (mortality 8.94%; 73.6 admissions/month; mean stay 11.0 days). Phase 1: 1,153 hospitalizations, 90 deaths (mortality 7.81%; 115.3 admissions/month; mean stay 8.5 days). In-hospital mortality decreased by 1.13 percentage points (relative reduction 12.7%), alongside a 56.6% increase in monthly admissions and a 23.2% reduction in length of stay. Implementation of a structured chest pain protocol was temporally associated with reduced AMI mortality, increased hospitalization volume, and shorter length of stay in São Luís. These findings support continued implementation of the STEMI telemedicine network launched in June 2025 and establish the pre-telemedicine baseline for future evaluation of the Salva Coração Program. Further studies with analytical designs and risk adjustment are needed for better characterization of the program's impact.

VALIDATION OF A DEEP LEARNING ALGORITHM FOR ATRIAL FIBRILLATION DETECTION USING A HOME SLEEP APNEA TEST COMPARED WITH HOLTER MONITORING IN HIGH-RISK PATIENTS

PEDRO HENRIQUE GIANJOPPE DOS SANTOS1; PALOMA RODRIGUES ROCHA1; DIEGO MUNDURUCA DOMINGUES1; SARA QUAGLIA DE CAMPOS GIAMPÁ1; MARIA DOLORES PENA CAZCO1; HORACIO GOMES PEREIRA FILHO1; CARLOS ALBERTO PASTORE1; GERALDO LORENZI-FILHO1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Background/Introduction: Atrial fibrillation (AF) is common among patients with obstructive sleep apnea (OSA) and represents a major risk factor for stroke. However, early detection of AF remains a challenge. We developed a deep neural network (DNN) model to detect AF using pulse-to-pulse intervals (PPIs) derived from photoplethysmography (PPG) signals acquired during a home sleep apnea test (HSAT). Objectives: To validate a DNN algorithm against the clinical gold standard (12-lead Holter electrocardiography [ECG]) in a high-risk prospective cohort, and to assess agreement between ECG-derived RR intervals (RRIs) and PPG-derived PPIs. Methods: Consecutive patients with hypertrophic cardiomyopathy underwent simultaneous Holter monitoring (SEER™ 12, GE Healthcare, USA) and HSAT (Biologix Sleep Test®, Biologix Sistemas S.A., Brazil). The DNN was applied to both RRIs and PPIs, and AF classifications were compared with Holter annotations as the reference standard. Beat-to-beat correspondence between RRIs and PPIs was evaluated using positive predictive value (PPV), sensitivity, and F1-score, with a 150-ms matching tolerance. Heart rate (HR) agreement was assessed per second and per minute using Bland-Altman analysis (mean bias, 95% limits of agreement [LoA]) and Pearson correlation (r). Results and Conclusions: We analyzed 27 patients (age: 51±14 years; 63% male; body mass index: 28±5 kg/m²). Mild OSA was present in 52% (oxyhemoglobin desaturation index: 9.2±2.5 events/h). AF prevalence was 14.8% (4/27). At the patient level, the DNN's classifications from PPIs and RRIs were fully concordant with Holter annotations (23 non-AF, 4 AF), yielding 100% accuracy, sensitivity, and specificity. Beat-matching performance was strong: PPV=0.858 (95% CI: 0.854-0.861), sensitivity=0.816 (0.811-0.820), and F1-score=0.830 (0.826-0.835). Second-to-second HR agreement showed r=0.815, bias=1.77 bpm, and LoA=-12.19 to 15.72 bpm. Minute-level agreement achieved r=0.939, bias=1.45 bpm, and LoA=-5.97 to 8.87 bpm. The proposed deep learning algorithm demonstrated strong concordance with Holter monitoring, supporting its potential role in AF screening using HSAT.

VALIDATION OF HEART RATE VARIABILITY METRICS DERIVED FROM PHOTOPLETHYSMOGRAPHY IN HOME SLEEP APNEA TEST COMPARED WITH ELECTROCARDIOGRAPHY

PALOMA RODRIGUES ROCHA1; PEDRO HENRIQUE GIANJOPPE DOS SANTOS1; DIEGO MUNDURUCA DOMINGUES1; SARA QUAGLIA DE CAMPOS GIAMPÁ1; GERALDO LORENZI-FILHO1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Background/Introduction: Heart rate variability (HRV) is an autonomic marker associated with sleep disorders and cardiovascular risk. Home sleep apnea tests (HSAT) based on photoplethysmography (PPG) enable prolonged acquisition of physiological signals, but require validation against the gold-standard electrocardiography (ECG). Objectives: To evaluate the agreement between HRV metrics derived from PPG-based HSAT and ECG obtained during simultaneous polysomnography (PSG). Methods: Patients simultaneously underwent full PSG with ECG (EMBLA N7000, Natus Medical; Alice 5, Phillips Respironics) and HSAT with PPG (Oxistar®, Biologix Sistemas). Overnight recordings were analyzed using a standardized protocol, including beat-to-beat synchronization, artifact exclusion, and segmentation into 5-minute windows, excluding wakefulness or segments with <80% valid coverage. Metrics included time-domain markers (heart rate, mean NN interval, SDNN, RMSSD) and frequency-domain markers (LF, HF, and LF/HF ratio). Global analysis used the nightly mean per study. Agreement was assessed using Pearson correlation (r) and Bland-Altman analysis (bias). An intra-night analysis was performed to evaluate temporal tracking of the LF/HF ratio, a marker of autonomic balance throughout the night. Results and Conclusions: A total of 322 patients were included (55±13 years; 53% male; body mass index: 30.6±5.7 kg/m²), totaling 20,005 valid 5-minute windows. In the global analysis, high agreement was observed for heart rate (r=1.00; bias -0.10 bpm) and mean NN interval (r=1.00; bias +1.52 ms). SDNN showed r=0.98 (bias -0.18 ms), while RMSSD showed r=0.94 (bias +4.03 ms). Among spectral metrics, LF showed r=0.99 (bias +1.30 ms²), and HF showed r=0.97 (bias -13.48 ms²). The LF/HF ratio showed strong agreement for the nightly mean (r=0.88; bias -0.53). In the intra-night analysis, the LF/HF ratio demonstrated stable temporal tracking, with a median correlation of 0.80 [0.62-0.91] and a median bias of -0.18 per study. HRV metrics derived from PPG showed high agreement with ECG, particularly for heart rate, mean NN interval, SDNN, LF, and HF. Despite greater variability in the LF/HF ratio, its performance remained consistent for both nightly mean and intra-night analyses. These findings support the use of PPG-derived HRV in autonomic assessment using HSAT.

EARLY INTEGRATION OF PALLIATIVE CARE IN ADVANCED HEART FAILURE: AN INTEGRATIVE REVIEW OF SHARED DECISION-MAKING

LEONARDO RIBEIRO PEIXOTO1; GABRIEL NOGUEIRA GAIA2; ALÉXIA ALVES DE CARVALHO1; SANDRYANNE MARIA RODRIGUES PATRIOTA1; KARINE ESPÍNOLA CARDINS GOMES1;

(1) HOSPITAL AGAMENON MAGALHAES - RECIFE - PE - BRASIL; (2) HOSPITAL NOSSA SENHORA DAS GRAÇAS - HOSPITAL ALFA - RECIFE - PE - BRASIL;

Background/Introduction: Advanced heart failure (HF) remains a leading cause of morbidity and mortality, with five-year survival rates around 50%, comparable to advanced malignancies. Patients experience a severe symptom burden, yet palliative care (PC) remains significantly underutilized. Recent epidemiological data (2024-2025) indicate that fewer than 18% of eligible HF patients receive PC. In low- and middle-income countries (LMICs), such as Brazil, where the BREATHE registry shows 1-year readmission rates of 46.4%, delayed integration of PC compromises shared decision-making regarding advanced therapies, highlighting a critical gap between clinical guidelines and real-world practice. Objectives: To synthesize real-world evidence on the clinical impact of early PC integration on quality of life (QoL), symptom burden, and the adequacy of shared decision-making in patients with advanced HF. Methods: An integrative review was conducted analyzing observational studies, registries, and meta-analyses published between 2024 and 2026 across PubMed and Embase. The analysis focused on quantifiable outcomes related to QoL (measured by KCCQ), psychological distress (anxiety/depression), hospital readmission rates, and documented advance care planning (ACP) in advanced HF populations. Results and Conclusions: Analysis of recent pooled data, including a 2026 meta-analysis of 2,165 patients, demonstrated that PC integration significantly improves QoL (SMD=1.12, p=0.009) and alleviates anxiety and depression (p<0.0001). Real-world cohorts indicate that PC interventions reduce hospital readmissions (RR=0.70, p=0.02) without adversely affecting mortality (RR=1.29, p=0.28). Despite these benefits, observational data from 2025 reveal that even when PC is consulted, ACP documentation remains alarmingly low, with only 3% of patients completing advance directives. Early PC integration in advanced HF provides substantial symptomatic and psychological relief while decreasing healthcare utilization. However, systemic barriers persistently hinder its implementation and the formalization of shared decision-making. Addressing these gaps is imperative to ensure therapeutic adequacy and align medical interventions with patient values.

EMPOWERING COMMUNITIES: SIGNIFICANT GAINS IN CONFIDENCE AND COMPETENCE FOLLOWING CPR TRAINING FOR NON-HEALTHCARE PROFESSIONALS IN PAKISTAN

MUHAMMAD UMER1; SADAF NAVEED2; MOIZ AHMED KHAN2; BASHIR HANIF2;

(1) TABBA HEART INSTIUTE - PAKISTAN; (2) TABBA HEART INSTITUTE - PAKISTAN;

Background/Introduction: Out-of-hospital cardiac arrest survival rates are heavily dependent on immediate bystander Cardiopulmonary Resuscitation (CPR). In low-resource settings, equipping non-healthcare professionals with these skills is critical. this study evaluated the effectiveness of a CPR training program for laypersons in Pakistan. Objectives: To evaluate the effectiveness of a Cardiopulmonary Resuscitation (CPR) training program for non-healthcare professionals in Pakistan and assess its role in improving community preparedness for out-of-hospital cardiac arrest emergencies. Methods: A cross-sectional survey was conducted following a standardized CPR training course offered by Tabba Heart Institute under the Pakistan Life Saver Program (PLSP). From February to September 2025, a total of 164 non-healthcare professionals were trained. A post-training survey was administered to assess participant perceptions of the training's relevance, utility, and impact on their confidence and skills. Results and Conclusions: The post-training survey revealed an overwhelmingly positive reception of the CPR training program. An absolute majority of participants strongly agreed that the training content was relevant to their needs (110/164, 67.1%), with an additional 43 (26.2%) agreeing, bringing the total agreement to 93.3%. Furthermore, the training's perceived utility was exceptionally high, as 136 participants (82.9%) strongly agreed that it would be useful in their work, culminating in a 95.7% total agreement rate. The effectiveness of the course delivery was also confirmed, with 94.5% of respondents (116 strongly agreeing, 39 agreeing) affirming that the training objectives were met. Finally, the program successfully aligned with participant expectations, with 96.3% (127 strongly agreeing, 31 agreeing) reporting that the training met or exceeded their expectations, underscoring a high level of overall satisfaction.

PROGNOSTIC FACTORS AND DIAGNOSTIC ACCURACY IN CONSTRICTIVE PERICARDITIS: MULTIMODAL INTEGRATION UNDER THE 2025 GUIDELINES

POLLYANA DESCONSI DE ALBUQUERQUE MARANHÃO1; TAYNÁ ANDRADE FRACASSIO1; LAENE PINTO ROSADO1; KITTARO OITTAVO MOREIRA TEIXEIRA DA LUZ1; MANUEL SALDANHA VIEGAS DUARTE2; JOÃO MARCOS DE OLIVEIRA LOURENÇO2; IVANA PICONE BORGES DE ARAGÃO2; CAMILLE CALDEIRA AGUIAR2; AMANDA SALOMÃO DE SOUZA2; VITOR MOREIRA ALVARENGA1; VITOR HUGO MUSSI CAMPOS2; VINICIUS DOS SANTOS FERNANDES1;

(1) HOSPITAL DE FORCA AEREA DO GALEAO - RIO DE JANEIRO - RJ - Brasil; (2) FACULDADE DE CIENCIAS MEDICAS DE MARICA - MARICÁ - RJ - Brasil;

Background/Introduction: Constrictive pericarditis is a restrictive syndrome resulting from the loss of pericardial elasticity, which leads to impaired ventricular filling. Although curable via pericardiectomy, diagnosis is often delayed due to a pathophysiology that mimics liver disease and other forms of heart failure. In light of the 2025 guidelines, inflammatory phenotyping through advanced imaging methods has become the cornerstone for guiding personalized therapies and preventing progression to definitive constriction Objectives: To evaluate clinical traits, the precision of imaging exams and predictors of mortality in patients with constrictive pericarditis undergoing surgical treatment. Methods: A retrospective study analyzing 84 patients who underwent pericardiectomy between 2002 and 2015. Clinical variables (signs of right-sided heart failure), laboratory data (Hemoglobin, B-type natriuretic peptide, and C-reactive protein), and imaging findings (transthoracic echocardiography and cardiac magnetic resonance) were analyzed. Mortality prediction was determined by univariate analysis using the Cox proportional hazards model (p < 0.05). Results and Conclusions: The mean age of the sample was 44 years, with a male predominance (77.4%). Idiopathic etiology was the most prevalent (69.1%), followed by tuberculosis (21.4%). Clinically, signs of right heart failure predominated, such as jugular venous distention (89%), edema (89%), and ascites (62%). Cardiac magnetic resonance (CMR) showed higher diagnostic sensitivity (95.9%) compared to echocardiography (53.6%). The overall lethality rate was 10.7%. Risk factors associated with death included: anemia (Hb < 13 g/dL), atrial fibrillation, pulmonary hypertension > 55 mmHg, and elevated levels of C-reactive protein (>7.4 mg/dL) and B-type natriuretic peptide (> 157 pg/dL). Constrictive pericarditis manifests as right-sided heart failure with low B-type natriuretic peptide levels. CMR is the method of choice due to its high sensitivity. Prognosis is associated with inflammatory and hemodynamic markers. According to the 2025 updates, the integration of imaging and biomarkers is crucial for early phenotyping, allowing for steroid-sparing strategies (such as interleukin-1 inhibitors) and surgical optimization.

TRAINING OF PREHOSPITAL HEALTHCARE PROFESSIONALS AS A STRATEGY FOR IMPLEMENTING AN ACUTE MYOCARDIAL INFARCTION CARE PATHWAY IN BRAZIL

GABRIELA BHERING GOMES1; MAYARA SANTOS MENDES1; LAÍS OLIVEIRA DE SOUZA1; EDUARDO VILLELA DE MORAES1; CLARA RODRIGUES ALVES DE OLIVEIRA1; LIDIANE APARECIDA PEREIRA DE SOUSA1; ANTÔNIO LUIZ PINHO RIBEIRO1; MILENA SORIANO MARCOLINO1;

(1) TELEHEALTH CENTER, UNIVERSITY HOSPITAL, UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Coronary artery disease remains a leading cause of mortality in Brazil. The implementation of structured care pathways is essential to ensure timely diagnosis and rapid myocardial reperfusion in acute myocardial infarction (AMI). In this context, prehospital care teams play a pivotal role, as they are often the first point of contact. Therefore, targeted training is a key component for the effective implementation of such public health strategies. Objectives: To describe and evaluate a training program for healthcare professionals as a strategy to support the implementation of an AMI care pathway within the Brazilian public health system. Methods: As part of a national initiative to implement an AMI care pathway, a structured educational intervention was conducted involving physicians and nurses from ambulance services in 2 Brazilian states. The training program was structured in 2 phases: (1) an online module, comprising theoretical content delivered via a digital platform, including educational materials and an evidence-based clinical guide developed by the project team; and (2) an in-person module, including lectures and five hands-on training stations. Clinical stations incorporated simulation techniques using case-based scenarios of patients with chest pain. Knowledge was assessed using identical pre- and post-tests based. Paired comparisons were performed using the paired t-test (significance level of 5%). Results and Conclusions: Among 444 eligible nurses and 197 physicians, 254 nurses (57.2%) and 143 physicians (72.6%) completed the online module. Of these, 183 nurses (72,1%) and 124 physicians (86,7%) attended the in-person training and completed the tests. Among nurses, mean test scores increased from 76.8±18.9 to 91.2±12.7 (p<0.001), and the most frequently incorrect answer was related to patient care during and after thrombolytic administration (16.9%). Among physicians, mean test scores increased from 73.5±17.6 to 85.9±13.1 (p<0.001), and the most frequent incorrect answer involved a clinical case about the initial management of atypical chest pain and the interpretation of an electrocardiogram (86,3%). In conclusion, the observed improvement in test scores suggests that the training intervention was associated with increased knowledge related to AMI management in the prehospital setting. These findings support the role of structured training as a key component in the implementation of care pathways for AMI within public health systems.

16105

TRANSCULTURAL ADAPTATION AND VALIDATION OF THE SELF-CARE OF CORONARY HEART DISEASE INVENTORY (SC-CHDI) FOR BRAZILIAN PORTUGUESE IN PATIENTS WITH CORONARY ARTERY DISEASE

EMILY JUSTINIANO1; ENEIDA REJANE RABELO DA SILVA1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: Knowledge, treatment adherence, and daily self-care practices are essential for maintaining clinical stability among patients with coronary artery disease (CAD). The Self-Care of Coronary Heart Disease Inventory (SC-CHDI) is the only instrument that directly assesses self-care in CAD patients. Due to the importance of this tool, this study was proposed. Objectives: To perform the cross-cultural adaptation and clinical validation of version 3.0 of the SC-CHDI for Brazilian Portuguese. Methods: Methodological research that followed the steps of cross-cultural adaptation according to Guillemin; Bombardier; Beaton (1993) and validation. In the pre-test, the instrument was applied to 40 patients and in the validation to 230. To assess face and content validity, the content validity index (CVI) was used. For reliability, Cronbach's alpha and McDonald's Omega were used. For construct validity, confirmatory factor analysis was performed, and for criterion validity, Pearson's correlation was performed between the SC-CHDI and the Cardiovascular Risk Factors Knowledge Questionnaire (Q-FARCS). Project approved under number CAEE 67651823.7.0000.5327. Results and Conclusions: In the cross-cultural adaptation stages, the main changes involved terms or expressions to facilitate understanding and ensure cultural equivalence. The instrument was named ""Avaliação do Autocuidado para Doença Arterial Coronariana". In face and content validation, the instrument obtained a total CVI of 0.94. Cronbach's alpha for section B was 0.87 and McDonald's omega for section A was 0.8 and for section C 0.66. Pearson's correlation coefficient showed a weak correlation between the Q-FARCS and sections A (r=0.34) and C (r = 0.36) and a moderate correlation with section B (r = 0.59). Factor analysis demonstrated excellent fits (Section A - χ^2 (24, n= 230) = 32.403, p= 0.117, CFI = 0.996, TLI = 0.94, RMSEA = 0.03 (90% CI [0.000, 0.070]), P = 0.681 and SRMR = 0.04; Section B - χ^2 (17, n= 230) = 28.593, p= 0.003, CFI = 0.992, TLI = 0.986, RMSEA = 0.054 (90% CI [0.013, 0.088]), p= 0.380 and SRMR = 0.01; Section C - χ^2 (7, n= 230) = 7.510, p= 0.378, CFI = 0.997, TLI = 0.994, RMSEA = 0.018 (90% CI [0.000, 0.084]), p= 0.710 and SRMR = 0.036). The SC-CHDI was adapted for Brazilian Portuguese. The evaluation of its psychometric properties suggests that the instrument is valid for measuring the self-care of Brazilian patients with CAD in institutions with a similar profile.

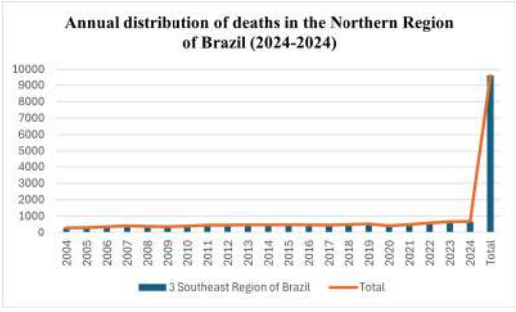
10-YEAR TREND ANALYSIS OF THE OBESITY ICD-10 CODE UNDERREPORT IN PARTICIPANTS WITH CONFIRMED BODY MASS ≥30KG/M²: A REAL-WORLD STUDY.

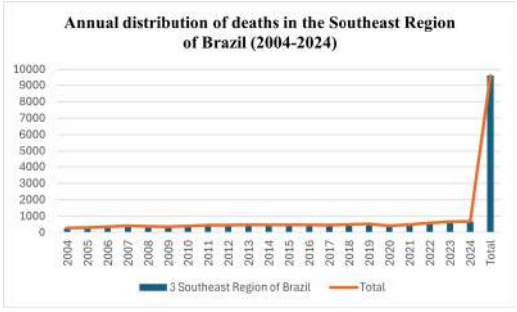
BEATRIZ SANTANA PRADO1; GIULIANO GENEROSO1; ROBERTA SARETTA1; KAROLINE RAZIMAVICIUS BARBADO1; ROBERTO KALIL FILHO1; LUCIANO FERREIRA DRAGER1;

(1) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Background/Introduction: Background: It has been estimated that 1 billion people have obesity Worldwide. Despite considerable advancements in the pharmacological treatment in recent years, obesity is still an overlooked condition. Underreporting of obesity code may be high in patients with obesity, contributing to our understanding of the real burden of this chronic condition. Objectives: Objective: To evaluate the 10-year trend report of obesity ICD-10 code among participants with confirmed body mass index ≥30Kg/m2 in a large sample of adults. Methods: Methods: We conducted a retrospective cohort analysis using the TriNetX Global Health Research Network, based on anonymized electronic medical records. We identified all adult patients (>18 years) with at least 2 reports of a body mass index (BMI) ≥ 30 Kg/m2 from 2016 to 2025. We used the International Classification of Diseases, 10th edition code E66. We defined the frequency of obesity code reporting during the whole period and by year. Stratified analysis by sex, ethnicity, and grade of obesity was performed. Results and Conclusions: Results: A total of 15,301,768 participants were included in the analysis (59.6% females, 66% self-reported whites, mean BMI: 34.4± 6.5 Kg/m²). The overall prevalence of obesity code reports during the period was only 46.7%. We observed a progressive increase in the obesity report during the 10-year period (Figure 1). However, in 2025, nearly 50% of adults with at least 2 BMI ≥ 30 Kg/m2 remained without a formal obesity diagnosis. Stratified analysis revealed that men, Asians and obesity grade 1 had lower obesity code reports than their counterparts (Figure 2). Conclusion: Despite considerable improvements in the obesity code report in the last 10 years, around 50% remained underreported. Particular attention should be devoted to the subgroup of adults according to sex, ethnicity and grade of obesity. Underreporting obesity may undermine its management across the board, from public health policies to therapeutic inertia.



16065



A COMPARATIVE STUDY ON MORTALITY FROM ACUTE AND SUBACUTE ENDOCARDITIS IN THE NORTH AND SOUTHEAST REGIONS OF BRAZIL (2004-2024)

PAULA GABRIELA COSTA DA CONCEIÇÃO BARBOSA1; ALANNE RYLLARI DA SILVA DOS SANTOS1; GABRIELA PIXUNA DIAS1; NAARA SILVEIRA ABDON MELO1; MANOELA CORREA DE SOUZA1; LARISSA CRISTINA MACHADO DE BARROS1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Background/Introduction: Endocarditis is an inflammation of the inner lining of the heart, known as the endocardium, with diverse etiologies, including bacterial and viral causes. The bacterial form is classified as acute or subacute, most commonly caused by Staphylococcus and Streptococcus, respectively. Treatment consists of antimicrobial therapy aimed at controlling infection and preventing systemic complications (KAMDE; ANJANKAR, 2022) Objectives: To comparatively analyze mortality due to acute and subacute endocarditis in the North and Southeast regions of Brazil over a 20-year period. Methods: This is a retrospective, quantitative epidemiological study of acute and subacute endocarditis cases (ICD-10: I33), based on data from the Mortality Information System (SIM/SUS), from 2004 to 2024. The mean mortality rate was calculated as the ratio between the number of deaths and the population, expressed per 100,000 inhabitants. Percentage variation was calculated as the relative difference between the highest and lowest values during the study period, divided by the lowest value and multiplied by 100. The rate ratio (RR) was used to assess the temporal trend, based on initial and final values. Other variables were analyzed using absolute frequencies (deaths by region/state, age group, and sex). Data were organized using Microsoft Excel™ Results and Conclusions: A total of 10,239 deaths were recorded, with 614 (5.9%) in the North and 9,625 (94.0%) in the Southeast, the mean annual mortality rates were 30.7 and 481.25 per 100,000 inhabitants, respectively. There was a percentage increase of 206.7% in the North (from 15 to 46 deaths) and 73.9% in the Southeast (from 387 to 673 deaths). The rate ratio indicated an increasing trend in both regions, with RR = 1.057 (5.7% increase) in the North and RR = 1.028 (2.8% increase) in the Southeast. The states of Pará (278; 2.7%) and São Paulo (5,188; 50.7%) showed the highest number of deaths. The most affected age group was 40-49 years in the North (90; 14.7%) and 50-59 years in the Southeast (1,680; 17.4%). Males were predominant in both regions, accounting for 403 (65.6%) in the North and 5,817 (60.4%) in the Southeast. The concentration of deaths in the Southeast may reflect population size and better reporting systems (NUNES MARINHO et al.,2025). Limitations include potential underreporting and inconsistencies in secondary data. The observed increase highlights the need for strengthened epidemiological surveillance and targeted public health actions.

19255

A DECADE OF SEX DISPARITIES IN HEART FAILURE OUTCOMES IN BRAZIL (2014–2025): A NATIONWIDE ANALYSIS

LETÍCIA ASEVEDO DANTAS1; VINICIUS SERGIO MARINHO1; ANDRÉ JORGE NOGUES DE ALMEIDA1; RENATO MAX FARIA1; GABRIELA GOMES DANTAS1; KAREN KAROLINE NOGUEIRA RAMOS COSTA1;

(1) UFRN - NATAL - RN - BRASIL;

Background/Introduction: Heart failure (HF) remains a leading cause of cardiovascular morbidity and mortality, placing a substantial burden on healthcare systems. Despite therapeutic advances, nationwide long-term temporal trends in sex-specific HF outcomes remain underexplored in Latin America. Objectives: The primary objective of this study was to investigate whether patient sex influences in-hospital mortality outcomes among individuals admitted with HF, analyzing a decade of nationwide trends in Brazil. Methods: An ecological time-series study (2014–2025) was conducted using the Brazilian Hospital Information System (SIH/DATASUS) and Census-adjusted demographic projections (IBGE). HF admissions were identified via ICD-10 (I50). Annual Percentage Change (APC) in hospitalization rates and in-hospital mortality was calculated using log-linear regression. Sex disparities were assessed via Relative Risk (RR) and chi-square tests ($p<0.05$). Results and Conclusions: A total of 2,428,167 HF hospitalizations were analyzed. Admissions steadily declined for both sexes (men: 115.2 to 106.3/100,000; women: 106.3 to 90.6/100,000). Paradoxically, in-hospital mortality increased, disproportionately affecting women. Female mortality rose from 10.1% to 12.1% (APC: +1.7%), whereas male mortality grew from 9.6% to 11.1% (APC: +1.6%). Overall, women exhibited a significantly higher risk of in-hospital death (RR 1.08; 95% CI 1.07–1.09; $p<0.001$), despite lower admission volumes. Brazil faces a critical paradox of declining HF hospitalizations and rising in-hospital mortality, predominantly among women. This trend is partially influenced by statistical denominator adjustments following the 2022 Census, as well as the 2020-2021 COVID-19 pandemic, which drastically reduced routine admissions while exacerbating lethality among hospitalized HF patients. A primary limitation is the reliance on administrative data, precluding the adjustment for major clinical confounders such as left ventricular ejection fraction and individual comorbidities. Nonetheless, these findings underscore an urgent need to investigate female-specific gaps in HF care and disease severity.

ACUTE MYOCARDIAL INFARCTION IN EMERGENCY CARE: TRENDS AND MORTALITY IN BRAZIL AND GERMANY (2010–2022)

LETÍCIA HANNA MOURA DA SILVA GATTAS GRACIOLLI1; SARA CHANG YOUN WUNG2; BEATRIZ MIRELI DE JESUS ESTRELA3; ANGÉLICA WANG WU3; LIGIA LUANA FREIRE SILVA3;

(1) FACULDADE DE MEDICINA DE JUNDIAI - JUNDIAÍ - SP - BRASIL; (2) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (3) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL;

Background/Introduction: Acute myocardial infarction (AMI) remains one of the leading causes of death worldwide and a central challenge in emergency cardiovascular care. Survival and long-term outcomes after AMI are highly dependent on early recognition, rapid access to emergency services, timely reperfusion therapy, and the organization of integrated care networks. Objectives: To compare Brazil and Germany regarding mortality associated with acute myocardial infarction, analyzing temporal trends from 2010 to 2022, sex differences, and health-system factors related to emergency care and access to reperfusion therapy. Methods: This retrospective, ecological, comparative study evaluated population-level mortality from acute myocardial infarction in Brazil and Germany between 2010 and 2022. Data were obtained from international mortality estimates reported by the World Health Organization and complemented by evidence from the Global Burden of Disease (GBD) framework and national cardiovascular statistics. Mortality rates were age-standardized and expressed per 100.000 inhabitants. Temporal trends were assessed descriptively. Sex-specific mortality patterns were analyzed when available. Differences in emergency care organization were discussed based on published data on reperfusion access, emergency medical services, and acute coronary syndrome networks. Results and Conclusions: Throughout the study period, both countries showed a decline in AMI mortality; however, Germany consistently exhibited lower mortality rates compared with Brazil. The reduction in mortality was more pronounced and stable in Germany, particularly in the earlier years of the series, reflecting widespread availability of percutaneous coronary intervention (PCI), efficient prehospital triage, and shorter door-to-balloon times. In Brazil, although AMI mortality declined over time, rates remained higher, with greater heterogeneity across regions. Mortality was higher among men in both countries. The persistence of higher mortality in Brazil suggests ongoing barriers to timely reperfusion, unequal access to catheterization laboratories, and delays in emergency presentation. Acute myocardial infarction mortality declined in both Brazil and Germany between 2010 and 2022; however, substantial disparities persist. Lower mortality in Germany underscores the impact of well-organized emergency cardiovascular systems and universal access to reperfusion therapy.

ADMISSION SERUM POTASSIUM ABNORMALITIES ARE STRONG PREDICTORS OF 30-DAY MORTALITY IN HOSPITALIZED PATIENTS FROM LATIN AMERICA

MATEUS AGUIAR DA COSTA LOPES1; RODRIGO NORONHA CAMPOS1; YASMIN TRINDADE1; GABRIEL MOSTARO FONSECA1; JULIANA CORRÊA DE OLIVEIRA CAIED1; RÔMULO FONSECA DE MORAES1; ANA BEATRIZ NEPOMUCENO CUNHA1; BRUNA GONÇALVES GUSTINELLI1; ALINE SABRINA HOLANDA TEIXEIRA MORAES1; RIANE RODRIGUES MARTION1; MARCELO CAPITO CASTILHO1; FLAVIA CORTEZ COLÓSIMO1;

(1) BENEFICENCIA PORTUGUESA - SAO PAULO - SP - Brasil;

Background/Introduction: Dyskalemia is a frequent and potentially modifiable abnormality in hospitalized patients, yet data from Latin America (LATAM) remain scarce. Whether admission serum potassium levels can serve as an early predictor of short-term mortality in this population is not well established. Objectives: We aimed to evaluate the association between potassium disturbances at admission and 30-day mortality in a large LATAM cohort. Methods: We conducted a retrospective cohort study using the TriNetX global federated database, including 31 healthcare organizations from the LATAM Collaborative Network. Adults hospitalized between January 2016 and December 2025 with at least one major comorbidity (diabetes, hypertension, heart failure, or chronic kidney disease) and an available admission serum potassium measurement were included. Patients were stratified into four groups: ≤3.4 mmol/L (hypokalemia), 3.5–5.0 mmol/L (normokalemia), 5.1–5.9 mmol/L (hyperkalemia), and ≥6.0 mmol/L (severe hyperkalemia). Propensity score matching was performed for age, sex, and comorbidities. The primary endpoint was 30-day mortality. Results and Conclusions: A total of 14,883 patients were included. After matching, any deviation from normal potassium levels was associated with a significant increase in short-term mortality. Severe hyperkalemia conferred the highest risk of death (8.3% vs. 3.1%; RR 2.67; p<0.001), followed by hyperkalemia (5.8% vs. 2.9%; RR 1.97; p<0.001) and hypokalemia (5.0% vs. 2.8%; RR 1.74; p<0.001). A clear gradient of risk was observed across potassium strata, with progressively higher mortality at more extreme values. Admission serum potassium is a powerful and readily available predictor of 30-day mortality in hospitalized patients in Latin America. Both hypo- and hyperkalemia nearly double the risk of death, while severe hyperkalemia is associated with a near threefold increase. These findings position dyskalemia as an early, actionable biomarker of risk, underscoring the need for prompt recognition and correction as a potential strategy to improve clinical outcomes.

16953

AGE-SPECIFIC DIVERGENCE IN INFECTIVE ENDOCARDITIS MORTALITY IN BRAZIL: A NATIONWIDE JOINPOINT ANALYSIS, 2000–2019

JOÃO VITOR FAZZIO DE ANDRADE CORDEIRO1; LETÍCIA MARTINS RAPOSO2; PAULO HENRIQUE GODOY2;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE FEDERAL DO ESTADO DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Infective endocarditis (IE) is associated with high morbidity and mortality, yet nationwide epidemiological trends in Brazil remain insufficiently characterized. Objectives: To assess temporal trends in IE-related mortality in Brazil from 2000 to 2019, focusing on age-specific patterns. Methods: Ecological time-series study using the Brazilian Mortality Information System. Deaths with mention of IE were identified from underlying or associated causes on death certificates. Age-standardized mortality rates (per 100,000 inhabitants) were calculated and stratified (0–29, 30–59, 60–79, ≥80 years). Temporal trends were analyzed using Joinpoint regression, estimating annual percent change (APC) and average annual percent change (AAPC) with 95% confidence intervals. Results and Conclusions: A total of 52,055 deaths with IE-related deaths were identified. Mortality increased markedly with age, reaching rates 9.3-fold higher than the national average in individuals ≥80 years and ~4-fold higher in those aged 60–79 years. Individuals aged 0–29 years had the lowest mortality (0.24/100,000), less than one-fifth of the national rate. Overall mortality showed a modest upward trend (AAPC: +0.74%; 95% CI: 0.32–1.11). Age-stratified analyses revealed heterogeneous patterns: mortality declined in individuals aged 0–29 years (AAPC: −2.53%; 95% CI: −3.20 to −1.86), remained stable in those aged 30–59 years, and increased in older groups (60–79 years: +1.75%; ≥80 years: +2.25%). Joinpoint analysis identified distinct inflection patterns across age groups. IE mortality in Brazil reveals a true age-specific divergence in mortality trends rather than a pattern driven solely by population aging. Increasing trends within older populations alongside sustained declines in younger groups suggest shifts in risk exposure, comorbidity burden, and disease profile. These findings support age-targeted strategies and reinforce the importance of stratified analyses to avoid misinterpretation of trends driven by population structure. Although based on administrative data subject to potential misclassification and reporting variability, the large-scale, nationwide nature of this analysis enables comprehensive assessment of temporal trends, providing evidence that would be challenging to obtain within the time frame of conventional prospective cohort studies.

21180

BURDEN OF ACUTE MYOCARDIAL INFARCTION HOSPITALIZATIONS AMONG YOUNG ADULTS IN BRAZIL, 2008–2025: A NATIONWIDE ANALYSIS

DENISE CRISTINA PACHECO1; MARIA ELIZABETH CORRÊA RODRIGUES2; JOSÉ ILTON SILVA JÚNIOR3; THIAGO CARVALHO BARRETO1; FERNANDA SEEMANN SCHÜTZ1; VINÍCIUS AUGUSTO RIBEIRO1; GUILHERME FERNANDES JUSTINO DA COSTA1; MARIEL DE QUADROS ZIMMERMANN1; ALANA QUEIROZ LEÃO4; HUMBERTO GRANER MOREIRA1;

(1) UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL; (2) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (3) UNIVERSIDADE FEDERAL RURAL DO SEMI-ARIDO - MOSSORÓ - RN - BRASIL; (4) UNIVERSIDADE EVANGELICA DE GOIAS - UNIEVANGELICA - ANÁPOLIS - GO - BRASIL;

Background/Introduction: Hospitalization rates for acute myocardial infarction (AMI) among young adults have been rising in high-income countries, but contemporary nationwide trends in Brazil remain incompletely characterized. Whether this pattern extends across all young adult age strata, sexes, and regions has not been systematically examined. Objectives: To characterize nationwide temporal trends in acute myocardial infarction (AMI) hospitalizations among young adults in Brazil from 2008 to 2025. Methods: We analyzed all hospital admissions with a principal diagnosis of AMI (ICD-10 I21–I22) among adults aged 20–49 years from Brazil's Hospital Information System (SIH-SUS), 2008 through 2025. Age-adjusted hospitalization rates per 100,000 adults aged 20–49 years were calculated by direct standardization using the 2022 Brazilian Census population as the reference. Temporal trends were assessed by linear regression of annual age-adjusted rates on calendar year, stratified by age group (20–29, 30–39, and 40–49 years) and sex; statistical significance of the annual slope was evaluated by two-tailed t-test, with P<0.05 considered significant. In-hospital case fatality rates and mean length of hospital stay were examined as secondary outcomes. Results and Conclusions: Between 2008 and 2025, hospitalizations for AMI among adults aged 20–49 years increased from 11,186 to 26,062 (+133.0%). The overall age-adjusted hospitalization rate rose from 13.9 to 24.9 per 100,000 (+79.2; R^2=0.90; P<0.001). Increases were observed across all three age strata and were most pronounced among adults aged 20-29 years (1.53 to 3.82 per 100,000; +149.1%; R^2=0.88; P<0.001), followed by 30-39 years (7.17 to 14.37; +100.4%; R^2=0.90; P<0.001) and 40-49 years (36.15 to 61.75; +70.8%; R^2=0.89; P<0.001). Absolute hospitalizations rose by 131.9% in men and 135.6% in women, with a stable male-to-female ratio of approximately 2.3:1. Despite the rising admission burden, in-hospital case fatality declined: among women aged 20–29 years, fatality fell from 7.5% to 2.4%, and from 5.6% to 2.7% among men aged 40–49 years. Mean length of hospital stay also shortened over the period. From 2008 through 2025, hospitalizations for AMI among young Brazilian adults more than doubled, with the steepest relative rise occurring in the youngest stratum (20–29 years). The paradox of markedly rising hospitalizations alongside declining in-hospital case fatality suggests improvements in acute care quality set against a growing underlying disease burden.

COLD SPELLS DRIVE A 21% SURGE IN CARDIOVASCULAR HOSPITALIZATIONS AMONG THE OLDEST OLD: A 13-YEAR TIME-SERIES IN SÃO PAULO, BRAZIL

THAUÃ PEREIRA DE MENEZES1; JULIA BARBAROTO TOSTA ARAUJO2; SAMUEL DE MATTOS ALVES1; PAULO JOSE FORTES VILLAS BOAS1; CAROLINA LETICIA ZILLI VIEIRA3; ADRIANA POLACHINI VALLE1;

(1) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL; (2) UNIFUNEC - SANTA FÉ DO SUL - SP - BRASIL; (3) HAVARD T. CHAN SCHOOL PUBLIC HEALTH - UNITED STATES;

Background/Introduction: Climatic variability is a recognized cardiovascular risk factor, particularly in older adults. In São Paulo, the largest urban center in Latin America, few studies have quantified the effect of habitual seasonality and extreme cold events on emergency cardiovascular hospitalizations, stratified by age group. Objectives: To quantify the effect of thermal seasonality and extreme cold months on emergency cardiovascular hospitalizations among older adults residing in the city of São Paulo (2008–2020), with age stratification Methods: Ecological time-series study with monthly data from January 2008 to December 2020 (156 months). Meteorological variables from the Mirante de Santana station (INMET) were used to calculate Effective Temperature (ET), Discomfort Index (DI), and Temperature–Humidity Index (THI). Emergency hospitalizations for acute myocardial infarction, arrhythmias, and heart failure in adults ≥60 years were obtained from DATASUS/SIH-SUS, stratified into 60–69, 70–79, and ≥80 years. Extreme cold months were defined as those with monthly minimum temperature ≤ P10 of the series (≤13.3 °C). Analyses included Pearson's correlation and Welch's t-test. Results and Conclusions: A total of 162,028 emergency cardiovascular hospitalizations were recorded among older adults (mean: 1,039/month). Hospitalizations were negatively correlated with all thermal indices (r between −0.49 and −0.58; p<0.001), with the strongest association for minimum temperature (r=−0.58). Winter showed 21.4% more hospitalizations than summer (1,148 vs. 946/month). In 16 extreme cold months (all in June–August), there was a 16.1% excess in hospitalizations among adults ≥60 years compared to other months (1,186 vs. 1,022; p<0.001). Vulnerability increased with age: 60–69 years (+13.7%), 70–79 years (+15.4%), and ≥80 years (+21.0%; r=−0.58 with THI). These findings demonstrate that cold — not heat — is the main climatic driver of cardiovascular hospitalizations among older adults in São Paulo, with a clear age-dependent vulnerability gradient. Seasonal climate alerts should be incorporated into health surveillance, focusing on June–August and adults aged ≥80 years. Limitations include monthly aggregation and absence of adjustment for confounders such as air pollution; future analyses with daily data and DLNM are warranted.

21071

EPIDEMIOLOGICAL PROFILE OF HOSPITALIZATIONS AND MORTALITY DUE TO CONGENITAL HEART DISEASES IN YOUTHS, ADULTS, AND OLDER ADULTS IN BRAZIL: A TEMPORAL ANALYSIS FROM 2021 TO 2025

BÁRBARA CHIODINI BARBOSA MAGALHÃES1; MARCOS SILVA RIBEIRO1; ALICE PEREIRA VIEIRA1; DÉBORAH CLEMENTINO NOBRE1; BÁRBARA VITÓRIA OLIVEIRA SANTOS1; GRAZIELE LOPES TELES2; NAYRA LIGIA QUIRINO GARCIA3;

(1) UNIVERSIDADE EVANGELICA DE GOIAS - UNIEVANGELICA - ANÁPOLIS - GO - BRASIL; (2) HOSPITAL ESTADUAL DE URGÊNCIAS GOVERNADOR OTÁVIO LAGE DE SIQUEIRA - GO - GOIÂNIA - GO - BRASIL; (3) HOSPITAL ESTADUAL DE URGÊNCIAS GOVERNADOR OTÁVIO LAGE DE SIQUEIRA - GOIÂNIA - GO - BRASIL;

Background/Introduction: Congenital heart diseases (CHD) are cardiac malformations present at birth, caused by alterations in embryonic development. They can range from asymptomatic cases to severe conditions requiring early intervention, being the most frequent congenital anomaly and an important cause of infant morbidity and mortality. Objectives: To compare the epidemiological profile of hospitalizations and mortality due to congenital heart disease in Brazil between 2021 and 2025, analyzing possible associations with sex, age group, number of deaths, and mortality rate. Methods: This analytical, descriptive, retrospective epidemiological study used data from the Brazilian Unified Health System Hospital Information System on hospitalizations and deaths due to congenital heart disease (ICD-10: Q20–Q28) from 2021–2025. Descriptive analyses, Shapiro-Wilk, Student's t-test, and chi-square (χ^2) tests were performed, adopting $p<0.05$ in SPSS. Results and Conclusions: Between 2021 and 2025, 102,438 hospitalizations and 5,879 deaths due to congenital heart disease were recorded in Brazil. The Southeast region concentrated the highest number of hospitalizations (42.4%) and deaths (37.6%), followed by the Northeast (27.5% and 25.4%). The highest incidence of hospitalizations occurred in children under 1 year old (46.6%), followed by the 1 to 4 year age group (15.9%) and the 5 to 9 year age group (7.7%). Regarding deaths, higher mortality was observed in children under 1 year old (73.4%). There was a statistically significant difference between age groups regarding hospitalizations and deaths ($p<0.001$), as well as a significant association between age and mortality ($p<0.001$), highlighting a greater impact of congenital heart disease on the pediatric population. In relation to sex, a slight predominance of hospitalizations was observed in females (50.8%), while deaths were more frequent in males (52.1%). Males had a higher average number of deaths ($p<0.001$), with a strong association between sex and death outcome ($\chi^2=5879.00$; $p<0.001$). Congenital heart disease constitutes a significant public health problem, especially in the first year of life, highlighting the need to strengthen prenatal care, expand early diagnosis, and improve neonatal and pediatric care within the health system to reduce hospitalizations and deaths.

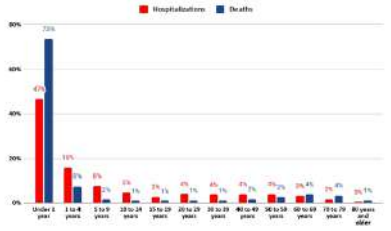

Figure 1 - Percentage of hospitalizations and deaths by age group with a diagnosis of congenital heart disease in Brazil from 2021 to 2025.

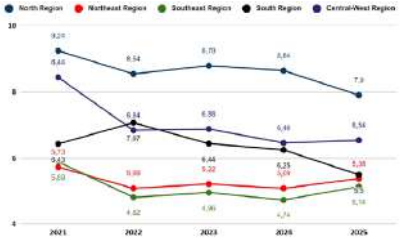

Figure 2 - Trend in the mortality rate from congenital heart disease in Brazil from 2021 to 2025.

16506

EPIDEMIOLOGICAL PROFILE OF HOSPITALIZATIONS FOR RHEUMATIC FEVER AND CHRONIC HEART DISEASE IN CEARÁ, BRAZIL: A 10-YEAR ANALYSIS (2015–2025)

MARIANA DE OLIVEIRA DA FROTA1; SOFIA MOURA DE SOUSA BRASIL2; ANA LUIZA BRANDÃO DE OLIVEIRA1; ANA CLARA RANGEL SAUNDERS1; GIOVANA PEREIRA GURGEL1; LUISA FARIAS EUCLIDES DE ARAUJO3; JOSE CIRO GAUGINSKI JUNIOR4;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE ESTADUAL DO CEARA - UECE - FORTALEZA - CE - BRASIL; (3) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL; (4) HOSPITAL SAO CAMILO FORTALEZA - FORTALEZA - CE - BRASIL;

Background/Introduction: Rheumatic Fever (RF) and its main sequela, Chronic Rheumatic Heart Disease (CRHD), remain significant public health challenges in developing countries, directly reflecting socioeconomic vulnerabilities and failures in primary care. In Brazil, despite the decline in the incidence of infectious diseases, hospitalization rates for rheumatic complications remain significant, with a direct impact on the quality of life and work capacity of the young population. In the state of Ceará, the healthcare network organization and the local demographic profile impose specific challenges for disease control and adherence to secondary prophylaxis. Objectives: The present study aims to analyze the epidemiological profile of hospitalizations for RF and CRHD in Ceará between 2015 and 2025 to support regional surveillance strategies and clinical management. Methods: This is a descriptive, retrospective, and quantitative study based on data from the Information Technology Department of the Unified Health System (DATASUS/TABNET). The study population comprised patients hospitalized in the state of Ceará with primary diagnoses classified according to ICD-10 in groups I00-I02 (Acute Rheumatic Fever) and I05-I09 (Chronic Rheumatic Heart Diseases). The analysis period covered January 2015 to December 2025. The variables analyzed were: sex, age group, and color/race. Results and Conclusions: Hospitalizations for rheumatic fever and its sequelae in Ceará (2015-2025) reveal a bimodal profile. Analysis showed 56% of occurrences in females and 44% in males, a disparity that widens in chronic cases, possibly due to greater biological susceptibility and the search for valve repairs. The age distribution confirmed two critical peaks: 5-19 years (acute) and 30-59 years (chronic), with the presence of the elderly (60+). This scenario suggests failed control of pharyngotonsillitis in childhood, culminating in severe valvulopathies in productive adulthood. Regarding color/race, the predominance of Pardo (74%), followed by White (12%), Black (3%), and Asian/Indigenous (1%), reflects Ceará's demographics and the socioeconomic vulnerability associated with the disease. However, the 10% of ignored data points to a weakness in surveillance. The pathology imposes a high burden on the SUS, centered in hubs like Fortaleza. The transition from sick youth to disabled adults reinforces the urgency of policies prioritizing secondary prophylaxis and early diagnosis in primary care to break the rheumatic heart disease progression cycle.

15873

GEOGRAPHIC DISPARITIES IN ICU ACCESS, INTERMUNICIPAL TRANSFERS, AND IN-HOSPITAL MORTALITY IN ACUTE MYOCARDIAL INFARCTION: A COHORT STUDY IN SÃO PAULO, BRAZIL (2015–2025)

ERLEI BISPO1; LUCYANA BAPTISTA2; DANIEL CRUZ1; LUÍSA REIS3; HELENA BEZERRA3; VERONICA MONTEIRO1; CRISTIANO BERARDO1;

(1) INSTITUTO DE MEDICINA INTEGRAL PROFESSOR FERNANDO FIGUEIRA - IMIP - RECIFE - PE - BRASIL; (2) REAL HOSPITAL PORTUGUES - RECIFE - PE - BRASIL; (3) FPS - FACULDADE PERNAMBUCANA DE SAUDE - RECIFE - PE - BRASIL;

Background/Introduction: In large middle-income countries such as Brazil, the uneven distribution of intensive care unit (ICU) beds can strongly influence how patients with acute myocardial infarction (AMI) are managed and their clinical outcomes. However, it is still unclear whether intermunicipal transfers interact with ICU availability at the receiving hospital to affect in-hospital mortality. Objectives: We tested the hypothesis that the effect of intermunicipal transfer on mortality in AMI patients varies according to the presence of ICU beds at the destination hospital, using data from São Paulo state. Methods: This retrospective cohort study analyzed 410,297 hospitalizations for AMI (ICD-10 I21 and I22) in São Paulo from 2015 to 2025, extracted from the SIH-SUS/DATASUS database. Intermunicipal transfer was defined as any distance >0 km between the patient's municipality of residence and the hospital. We performed multivariable logistic regression with a prespecified interaction term between transfer status and ICU availability at the destination. Adjusted predicted mortality probabilities were estimated, and geospatial analyses (including choropleth maps, flow mapping for transfers >50 cases, global Moran's I, and local LISA) were used to examine care flows and spatial clustering of adjusted mortality by municipality of residence. Results and Conclusions: Overall in-hospital mortality was 9.4%. ICU admission occurred in 39.2% of cases and intermunicipal transfers in 28.3%. Higher mortality was independently associated with age ≥65 years (OR 2.61; 95% CI 2.55–2.67), ICU admission (OR 1.50; 95% CI 1.47–1.53, likely due to indication bias), and lack of ICU in the municipality of origin (OR 1.09; 95% CI 1.04–1.14). Reperfusion therapy remained strongly protective (OR 0.31; 95% CI 0.30–0.32). There was a significant interaction between transfer and ICU availability at destination (OR 1.18; 95% CI 1.12–1.25; p<0.001). Adjusted mortality probabilities ranged from 7.99% in non-transferred patients in municipalities without ICU to 9.31% in those admitted locally to hospitals with ICU. Geospatial analysis revealed centripetal flows toward tertiary centers and clear spatial clustering of higher adjusted mortality by municipality of origin (Moran's I = 0.52; p<0.001), particularly in less structured regions. We conclude that geographic disparities in ICU access shape transfer patterns and influence in-hospital mortality in AMI through their interaction with the structure of the receiving hospital.

Tabela 1. Multivariable logistic regression for in-hospital mortality in patients with acute myocardial infarction (2015–2025)

Variables	P value	Adjusted OR	95% CI
Age (categorized)	<0.001	2.61	2.55–2.67
Gender	<0.001	0.82	0.80–0.84
Legal nature of institution	<0.001	1.11	1.09–1.13
Reperfusion	<0.001	0.31	0.30–0.32
ICU admission	<0.001	1.50	1.47–1.53
Municipality of origin	<0.001	1.09	1.04–1.14
Intermunicipal transfer	<0.001	0.90	0.85–0.94
Municipality of destination	<0.001	1.08	1.04–1.11
Interaction (Transfer × Destination)	<0.001	1.18	1.12–1.25

Note: AUC = 0.70, Brier score = 0.08, and calibration plot showed good agreement between predicted and observed probabilities, with no evidence of systematic deviation.

Figure 1A. Interaction between Transfer Status and ICU availability at destination

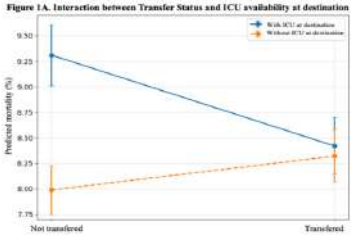

Figure 1B. Acute myocardial infarction death in intensive care units and intermunicipal flows in the state of São Paulo, 2015–2025 (flows >50 cases)

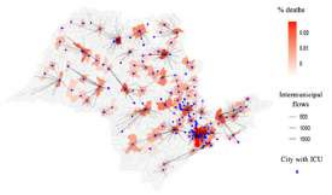

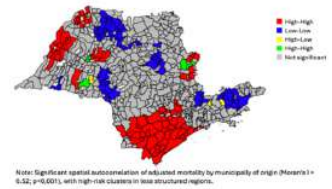

Figure 1C. Local spacial autocorrelation analysis (LISA) of adjusted mortality from acute infarction in municipalities of São Paulo State

Note: Significant spatial autocorrelation of adjusted mortality by municipality of origin (Moran's I = 0.52; p<0.001), with high-risk clusters in less structured regions.

GEOGRAPHIC INEQUALITY IN CORONARY ANGIOPLASTY PROVISION FOR ACUTE MYOCARDIAL INFARCTION IN BRAZIL: A NATIONWIDE ECOLOGICAL TIME-SERIES STUDY, 2015-2025

NILSON HITOSHI YOSHIMOTO1; TAUANI CRISTINA ASSIS MOREIRA2; FERNANDA ARAÚJO GOMES3; MARIA FERNANDA BARBOSA FRANCISCO4; SOFIA MACHADO OLIVEIRA5; ALICE BEATRIZ SOARES PEREIRA6; ANA CLARA ARAGÃO FERNANDES7;

(1) CENTRO UNIVERSITÁRIO FACULDADE DE MEDICINA DO ABC (FMABC) - SANTO ANDRÉ - SP - BRASIL; (2) UNIVERSIDADE DE RIO VERDE - RIO VERDE - GO - BRASIL; (3) UNIVERSIDADE SALVADOR - SALVADOR - BA - BRASIL; (4) PONTIFÍCIA UNIVERSIDADE CATÓLICA DE MINAS GERAIS - POÇOS DE CALDAS - SP - BRASIL; (5) UNIG - NOVA IGUAÇU - RJ - BRASIL; (6) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL; (7) HOSPITAL FEDERAL SERVIDORES DO ESTADO DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Acute myocardial infarction remains a major cause of cardiovascular morbidity and mortality and requires timely access to reperfusion therapy, particularly coronary angioplasty. In Brazil, nationwide analyses comparing the burden of myocardial infarction hospitalizations with the regional provision of interventional treatment remain scarce. Objectives: To assess regional inequalities in coronary angioplasty provision relative to acute myocardial infarction hospitalizations in Brazil from 2015 to 2025. Methods: Ecological time-series study using secondary data from the Brazilian Unified Health System Hospital Information System from 2015 to 2025. Hospitalizations for acute myocardial infarction, classified according to ICD-10, and coronary angioplasty procedures were analyzed nationwide and stratified by geographic region and year. The angioplasty-to-hospitalization ratio was used as an indirect indicator of the balance between care demand and interventional treatment supply. Ethics committee review was waived because only public, aggregated, non-identifiable data were used. Results and Conclusions: The national angioplasty-to-hospitalization ratio was 68.68% over the study period, with substantial regional variation. The South showed the highest mean ratio (101.16%), with peaks in 2017 and 2018, whereas the North had the lowest mean (43.26%) and a further decline in 2020. The Northeast remained persistently low, with a mean of 53.88%. The Central-West showed a declining trend, and the Southeast maintained an intermediate mean ratio of 64.95%, with yearly oscillations. These findings reveal persistent regional inequality in the provision of interventional cardiovascular care in Brazil. Although this metric does not account for clinical indication, timing, or angioplasty subtype, it highlights the need to strengthen regional cardiovascular care networks and expand equitable access to hemodynamic services.

16185

GLOBAL TRENDS IN CARDIOVASCULAR RISK FACTORS: A JOINPOINT ANALYSIS ACROSS WHO REGIONS (1990–2022)

DION CANDELARIA1; TIFFANY ATKINS2; JULIE REDFERN2;

(1) SUSAN WAKIL SCHOOL OF NURSING AND MIDWIFERY, FACULTY OF MEDICINE AND HEALTH, THE UNIVERSITY OF SYDNEY - AUSTRALIA; (2) INSTITUTE FOR EVIDENCE-BASED HEALTHCARE, FACULTY OF HEALTH SCIENCE AND MEDICINE, BOND UNIVERSITY - AUSTRALIA;

Background/Introduction: Cardiovascular disease (CVD) is largely driven by modifiable risk factors. However, less is known about how these risk factors have evolved over time across regions, and whether progress has been consistent. Understanding these trends helps to inform targeted prevention strategies and guide policy prioritisation across diverse health system contexts. Objectives: To examine temporal trends and quantify changes in prevalence of major CVD risk factors (diabetes, hypertension, cholesterol, physical activity, tobacco smoking) across the six World Health Organization (WHO) regions. Methods: We accessed noncommunicable disease risk factor data from the WHO Global Health Observatory, a comprehensive global database that compiles health indicators from 190+ countries. We extracted prevalence (%) estimates for key CVD risk factors from 1990 to 2022. Joinpoint regression analysis was used to calculate the annual percentage change (APC) for each segment and the average annual percentage change (AAPC) with 95% confidence intervals across the entire time trend. Results and Conclusions: Global trends in CVD risk factors showed a mixed pattern, with improvements in some areas while showing worsening trends in others. Favourable trends were observed for hypertension, tobacco use, and cholesterol. Hypertension prevalence declined in most regions between 1990 and 2019, with the greatest reduction in Europe (AAPC=−1.54, 95% CI: −1.55 to −1.53), although the Western Pacific showed a slight increase (AAPC=0.10, 95% CI: 0.08 to 0.12). Tobacco use decreased across all regions between 2000 and 2020, most markedly in South-East Asia (AAPC=−3.50, 95% CI: −3.56 to −3.43), from 54.1% to 26.6%. Total cholesterol declined modestly in several regions, but increased slightly in the Western Pacific (AAPC=0.25, 95% CI: 0.07 to 0.43). In contrast, diabetes prevalence increased across all regions between 1990 and 2022, highest increase in the Eastern Mediterranean (AAPC=2.58, 95% CI: 2.57 to 2.59) and lowest in Africa (AAPC=1.58, 95% CI: 1.55 to 1.61). Insufficient physical activity also increased in five regions between 2000 and 2022, Africa being the only exception (AAPC=−1.10, 95% CI: −1.19 to −1.01). Global trends in CVD risk factors were mixed. Rising diabetes prevalence and increasing physical inactivity signal ongoing and emerging challenges. These divergent patterns highlight the need for region-specific prevention strategies that address multiple risk factors and support sustained, system-level approaches to cardiovascular health.

Average Annual percent change (AAPC), 95%CI, and p-value for five risk factors among 6 WHO regions

WHO Region	Diabetes prevalence 1990-2022	Hypertension prevalence 1990-2019	Mean crude total cholesterol (mmol/l) 1990-2018	Insufficient physical activity prevalence 2000-2022	Tobacco smoking 2000-2020

IMPACT OF INSTITUTIONAL EZETIMIBE PROVISION ON THE LIPID PROFILE OF PATIENTS WITH HIGH/INTERMEDIATE CARDIOVASCULAR RISK IN A TERTIARY CARDIOMETABOLISM OUTPATIENT CLINIC

PATRICIA DE SOUZA MAGALHAES1; RAFAELA ANDRADE PENALVA FREITAS1; AMANDA RAQUEL COSTA CRUZ1; BRUNO LEAL MARTINS1; MARIO HENRIQUE CALIANO1; MATHEUS SACCO GOMES1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Background/Introduction: LDL-c reduction is the cornerstone of secondary cardiovascular prevention, with the relationship between low levels and the reduction of ischemic events being causal and dose-dependent. The Brazilian Society of Cardiology (SBC) guidelines establish strict targets for patients with this risk profile; however, the unavailability of ezetimibe in the National List of Essential Medicines (RENAME) of the Brazilian Unified Health System (SUS) imposes access barriers that compromise adherence and lipid control in this vulnerable population. Objectives: To evaluate the impact of direct outpatient dispensing of ezetimibe 10mg on the reduction of LDL-c levels and the successful achievement of therapeutic targets in these patients followed at a tertiary cardiometabolism outpatient clinic. Methods: A retrospective analytical study was conducted with adult patients using statins who received ezetimibe institutionally between August 2025 and February 2026. Paired demographic and laboratory data (pre- and post-intervention) were analyzed. The Wilcoxon test was used to compare means, the McNemar test for the proportion of targets, and Spearman's correlation. A 5% significance level was adopted. Inclusion criteria comprised patients ≥18 years old with prior statin use who received institutional ezetimibe 10mg and had LDL-c measurements available pre- and post-intervention. Exclusion criteria were incomplete medical records, medication suspension due to intolerance/adverse effects, and any record of poor adherence. Results and Conclusions: Results: The sample (mean age 66.8±1.2 years; 55.8% women) showed a statistically significant reduction in LDL-c, from an initial mean of 92.7 mg/dL to 78.8 mg/dL post-treatment (p < 0.001). The mean absolute Delta LDL was -13.9±3.7 mg/dL, representing a percentage drop of -11.5%. Patients who achieved the target post-intervention recorded a mean LDL-c reduction of -27.5% (p < 0.001). The intervention was decisive for clinical success: the rate of patients meeting the strict target (< 50 mg/dL) doubled, jumping from 22% to 45% (p < 0.001), with a significant association with comorbidities such as CAD, T2DM, and HTN (p < 0.001). Conclusion: The direct provision of ezetimibe at the tertiary level circumvents access barriers in the SUS, ensures adherence, and doubles the efficacy in achieving lipid targets. It is statistically proven that institutional access is the definitive strategy for effective cardiovascular protection in high-risk patients.

IMPACT OF SOCIAL VULNERABILITY ON HEART FAILURE HOSPITALIZATIONS IN BRAZIL: A REGIONAL AND TEMPORAL ANALYSIS (2019–2025)

TIAGO NOGUES ALMEIDA1; ANDRE JORGE ALMEIDA1; ICARO HEICKMEN TAVEIRA MELO1; LUCAS DE QUEIROZ MENEZES1; MIGUEL CHAVES LENZI2; VICTOR FEITOSA GALDINO3; DIEGO NOGUES ALMEIDA4; RODRIGO BESSA5; RAQUEL CRISTINA FARIAS DE MEDEIROS QUEIROZ1; NATAN REIS BRITO1; DEBORA DE QUEIROZ MENEZES6; MATEUS WERNER GABRIEL VALENÇA GOMES1;

(1) UFRN - NATAL - RN - BRASIL; (2) UNIVERSIDADE ESTADUAL DO RIO GRANDE DO NORTE - MOSSORÓ - RN - BRASIL; (3) FPS - FACULDADE PERNAMBUCANA DE SAUDE - RECIFE - PE - BRASIL; (4) UNIVERSIDADE FEDERAL DE ALAGOAS - MACEIÓ - AL - BRASIL; (5) UNIVERSIDADE POTIGUAR (UNP) - NATAL - RN - BRASIL; (6) FACULDADE DE MEDICINA DE OLINDA - OLINDA - PE - BRASIL;

Background/Introduction: Heart failure (HF) remains a major public health challenge in Brazil, accounting for a substantial burden of hospitalizations and healthcare costs within the Unified Health System (SUS). Although regional disparities are well documented, the relationship between social vulnerability and HF outcomes remains poorly defined. The Social Vulnerability Index (SVI) provides a multidimensional framework to assess these inequalities. This study explores the paradoxical relationship between social vulnerability and HF hospitalization rates, particularly during the post-pandemic recovery period. Objectives: To analyze temporal trends and regional disparities in HF hospitalizations in Brazil from January 2019 to April 2025, and to evaluate their correlation with SVI and Family Health Strategy (FHS) coverage across macro-regions. Methods: We conducted an ecological retrospective time-series study using data from the Brazilian Hospital Information System (SIH/DATASUS) between January 2019 and April 2025. Outcomes included HF hospitalizations, hospitalization rates per 100,000 inhabitants, in-hospital mortality, and mean costs, stratified by macro-region. These indicators were correlated with SVI (used as a proxy for regional social vulnerability) and FHS coverage rates. Spearman's rank correlation (ρ) and linear regression were applied. Given the ecological design, findings were interpreted at the population level. Results and Conclusions: Between 2019 and 2025, Brazil recorded over 1.2 million HF hospitalizations. A persistent regional paradox emerged: lower-SVI regions (South and Southeast) had higher hospitalization rates (e.g., South: 148.93/100,000), whereas higher-SVI regions (North and Northeast) showed lower rates but higher in-hospital mortality and case fatality, a disparity that intensified in 2024–2025. SVI was inversely correlated with hospitalization rates ($\rho = -0.75$; $p<0.05$) and positively correlated with in-hospital mortality ($\rho = 0.80$; $p<0.05$). Mean hospitalization costs increased by ~60%, reaching BRL 2,395.44 in 2024. HF hospitalization patterns in Brazil reveal a structural mismatch between healthcare utilization and outcomes. The inverse association between SVI and hospitalization rates likely reflects underdiagnosis and limited access to care in vulnerable regions, masking true disease burden. The post-pandemic rise in mortality and costs reinforces the need for strategies that address structural inequities and expand equitable access to cardiovascular care.

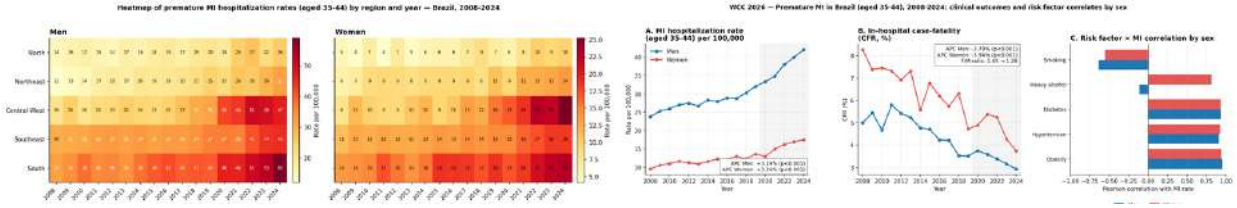
17752

MORTALITY FROM ISCHEMIC HEART DISEASE IN BRAZIL BEFORE, DURING, AND AFTER THE COVID-19 PANDEMIC

MARCELA KHERLAKIAN BARONIAN1; TROY RICHARD CARNEIRO FILHO1; GEOVANNA OLIVEIRA ARAÚJO SILVA1; HUMBERTO GRANER MOREIRA2;

(1) UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL; (2) FACULDADE DE MEDICINA DA UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL;

Background/Introduction: The COVID-19 pandemic raised global concern about a potential sustained increase in cardiovascular mortality, whether through direct viral effects or through disruption of health care systems. Questions remain regarding a possible postpandemic legacy in the incidence of ischemic heart disease, including hypotheses of a prolonged effect after mass vaccination. Objectives: We aimed to evaluate the trajectory of mortality from ischemic heart disease in Brazil before, during, and after the pandemic, and to assess the presence of excess mortality and any persistent effect in the postpandemic period. Methods: We conducted an ecologic time-series study using data from the Brazilian Mortality Information System (SIM/DATASUS). Deaths with an underlying cause coded as ischemic heart disease (ICD-10 I20–I25) were retrieved, and annual crude mortality rates were calculated by sex and age group. Mortality rates (per 100,000 inhabitants) were standardized for age and sex by the direct method, using the 2020 Brazilian population as the reference. The study period was stratified into pre-pandemic (2010–2019), pandemic (2020–2022), and post-pandemic (2023–2024) phases. The average annual percent change (AAPC) was estimated by linear regression on the natural logarithm of the standardized rates, under a log-linear assumption over time. Results and Conclusions: Age- and sex-adjusted rates declined progressively during the pre-pandemic period, from 92.95 per 100,000 inhabitants in 2010 to 79.96 in 2019 (AAPC, −1.7%). During the pandemic, the downward trajectory was maintained, with rates of 72.04 in 2020, 73.60 in 2021, and 74.31 in 2022, with no evidence of a sustained increase relative to the historical pattern (AAPC, −2.3%). In the post-pandemic period, the decline continued, with rates of 70.46 in 2023 and 69.14 per 100,000 inhabitants in 2024 — the lowest values of the series (AAPC, −3.6%). As compared with the final pre-pandemic year (2019), the absolute reduction was approximately 13.5% by 2024. This pattern was consistent across both sexes. Mortality from ischemic heart disease in Brazil showed a continuous decline between 2010 and 2024, with no evidence of an increase during the pandemic or of an adverse legacy in the post-pandemic period. These findings suggest that, at the population level and after adjustment for age and sex, there was no excess cardiovascular mortality attributable to the pandemic or post-vaccination periods.



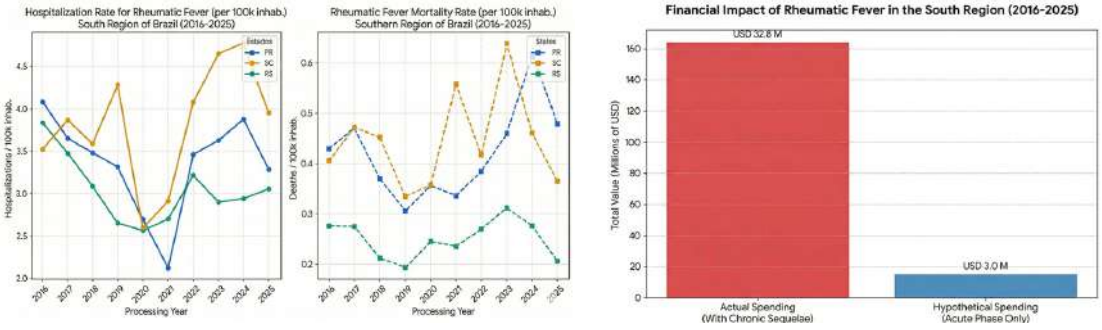
17785

OBESITY AND ALCOHOL AS CARDIOMETABOLIC AXES OF ACUTE MYOCARDIAL INFARCTION IN YOUNG BRAZILIAN ADULTS: A SEX-STRATIFIED ANALYSIS (2008-2024)

ANDREZA RIBEIRO PINHO1; MATHEUS COSTA BARROS2;

(1) UNICAMP - CAMPINAS - MT - BRASIL; (2) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL;

Background/Introduction: Acute myocardial infarction (AMI) in Brazil is no longer a disease exclusively associated with aging: between 2008 and 2024, hospitalizations among adults aged 35 to 44 nearly doubled, while in-hospital case-fatality declined. Objectives: This divergent scenario, whose sex-specific dimensions and cardiometabolic correlates remained scarcely explored, motivated this study. Methods: This is an ecological time-series study, linking hospitalizations (ICD-10 I21-I22) and deaths from the Brazilian Hospital Information System (SIH-SUS), by sex and federative unit, with IBGE population estimates and annual sex-stratified prevalences of five risk factors (obesity, hypertension, diabetes, smoking, and heavy alcohol use) from Vigitel (except 2022). The annual percent change (APC) was calculated using log-linear regression, along with stratified Pearson/Spearman correlations and standardized β coefficients, comparing the pre-pandemic and pandemic subperiods. Results and Conclusions: The AMI hospitalization rate per 100,000 inhabitants rose from 23.74 to 42.01 in men (APC +3.19%) and from 9.58 to 17.48 in women (APC +3.24%), both p<0.001, with an approximately threefold acceleration after 2020. Conversely, in-hospital case-fatality fell from 5.00% to 2.94% in men and from 8.27% to 3.75% in women (APC ≈ −3.9%, p<0.001), narrowing — but not eliminating — the female disadvantage: the female-to-male case-fatality ratio declined from 1.65 in 2008 to 1.28 in 2024, with young women dying proportionally more often than men in every one of the 17 years analysed. Obesity was the strongest correlate in both sexes (r ≈ 0.95). Notably, however, the female prevalence of heavy alcohol use nearly doubled over the period (9.6% to 15.7%) and correlated strongly with the rise in female infarction rates (r=+0.81), while remaining silent in men (r=−0.11), consistent with recent evidence of greater female cardiovascular vulnerability to heavy episodic drinking. In standardized multivariate regression, obesity dominated in men (β=1.18); in women, obesity (β=0.66) and hypertension (β=0.42) contributed independently. Premature AMI in Brazil is not merely a growing problem, but a transforming one: while Brazil has achieved genuine gains in mortality, the accelerating incidence and persistent female disadvantage expose the limits of an approach still insufficiently differentiated by sex. Obesity consolidates as a universal therapeutic axis, while heavy alcohol use emerges as a distinctly female preventive target.



19720

PERSISTENT CLINICAL AND ECONOMIC BURDEN OF RHEUMATIC HEART DISEASE IN SOUTHERN BRAZIL DESPITE UNIVERSAL HEALTHCARE ACCESS

GONÇALO DUARTE BAPTISTA NEVES GRIFO1; THEO SANTOS FRANCO1; ANA KARYN EHRENFRIED FREITAS1;

(1) UNIVERISADE POSITIVO - CURTIBA - PR - BRASIL;

Background/Introduction: Rheumatic fever remains a leading preventable cause of morbidity and recurrent episodes are the primary driver of progression to advanced Rheumatic Heart Disease (RHD). Despite its preventable nature, the prevalence of severe valvular lesions persists as a significant burden in middle-income settings. Southern Brazil provides a relevant scenario to assess the impact of disease recurrence and the frequency of late-stage presentations in a region with broad healthcare access. Objectives: To evaluate hospitalization patterns, mortality trends, and the economic impact of rheumatic fever and RHD in Southern Brazil between 2016 and 2025, thereby assessing whether healthcare availability has reduced the severe disease burden. Methods: A population-based study using the Brazilian Unified Health System database analyzed hospitalizations for acute rheumatic fever and chronic RHD in Southern Brazil from 2016 to 2025. Analyzed variables included admissions, in-hospital deaths, case-fatality rate, admission type, age distribution, and direct hospitalization costs. Additionally, all rates were standardized per 100,000 inhabitants. Results and Conclusions: A total of 11,995 hospitalizations were recorded, 63% as emergency admissions. More than 60% of this were urgent. By 2024, hospitalization rates reached 4.77 per 100,000 inhabitants in Santa Catarina. Indeed, Paraná presented nearly 8/100000 severe admissions annually, with the highest mortality rate as 0.62 per 100,000. There were 1,099 in-hospital deaths, increasing from 107 in 2016 to 140 in 2024. Overall case-fatality was 9,16%, reaching 11% in Paraná. Furthermore, hospitalizations increased with age, peaking at 60-69 years, consistent with cumulative valvular damage. Overall, rheumatic conditions represent ~1 in 250 cardiovascular hospitalizations, concentrated in advanced stages. Total costs exceeded USD 32 million, with >98% attributable to chronic RHD sequelae. Hospitalizations for chronic disease were ~11 times more expensive than acute episodes, accounting for most valvular expenditures. Conclusion: Despite universal healthcare availability, rheumatic fever and RHD remain persistent onerous in Southern Brazil. The predominance of emergency admissions, persistent mortality and concentration of costs in advanced disease suggest gaps in sustained secondary prevention and long-term care. Strengthening primary care follow-up and ensuring benzathine penicillin may reduce preventable late-stage burden and improve system efficiency.

PREVALENCE, PHARMACOLOGICAL TREATMENT, AND CONTROL OF HYPERTENSION: TRENDS OVER UP TO 11 YEARS OF FOLLOW-UP IN THE BRAZILIAN LONGITUDINAL STUDY OF ADULT HEALTH (ELSA-BRASIL)

MARCOS HENRIQUE FEITAL NUNES1; MÁRCIO GONÇALVES DE SOUSA1; ISABELA MARTINS BENSENOR2; PAULO ANDRADE LOTUFO2; FERNANDO HENPIN YUE CESENA1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (2) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Background/Introduction: Hypertension is one of the main determinants of cardiovascular morbidity and mortality and has a high prevalence in the adult population. Although its relevance is widely recognized, studies assessing longitudinal trends in hypertension in Brazil are limited. Objectives: To describe changes in the prevalence, pharmacological treatment of hypertension, and blood pressure (BP) control (BP <130/80 mmHg or <140/90 mmHg) over up to 11 years of follow-up in the Brazilian Longitudinal Study of Adult Health (ELSA-Brasil). Methods: This prospective longitudinal cohort study included public servants from six Brazilian state capitals, using data collected during the first (2008–2010), second (2012–2014), and third (2017–2019) visits of the ELSA-Brasil study. Hypertension was defined as BP ≥140/90 mmHg or use of antihypertensive medication. Prevalence ratios and ratios for pharmacological treatment and BP control across visits, adjusted for sex, age, race/skin color, and educational level, were estimated using generalized estimating equations. Results and Conclusions: A total of 15,088, 13,949, and 12,289 participants were included in visits 1, 2, and 3, respectively. Crude hypertension prevalence rates were 36.0% (95% CI: 35.2%–36.7%), 41.0% (95% CI: 40.2%–41.8%), and 45.8% (95% CI: 44.9%–46.7%) at visits 1, 2, and 3, respectively. Adjusted analyses showed stability in prevalence between visits 1 and 3 (Figure 1-A). Between visits 1 and 2, there was an increase in the proportion of pharmacological treatment (Figure 1-B), concomitant with a significant increase in BP control (Figure 1-C and 1-D). Between visits 2 and 3, there was a reduction in the proportion of pharmacological treatment (Figure 1-B), with stability in BP control (Figure 1-C and 1-D). Between visits 1 and 3, there was no significant difference in drug treatment rates (Figure 1-B), but BP control improved significantly (Figure 1-C and 1-D). At the final visit, the crude rate of medication use was 80.4%; however, 38.1% and 61.2% of individuals did not achieve adequate BP control, considering the 140/90 mmHg and 130/80 mmHg thresholds, respectively. Conclusion: Over up to 11 years of follow-up in ELSA-Brasil, hypertension prevalence and pharmacological treatment rates remained stable, while BP control indicators improved. However, target attainment remains insufficient, underscoring the need for more effective implementation strategies.

16831

PROFILE OF COMORBIDITIES ASSOCIATED WITH PREVIOUS CARDIOVASCULAR EVENTS IN A RENAL SCREENING CAMPAIGN IN SERGIPE

JOÃO GABRIEL SANTANA TRINDADE1; SHEYLA CRISTINA TONHEIRO FERRO DA SILVA1; JEROCÍLIO MACIEL DE OLIVEIRA JÚNIOR2; SUSAN SOARES DE CARVALHO3;

(1) UNIVERSIDADE FEDERAL DE SERGIPE - ARACAJU - SE - BRASIL; (2) UNIVERSIDADE TIRADENTES - ESTÂNCIA - SE - BRASIL; (3) CENTRO UNIVERSITARIO TIRADENTES- UNIT - ARACAJU - SE - BRASIL;

Background/Introduction: INTRODUCTION: The occurrence of cardiovascular events, such as acute myocardial infarction and stroke, is related to multiple comorbidities. These individuals often present several risk factors that are underdiagnosed and silently accelerate the cardio-renal decline, which justifies population screening strategies for proper management. Objectives: OBJECTIVE: To assess the metabolic, hemodynamic, and renal profiles of patients with previous cardiovascular events during the World Kidney Day campaign. Methods: METHODS: The activities took place in public squares in the cities of Aracaju, Nossa Senhora do Socorro, and Estância on March 13, 2025, where healthcare professionals conducted a cross-sectional screening study among the general population using the SCORED renal risk score. Demographic data and comorbidities reported in the questionnaire were collected. Individuals who scored ≥ 4 points were referred for creatinine measurement using a reagent strip–based point-of-care automatic analyzer. Systolic Blood Pressure (BP) ≥ 140 mmHg and/or diastolic BP ≥ 90 mmHg and capillary blood glucose > 99 mg/dL were considered altered. The Estimated Glomerular Filtration Rate (eGFR) was calculated using the CKD-EPI 2021 equation (without the race coefficient) and classified as follows: stage 1–2 (≥ 60 mL/min), stage 3a (45–59 mL/min), stage 3b (30–44 mL/min), stage 4 (15–29 mL/min), and stage 5 (< 15 mL/min). Results and Conclusions:). RESULTS: Among the 549 participants evaluated, 51 (9.3%) reported a history of cardiovascular events. The mean age of this group was 62.2 (± 12.7) years, and 60.8% were female. Among these patients, 92.2% reported arterial hypertension, 70.6% diabetes mellitus or prediabetes, and 27.5% heart failure. Additionally, 68.6% of patients presented altered capillary blood glucose, with an overall mean of 168.4 mg/dL and an average of 202.7 mg/dL among those with abnormal values. Regarding blood pressure, approximately 31.4% had uncontrolled levels, with a mean of 136.4/76.7 mmHg. Only 1.9% of patients had a previous diagnosis of CKD; however, the mean creatinine level was 2.83 mg/dL, and the mean eGFR was 62.6 mL/min. According to eGFR classification, 53.3% were in stages 1–2, 31.1% in stage 3a, 13.3% in stage 3b, and 2.2% in stage 4. CONCLUSION: The campaign identified a high prevalence of metabolic, hemodynamic, and renal alterations among patients with previous cardiovascular events, revealing frequent subclinical dysfunctions.

19783

SEASONAL VARIATION IN CARDIOVASCULAR MORTALITY AND HOSPITALIZATIONS IN BRAZIL: A NATIONWIDE TIME-SERIES ANALYSIS

JOÃO VITOR LEVINDO COELHO NOVAES1; LUIZ FERNANDO AVELAR DOS SANTOS2; FLAVIA MARIA DE FREITAS FARIA1; ISADORA SOARES BICALHO GARCIA3; MARCUS VINÍCIUS BOLÍVAR MALACHIAS2;

(1) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (2) FACULDADE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Seasonal cardiovascular variation is well established in temperate high-income settings, but national evidence from tropical and subtropical low- and middle-income countries remains limited. Objectives: To assess long-term trends and seasonal variation in cardiovascular mortality and in MI and stroke hospitalizations across Brazil's 27 federative units from January 2008 through December 2022. Methods: We conducted a nationwide ecological time-series study using monthly mortality data from the Mortality Information System and hospitalizations for myocardial infarction (MI) and stroke reimbursed by the Brazilian Unified Health System. Age-standardized mortality rates were calculated using the WHO world standard population. Long-term trends were estimated with Joinpoint regression and expressed as annual percent change (APC) and average annual percent change (AAPC). Seasonal patterns were modeled with generalized additive models. Results and Conclusions: National age-standardized mortality declined for overall cardiovascular disease (CVD; AAPC, −1.56%), MI (−1.25%), and stroke (−5.00%). After 2020, CVD mortality increased (APC, +3.57%; P<0.05), most markedly in the Southeast (+6.57%) and South (+6.16%). CVD and MI mortality peaked during May–August, with stronger seasonality in the South and Southeast and weaker or absent seasonality in the North and Northeast. Stroke mortality did not show a consistent seasonal peak. MI and stroke hospitalizations peaked from July to October and were lowest from February to April. The North had stagnant or worsening mortality trends and the lowest hospitalization rates. Cardiovascular outcomes in Brazil show clinically relevant seasonality and marked regional heterogeneity. Cool-season peaks were more evident in colder regions, whereas less favorable mortality trends and lower hospitalization rates in the North are consistent with persistent inequities in timely cardiovascular care. The post-2020 increase in mortality coincided with the COVID-19 period and supports climate-sensitive, equity-oriented cardiovascular planning.

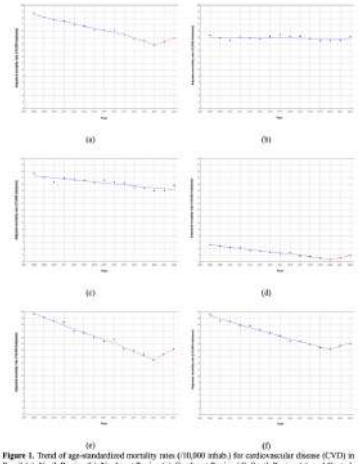

Figure 1. Trend of age-standardized mortality rates (/10,000 inhab.) for cardiovascular disease (CVD) in Brazil (a), North Region (b), Northeast Region (c), Southeast Region (d), South Region (e), and Central-West Region (f), from 2008 to 2022. APC represents the annual percent change.

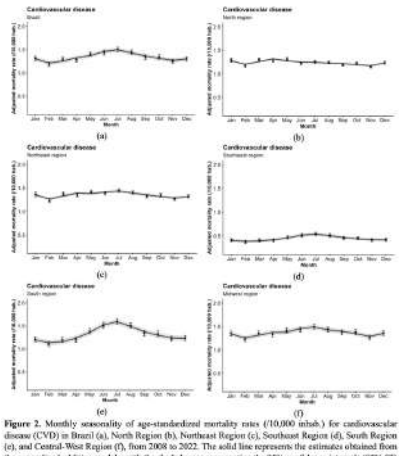

Figure 2. Monthly seasonality of age-standardized mortality rates (/10,000 inhab.) for cardiovascular disease (CVD) in Brazil (a), North Region (b), Northeast Region (c), Southeast Region (d), South Region (e), and Central-West Region (f), from 2008 to 2022. The solid line represents the estimates obtained from the generalized additive models, with the shaded areas representing the 95% confidence intervals (95% CI) of the estimates. The dots represent the actual estimates of mortality rates, with the segments representing the respective 95% CI.

17880

SOCIOECONOMIC AND REGIONAL INEQUALITIES AS INDEPENDENT DETERMINANTS OF DISABILITY RETIREMENT AFTER CORONARY ARTERY DISEASE IN BRAZIL: ANALYSIS OF 117,175 BENEFITS

ALAÉRCIO MARAN FILHO1; RODOLFO ANTONIO CORONA2; CAYRO GABRIEL MARAN3; VILIAN VELOSO DE MOURA FÉ1; PAULO EMANUEL FERNANDES1; SOFIA COSTA DE CARVALHO1; ENZO MAY DE MIO1; ESTEFANIA ARTEAGA HERRERA1; BRUNO MAHLER MIOTO1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) HOSPITAL UNIVERSITARIO MARIA APARECIDA PEDROSSIAN - CAMPO GRANDE - MS - BRASIL; (3) HOSPITAL REGIONAL DE MATO GROSSO DO SUL - CAMPO GRANDE - MS - BRASIL;

Background/Introduction: Functional outcomes and return to work after acute coronary events are closely related to time to myocardial reperfusion and access to structured cardiovascular rehabilitation. In Brazil, inequities in technological resources and socioeconomic disparities may influence long-term outcomes, contributing to progression from temporary disability to permanent retirement. Objectives: To evaluate geographic and socioeconomic factors as independent predictors of disability retirement due to ischemic heart disease in beneficiaries of the National Social Security Institute (INSS). Methods: Retrospective cross-sectional study based on administrative data from the INSS. Benefits related to ischemic heart disease (ICD I20–I25) granted between 2023 and 2026 were included, totaling 117,175 cases, covering sickness benefit and disability retirement. The outcome was disability retirement. Descriptive and bivariate analyses (chi-square, Student's t-test) were performed, followed by multivariate logistic regression including age, sex, initial monthly income (RMI), region, and insured category (urban vs. rural). Results are presented as odds ratios (OR) with 95% confidence intervals (95%CI). Lack of detailed clinical variables limits causal inference, as adjustment for disease severity, type of treatment, and rehabilitation access was not possible. Results and Conclusions: Disability retirement rate was 7.6%. Retired individuals were older (58.5 vs. 54.0 years) and had lower income (1.19 vs. 1.38 minimum wages; p<0.001). In multivariate analysis, age (OR 1.095; 95%CI 1.091–1.099) and lower income (OR 0.51; 95%CI 0.48–0.54) were the main predictors. Female sex was protective (OR 0.80; 95%CI 0.76–0.85). Higher risk was observed in the North (OR 1.58; 95%CI 1.42–1.76), Northeast (OR 1.34; 95%CI 1.26–1.42), and Central-West (OR 1.22; 95%CI 1.12–1.33) compared to the Southeast, with no difference in the South. Rural affiliation was not associated after adjustment. Permanent disability after ischemic heart disease in Brazil is strongly associated with socioeconomic and regional factors. Higher risk in the North, Northeast and Central-West regions and among lower-income individuals suggests a possible influence of structural inequalities in access to care and functional recovery, with relevant impact on the social security system. These findings highlight the need to expand cardiovascular emergency care networks and rehabilitation access, particularly in vulnerable regions, as strategy to reduce work disability.

Table 1 – Sociodemographic and economic characteristics of beneficiaries of sickness benefits and disability retirement due to ischemic heart disease (2023 – 2026).

Variable	Sickness benefit (n=108.267)	Disability retirement (n=8.908)	p-value
Age (years)			<0,001

SPATIO-TEMPORAL ANALYSIS OF PREMATURE CARDIOVASCULAR MORTALITY IN CEARÁ (2014-2024)

MARIANA DE OLIVEIRA DA FROTA1; SOFIA MOURA DE SOUSA BRASIL2; LUISA FARIAS EUCLIDES DE ARAUJO3; JOSE CIRO GAUGINSKI JUNIOR4;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE ESTADUAL DO CEARÁ - UECE - FORTALEZA - CE - BRASIL; (3) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL; (4) HOSPITAL SAO CAMILO FORTALEZA - FORTALEZA - CE - BRASIL;

Background/Introduction: Cardiovascular diseases (CVD) are the leading cause of death globally and in Brazil, imposing a heavy socioeconomic burden on healthcare systems. When occurring prematurely in individuals of working age, the impacts are even more devastating. In the state of Ceará, mortality dynamics are non-uniform, influenced by a complex network of demographic, epidemiological, and socio-spatial factors. Understanding how these deaths are distributed across time and territory is essential for identifying vulnerable areas and guiding effective preventive and clinical actions. Objectives: This study aims to analyze the spatio-temporal patterns of premature cardiovascular mortality in Ceará from 2014 to 2024, identifying trends in rate evolution and mapping high-risk geographic clusters to support public health policies. Methods: An ecological and retrospective study was conducted on premature cardiovascular mortality (ages 30–69) in Ceará. Data were extracted from SIM/DATASUS (ICD-10, Chap. IX) and IBGE. Joinpoint regression was used to analyze temporal trends and calculate the Annual Percent Change (APC). Spatial analysis was performed by distributing standardized rates into quartiles, allowing for a visual comparison of the mortality burden across the state's Health Regions. Results and Conclusions: The analysis reveals an epidemiological transition marked by initial progress followed by recent setbacks. Between 2014 and 2019, a moderate downward trend in standardized mortality rates was observed, with an Annual Percent Change (APC) of -1.2%. This initial decline can be attributed to the expansion of Primary Health Care and access to hypertension and diabetes therapies. However, from 2020 onwards, the data indicate a slight reversal of this trend (APC = +0.5%), a phenomenon intensified by the impacts of the COVID-19 pandemic, including post-infection cardiovascular sequelae and the postponement of elective procedures and chronic disease monitoring. Spatially, the quartile distribution highlighted significant inequalities. The highest mortality rates were concentrated in the Fortaleza Metropolitan Area and Cariri region, which comprised the upper quartile. Despite greater technological support, these regions face a higher density of urban risk factors. The lower quartile, with lower rates, was predominantly located in the Sertão dos Inhamuns, possibly indicating underreporting. These findings reinforce the need to decentralize cardiovascular stabilization units to optimize emergency care outside major urban centers.

Figure 1: Spatial distribution of cardiovascular mortality in the state of Ceará by quartiles, 2015–2025.

TEMPORAL CHANGES IN STROKE BURDEN AND HEALTHCARE EXPENDITURES IN BRAZIL DURING AN INTERNATIONAL PUBLIC HEALTH EMERGENCY: A NATIONWIDE INTERRUPTED TIME-SERIES (ITS) ANALYSIS

ISRAEL JUNIOR BORGES DO NASCIMENTO1; ROMEU VALE SANT'ANNA2; SHEILA CRISTINA OURIQUES MARTINS3;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) STROKE UNITE AT THE HOSPITAL RISOLETA TOLENTINO NEVES (HRTN), BELO HORIZONTE, MINAS GERAIS, BRAZIL - BELO HORIZONTE - MG - BRASIL; (3) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: Cerebrovascular diseases have always impacted the Brazilian healthcare system, disproportionately affecting socially vulnerable subgroups. Objectives: We evaluated temporal trends, regional variability, and demographic disparities in stroke-related hospitalizations and in-hospital mortality rates in Brazil between 2018-2025. Methods: This is a large nationwide, ecological time-series study using monthly stroke-related evidence registered from all regions of Brazil during a 8-years period in the Brazilian Unified Health System/DATASUS. Primary outcomes included hospital admissions (AIH), deaths, mortality rate, mean length of hospital stay, total hospitalization costs, and mean hospitalization cost per-admission (AIH value). For estimating the annual percent change (APC) and classifying temporal trends, we used Prais-Winsten regression models, while the Interrupted time-series (ITS) analyses considered changes across two pre-defined timepoints (March, 2020/"pandemic onset" and January, 2022/"post-pandemic recovery stage"). Results and Conclusions: Over an 8-year period, 1,773,829 stroke-driven hospital admissions and 251,235 in-hospital deaths were registered, corresponding to a hospital mortality rate of 14.2%. Mean length of hospital stay was 7.2 days, with total hospitalization expenditure of around BRL3 billions and mean AIH value of BRL1,633. Older adults aged 60-79 were prevailing (917,189 admissions), whereas the highest mortality burden was observed at the oldest-old (≥ 80 years, 75,466 deaths). Geographically, the Southeast demonstrated the highest burden, with 753,402 admissions and 108,942 deaths, followed by the Northeast, with 465,992 admissions and 72,322 deaths. We observed that stroke admissions (APC4.11%; 95%CI 2.62–5.63), deaths (APC2.19%; 95%CI 1.14–3.26), total hospitalization costs (APC10.10%; 95%CI 7.91–12.34), and mean AIH value (APC5.38%; 95%CI 4.57–6.19) significantly increased with time, whereas mortality rates declined (APC−1.98%; 95%CI −3.47/−0.47). During the pandemic, ITS analysis showed immediate reductions in admissions (−14.09%; 95%CI −18.83/−9.08) and deaths (−9.00%; 95%CI −13.00/−4.82), followed by concomitant enhance in mortality rates (+5.92%; 95%CI 1.90–10.10). As for the post-pandemic stage, mortality rates declined immediately (−7.55%; 95%CI −14.20/−0.38) and over time (−0.47%; 95%CI −0.83/−0.10), while total hospitalization costs (+18.95%; 95%CI 5.62–33.96) and mean hospitalization costs per admission (+12.92%; 95%CI 8.52–17.50) increased substantially.

TEMPORAL TRENDS AND INEQUALITIES IN MORTALITY FROM CHAGAS DISEASE IN BRAZIL (2020–2024)

ANA LAURA SANTOS DE ALMEIDA1; THALYTA DE SOUZA ALVES1; DAVI NUNES SANTOS DE ALMEIDA2; THAIS DE SOUZA ALVES2; AURIMARCIA DA SILVA TORRES3;

(1) UFRN - NATAL - RN - BRASIL; (2) UNIVERSIDADE POTIGUAR (UNP) - NATAL - RN - BRASIL; (3) HOSPITAL DE SERVIDORES DO ESTADO - RECIFE - PE - BRASIL;

Background/Introduction: Despite advances in vector control, Chagas disease remains a significant public health concern in Brazil, with increasing impact among older populations and a heterogeneous distribution across the national territory. Objectives: To analyse temporal trends and the epidemiological profile of mortality from Chagas disease in Brazil, exploring demographic and regional inequalities. Methods: Ecological, descriptive, and analytical study using data from the Mortality Information System (DATASUS), including deaths due to Chagas disease (ICD-10: B57) between 2020 and 2024. Demographic and geographic variables were analyzed. Absolute mortality counts and population-adjusted mortality rates (per 100,000 inhabitants) were calculated. Temporal trend analysis was performed to assess changes over time, along with descriptive comparisons across age groups, sex, and regions. Results and Conclusions: A total of 19,887 deaths from Chagas disease were recorded in Brazil between 2020 and 2024, with a 9.9% reduction in the absolute number of deaths over the period. When adjusted for population, the mortality rate showed a progressive decline, decreasing from 1.97 to 1.72 deaths per 100,000 inhabitants, reinforcing a consistent downward trend. There was a marked predominance among individuals aged 60 years or older (82.6%), consistent with the chronic and late manifestations of the disease. Sex distribution showed a slight male predominance (51.7%). Regionally, deaths were more concentrated in the Southeast (46%), followed by the Northeast and Central-West, reflecting both the historical distribution of the endemic disease and inequalities in the organization of the healthcare system. Despite the overall reduction, the persistence of high mortality among older adults and regional heterogeneity suggests the maintenance of higher-risk populations, as well as possible underdiagnosis in areas with limited access to healthcare services. The concentration of deaths among older individuals and regional disparities highlight the need for targeted strategies focused on early diagnosis, management of Chagas cardiomyopathy, and reduction of inequities in healthcare access. Limitations include the ecological design, the possibility of underreporting, and inconsistencies in DATASUS data entry, as well as the lack of adjustment for comorbidities and socioeconomic factors.

TEMPORAL TRENDS IN MORTALITY FROM NON-RHEUMATIC AORTIC STENOSIS IN BRAZIL: IS POPULATION AGING SUFFICIENT TO EXPLAIN THE INCREASE?

MARIA CRISTINA MEIRA FERRIRA1; LARISSA FRANCO ANDRADE1; GLAUCIA MARIA MORAES OLIVEIRA1;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Non-rheumatic aortic stenosis (AS) has been described as a 21st-century epidemic driven by population aging. However, whether the increase in AS-related mortality in Brazil can be explained solely by aging remains uncertain. Objectives: To assess temporal trends in mortality from non-rheumatic AS in Brazil and determine whether population aging alone accounts for the observed increase. Methods: Population-based study of basic-cause mortality due to non-rheumatic aortic stenosis among individuals aged ≥50 years in Brazil from 2000 to 2023 (pre-incorporation period of transcatheter aortic valve implantation (TAVI) in the Brazilian Unified Health System (SUS). Results and Conclusions: RESULTS: Among individuals aged ≥50 years, 28,180 deaths were recorded between 2000 and 2023, increasing by 375%, while the corresponding population grew by 105%. The increase was particularly pronounced among those aged ≥80 years, with deaths rising by 435% despite a 44% increase in the corresponding population.Crude mortality rate increased from 1.68 in 2000 to 3.8 in 2023 per 100,000, and age- and sex-standardized mortality increased from 1.7 to 3.6 per 100,000. A temporal shift in sex pattern was observed, with higher rates initially in women and subsequently in men. Most federations states showed increasing standardized mortality. Regions with historically high rates (South/Southeast regions) continued to rise, while previously low-reporting states (North/Northeast regions) began registering deaths. Regression analysis confirmed a significant upward trend (APC 3.12% year; 95% CI 2.94–3.31; p<0.001), higher in men (3.74%) than women (2.61%), with predominance in ≥80 years (3.8%). CONCLUSION: The increase in age-standardized mortality—particularly in advanced ages—cannot be attributed to population aging alone. These findings support a multifactorial process, consistent with disease unmasking, driven by increased detection, improved data quality, and evolving diagnostic and therapeutic paradigms in AS.

THE GLOBAL BURDEN OF ALCOHOLIC CARDIOMYOPATHY: EPIDEMIOLOGICAL TRENDS, SOCIOECONOMIC DISPARITIES AND POLICY IMPLICATIONS

JOSE GREGORIO VALERO RODRIGUES1; ISABELA ISABELA LIRA VIEIRA1; CAROLINA SALLES TANNURI BARRETO CONCEIÇÃO1; ANNA LAURA HARUMI1; GUILHERME CESAR FERNANDES DE OLIVERA DA COSTA1; WESLEY RODRIGO NOGUEIRA DIAS1; ANNA CECILIA MACHADO1; ANDRE CAMARGO MAZZOCCHI1; GIULIA FERNADES DE OLIVEIRA DA COSTA1; ADRIANA MUNFORD LIMA PIMENTEL1; LEONARDO CASTRO NUNES1; EVANDRO TINOCO MESQUITA1;

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL;

Background/Introduction: Alcoholic cardiomyopathy (ACM) accounts for approximately 36% of dilated cardiomyopathy cases, driven by the toxic effects of chronic ethanol consumption on cardiac structure. Beyond individual health, ACM imposes a substantial global economic burden. Despite being a preventable condition, its epidemiology is profoundly shaped by regional, cultural, and socioeconomic disparities. Objectives: To evaluate the global, regional, and demographic burden of ACM, emphasizing the impact of the Socio-demographic Index (SDI) and socioeconomic inequalities on disease distribution, with specific observations regarding the Americas. Methods: A global burden of disease (GBD) analysis was conducted using data from the GBD Study 1990–2021. DALYs, mortality, and prevalence were analyzed and stratified by sex, age, and SDI. Temporal trends were assessed using estimated annual percentage change (EAPC). Cross-country inequalities were evaluated through macroeconomic indicators to characterize socioeconomic gradients in disease distribution. Results and Conclusions: ACM disproportionately affects males, with incidence peaking between 60 and 64 years of age. High and high-middle SDI nations bear the greatest disease burden. Regional disparities are substantial: in Eastern Europe, the elevated burden reflects high per capita distilled alcoholic beverages consumption and historically limited implementation of alcohol control policies, whereas in East Asia, the risk is amplified by the prevalence of ALDH2 Glu504Lys allele. In the Americas, notable contrasts are observed; while Southern Latin America exhibited the fastest decline in mortality globally (EAPC: -6.69%) and the Andean region recorded the lowest disease burden worldwide, the Caribbean faces increasing mortality rates. Globally, although age-standardized rates have decreased, the absolute number of cases has risen. These findings reveal a heterogeneous global burden shaped by socioeconomic, genetic, and behavioral determinants, with rising absolute case numbers offsetting gains in age-standardized rates. ACM remains a significant public health burden shaped by socioeconomic determinants. The SDI gradient and regional heterogeneity in genetic susceptibility underscore the need for risk-stratified epidemiological surveillance. Systematic integration of alcohol consumption history into cardiovascular risk evaluation may improve early identification of high-risk populations, particularly older males in high and high-middle SDI regions.

TRENDS IN HOSPITAL MORBIDITY AND MORTALITY FROM HEART FAILURE IN THE BRAZILIAN ADULT POPULATION, 1994–2025: A MORE-THAN-THREE-DECADE ANALYSIS

FLÁVIO HENRIQUE DO NASCIMENTO REGES1; TROY RICHARD CARNEIRO FILHO1; DENISE CRISTINA PACHECO1; HUMBERTO GRANER MOREIRA2;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL; (2) UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL;

Background/Introduction: Heart failure (HF) is one of the leading causes of cardiovascular hospitalization in Brazil. Over the past three decades, substantial efforts have been made to reduce HF-related morbidity and mortality, encompassing pharmacological therapies and device-based interventions. Despite meaningful improvements in clinical outcomes, HF hospitalization rates remain elevated. Additionally, demographic changes, population aging, and structural transformations in the healthcare system may influence hospitalization patterns over time. Objectives: To analyze trends in HF hospitalization rates and in-hospital mortality among the adult Brazilian population from 1994 to 2025. Methods: We obtained data from the Brazilian Ministry of Health (DATASUS) on hospital admissions for HF among adults (≥20 years of age) in Brazil from 1994 through 2025. Hospitalization rates (admissions per 100,000 inhabitants) and in-hospital mortality rates (deaths per 1,000 admissions) were calculated and adjusted for age and sex by the direct method, using the 2022 Brazilian Census count (IBGE) as the reference population. Temporal trends were assessed with log-linear Poisson regression. Results and Conclusions: A total of 10,183,329 HF admissions were recorded during the study period. The hospitalization rate decreased significantly, from 357.6 to 94.1 admissions per 100,000 inhabitants (R^2=0.907; P<0.001), a pattern that was consistent in both men and women and across all age groups studied. In-hospital mortality, however, increased significantly, from 55 to 98 deaths per 1,000 admissions, in both sexes and more markedly among adults older than 60 years. Over the same period, the number of public hospital beds (SUS) decreased by 35%, from 506,000 to 360,000, while the ratio of HF admissions per bed per year remained stable (P=0.56). Mean length of hospital stay increased from 6.0 to 8.2 days. Although the absolute number of hospitalizations and the admission rates for HF in the adult population decreased between 1994 and 2025, in-hospital mortality rose significantly. Taken together, these findings suggest that, with the reduction in SUS bed availability, patients with more severe disease are preferentially being admitted. Data from the private sector are lacking, which limits a broader assessment of the quality of HF care in Brazil.

ANALYSIS OF CARDIAC FRACTAL DIMENSION AFTER EXPOSURE TO A PESTICIDE USED FOR DENGUE CONTROL: A PRECLINICAL STUDY

ISABELLE TIBURCIO PECIN FERREIRA1; LUCIANA SANAE OTA1; CAMILLE ANGÉLICA PEREIRA DA SILVA1; KAREN GALVÃO VALERIANO1; RAFAELA PIRES ERTHAL1; GLAURA SCANTAMBURLO ALVES FERNANDES1; FRANCIS LOPES PACAGNELLI1;

(1) UNIVERSIDADE DO OESTE PAULISTA - UNOESTE - PRESIDENTE PRUDENTE - SP - BRASIL;

Background/Introduction: Dengue is a disease associated with high rates of mortality and disability. One of the control strategies used to combat its vector is malathion spraying, which may have potential cardiotoxic effects. However, the impact of this pesticide on the organization of the extracellular matrix in the developing heart remains unclear. Objectives: This study aimed to evaluate the effects of malathion exposure on cardiac extracellular matrix organization during development. Methods: The study was approved by the Animal Ethics Committee (Protocol 7880). Eighteen female Wistar rats, aged 21 days, were randomly assigned to three experimental groups (n = 6 per group): malathion at 10 mg/kg (M10), malathion at 50 mg/kg (M50), and a control group (CT) receiving soybean oil at an equivalent volume, administered via gavage. At postnatal day 60, animals were euthanized and hearts were dissected. The left ventricle was stained with Picrosirius Red and analyzed using images obtained from a LEICA microscope equipped with a video camera and a 40× objective (400× magnification). Three images per animal were captured and processed using Image-Pro Plus software. Images were binarized, and collagen organization was quantified using ImageJ software. Data normality was assessed using the Shapiro–Wilk test, followed by Kruskal–Wallis and Dunn's post hoc tests ($p < 0.05$). Results and Conclusions: No significant differences were observed in collagen fractal dimension among groups (CT: 1.62 ± 0.14 au; M10: 1.49 ± 0.13 au; M50: 1.58 ± 0.10 au; $p = 0.25$). Malathion exposure during cardiac development did not induce structural alterations in cardiac collagen organization.

CARDIAC IMPACT OF DAPAGLIFLOZIN IN CHRONIC ARTERIAL HYPERTENSION

ANNA CLARA CONSORTI DOS SANTOS1; GABRIELA BRANDAO1; ELIDA PAULA BENQUIQUE OJOPI1; DIJON HENRIQUE SALOME CAMPOS1; ANA PAULA SARAIVA MARREIROS1; EDER ANDERSON RODRIGUES1; LUANA URBANO PAGAN1; PRISCILA PORTUGAL SANTOS1; RENATA AMORIM COELHO1; MARCOS VINICIUS MORAIS DE CAMPOS PINHEIRO1; KATASHI OKOSHI1; MARINA POLITI OKOSHI1;

(1) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL;

Background/Introduction: Systemic arterial hypertension (SAH) is a major cause of cardiac remodeling and heart failure with both preserved and reduced ejection fraction. Sodium-glucose cotransporter-2 (SGLT2) inhibitors are recommended for heart failure treatment. The effects of SGLT2 inhibitors on cardiac remodeling under sustained arterial hypertension have not been established. Objectives: To evaluate the effects of the SGLT2 inhibitor dapagliflozin (DAPA) on hypertension and cardiac remodeling in middle aged-spontaneously hypertensive rats (SHR). Methods: Male SHR and normotensive Wistar rats aged 14 months were assigned into four groups: Control (n=14); Control-DAPA (n=14); SHR (n=15); and SHR-DAPA (n=14). The treated groups received DAPA added to the rat chow at a dosage of 10 mg/kg/day for 12 weeks. Before treatment, echocardiograms were performed to assure homogeneity between groups (data not shown). At the end of the study, structural heart and functional left ventricular parameters were assessed by echocardiogram. Caudal blood pressure was evaluated by pletismography before and after treatment. Statistical analysis: two-way ANOVA and Bonferroni or Kruskal–Wallis and Dunn's test, and repeated measures ANOVA. Results and Conclusions: Results: Blood pressure was higher in SHR and SHR-DAPA than their controls. Blood pressure was higher at the end of the experiment than the initial evaluation in SHR and SHR-DAPA groups and did not differ between SHR-DAPA and SHR (Table 1). Body weight was lower in Control-DAPA than Control and lower in SHR and SHR-DAPA than their controls; no difference was observed between SHR-DAPA and SHR. Both SHR-DAPA and SHR had left atrium dilation, concentric left ventricle (LV) hypertrophy, and diastolic dysfunction. Ejection fraction did not differ between groups. Except for a significantly higher tissue Doppler imaging (TDI) of the mean systolic velocity of the mitral annulus (mean S') in SHR-DAPA than SHR, no more differences were observed between SHR-DAPA and SHR groups (Table 2). Conclusion: Long-term use of dapagliflozin does not modulate body weight and caudal blood pressure in middle-aged-spontaneously hypertensive rats under sustained hypertension. Cardiac remodeling is not changed by dapagliflozin, except for a slightly improvement in TDI mean S' in the treated SHR group.

Table 1: Blood pressure data

CARDIOPROTECTIVE EFFECTS OF CILOSTAZOL IN EXPERIMENTAL METABOLIC SYNDROME

STEPHANI CORREIA BRAZÃO1; LIS JAPPOUR AUTRAN1; ANA BEATRIZ ARAÚJO MENDES2; GABRIEL FERREIRA LIMA1; NIKOLAS CUNHA ASSIS1; NADIA ALICE VIEIRA MOTTA1; FERNANDA CARLA FERREIRA BRITO1;

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Metabolic syndrome (MS) is a public health challenge, characterized by a cluster of metabolic alterations, including obesity, hypertension, dyslipidemia, hyperglycemia and hypertension (Engin, A. Adv Exp Med Biol. 2017). This condition increases the risk of cardiovascular disease. Cilostazol (CZ), a phosphodiesterase-3 (PDE3) inhibitor used in the treatment of intermittent claudication, exhibits vasodilatory, antiplatelet effects, as well as pleiotropic properties, such as anti-inflammatory and antioxidant properties (Brazão SC. Life Sci. 2023). We hypothesized that CZ may exert beneficial effects in the treatment of MS. Objectives: This study aims to evaluate the cardioprotective properties of cilostazol using a model of metabolic syndrome induced in spontaneously hypertensive rats (SHR). Methods: Male SHR rats (8 weeks old) were housed under controlled temperature, humidity, and a 12 h light/dark cycle. Animals were randomly assigned to four groups (n=8): WKY (Wistar Kyoto normotensive rats) and SHR, both fed a standard diet for 12 weeks; MS (SHR fed a hypercholesterolemic) and MS+ CZ (SHR fed a hypercholesterolemic treated with CZ). The experimental protocol lasted 12 weeks, and during the last 15 days, WKY, SHR, and MS groups received vehicle (tween: ethanol/ water), while the MS + CZ group received CZ (30 mg/kg/day), administered by gavage. Blood pressure was measured at the end of the study, and rats were anesthetized and euthanized for functional, biochemical, and molecular analyses (CEUA 1479140219). Data was analyzed using one-way ANOVA followed by post-hoc Bonferroni Multiple Comparison Test, $p<0.05$. Results and Conclusions: The MS model exhibits alterations in lipid profile and elevated systolic blood pressure (SBP). CZ reduced SBP and LDL cholesterol levels, ($p<0.05$). The MS group showed prolongation of QT and QTc intervals, increased SαT and RαT intervals, reduced R-wave and T-wave amplitudes, decreased heart rate variability parameters (SDNN and RMSSD), and decrease ejection and shortening fractions compared to the WKY group. On the other hand, the MS+CZ reduced SαT and RαT intervals, increased R and T-wave amplitudes, and improved RMSSD compared to the MS group, ($p<0.05$). Western blot analysis demonstrated increased expression of NOX2, NOX4, p-AKT, NF-κB, and BAX in the MS group, whereas CZ treatment significantly reduced the expression of these proteins ($p < 0.05$). These findings suggest that cilostazol exerts cardioprotective effects in metabolic syndrome.

CARDIOPROTECTIVE EFFECTS OF NEROL COMPLEXED WITH B-CYCLODEXTRIN IN MYOCARDIAL INFARCTION: MODULATION OF THE ANTIOXIDANT SOD/CAT AND AKT/P-AKT PATHWAY

DANIELLA SANTOS NASCIMENTO1; JOAO CRUZ-FILHO1; DANILO LUSTRINO1; EVALEIDE DINIZ DE OLIVEIRA1; DAVI SANTANA SOUZA1; CARLA MARIA LINS DE VASCONCELOS1;

(1) UNIVERSIDADE FEDERAL DE SERGIPE - ARACAJU - SE - BRASIL;

Background/Introduction: Cardiovascular diseases, especially acute myocardial infarction (MI) is major causes of death and involve hypoxia and ROS-induced damage. O nerol, a monoterpene with antioxidant and L-type calcium channel blocking action, may exert cardioprotective effects. Objectives: Evaluate the cardioprotective effect of nerol (N) and the nerol–β-cyclodextrin complex (CN) in MI in rats. Methods: Approved by the Animal Ethics Committee (CEUA no. 4214070723), adult Wistar rats were divided into 6 groups (n = 6): 1) CTR, 2) MI+βCD, 3) MI+N (10 mg/kg), and 4, 5 e 6) MI+CN (5, 10, or 25 mg/kg). O MI was induced by isoproterenol (ISO, 100 mg/kg for 2 days, i.p.), and 30 min later, animals were treated with N or CN. The parameters were evaluated: LVDP, ECG, heart rate variability, infarct size, biochemical markers of tissue damage, ROS levels, and the activity and expression of SOD, CAT, and AKT/pAKT. Data are expressed as mean ± SEM, with $p < 0.05$ considered statistically significant. Results and Conclusions: CN10 showed superior cardioprotection compared to N10 and CN5/25, as evidenced by reduced infarct size and CK-MB levels, along with increased LVDP. The results showed that the increase in heart weight/body weight (3.9 ± 0.1 mg/g) and heart weight/tibia length (247.9 ± 13.1 mg/cm) in the MI group was reduced by CN10 (2.9 ± 0.1 mg/g and 207.7 ± 9.3 mg/cm, respectively). Elevated infarct size and CK-MB levels in the MI group (34.2 ± 3.2% and 57.8 ± 3.1 U/L) were reduced by CN10 (3.2 ± 0.9% and 4.3 ± 1.2 U/L). CN10 also improved LVDP (from 10.3 ± 1.8 to 53.1 ± 3.1 mmHg), reduced heart rate from 333.3 ± 23.3 to 222.1 ± 10.6 bpm, normalized ECG alterations (QTc from 129 ± 1.5 to 101.9 ± 10.5 ms), and decreased the incidence of ST-segment elevation from 67% to 30%. In addition, CN10 improved sympathetic autonomic modulation compared to the MI group (decreasing the LF/HF from 0.1 ± 0.01 to 0.02 ± 0.003 nu) and increased SOD and CAT activities (from 0.6 ± 0.1 to 1.7 ± 0.4 U/µg and from 0.7 ± 0.06 to 3.0 ± 0.4 U/µg, respectively), associated with reduced ROS production (from 3.83 ± 0.18 to 1.06 ± 0.01 a.u.). Furthermore, CN10 increased the expression of SOD2 (from 0.72 ± 0.02 to 1.4 ± 0.03 a.u.) and AKT/p-AKT (from 0.7 ± 0.05 to 1.1 ± 0.01 a.u. and from 0.6 ± 0.02 to 0.9 ± 0.02 a.u., respectively). Thus, CN10 promoted cardioprotection by restoring cardiac contractile and electrical function, reducing myocardial injury, increasing antioxidant enzyme activity, and decreasing ROS production.

Background/Introduction: Environmental factors play an important role in the development of cardiovascular diseases (CVD), including exposure to endocrine-disrupting chemicals (EDC). Among EDC, per- and polyfluoroalkyl substances (PFAS) comprise a class of chemicals that have gained attention due to their high resistance to degradation and widespread use in industrial and consumer products. Perfluorooctanoic acid (PFOA) is the most widely studied and the main representative compound of this class. It is widely detected in the environment and in human populations, and commonly found in nonstick cookware and water- and grease-resistant packaging materials. Previous studies have shown that PFOA exposure is associated with metabolic, reproductive, and carcinogenic effects. Despite these effects, the cardiovascular impact of PFOA exposure remains poorly explored. Objectives: Given the widespread human exposure to PFOA, understanding its potential impact on cardiovascular health is of significant public health relevance. Thus, this study aimed to evaluate the effects of exposure to different doses of PFOA on the cardiovascular system in adult male mice Methods: Adult male mice were divided into control (CT), PF-L (0.1 µg/kg/day PFOA), and PF-H (0.1 mg/kg/day PFOA). PFOA was administered via drinking water for 90 days. Body mass (BM), adiposity index, systolic blood pressure (SBP), cardiac electrophysiology by electrocardiogram (ECG), cardiac mass, and left ventricle (LV) wall thickness were evaluated. Ethical approval n. 6891070125. Statistical analyses were performed using one-way ANOVA with Holm-Sidak post hoc test. Results and Conclusions: Both PF-L and PF-H groups increased BM gain and adiposity index compared to CT, reinforcing the obesogenic potential of PFOA exposure. SBP was elevated in both exposed groups in relation to CT. In addition, cardiac function was impaired, as evidenced by alterations in ECG parameters. The QRS complex duration was increased in both groups, and a reduction in T-wave integral was observed in the PF-H group, suggesting impaired ventricular depolarization and repolarization. Furthermore, both PFOA-exposed groups exhibited greater cardiac mass and thicker LV walls than CT, indicating cardiac hypertrophy and structural remodeling. PFOA exposure appears to promote an obesogenic and hypertensive phenotype, accompanied by cardiac remodeling and impairments in cardiac function, suggesting detrimental effects on cardiovascular health.

CITRUS BERGAMIA LEAF EXTRACT REVERSES CARDIAC DAMAGE INDUCED BY CHRONIC CONSUMPTION OF A HIGH SUGAR-FAT DIET

JORDANNA CRUZEIRO1; JULIANA SILVA SIQUEIRA1; THIAGO LUIZ NOVAGA PALACIO1; MARIANA DE FARIAS SOUZA KLEIN1; DIJON HENRIQUE SALOMÉ DE CAMPOS1; SILMÉIA GARCIA ZANATI BAZAN1; CAMILA RENATA CORRÊA1;

(1) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL;

Background/Introduction: Contemporary dietary patterns characterized by unhealthy eating habits, particularly the chronic consumption of hypercaloric diets rich in fat and sugar, have become a major global health concern strongly associated with cardiovascular diseases and progressive cardiac dysfunction. In this context, Citrus bergamia leaf extract (BLE) emerges as a potential treatment for HSFD-associated cardiac comorbidities due to its cardioprotective and hypolipidemic effects. Objectives: This study aimed to evaluate the cardioprotective effect of Citrus bergamia leaf extract on the progression of HSFD-induced cardiac dysfunction. Methods: Male Wistar rats were divided into Control (C; n=12), receiving a standard chow diet and High sugar-fat diet (HSFD; n=22), receiving a high sugar-fat diet with 25% sucrose in drinking water for 20 weeks. Body weight (BW) and echocardiographic evaluation were assessed to confirm HSFD-associated cardiac dysfunction. Subsequently, the HSFD group was allocated into two groups: HSFD (n=12) and HSFD+BLE (n=10). Treatment was administered daily for 10 weeks by gavage (50mg/Kg). At the end of the experimental period, echocardiographic analyses were repeated in the same animals, CEUA:1393/2021. Normality and variance were tested by Shapiro–Wilk test and Levene's test. For parametric data, comparisons were performed using linear mixed-effects models for repeated measures followed by Sidak's post hoc test. For nonparametric data, analyses were performed using the Friedman test for repeated measures followed by Dunn's post hoc test. ($p<0.05$). Results and Conclusions: The analyses demonstrated that the HSFD group at 20 and 30 weeks showed increased Posterior Wall Thickness in diastole (PWTd), Isovolumetric Relaxation Time (IVRT), Deceleration Time (DT), E/E' ratio, and systolic blood pressure (SBP), along with reduced Lateral S', Lateral E', Septal S', Mean S', Mean E', and E'/A' ratio compared with C group at 20 and 30 weeks. At 30 weeks, the HSFD group showed increased BW compared with 20 weeks and reduced ejection fraction (EF) compared with the C groups at 20 and 30 weeks. The BLE-treated group showed increased BW, PWT in systole (PWTs), EF, Lateral S', Lateral E', Septal S', Mean S', Mean E', and E'/A' ratio, along with reduced PWTd, IVRT, DT, and E/E' ratio compared with 20 weeks. In conclusion, treatment with BLE reversed the structural and functional cardiac damage induced by the HSFD, confirming its potential cardioprotective effect even without dietary pattern modification.

DAPAGLIFLOZIN IMPROVES CARDIAC FUNCTION AND REDUCES MYOCARDIAL DAMAGE IN METABOLIC SYNDROME IN A MURINE MODEL

CAROLINA SILVA VALENTIM1; PERICLES FABRÍCIO GOMES FILHO1; CHERLEY BORBA VIEIRA ANDRADE1; RAÍSSA LEAL DE CARVALHO DOS SANTOS CUNHA1; REBECCA ROOSEVELT DA CONCEICAO SOUZA1; ISALIRA PEROBA RAMOS2; JÉSSICA GOMES PEREIRA1; PATRÍCIA CRISTINA LISBOA1; KÍSSILA RABELO1; JORGE JOSÉ CARVALHO1; JEMIMA FUENTES RIBEIRO SILVA1;

(1) UNIVERSIDADE ESTADUAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: A high-fat diet combined with fructose in drinking water (HFF) promotes the accumulation of toxic lipids in cardiomyocytes, contributing to the development of cardiac dysfunction. Objectives: The objective was to evaluate the cardiometabolic effect of dapagliflozin in C57BL/6 mice fed an HFF diet. Methods: The experiment was approved by the Ethics Committee (CEUA No. 10/2024). The diet was provided for 16 weeks, and treatment with dapagliflozin 10 mg/kg/day (D10) or vehicle was administered from the 10th to the 16th week via orogastric gavage. Biometric parameters were assessed by magnetic resonance imaging, fasting blood glucose, and insulin resistance using the HOMA-IR index. The biochemical profile included total cholesterol, LDL, CK-MB, and CK-NAC. Cardiac function was assessed by echocardiography, while systolic blood pressure (SBP) was measured by tail plethysmography. Cardiomyocyte area was determined by histological analysis using hematoxylin and eosin (H&E) staining. Data were presented as mean ± standard deviation and analyzed using one-way ANOVA or two-way ANOVA, followed by Tukey's post-hoc test ($p < 0.05$) using GraphPad Prism software (v.10.6.1). Results and Conclusions: Animals in the HFF group showed increased body weight, fat mass, glycemic homeostasis, lipid profile, and systolic blood pressure compared to the control group (CTR). In contrast, the HFF+D10 group showed a reduction in these parameters. Regarding cardiac damage, the HFF group showed increased levels of these markers, along with reduced ejection fraction, shortening fraction, and interventricular septal thickness during systole, in the absence of hypertrophy. The HFF+D10 group showed reduced cardiac damage markers and improved echocardiographic parameters. The CTR+D10 group showed results similar to the CTR group in all analyses performed. HFF consumption promoted phenotypic characteristics of metabolic syndrome in addition to inducing myocardial injury and systolic dysfunction. The HFF+D10 group attenuated metabolic and hemodynamic changes, reduced markers of cardiac damage, and improved systolic function, highlighting its potential cardioprotective effect. These results reinforce the role of dapagliflozin as a promising therapeutic strategy for cardiovascular protection under conditions of metabolic overload.

DIETARY MACRONUTRIENT COMPOSITION DICTATES FUNCTION OVER MORPHOLOGY: CORRELATIONAL INSIGHTS INTO MORPHOFUNCTIONAL CARDIAC REMODELING IN OBESITY

THIAGO LUIZ NOVAGA PALACIO1; JULIANA SILVA SIQUEIRA1; JORDANNA CRUZEIRO1; MARINA DE PAULA SALOMÉ SANTOS1; MARIANA DE FARIAS SOUZA KLEIN1; SILMEIA GARCIA ZANATI BAZAN1; CAMILA RENATA CORREA1;

(1) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL;

Background/Introduction: The chronic consumption of simple sugars and saturated fat-enriched foods leads to obesity and cardiac remodeling (CR). However, the isolated impacts of macronutrient intake on morphological and functional disturbances remain poorly understood. Objectives: This study aimed to correlate specific dietary macronutrients with morphofunctional cardiac remodeling in obesity. Methods: Male Wistar rats were randomly assigned to two groups (n=12/group) and fed a Control (CTRL) or a hypercaloric diet, enriched with sucrose, fructose, and saturated fatty acids (stearic, palmitic, and myristic) and 25% sucrose water (CR) for 20 weeks (CEUA: 1150/2015). In vivo dietary intake, nutritional status, metabolic and hormonal parameters, and echocardiogram were assessed. Data were analyzed using the Shapiro-Wilk test, followed by a student t-test or Rank Sum Test and Pearson correlation (α=5%). Results and Conclusions: CR group exhibited higher caloric, carbohydrate, and fat intake ($p<0.005$), combined with increased body weight and systolic blood pressure ($p<0.001$), despite lower total food and protein intake ($p<0.001$). In addition, morphofunctional cardiac remodeling was effectively induced in this group. Correlation analysis revealed divergent remodeling aspects. In CTRL, increased caloric, lipidic, and proteic intake correlated with prolonged E-wave deceleration time (EDT), suggesting a physiological volumetric adaptation. In contrast, CR presented a morphofunctional decoupling. Caloric intake correlated negatively with left ventricular end-diastolic diameter (LVDd; $r = -0.599$, $p = 0.039$) and positively with fractional shortening (FS%; $r = 0.601$, $p = 0.039$). Markedly, fat and protein intake intensified this concentric/hyperdynamic phenotype (LVDd; $r = -0.685$, $p = 0.014$; FS%; $r = 0.726$, $p = 0.007$; ejection fraction; $r = 0.499$, $p = 0.099$). Conversely, final body weight positively correlated with LVDd ($r = 0.579$, $p = 0.048$) and negatively with systolic function (FS%; $r = -0.662$, $p = 0.019$; ejection fraction; $r = -0.722$, $p = 0.008$). In conclusion, specific poor quality dietary macronutrients correlate with functional over morphological cardiac remodeling in obesity.

EFFECTS OF TESTOSTERONE UNDECANOATE ON CARDIAC REMODELING AND ITS ASSOCIATION WITH OXIDATIVE STRESS AND INFLAMMATION MARKERS IN INTACT MALE AND FEMALE WISTAR RATS.

GUILHERME GUILHERME CARVALHO SERENA1; GUSTAVO RICARDO KRUPP PRAUCHNER1; VICTOR CAMARATTA DOSSIN BASTOS1; LUCAS SCHERER LOUZADA1; NICOLE SOARES LIMA1; BRUNO ALONSO ESTIVALLET1; JULIA MENEGOTTO PIAMOLINI1; ALEX SANDER DA ROSA ARAUJO1; ALEXANDRE LUZ DE CASTRO1; ANGELA TEREZINHA DE SOUZA WYSE1;

(1) UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: The use of anabolic androgenic steroids (AAS) at supraphysiological doses in non-clinical settings is associated with atherosclerotic disease, pathological cardiac remodeling, and oxidative stress. Testosterone undecanoate (TU) is a long-acting AAS with greater clinical availability, but has limited preclinical research, particularly in female models. Objectives: To evaluate the effects of TU on cardiac remodeling and associated mechanisms of oxidative stress and inflammation in male and female Wistar rats. Methods: Intact male and female Wistar rats at 90 postnatal days (PND) received a single subcutaneous administration of TU at 125 mg/kg or castor oil. At 120 PND, animals were submitted to echocardiography, followed by euthanasia. Organs were weighed and normalized to tibial length. For morphological evaluation, the heart was sectioned after formalin fixation, and cardiac structures were measured. Biochemical analysis for oxidative stress and qPCR for inflammation were performed. Data were analyzed by two-way ANOVA, Tukey's test and t-test (CEUA: 44789). Results and Conclusions: Echocardiography showed that TU-treated females exhibited reduced heart rate alongside increased anterior wall thickness in systole, greater end-diastolic volume, and higher cardiac output (p<0.05). In TU-treated males, ejection fraction and fractional area change were reduced (p<0.05). Morphological analysis revealed a higher heart/tibia index in TU-treated females (p<0.05), with increased septal and left ventricular wall thickness (p<0.05). In males, no change in heart/tibia index was observed; however, increased septal thickness and bilateral ventricular wall thickening were detected (p<0.05). Biochemical analysis showed that TU reduced sulfhydryl levels and the SOD/CAT ratio while increasing nitrite concentration in treated males (p<0.05). In females, TU increased SOD activity (p<0.05) without altering the other parameters tested (p>0.05). Lipid oxidative stress, assessed by TBARS, was elevated in both sexes (p<0.05). Treated females exhibited reduced IL-6 levels (p<0.05), with no changes in IL-1β or IL-10 expression. TU induced sex-dependent cardiac remodeling accompanied by distinct oxidative stress profiles in males and females, with lipid peroxidation representing a shared mechanism of injury across both sexes. These findings underscore the sexual dimorphism in the cardiovascular response to AAS and support the use of TU as a viable model for preclinical research. Supported by CNPq.

EXPOSURE TO BISPHENOL S AND HIGH-FAT DIET INTAKE INDUCES VASCULAR REMODELING AND PRO-ATHEROGENIC PROFILE IN MALE MICE

MARIA EDUARDA LIMA DA SILVA1; GUILHERME DOS SANTOS REIS1; GABRIEL XIMENES DE OLIVEIRA1; LUIZA DA FRANÇA LOSITO1; D'ANGELO CARLO MAGLIANO1; ANTONIO CLAUDIO LUCAS DA NÓBREGA1; ELIETE DALLA CORTE FRANTZ1; BEATRIZ ALEXANDRE-SANTOS1;

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL;

Background/Introduction: Cardiovascular diseases (CVD) are the main cause of death worldwide, and one characteristic of many CVD is vascular remodeling. The development of CVD is influenced by several risk factors, including obesity and environmental factors, such as exposure to endocrine disruptors (ED). It is well known that bisphenol A (BPA), used in the manufacture of plastic and epoxy resins, is an ED that induces pathological cardiovascular outcomes. Due to its adverse health effects, BPA has been extensively regulated, leading to the use of bisphenol S (BPS) as its main substitute. BPS has been described as an ED with adverse cardiovascular effects, but its impact on vascular remodeling and atherogenic parameters remains unclear. Objectives: This study aims to investigate the impact of BPS exposure and high-fat (HF) diet intake on vascular remodeling and atherogenic parameters. Methods: Adult male mice were divided into SC (control diet), SCB (control diet + BPS), HF (high-fat diet), and HFB (high-fat diet + BPS). BPS was administered at a dose of 25µg/Kg/day through drinking water for 12 weeks. Body weight (BW) (g), total cholesterol and HDL levels (mg/dL), atherogenic index, systolic blood pressure (SBP) variation (mmHg), and aortic morphology were assessed. Statistical analyses were performed using one-way ANOVA with Holm-Sidak post hoc tests. Ethical approval 1929240521. Results and Conclusions: All interventions increased BW and total cholesterol levels in comparison to SC. These parameters were also elevated in HF and HFB in relation to SCB. HDL levels did not vary among groups; however, SCB, HF, and HFB increased the atherogenic index in relation to SC. All groups had higher SBP variation than SC, with increases in HF and HFB compared with SCB. SCB, HF, and HFB presented a thicker aortic wall, but only HF increased lumen size in comparison to SC. All interventions increased circumferential wall tension and tensile stress in relation to SC. Only HF and HFB reduced elastic fiber density in relation to the SC group. These findings indicate that both BPS exposure and high-fat diet intake promoted a pro-atherogenic profile and adverse vascular remodeling but the combined exposure did not act synergistically in worsening cardiovascular parameters.

GAMMA-ORYZANOL IMPROVES CARDIAC FUNCTION BY MODULATING HEPATIC PROTEOMIC SIGNATURES IN DIET-INDUCED METABOLIC DYSFUNCTION

JULIANA SILVA SIQUEIRA1; THIAGO LUIZ NOVAGA PALACIO1; JORDANNA CRUZEIRO1; DIJON HENRIQUE SALOMÉ DE CAMPOS1; GILDA AIELLO2; GIANCARLO ALDINI2; SILMEIA GARCIA ZANATI BAZAN1; ALFONSINA D'AMATO2; CAMILA RENATA CORREIA1;

(1) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL; (2) UNIVERSITÀ DEGLI STUDI DI MILANO - ITALY;

Background/Introduction: The chronic consumption of diets rich in sugar and fat can lead cardiovascular disease, condition strongly associated with metabolic dysfunction. In this context, the liver plays a central role in lipid metabolism. Gamma-oryzanol (ORY), a bioactive compound with antioxidant and hypolipidemic properties, has been investigated for metabolic disorders; however, its impact on hepatic pathways linked to cardiovascular risk remains unclear. Objectives: The aim was to investigate the effect of ORY on hepatic metabolic pathways associated with cardiovascular function using a proteomic approach in a model of metabolic dysfunction. Methods: Male Wistar rats were assigned to three groups (n=6/group): control (CTRL), high sugar-fat diet (HSF), and HSF supplemented with ORY (0.5% w/w) for 30 weeks (CEUA 1451/2024). Plasma triglycerides and very low-density lipoprotein (VLDL) were evaluated. Cardiac function was assessed by echocardiography. Liver proteomics was performed by LC-MS/MS, processed using MaxQuant (FDR = 1%), and analyzed with Ingenuity Pathway Analysis. Data were analyzed using one-way ANOVA or Kruskal–Wallis test with post hoc comparisons (α = 5%). Results and Conclusions: The HSF diet increased triglycerides and VLDL, while ORY attenuated these alterations (p<0.05). Proteomic analysis identified 2,194 hepatic proteins and revealed that HSF induced molecular signatures associated with increased heart rate (z=1.13) and cardiac contractility (z=1.13), driven by the upregulation of proteins involved in calcium handling (ATP2A2), sarcomeric structure (ACTC1, MYH6/7, MYL3, TPM1), and cytoskeletal organization (DES, JUP). Echocardiographic analysis demonstrated that HSF impaired cardiac function, with reduced S' (p < 0.001) and increased E/E' (p < 0.001), as well as a higher Tei index (p < 0.05), indicating that this molecular profile reflects a compensatory response rather than improved function. ORY supplementation downregulated these proteins, attenuated the predicted activation of heart rate (z=-0.78) and contractility (z=-0.08), and restored systolic (S') and diastolic (E/E') function. These findings demonstrate that HSF induces a maladaptive, compensatory activation of contractility-related pathways that is insufficient to preserve cardiac function, while ORY restores both molecular and functional homeostasis, highlighting its therapeutical potential in modulating liver–heart axis dysfunction. Financial support: FAPESP (2022/16108-4)

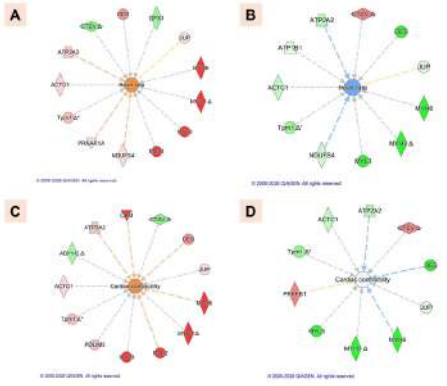

Table 1. Effects of gamma-oryzanol on lipidic and echocardiographic parameters.

	Control	HSF	HSF+ORY
Triglycerides (mg/dL)	56.60±8.8[a]	120.30±2.5[b]	79.80±12.92[c]
VLDL (mg/dL)	12.33±3.72[a]	24.00±0.82[b]	16.00±2.83[a]
S mean	5.68±0.30[a]	4.94±0.47[b]	5.66±0.22[a]
E/E'	13.48±0.99[a]	18.36±3.78[b]	14.16±1.35[a]
TEI index	0.27(0.17-0.39)[a]	0.42(0.41-0.51)[b]	0.26(0.19-0.47)[a,b]

Data are presented as mean values. S': systolic myocardial velocity; E/E': ratio between early diastolic transmitral flow velocity and early diastolic mitral annular velocity; TEI index: myocardial performance index. TEI index is presented as median (interquartile range); other variables are presented as mean values. Different letters indicate statistically significant differences between groups (p < 0.05).

(1) UNIVERSIDADE ESTADUAL DO NORTE FLUMINENSE DARCY RIBEIRO - CAMPOS DOS GOYTACAZES - RJ - BRASIL;

Background/Introduction: PRKAG2 cardiac syndrome (PCS) is an autosomal dominant disorder caused by variants in the PRKAG2 gene, which encodes the γ2 subunit of AMP-activated protein kinase (AMPK). It manifests with glycogen accumulation in cardiomyocytes, ventricular hypertrophy (VH), ventricular pre-excitation (VPE), and risk of sudden cardiac death (SCD). Objectives: Evaluate electrical, structural, autonomic, and gene expression alterations in Prkag2-p.His398Gln knock-in (KI) mice. Methods: Prkag2-p.His398Gln KI C57BL/6J mice were generated via CRISPR/Cas9 homology-directed repair. Male and female KI and wild-type (WT) mice underwent electrocardiography, echocardiography, and autonomic modulation assessment. Gene expression of Slc2a4 (GLUT4 transporter) and Gys1 (glycogen synthase) was quantified by SYBR Green qPCR in atrial and ventricular tissues. Results and Conclusions: Electrocardiography showed atrial fibrillation, supraventricular tachycardia, ventricular preexcitation, and left ventricular (LV) overload in female KI mice. Male KI exhibited first-degree atrioventricular block with LV overload. Echocardiography revealed hypertrophy-like changes in the mid/proximal LV thirds with elevated fractional shortening and ejection fraction in females, and apical hypertrophy in males. Sympathovagal analysis indicated higher sympathetic and lower parasympathetic activity in female KI mice, with small-to-moderate sympathetic increases and variable parasympathetic changes in males. Gene expression analysis demonstrated upregulated Slc2a4 in KI female atria (vs. WT females) and upregulated Gys1 in KI male hearts (vs. WT males), without similar changes in females. These findings confirm that Prkag2-p.His398Gln KI mice recapitulate the PCS phenotype in a sex-specific manner, mirrored by Slc2a4 and Gys1 expression patterns. Further studies are needed to fully characterize this first Brazilian PCS animal model.

IMPACT OF BETA-BLOCKER DISCONTINUATION AFTER MYOCARDIAL INFARCTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

CAUÃ PIMENTEL MARTINS FERNANDES1; LUIZ FILIPE TORRES TORRES ALENCAR1; DAVI PONTE PIERRE1; ISRAEL NASCIMENTO COUTINHO COSTA1; NICOLE AIRES PERAZOLO1; TIAGO MOURA FAÇANHA1; VANESSA ARAUJO PINHEIRO1; MARINA DE ANDRADE NORÕES BEZERRA1; LUCAS MACÊDO AURÉLIO PAIVA1; JOÃO PEDRO TEIXEIRA BENTES MONTEIRO1; MAYRA DIÓGENES BRAGA LIMA1; MATEUS PAIVA MARQUES FEITOSA1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Background/Introduction: Beta-blockers have historically been a cornerstone of secondary prevention after myocardial infarction (MI), although their long-term benefit in the contemporary era remains uncertain. In stable patients without heart failure or left ventricular dysfunction, the benefit of prolonged therapy beyond the first year remains unclear, particularly in the context of modern reperfusion and medical therapy. Recent evidence has suggested that discontinuation may be safe, raising questions about the need for continued treatment in this population. Objectives: This study aims to evaluate the safety and clinical impact of beta-blocker discontinuation in stable patients after myocardial infarction. Methods: A systematic review and meta-analysis was conducted in accordance with PRISMA guidelines. A total of 128 records were screened. Studies enrolling stable patients after MI, without heart failure or significant left ventricular dysfunction (LVEF >40%), receiving beta-blockers for at least one year, and comparing continuation versus discontinuation were included. Both randomized and non-randomized studies were considered. Data were synthesized using random-effects models. Results and Conclusions: A total of 6 studies were included, comprising 34,303 patients. The mean age ranged from approximately 60 to 64 years, and the majority of patients were male. Hypertension (approximately 40–60%) and diabetes (approximately 10–30%) were common across studies, and most patients underwent percutaneous coronary intervention, with preserved left ventricular ejection fraction in most populations. Multivessel disease was frequently reported. The duration of beta-blocker therapy prior to discontinuation varied across studies, ranging from less than 6 months to more than 1 year after myocardial infarction. There was no statistically significant difference between groups in major adverse cardiovascular events (HR 1.09, 95% CI 0.94–1.27) or all-cause mortality (HR 1.07, 95% CI 0.94–1.22). However, beta-blocker discontinuation was associated with a higher risk of recurrent myocardial infarction (HR 1.17, 95% CI 1.01–1.35). These findings suggest that in stable patients after myocardial infarction, discontinuation of beta-blockers after long-term use is not associated with increased mortality but may be associated with a higher risk of recurrent myocardial infarction, highlighting a potential trade-off between long-term safety and protection against ischemic events.

Background/Introduction: Menopause is characterized by a decline in female sex hormones, which directly affects vascular integrity and increases cardiovascular risk. This may lead to alterations in blood flow (BF) patterns and contribute to endothelial dysfunction mainly due to decreased nitric oxide bioavailability. Objectives: To determine endothelial function in response to increased disturbed blood flow in postmenopausal women. Methods: Young women (YW; 25±4 years; n=13) and postmenopausal women (PMW; 56±4 years; n=19) underwent a 30-min partial forearm blood flow occlusion (75 mmHg) to disturb brachial artery blood flow (DBF) and induce transient endothelial dysfunction. Hemodynamic parameters and endothelial function [flow-mediated dilation, FMD] were assessed using vascular ultrasound. Blood samples were collected before and during the DBF for plasma nitrate measurement. The data were presented as mean and standard deviation. Two-way ANOVA was performed, followed by Fisher's post test. The study was approved by the research ethics committee (CAAE 71649823.6.0000.524). Results and Conclusions: The cuff occlusion increased antegrade BF (YM, baseline: 177.50 ± 80.30 vs DBF: 272.24 ± 101.69; PMW, baseline: 266.76 ± 111.29 vs DBF: 316.05 ± 101.36 mL/min; p<0.01), retrograde BF (YM, baseline: 39.80 ± 17.46 vs DBF: 132.74 ± 62.61; PMW, baseline: 73.15 ± 37.57 vs DBF: 129.57 ± 79.86 mL/min; p<0.01) and the oscillatory shear index (YM, baseline: 0.19 ± 0.07 vs DBF: 0.32 ± 0.04; PMW, baseline: 0.22 ± 0.07 vs DBF: 0.27 ± 0.10 mL/min; p=0.03), whereas it decreased mean BF (YM, baseline: 135.34 ± 58.96 vs DBF: 73.32 ± 29.11; PMW, baseline: 233.96 ± 93.69 vs DBF: 124.36 ± 85.74 mL/min; p<0.01) in both groups, returning to baseline levels after five minutes of recovery. Additionally, the DBF decreased FMD only in the postmenopausal women (Baseline: 10.09 ± 4.58 vs Post-DBF: 6.89 ± 3.40%; p=0.01), while nitrate levels remained unchanged. In summary, preliminary data indicate that disturbed blood flow was associated with decreased flow-mediated dilation only in postmenopausal women, suggesting a transient endothelial dysfunction in this population.

NUCLEOLAR STRESS ALTERS MYOCARDIAL ELECTROPHYSIOLOGY AND MITOCHONDRIAL STRESS RESPONSES

NAOMI AMANDA BROWN1; RACHEL SUTCLIFFE1; NATASHA BEASLEY1; BETHAN ROPER-JONES1; RESHMA CHAUHAN1; MARCIN J WOZNIAK1;

(1) UNIVERSITY OF LEICESTER - UNITED KINGDOM;

Background/Introduction: The nucleolus plays a critical role in ribosome biogenesis and the regulation of cellular stress responses. Markers of nucleolar instability have been observed in myocardial biopsies from multimorbid cardiac surgery patients; however, the functional consequences of nucleolar dysfunction on the myocardium remain poorly understood, particularly under conditions of ischaemic stress. Objectives: This study aimed to investigate whether pharmacological induction of nucleolar stress using camptothecin (CPT) modifies myocardial vulnerability to ischaemia–reperfusion (I/R) injury and alters myocardial stress-response pathways. Methods: Hearts from male C57BL/6J mice (30.56 ± 0.72 g) perfused by Langendorff apparatus were randomly divided into four groups: normoxic continuous perfusion (120 minutes) of CPT (1 µM) or vehicle; and 30 minutes perfusion of CPT (1 µM) or vehicle followed by 30 minutes of global ischaemia and 60 minutes of reperfusion. Functional measures included heart rate and monophasic action potential duration (APD). LDH release and TTC staining were used to measure infarct size. Transcriptomic profiling was performed using RNA sequencing with gene set enrichment analysis. Results and Conclusions: CPT-induced nucleolar stress resulted in electrophysiological remodelling, characterised by a progressive reduction in heart rate (63% of baseline at 2 hours; P = 0.0023), prolongation of mid-to-late repolarisation (APD50-90), and increased action potential triangulation (2 hours; P = 0.0066). Myocardial injury was demonstrated by increased LDH release (2 hours; P = 0.0398) and a four-fold increase in infarct size (2 hours; P < 0.0001). Under I/R conditions, nucleolar stress altered functional responses, including reduced heart rate (2 hours; P = 0.0207) and attenuation of I/R-induced repolarisation shortening. Transcriptomic analysis demonstrated enrichment of nucleolar-associated pathways, including rRNA processing and ribosome biogenesis and DNA damage repair pathways in CPT-perfused hearts. Pathways related to mitochondrial metabolism and energy production were enriched following CPT perfusion, but attenuated or downregulated in the presence of I/R. Our study shows that nucleolar stress alters myocardial electrophysiology and injury whilst modulating the cardiac response to ischaemic stress. These findings identify nucleolar dysfunction as a regulator of myocardial vulnerability and a potential therapeutic target in multimorbid patients undergoing cardiac surgery.

POSITIVE AIRWAY PRESSURE THERAPY IN PATIENTS WITH HEART FAILURE AND SLEEP-DISORDERED BREATHING: A SYSTEMATIC REVIEW AND META-ANALYSIS

CAUÃ PIMENTEL MARTINS FERNANDES1; LUIZ FILIPE TORRES DE ALENCAR1; GERMANO FREIRE BEZERRA FILHO1; JOÃO DA SILVA FERREIRA MARINHO1; ANTONIO ARAGÃO XEREZ JUNIOR1; JUAN LUKA DIAS MOTA1; VANESSA ARAUJO PINHEIRO1; JOÃO PEDRO TEIXEIRA BENTES MONTEIRO1; ARTUR DIÓGENES VASQUES FARIAS1; GABRIEL FONTENELE XIMENES1; LUCAS MACÊDO AURÉLIO PAIVA1; JEFFERSON LUIS VIEIRA2;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (2) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Background/Introduction: Sleep-disordered breathing, including obstructive and central sleep apnea, is highly prevalent among patients with heart failure and is associated with intermittent hypoxemia, sleep fragmentation, sympathetic activation, reduced functional capacity, impaired quality of life, and worse cardiovascular outcomes. Positive airway pressure therapies, including CPAP, APAP, and adaptive servo-ventilation, have been proposed to reduce respiratory events and improve cardiac performance. However, previous trials have shown conflicting results regarding their effects on mortality, oxygenation, left ventricular function, and symptoms. Objectives: This study aims to evaluate the efficacy and impact of positive airway pressure therapy compared with non-positive airway pressure strategies in patients with heart failure and sleep-disordered breathing. Methods: A systematic review and meta-analysis was conducted in accordance with PRISMA guidelines. A total of 3996 records were identified from PubMed, Embase, and Cochrane. After removal of 1169 duplicates, 2827 articles were screened, and 156 full-text articles were assessed for eligibility. Reports were excluded due to wrong publication type, overlapping populations, wrong population/control group/outcome, or unavailable full text. A total of 19 studies were included. Outcomes were synthesized using random-effects models. Results and Conclusions: A total of 19 studies were included, comprising 2,566 patients. Of these, 398 patients received CPAP/APAP/PAP therapy, 889 received adaptive servo-ventilation, and 1,279 were allocated to control, sham, usual care, or non-positive airway pressure strategies. Positive airway pressure therapy was not associated with a significant reduction in mortality compared with control (HR 1.07, 95% CI 0.83–1.39; p = 0.60). NT-proBNP/BNP was assessed in three studies, and all showed reductions after positive airway pressure therapy. Therapy significantly reduced apnea-hypopnea index (MD -18.47 events/h, 95% CI -21.58 to -15.36; p < 0.00001), improved left ventricular ejection fraction (MD 3.48%, 95% CI 1.50 to 5.46; p = 0.0006), and reduced daytime sleepiness (MD -1.98, 95% CI -3.52 to -0.45; p = 0.01). We concluded that positive airway pressure therapy improves respiratory control, left ventricular systolic function, neurohormonal markers, and daytime symptoms in patients with heart failure and sleep-disordered breathing, but no significant mortality benefit was observed.

PROGNOSTIC VALUE OF THE HEART SCORE FOR PREDICTING ACUTE ISCHEMIC EVENTS IN EMERGENCY DEPARTMENT PATIENTS PRESENTING WITH CHEST PAIN

YASMIN BRAGA DE SOUZA1; RAFAEL SANTOS TEIXEIRA1; BRUNO TREGNAGO GARCIA2; GABRIELE DA CUNHA CARDOSO3; MAURÍCIO DA SILVA TELLES4; ARTHUR XAVIER LACERDA5; PAULO NOSCHANG FILHO6;

(1) UNIVERSIDADE LUTERANA DO BRASIL- ULBRA - CANOAS - RS - BRASIL; (2) UNIVERSIDADE DE CAXIAS DO SUL - CAXIAS DO SUL - RS - BRASIL; (3) UNIG - NOVA IGUAÇU - RJ - BRASIL; (4) UNIVERSIDADE FEDERAL DO RIO GRANDE - RIO GRANDE - RS - BRASIL; (5) UNIVERSIDADE DO ESTADO DE MATO GROSSO - CÁCERES - MT - BRASIL; (6) UNISINOS - SÃO LEOPOLDO - RS - BRASIL;

Background/Introduction: Chest pain is a common cause of emergency department visits, requiring rapid identification of patients at risk for acute coronary syndrome. The HEART Score is a validated risk stratification tool, but real-world data from Brazilian populations remain limited. Objectives: To evaluate the association between HEART Score stratification and acute ischemic events, as well as its relationship with in-hospital outcomes in patients presenting with chest pain. Methods: Retrospective observational study including adult patients evaluated under an institutional chest pain protocol in a tertiary hospital between January and December 2025. Patients were stratified according to HEART Score into low (0–3), intermediate (4–6), and high risk (7–10). The primary outcome was acute ischemic event. Diagnostic performance metrics of the HEART Score were calculated. Results and Conclusions: A total of 131 patients were included, of whom 38 (29.0%) had acute ischemic events. High-risk HEART Score classification was significantly associated with ischemic events (54.1% vs. 2.2%, p<0.001). HEART Score ≥4 showed 97.3% sensitivity and 98.1% negative predictive value for acute ischemic event, while high-risk classification demonstrated 97.8% specificity and 90.9% positive predictive value. High HEART Score was also associated with increased rates of hospitalization, coronary angiography, and revascularization. These findings support the HEART Score as a robust and clinically useful tool for risk stratification of chest pain patients in the emergency setting.

ROLE OF DAPAGLIFLOZIN IN ATTENUATING CARDIAC REMODELING AND MODULATING SIRTUIN GENE EXPRESSION IN TYPE 1 DIABETES

ANA PAULA SARAIVA MARREIROS1; PAULA GRIPPA SANT'ANA1; ELIDA PAULA BENQUIQUE OJOPI1; ALEXANDRE DIAS MUNIZ1; ANA LUIZA BARIONI MEIRELLES1; ANNA CLARA CONSORTI SANTOS1; EDER ANDERSON RODRIGUES1; LIDIANE MOREIRA SOUZA1; LUANA URBANO PAGAN1; GABRIELA BRANDÃO1; KATASHI OKOSHI1; MARINA POLITI OKOSHI1;

(1) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL;

Background/Introduction: Inhibition of sodium-glucose co-transporter 2 (SGLT2) induces well established cardiovascular benefits in high-risk patients with Type 2 diabetes mellitus (DM). However, only a few studies have evaluated the cardiovascular effects of SGLT2 inhibition in individuals with Type 1 DM. The mechanisms involved in beneficial effects have not yet been fully clarified. Studies suggest that SGLT2 inhibitors interact with sirtuins, proteins that modulate cellular survival and apoptosis, autophagy, mitochondrial function, and stress response. Objectives: To analyze the effects of the SGLT2 inhibitor dapagliflozin (Dapa) on cardiac structure, left ventricular function, and myocardial gene expression of sirtuins 1, 3, 5, 6 e 7 in rats with streptozotocin-induced DM. Methods: Male Wistar rats were assigned into control (C), C treated with Dapa (C-Dapa), DM, and DM treated with Dapa (DM-Dapa) groups. DM was induced by a single streptozotocin injection, 50 mg/kg. Dapa was added to rat chow at a dosage of 10 mg/kg/day for 16 weeks. Cardiac remodeling was evaluated by echocardiogram at the end of the study and gene expression by RT-qPCR. Statistical analysis: ANOVA complemented by Tukey or Kruskal–Wallis and Dunn tests (p<0.05). Results and Conclusions: Results: Final body weight was lower in DM and DM-Dapa than their controls and higher in DM-Dapa than DM. Glycemia and echocardiogram data are shown in the Table. Gene expressions of sirtuins 1 and 5 were lower in DM than C and gene expressions of sirtuins 3, 6 and 7 did not differ between groups. Conclusion: Long-term dapagliflozin attenuates body weight loss, hyperglycemia, left cardiac chambers dilation, left ventricular hypertrophy, and systolic and diastolic dysfunction in rats with Type 1 diabetes mellitus. Gene expression of sirtuins 1 and 5 is also modulated by dapagliflozin.

SEX-DEPENDENT CARDIOMETABOLIC EFFECTS OF CHRONIC MILD HYPERHOMOCYSTEINEMIA IN AGED WISTAR RATS

GUSTAVO RICARDO KRUPP PRAUCHNER1; GUILHERME CARVALHO SERENA1; LUCAS SCHERER LOUZADA1; BRUNO ALONSO ESTIVALLET1; VICTOR CAMARATTA DOSSIN BASTOS1; ANGELA WYSE1;

(1) UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: Introduction: Homocysteine (Hcy) is a non-proteinogenic sulfur-containing amino acid generated during methionine metabolism. Physiological plasma levels range from 5 to 15 µmol/L, and elevations are characterized as hyperhomocysteinemia (HHcy). Mild HHcy, defined by plasma homocysteine levels of 16–30 µmol/L, is associated with oxidative stress, metabolic imbalance, and increased cardiovascular risk. Although these effects are described, the sex-specific impact of chronic HHcy on cardiometabolic parameters remains poorly understood. Objectives: Objectives: To investigate the effects of chronic mild HHcy on cardiac structure, lipid profile, adipose tissue distribution, estrous cycle, and biochemical/biomolecular markers in aged male and female Wistar rats. Methods: Methods: Twelve-month-old Wistar rats received DL-homocysteine (0.03 µmol/g, s.c., twice daily) or saline for 30 days. The estrous cycle was monitored in females. Serum and cardiac tissues were collected for biochemical, morphometric, histological, and ultrastructural analyses, and data were analyzed by two-way ANOVA (procedures approved by the institutional animal ethics committee). Results and Conclusions: Results: HHcy increased reactive oxygen species in both sexes ($p<0.05$). In males, HHcy elevated triglycerides and VLDL, increased AST activity, reduced butyrylcholinesterase (BuChE), and increased cardiac mass relative to tibial length and total collagen area ($p<0.05$), indicating hypertrophic remodeling. The atherogenic index of plasma and matrix metalloproteinase-9 expression were also increased ($p<0.05$), with ultrastructural changes including sarcoplasmic reticulum dilation, glycogen accumulation, and altered intercellular junctions. In females, HHcy increased visceral adiposity, elevated ALT and BuChE activity, worsened the Castelli I index ($p<0.05$), and reduced proestrus frequency compared to controls, without cardiac hypertrophy. Histology showed increased cardiomyocyte necrosis and reduced total collagen area ($p<0.05$), along with greater mesenteric and gonadal fat deposition ($p<0.05$). Conclusion: Chronic mild HHcy promotes sex-dependent cardiometabolic dysfunction. Both sexes show increased ROS, but males develop a lipid-driven hypertrophic cardiac phenotype, whereas females exhibit a pro-atherogenic profile associated with increased adiposity. These findings highlight the roles of redox imbalance, lipid metabolism, and cholinergic signaling in sex-specific cardiovascular risk under HHcy conditions. Supported by CNPq.

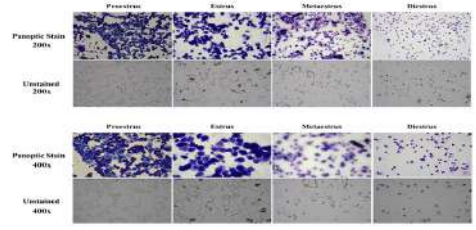

Figure 2. Representative vaginal cytology of female Wistar rats across the estrous cycle stages: proestrus, estrus, metestrus, and diestrus. Images are shown at 200× and 400× magnifications, with Panoptic-stained and unstained preparations. Proestrus is characterized by predominance of nucleated epithelial cells; estrus by abundant cornified epithelial cells; metestrus by a mixed cell population including leukocytes; and diestrus by predominance of leukocytes.

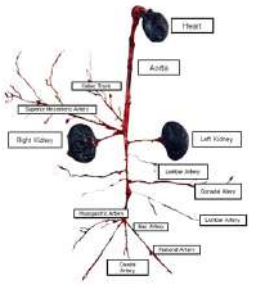

Figure 1. Vascular anatomy of a control male Wistar rat at 395 postnatal days. The image shows the heart and major arterial branches, including the aorta, celiac trunk, superior mesenteric artery, renal arteries supplying the right and left kidneys, lumbar arteries, gonadal artery, common iliac artery, hypogastric artery, femoral artery, and caudal artery.

THE ROLE OF THE ATP-SENSITIVE PURINERGIC P2X7 RECEPTOR IN HEART STRUCTURAL AND FUNCTIONAL ALTERATIONS INDUCED BY SARS-COV-2 IN A HUMANIZED MOUSE MODEL

JÚLIA COSTA DE SOUSA1; GABRYEL BARROS DE SÁ1; MARCIA GRACINDO DA SILVA1; ANDRÉ LUIZ GOUVÊA DE SOUZA1; ANNA LUISA ROSA ALVES1; ELEONORA KURTENBACH1;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Since its onset in 2019, COVID-19 spread worldwide, culminating in a pandemic that had profound impacts on healthcare systems. In the heart, patients may develop, during and after infection (long COVID), disorders such as myocarditis and arrhythmias. Objectives: In this study, we investigated the structural alterations of cardiac tissue in K18-hACE2 humanized transgenic mice infected with active SARS-CoV-2. Methods: To assess the involvement of P2X receptors, both K18-hACE2 and K18-hACE2/P2X7 knockout animals were used, divided into six groups: SARS-K18, SARS-K18/BBG (that received additionally Brilliant Blue G, a P2X antagonist receptor) and SARS-K18/P2X7-/- groups that received 2.5 x 10^4 PFU/mL of SARS-CoV-2 intranasally; MOCK-K18, MOCK-K18/BBG and MOCK-K18/P2X7-/- that received virus-free media. Results and Conclusions: After 5 days of infection, electrocardiogram analysis revealed bradycardia in SARS-K18 animals. After 7 days of infection, animals were euthanized, and hearts were processed for structural and cellular analysis. Results showed a significant reduction in heart weight in SARS-K18 mice compared to the animals from MOCK-K18, SARS-K18/BBG and SARS-K18/P2X7-/- groups. Furthermore, histological analysis revealed inflammatory infiltrate and a decrease of cardiomyocyte cross-sectional area in SARS-K18 and SARS-K18/BBG animals, indicating cardiac atrophy. LC3-II (an autophagy marker) expression was increased, while P62 protein concentrations (delivers ubiquitinated proteins to autophagossome) were reduced in SARS-K18, confirming enhanced autophagic flux induced by infection. The MAFBx and MuRF-1 E3 ligases, from the ubiquitin-proteassome system of protein degradation also showed increased expression in animals from SARS-K18 groups compared to MOCKs groups. Expression of the main cardiac gap junction proteins, Connexin-40 and -43, was significantly reduced in animals from SARS-K18 groups, which may be related to the bradycardia. We suggest that SARS-CoV-2 infection induced cardiac atrophy through increased autophagy in K18-hACE2 mice, and that this atrophy was prevented by P2X7 receptor deletion. Further investigations will address potential morphofunctional alterations caused by the SARS-CoV-2 infection.

TITLE EVALUATION OF ALGINATE SCAFFOLD AND HUMAN AMNIOTIC MEMBRANE ON VENTRICULAR REMODELING AFTER MYOCARDIAL INFARCTION IN AN EXPERIMENTAL MODEL

DANIELLE DE PAULA E SILVA CARNEIRO BASAGLIA1; FELIPE SANTANA LOBO1; RICARDO ABBUD TORRES XAVIER1; EDILAINE BRAGA DE SOUZA1; LUIZ NEVES NETO1; LUIZE KREMER GAMBA1; HELCIO GIFFHORN1; JÚLIO CÉSAR FRANCISCO1; LUIZ CÉSAR GUARITA-SOUZA1;

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL;

Background/Introduction: Acute Myocardial Infarction (AMI) is associated with high morbidity and mortality worldwide. Cardiac regeneration after AMI remains a challenge, since conventional therapies do not promote effective tissue repair. Objectives: To evaluate the potential of alginate scaffolds and human amniotic membrane in promoting cardiac tissue regeneration after myocardial infarction through functional and histological analysis in a preclinical rat model. Methods: After approval by the Animal Ethics Committee of UFPR (Protocol: 23075.046582/2024-88), AMI was induced in 60 male Wistar rats by coronary artery ligation. Seven days later, baseline echocardiography was performed to assess left ventricular ejection fraction (LVEF), end-diastolic volume (LVEDV), and end-systolic volume (LVESV) using the Simpson method. After post-AMI mortality, surviving animals were randomized into three groups: Control – untreated AMI (n=12); Alginate – implantation of a 3D-printed alginate scaffold (n=10); and Amniotic Membrane – implantation of decellularized human amniotic membrane (n=14). Final echocardiographic evaluation was performed 30 days after AMI induction. Results and Conclusions: At 7 days after AMI (D7), the control, alginate, and amniotic membrane groups showed distinct LVEF values (44% vs 53.3% vs 36.9%; p=0.009). At 30 days (D30), significant differences in LVEF persisted among the groups (38.9% vs 60.2% vs 41.6%; p=0.005). No significant intergroup differences in LVESV were observed at D7 or D30. However, intragroup analysis showed a significant LVESV increase only in the control group between D7 and D30 (p=0.008). Similarly, no significant differences in LVEDV were found among groups, although only the control group showed a significant increase over time (p=0.013). These findings suggest that the evaluated biomaterials may attenuate post-AMI ventricular remodeling, particularly in the alginate scaffold group, which demonstrated better preservation of ventricular function and less ventricular dilation progression compared with the control group.

HOME-BASED HIGH-RESISTANCE INSPIRATORY MUSCLE STRENGTH TRAINING ATTENUATES SYMPATHETIC-CARDIOVASCULAR REACTIVITY TO ACUTE MENTAL STRESS IN LONG COVID PATIENTS: A RANDOMIZED, DOUBLE-BLIND, SHAM-CONTROLLED TRIAL

THAIS SILVA RODRIGUES1; ARTUR O SALES2; BRUNA E ONO2; JOÃO E IZAIAS2; FERNANDA M C COLOMBO3; MARIA C C IRIGOYEN3; HELENA N M ROCHA4; PEDRO P S SOARES4; ANTONIO C L NÓBREGA4; NATALIA G ROCHA4; RENATA MOLL BERNARDES2; ALLAN R K SALES2;

(1) INSTITUTO D'OR DE PESQUISA E ENSINO - RIO DE JANEIRO - SP - BRASIL; (2) INSTITUTO D'OR DE PESQUISA E ENSINO - RIO DE JANEIRO - RJ - BRASIL; (3) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (4) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL;

Introdução/Fundamentos: We have recently demonstrated that Long COVID patients exhibit exaggerated sympathetic-cardiovascular reactivity during acute mental challenges, indicating an increased cardiovascular risk. Conversely, home-based high-resistance inspiratory muscle strength training (IMST) reduces muscular sympathetic nerve activity (MSNA), lowers mean arterial pressure (MAP) and improves vascular function in other populations. Objetivos: Therefore, IMST may be a promising strategy to attenuate sympathetic-cardiovascular reactivity to mental stress (MS) in Long COVID patients Métodos: To test this hypothesis, a randomized, double-blind, sham-controlled clinical trial (Identifier: NCT06091384) with 6 weeks of home-based high-resistance IMST (30 breaths/day, 6 days/week at 75% PImax) vs. SHAM (30 breaths/day, 6 days/week at 15% PImax) was conducted. MSNA (Microneurography), brachial artery blood flow (BABF, Ultrasound-Doppler), MAP (Finomenter), and heart rate (HR, ECG) were measured during 3 min of MS (Stroop color test) before and after 6 weeks of intervention. Resultados e Conclusões: Thirty-one Long COVID patients completed the study, 15 in IMST (men 9, age: 49.9±8.2 years and BMI: 32.0±6.25kg/m²) and 16 in SHAM (men 7, age: 51.9±10.9 years, BMI: 34.0±5.66 kg/m²). IMST was safe, well tolerated, had excellent adherence (≈96), and increased the PImax (P<0.05). IMST decreased the burst frequency and incidence MSNA, and MAP responses to MS (P<0.001 for all), but did not change HR and BABF (P>0.05 for both). No changes were observed in the studied variables in SHAM (P>0.05). Importantly, the perceived stress levels to MS conducted before and after 6 weeks of IMST or SHAM were similar (P>0.05). Our findings clearly indicate that home-based high-resistance IMST attenuates sympathetic-cardiovascular reactivity to MS in Long COVID patients, suggesting it may be a promising strategy for lowering cardiovascular risk. These results will need to be confirmed in larger trials.

HYPERGLYCEMIA IS ASSOCIATED WITH FIBROBLAST-ENRICHED THROMBOSPONDIN-2 UPREGULATION IN DIABETIC MOUSE HEARTS

PAULO H S MARAZZI-DINIZ1; BECKY BYLE2; THEMIS KYRIAKIDES2;

(1) VASCULAR BIOLOGY AND THERAPEUTICS PROGRAM, YALE SCHOOL OF MEDICINE, UNITED STATES - UNITED STATES; (2) VASCULAR BIOLOGY AND THERAPEUTICS PROGRAM, YALE SCHOOL OF MEDICINE, UNITED STATES - UNITED STATES;

Introdução/Fundamentos: Diabetic cardiomyopathy is characterized by early myocardial fibrosis and ventricular stiffening, yet the fibroblast-specific molecular signals linking hyperglycemia to extracellular matrix remodeling remain incompletely defined. Thrombospondin-2 (TSP2) is a matricellular protein involved in collagen organization and tissue mechanics, but its regulation in the diabetic heart is not well established. Objetivos: We assessed the hypothesis that diabetes and high-glucose exposure are associated with increased TSP2 expression in cardiac fibroblast-lineage cells. Métodos: Single-cell RNA sequencing data from 17-week-old male diabetic db/db and control db/h mouse hearts were analyzed by pseudobulk aggregation across mice and by cardiac cell lineage (n=8/group). Thbs2 transcript abundance was compared between diabetic and control hearts and across non-myocyte populations. A second single-cell dataset from older diabetic mice was used to assess lineage specificity. Primary wild-type mouse cardiac fibroblasts were cultured under low- and high-glucose conditions, and TSP2 protein expression was evaluated by Western blot with GAPDH normalization. Resultados e Conclusões: Diabetic db/db hearts demonstrated an approximately two-fold increase in Thbs2 transcript abundance compared with db/h controls (p=0.0002). Lineage-level analysis identified fibroblasts and pericytes as the dominant contributors to cardiac Thbs2 expression, with fibroblasts showing the highest absolute expression and diabetic induction (p<0.001). The independent older-mouse dataset further supported fibroblast-enriched TSP2 expression. Western blot analysis showed an approximately three-fold increase in GAPDH-normalized TSP2 protein in high-glucose versus low-glucose cardiac fibroblasts (p=0.0414; n=2 per condition), consistent with the transcriptomic findings but requiring replication. These results suggest that hyperglycemia-associated TSP2 upregulation in cardiac fibroblasts may represent a fibroblast-centered mechanism linking diabetes to myocardial matrix remodeling, extending prior evidence that high glucose drives TSP2 elevation in dermal fibroblasts and contributes to impaired healing in diabetes.

HIGH PREVALENCE OF SARCOPENIA IN ELDERLY PATIENTS WITH CHRONIC CHAGAS CARDIOMYOPATHY: A CROSS-SECTIONAL STUDY

LUIZ ARTHUR DE OLIVEIRA NANTES1; ARTHUR MORAES DOS SANTOS1; VIVIANE PATRÍCIA LOPES CARDOSO1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Background/Introduction: Chronic Chagas cardiomyopathy (CCC) induces a state of chronic inflammation and heart failure, which act as potential triggers for sarcopenia. Although this underdiagnosed geriatric syndrome drastically worsens prognosis, its comparative prevalence between the clinical forms of chronic Chagas disease (CCD) remains uncertain. Objectives: To compare the prevalence of sarcopenia in elderly patients with the cardiac form (CF) and the indeterminate form (IF) of CCD, and to identify independent risk factors associated with this syndrome. Methods: This cross-sectional analytical study evaluated 130 patients aged ≥ 60 years with a serological diagnosis of CCD from a tropical disease referral outpatient clinic. Patients were divided into CF (with electrocardiographic/echocardiographic alterations) and IF (without cardiac involvement) groups. Sarcopenia was diagnosed using the strict EWGSOP2 criteria: low muscle strength (handgrip dynamometry) plus low appendicular skeletal muscle mass (bioelectrical impedance analysis). Comorbidities (Charlson Comorbidity Index), nutritional status (Mini Nutritional Assessment), and inflammatory markers (hs-CRP) were assessed. Statistical analysis included Chi-square test and multivariate logistic regression, with significance set at $p < 0.05$. Results and Conclusions: Out of 130 patients (mean age 68.4 ± 6.1 years), 62 (47.7%) had IF and 68 (52.3%) had CF. Global sarcopenia prevalence was 36.9%, indicating a high burden. However, stratified analysis revealed a drastic difference: 58.8% (40/68) in the CF group met the criteria for sarcopenia, compared to only 11.3% (7/62) in the IF group ($p < 0.001$). Multivariate logistic regression identified the following independent predictors for sarcopenia: presence of the cardiac form (OR 7.9; 95% CI 3.1–20.3), worse nutritional status (OR 3.1; 95% CI 1.4–6.9), and elevated hs-CRP levels (OR 2.4; 95% CI 1.1–5.2). Sarcopenia is highly prevalent in elderly patients with CCD, but the risk is intrinsically linked to cardiomyopathy rather than the infection alone. The cardiac form independently increased the odds of sarcopenia nearly eightfold. These findings highlight the critical need to incorporate routine muscle mass and strength assessments into the cardiological follow-up of Chagas patients, targeting the highest-risk subgroup for early multimodal rehabilitation to improve functional capacity and prognosis.

LISTENING TO ELDERLY HEART FAILURE PATIENTS: PATIENT-REPORTED QUALITY OF LIFE PREDICTS MORTALITY BETTER THAN PHYSICIAN-ASSESSED FUNCTIONAL CLASS

CAROLINA JERONIMO MAGALHAES1; RODRIGO RUFINO PEREIRA SILVA1; JESSICA MYRIAN DE AMORIM GARCIA2; JULIO FRANSCISCO DE MOURA JUNIOR2; LENA SANTANA SILVA2; FRANCISCO BANDEIRA2;

(1) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL;

Background/Introduction: The prevalence of heart failure (HF) is rising significantly due to improved treatment and longer life expectancy. Health status assessments by healthcare providers may differ from patients' perspectives, particularly in the elderly population. Literature on quality of life (QoL) in this demographic, especially among hospitalized patients, remains limited. Objectives: This study evaluates the association between QoL assessed by the Kansas City Cardiomyopathy Questionnaire (KCCQ), New York Heart Association (NYHA) functional class, and mortality. Methods: Cross-sectional study of elderly in-patients with HF at a tertiary cardiology center in Brazil. The KCCQ assessed QoL 15 days prior to admission, and NYHA classification was recorded at admission. KCCQ scores of 0–49 represented poor health status, and 50–100 represented good health status. Results and Conclusions: A total of 196 patients were enrolled, with a mean age of 73±6 years; 53.6% were male. Mean KCCQ score was 54.8±19.7; poor QoL was observed in 39.4% of patients, whereas 60.6% had good QoL. Regarding NYHA functional class, 54.4% were in class III or IV, and 45,6% were in class I or II at admission. Overall, 81.1% of patients were discharged, 9.2% had prolonged hospitalization, and 9.7% died. Among patients with poor QoL, 18.3% died versus 81.7% who survived. Conversely, among those with good QoL, 93.6% had good outcomes versus 6.4% mortality (q=0.016). Regarding NYHA functional class, 11% of patients in class III or IV died, whereas 89% survived; those in class I or II had 92% with good outcomes and 8% mortality (p=0.615). In conclusion, within this sample, poor QoL as assessed by KCCQ was a statistically significant predictor of mortality in elderly patients with HF, whereas NYHA functional class assessed by healthcare providers was not.

PERIOPERATIVE MYOCARDIAL INFARCTION AS THE LEADING CAUSE OF DEATH IN ELDERLY LIVER TRANSPLANT RECIPIENTS: A CALL FOR CARDIOVASCULAR RISK STRATIFICATION

ANDRE LUIZ DIAS LIMA BONFIM1; MARCOS MORAIS DE MEIS1; PAULO MACHADO PONTES1; MARIANA CRISTINA MAYWORN1; JOAO VICTOR PROVETI MORAES1; LAURA CRISTINA MACHADO PINTO1; ELIZABETH BALBI1; LUCIO F PACHECO MOREIRA1; LUIS FILIPE AZEVEDO DE CARVALHO1;

(1) IDOR - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Liver transplantation is the definitive treatment for end-stage liver disease, with increasing use worldwide. As surgical techniques advance, it has expanded to elderly patients with significant cardiovascular comorbidities. Perioperative myocardial infarction (MI) and cardiovascular complications are the main causes of morbidity and mortality, accounting for up to 50% of early hospitalizations and 40% of deaths within the first month. Cardiovascular risk stratification, however, remains heterogeneous and challenging. Objectives: To assess the incidence of death due to perioperative MI in liver transplant patients and compare outcomes between elderly (≥70 years) and younger (<70 years) individuals. Methods: Observational, retrospective, cross-sectional study conducted at a tertiary private hospital in Brazil. Adult patients who underwent liver transplantation between January 2020 and May 2025 were included and categorized by age (≥70 vs. <70 years). Data were obtained from electronic medical records. The primary outcome included death due to perioperative MI, defined as events occurring during hospitalization or within 30 days after transplantation, according to the Fourth Universal Definition. Secondary outcomes included overall mortality and other causes of death, such as infection and graft dysfunction. Results and Conclusions: 241 patients were evaluated, 42 (17.4%) aged ≥70 years and 199 (82.6%) aged <70 years. In the group ≥70 years old, there were 4 deaths (9.5%), of which 3 (7.1%) were due to perioperative infarction and 1 (2.4%) due to infection. In the <70 years old group, there were 9 deaths (4.5%), 2 (1.0%) due to heart attack, 5 (2.5%) due to infection and 2 (1.0%) due to graft dysfunction. Perioperative infarction deaths were significantly higher in patients aged ≥ 70 years (7.1% vs. 1.0%). Considering the proportional mortality in deaths, perioperative infarction corresponded to 75% of deaths in the group ≥70 years and 22.2% in the group <70 years, highlighting the greater cardiovascular vulnerability of the first group. Although liver transplantation is increasingly performed in the elderly, the presence of comorbidities and low physiological reserve may contribute to the prognosis. The high proportion of heart attacks as a cause of death reinforces the importance of rigorous preoperative cardiovascular risk stratification, in addition to the need for preventive strategies and individualized management to reduce mortality in this subgroup.

TIME OUT OF HOME AND MORTALITY IN OLDER ADULTS WITH HEART FAILURE AFTER ACUTE CARE

JOÃO PAULO QUESSADA ALIBERTI1; BRUNO DEMARTINI CARVALHO1; VINICIUS HATANAKA DIAS1; TAMIRES LUKENCZUK SAID DIAS1; CAIO DE ASSIS MOURA TAVARES2; MARLON JULIANO ROMERO ALIBERTI3;

(1) IRMANDADE SANTA CASA DE LONDRINA - LONDRINA - PR - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (3) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Background/Introduction: Time out of home reflects days lost to healthcare utilization and death, capturing the overall burden of disease. Although proposed as a patient-centered outcome in older adults with heart failure (HF), its prognostic value remains unclear. Objectives: To identify determinants of time out of home during the first year after an acute outpatient event in older adults with HF and to evaluate its association with subsequent 3-year mortality. Methods: This prospective cohort study included patients aged ≥60 years with HF who were consecutively admitted (2014–2020) to an acute care day hospital at a large academic medical center in São Paulo, Brazil. Time out of home was calculated during the first year following the acute event as the number of calendar days spent in emergency departments, hospitals, post-acute care settings, or nursing homes, plus days lost to death. Sociodemographic and clinical characteristics, frailty, and the Cardiac and Comorbid Conditions Heart Failure (3C-HF) score, a validated measure of HF severity, were assessed. First-year survivors were followed for 3 additional years for all-cause mortality. Negative binomial regression identified factors associated with time out of home, and multivariable Cox proportional hazards models evaluated the association between time out of home and time to death over 3 years. Results and Conclusions: Among 326 patients (mean age 80.9 ± 7.7 years; 38.0% female; 59.8% identified as White), 195 (59.8%) had ≤7 days out of home, 40 (12.2%) had 8–14 days, and 91 (28.0%) had ≥15 days. Greater time out of home was associated with non-White race/ethnicity, ≥8 years of education, frailty, and greater heart failure severity (3C-HF) (Figure 1). Among 254 first-year survivors, greater time out of home during the first year was associated with higher subsequent 3-year mortality (≤7 days: 42%; 8–14 days: 58%; ≥15 days: 66%; p<0.001) (Figure 2). After adjustment for sociodemographic and clinical factors, frailty, and HF severity, ≥15 days out of home was associated with a twofold higher hazard of 3-year mortality compared with ≤7 days during the first year (HR 2.0, 95% CI 1.3–3.1).

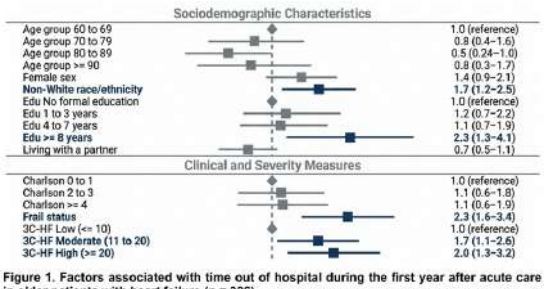

Figure 1. Factors associated with time out of hospital during the first year after acute care in older patients with heart failure (n = 326)
Edu: education level; Charlson: Charlson comorbidity index; 3C-HF: Cardiac and Comorbid Conditions Heart Failure. Estimates are presented as incidence rate ratios (IRRs) with 95% confidence intervals.

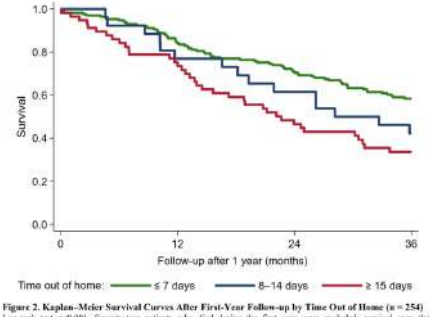

Figure 2. Kaplan–Meier Survival Curves After First-Year Follow-up by Time Out of Home (n = 254)
Log-rank test p<0.001. Seventy-two patients who died during the first year were excluded; survival over the subsequent 3 years was analyzed among the 254 patients who survived the first year after acute care day hospital admission.

A DECADE OF SURVIVAL: LONG-TERM FOLLOW-UP OF HEART TRANSPLANT RECIPIENTS AT A TERTIARY CENTER

MARIA ISABEL SOUSA VIDAL1; PEDRO HENRIQUE DE MORAIS LUVIZOTTO1; MILENA MONTANS JORDÃO1; MAÍRA KÜSTER MACHADO1; PIETRA MOREIRA VIEIRA1; CAROLINA CASADEI DOS SANTOS1; PLÍNIO JOSÉ WHITAKER WOLF1; JOÃO MANOEL ROSSI1; MARCO AURÉLIO FINGER1; FERNANDA DE BRITO FORTUNA1; PEDRO HENRIQUE CHAVES DE SOUZA AGUIAR1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Background/Introduction: Heart transplantation (HTx) is an established therapy for advanced heart failure. The average survival rate for patients is approximately 7 years in Brazil and 12 years worldwide. However, many patients exceed this average, developing various comorbidities and requiring specific longitudinal follow-up. Objectives: Profile of HTx survivors >10 years. Methods: A total of 521 HTx have been performed at our hospital since 1991; patients with a survival rate of more than 10 years were selected for this study. Following the implementation of electronic medical records in 2020, patients without electronic data were excluded. We analyzed demographic data, HTx etiology, pre- and post-transplant comorbidities, late complications, immunosuppression protocols, echocardiographic findings, and screenings for cardiac allograft vasculopathy (CAV). Results and Conclusions: Eighty-four (84) patients with survival exceeding 10 years were identified. Mean age at HTx was 46.6 years, with a male predominance (65.5%). The primary etiology was Chagas cardiomyopathy (31.8%), followed by dilated (27.1%) and ischemic cardiomyopathy (22.4%). Most frequent pre-HTx comorbidities were arterial hypertension (47.6%) and dyslipidemia (29.8%); post-HTx, dyslipidemia prevalence rose to 59.5%. Main late complications included Chagas disease reactivation (17.9%), occurring at a mean of 1.1 years post-HTx, cellular rejection (15.5%), and cytomegalovirus infection (13.1%). The immunosuppressive regimen predominantly used mycophenolate (87.6%) and cyclosporine (46.4%). mTOR inhibitors (everolimus/sirolimus) were used in 13.5% of patients. Echocardiography showed a mean ejection fraction (EF) of 63.0%, with only 4.8% having an EF < 50%. Moderate-to-severe tricuspid regurgitation was present in 31.0%, and left atrial enlargement in 28.0%. Screening for cardiac allograft vasculopathy (CAV) was performed in 67 patients (79.8%), with a 9.0% positivity rate. Overall mortality was 25.0% (21 patients), with a mean interval of 19.3 years between HTx and death. This study delineated the clinical and echocardiographic profile of long-term HTx survivors. The predominance of Chagas etiology, often associated with lower CAV incidence and fewer comorbidities, reflects both a favorable prognosis for this group and the Brazilian epidemiological profile. The low prevalence of CAV in this cohort (9.0%) reinforces its role as a critical survival-limiting factor, as its relative absence was a hallmark of patients who successfully exceeded a decade of survival.

(1) INSTITUTO DE PREVIDENCIA DOS SERVIDORES DO ESTADO DE MINAS GERAIS, IPSEMG, BELO HORIZONTE, BRASIL - BELO HORIZONTE - MS - BRASIL; (2) INSTITUTO DE PREVIDENCIA DOS SERVIDORES DO ESTADO DE MINAS GERAIS, IPSEMG, BELO HORIZONTE, BRASIL - BELO HORIZONTE - MG - BRASIL; (3) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Interpretation of variants of uncertain significance (VUS) in sarcomeric genes remains a major challenge in inherited cardiomyopathies. Comprehensive phenotyping and robust segregation data are essential for accurate variant classification. Objectives: To evaluate genotype–phenotype correlation and segregation patterns of the MYH7 c.1498G>A variant in a multigenerational family with hypertrophic cardiomyopathy (HCM), and to assess evidence supporting reclassification. Methods: Thirteen phenotypically affected individuals across three generations were identified within a 34-member family and followed in an observational cohort for up to 25 years. Non-obstructive HCM was diagnosed by echocardiography. Seven surviving affected relatives underwent genetic testing (two by whole-genome next-generation sequencing and five by Sanger sequencing). Co-segregation between genotype and phenotype was evaluated according to American College of Medical Genetics and Genomics (ACMG) criteria. Genetic testing of phenotypically negative relatives is currently underway to further strengthen segregation analysis. Results and Conclusions: The MYH7 c.1498G>A variant, previously classified as a VUS, was detected in the proband and in all tested affected relatives. No alternative pathogenic sarcomeric variants were identified. Consistent co-segregation between the variant and the HCM phenotype was observed across generations. Clinical expression was early (median diagnosis 16.5 years) and severe: syncope occurred in 75%, atrial fibrillation in 50%, complete atrioventricular block in 25%, and sudden cardiac death in 38% of affected individuals. Although baseline systolic function was preserved, 33% progressed to heart failure with reduced ejection fraction during long-term follow-up. In this multigenerational family, the MYH7 c.1498G>A variant demonstrates strong genotype–phenotype co-segregation and aggressive clinical expression. These findings provide substantial clinical evidence supporting reclassification from VUS to likely pathogenic and highlight the importance of detailed familial phenotyping in variant interpretation.

Clinical Variable	n / 12	Prevalence (%)
Fatigue	11 / 12	91.7%
Dyspnea	10 / 12	83.3%

AFICAMTEN VERSUS METOPROLOL IN PATIENTS WITH OBSTRUCTIVE HYPERTROPHIC CARDIOMYOPATHY: A FREQUENTIST NETWORK META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

MARIA CLARA ZIMERER REATTO DIMAS DE MELO PIMENTA PESSOA DE MELLO1; OCÍLIO RIBEIRO GONÇALVES2; FRANCISCO WESLLEY TEIXEIRA COIMBRA2; IANNN MESSIAS LIMA EUFRASIO3; LUIS FELIPE VIEIRA NUNES PORTO2; PAWEŁ ŁAJCZAK4; VICTOR HUGO PINHEIRO DOS SANTOS5;

(1) UNIVERSIDADE FEDERAL DOS VALES DO JEQUITINHONHA E MUCURI - TEÓFILO OTONI - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DO PIAUI - PIAUÍ - PI - BRASIL; (3) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL; (4) MEDICAL UNIVERSITY OF SILESIA - POLAND; (5) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Background/Introduction: INTRODUCTION: While beta-blockers are the standard initial therapy for symptomatic obstructive hypertrophic cardiomyopathy (oHCM), their effectiveness is poorly documented. Aficamten, a cardiac myosin inhibitor, effectively reduces outflow gradients and improves symptoms when added to existing regimens. The question remains, however, whether aficamten alone is more clinically effective than traditional beta-blocker such as metoprolol. Objectives: OBJECTIVE: This meta-analysis aimed to compare Aficamten and Metoprolol in oHCM. Methods: METHODS: The study was reported according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement with NMA extension. Study selection included only randomized controlled trials (RCTs). Main outcomes were: (1) improvement of ≥1 NYHA functional class, (2) peak oxygen uptake as assessed during cardiopulmonary exercise testing, (3) change of left ventricular outflow tract (LVOT) gradient at rest and (4) after the Valsalva maneuver from baseline, (5) change in Kansas City Cardiomyopathy Questionnaire clinical summary score (KCCQ-CSS) from baseline. A frequentist framework was used for the NMA to integrate direct and indirect evidence across interventions. All analyses employed a random-effects model. Treatment effects were expressed as risk ratio (RR) with 95% confidence intervals (CIs) for binary outcomes and standardized mean difference (SMD) for continuous outcomes. Results and Conclusions: RESULTS: Four RCTs comprising 527 patients were included. Aficamten showed higher rates of improvement ≥1 in NYHA scores (RR 1.86 [1.29; 2.68]) and significantly higher peak oxygen uptake (SMD 0.88 (0.60; 1.16)) and KCCQ-CCS (SMD 0.43 (0.16; 0.69)) compared to metoprolol. Also, aficamten showed lower LVOT at rest (SMD -1.18 (-1.47; -0.89)) and lower LVOT after valsalva maneuver (SMD -1.10 (-1.38; -0.82)) compared to the beta-blocker. CONCLUSION: This meta-analysis demonstrates that aficamten achieved better outcomes compared to metoprolol regarding improving NYHA functional class, exercise capacity, and quality of life in oHCM patients. Furthermore, aficamten achieved significantly greater reductions in LVOT gradients. These findings need to be further investigated through head-to-head comparisons in larger RCTs and different populations.

19862

ASSOCIATION BETWEEN NT-PROBNP LEVELS AND EVOLUTIONARY STAGES OF CHAGASIC CARDIOMYOPATHY

LEIDE DAIANA SILVEIRA CARDOSO1; LUCIANO FREITAS FERNANDES2; ARIELA MOTA FERREIRA2; GLAUCIA REJANNY TEIXEIRA FERNANDES2; ANA BEATRIZ CARDOSO SENA2; MATHAUS HENRIQUE REIS SILVA1; MARCOS GABRIEL DE JESUS RODRIGUES2; MAYRA DOMINGUES CARDOSO2;

(1) IRMANDADE NOSSA SENHORA DAS MERCÊS - SANTA CASA DE MONTES CLAROS - MONTES CLAROS - MG - BRASIL; (2) UNIVERSIDADE ESTADUAL DE MONTES CLAROS - MONTES CLAROS - MG - BRASIL;

Background/Introduction: Chagas disease remains an important cause of cardiovascular morbidity and mortality in Latin America, with chronic Chagasic cardiomyopathy representing its most severe form. Stratification of disease severity is essential in clinical practice, and biomarkers such as NT-proBNP have been associated with ventricular dysfunction and worse prognosis. However, their relationship with the different evolutionary stages of the disease has not yet been fully established. Objectives: To evaluate the association between NT-proBNP levels and the severity of Chagasic cardiomyopathy. Methods: This was an observational, cross-sectional, and analytical study conducted using a database from a referral center in northern Minas Gerais, Brazil. Patients with Chagas disease who had both cardiomyopathy classification and NT-proBNP measurements available were included. Disease severity was categorized into stages A, B1, B2, C, and D, according to the Brazilian Society of Cardiology. NT-proBNP was analyzed as a continuous variable. The Kruskal–Wallis test was used, followed by Dunn's post hoc test. A p-value < 0.05 was considered statistically significant. Results and Conclusions: A total of 115 patients were included. A progressive increase in NT-proBNP levels was observed according to cardiomyopathy severity, with median values of 115.0 pg/mL (A), 108.0 pg/mL (B1), 355.0 pg/mL (B2), 775.0 pg/mL (C), and 5468 pg/mL (D). There was a statistically significant difference between stages ($H = 51.47$; $p < 0.001$; $\varepsilon^2 = 0.45$). A more pronounced increase was noted from stage B2 onward, suggesting an inflection point in biomarker elevation. In the post hoc analysis, stages C and D showed significantly higher levels compared to early stages ($p < 0.001$). NT-proBNP levels are significantly associated with the severity of Chagasic cardiomyopathy, showing a progressive increase with a more marked rise beginning at stage B2. These findings reinforce its role as a severity marker and suggest its potential use as a complementary tool in disease stratification.

ATRIAL FIBRILLATION IN HYPERTROPHIC CARDIOMYOPATHY: A RISK MARKER FOR STROKE AND SYMPTOMS

PAULO RAFAEL GONÇALVES SILVA VON ZUBEN1; VINICIUS COUTO MABILIA2; JULIANO CARDOSO NOVAES3; FABIO FERNANDES3; LUIZA ROCHA SILVA1; LORAINNY APARECIDA DE ALENCAR VEIGA1; VAGNER MANDRINI3; VIVIANE TIEMI HOTTA3; BARBARA MARIA IANNI3; LUCIANO NASTARI3; CHARLES MADY3; MURILO DE OLIVEIRA ANTUNES3;

(1) HOSPITAL SANTA MARCELINA - SAO PAULO - SP - BRASIL; (2) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL; (3) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Background/Introduction: Background: Hypertrophic cardiomyopathy (HCM) is a disease with a heterogeneous course, in which the identification of markers associated with worse clinical outcomes remains challenging. Atrial fibrillation (AF) is a frequent arrhythmia in this population and may influence relevant outcomes, such as symptoms and thromboembolic events. However, data from Brazilian cohorts are still limited. Objectives: Objective: To evaluate the correlation between AF and morbidity and mortality in patients with HCM Methods: Methods: Retrospective Brazilian cohort of patients with HCM, divided into two groups according to the presence or absence of AF, evaluating their characteristics and clinical outcomes. Continuous variables were presented as arithmetic means and standard deviation (SD), and categorical variables as absolute and relative frequencies. A p value < 0.05 was considered statistically significant. Results and Conclusions: Results: A total of 732 patients were included, 53.7% male, with a mean age of 54±16.5 years. Atrial fibrillation (AF) was present in 144 patients (19.7%). The AF group was older (60±13.4 vs. 52.5±16.9 years; p<0.001), had lower left ventricular ejection fraction (60.8±9.5% vs. 63.8±9.1%; p<0.001), and larger left atrial diameter (48±7.7 vs. 42.4±6.9 mm; p<0.001). Dyspnea symptoms were more frequent in the AF group (59.7% vs. 41.7%; p<0.001). Furosemide use was more common among patients with AF (31.3% vs. 9.5%), associated with a higher likelihood of use (OR 4.31; 95%CI: 2.78–6.68; p<0.001). The overall prevalence of stroke was 9.4%, being higher in the AF group (20.1% vs. 6.8%; p<0.001), with an approximately threefold increased risk (RR 2.96; 95%CI: 1.90–4.60; p<0.001). In the multivariate analysis, age, left atrial diameter, diuretic use, and presence of symptoms were independently associated with AF. Mortality for all causes was no statistic relevant (p=0,098), dispite more prevalente (20,9% vs 15,1%). Conclusions: AF was a frequent complication in HCM, associated with a worse clinical profile, greater symptom burden, and higher need for diuretics. Patients with AF had an approximately threefold higher risk of stroke, reinforcing its prognostic relevance in this population.

BIOELECTRICAL IMPEDANCE-DERIVED PHASE ANGLE FOR DETECTING MUSCLE WEAKNESS IN DECOMPENSATED HEART FAILURE: DIAGNOSTIC PERFORMANCE AND OPTIMAL CUTOFF

FLÁVIO ANDRADE CAMACHO1; THALITA VICENTE BRANDÃO1; RAÍLLA KLING DUTRA1; MARIA DE FÁTIMA MARTINS GIL DIAS2; VINÍCIUS MARINHO COELHO2; ANA BEATRIZ DOS SANTOS RIBEIRO3; ISABELLA DE MEDEIROS MORAES3; RAYANE FARIAS AUGUSTO PENNA3; ANDRÉ CASARSA MARQUES2; LEONARDO ANDRADE FERNANDES DE LUCA2; GABRIELLE DE SOUZA ROCHA1; RENATA FRAUCHES MEDEIROS1;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL; (2) REDE DOR - RIO DE JANEIRO - RJ - BRASIL; (3) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL;

Background/Introduction: Muscle weakness is a frequent complication in hospitalized patients with decompensated heart failure (DHF). Bioelectrical impedance–derived phase angle (PhA) reflects cellular integrity and muscle quality, but its role in identifying weakness during DHF remains unclear. Objectives: To evaluate the association between PhA and muscle weakness and its ability to discriminate against this condition in inpatients with DHF. Methods: A cross-sectional study with patients aged ≥60 years hospitalized for DHF. PhA was measured by bioelectrical impedance analysis. Muscle strength was evaluated using handgrip strength (HGS) and the Medical Research Council (MRC) scale. Diagnostic performance was evaluated using ROC curves and Youden's index. A significance level of p < 0.05 was adopted. This study was approved by the local Research Ethics Committee of the and all participants signed informed consent. Results and Conclusions: Seventy-three patients were analysed. Muscle weakness was identified in 37 (50.7%) patients using HGS and in 23 (31.5%) using the MRC scale. PhA did not differ between sexes (4.80 [1.30]° in men vs. 5.15 [1.70]° in women, p=0.407) and correlated positively with HGS in men only (rs=0.757, p<0.001). Higher PhA was independently associated with lower likelihood of muscle weakness even after adjustment for age and sex (OR 0.40, 95%CI 0.21–0.76, p=0.006 for HGS; OR 0.25, 95%CI 0.09–0.65, p=0.005 for MRC). PhA showed moderate discriminatory ability for detecting muscle weakness defined by HGS (AUC=0.742, 95% CI 0.628–0.855) and the MRC scale (AUC=0.788, 95% CI 0.681–0.895). An optimal cutoff of 4.95° yielded 86.9% sensitivity and 64.0% specificity. After adjustment for age and sex, discriminatory performance improved, particularly for the MRC scale (AUC=0.881, 95% CI 0.788–0.955), with a significant increase compared with the unadjusted model (p=0.033). These findings suggest that PhA is independently associated with muscle weakness in DHF and may serve as a practical bedside screening tool to enable earlier targeted interventions and mitigate functional decline during hospitalization.

CA-125 AS A BIOMARKER OF CONGESTION AND PROGNOSIS IN HEART FAILURE: A SYSTEMATIC REVIEW

LARA LORRAYNE FREITAS GOMES1; RENATA QUEIROZ CORREA1; ANDRÉ RODRIGUES DURÃES1;

(1) HOSPITAL GERAL ROBERTO SANTOS - SALVADOR - BA - BRASIL;

Background/Introduction: Heart failure (HF) is associated with high morbidity and mortality. CA-125 has emerged as a biomarker reflecting congestion and adverse outcomes, but its clinical role remains uncertain. Objectives: To evaluate the diagnostic and prognostic value of CA-125 in detecting congestion in acute or decompensated HF. Methods: Systematic review conducted according to PRISMA-DTA. Databases (PubMed, Embase, Web of Science, Cochrane, Google Scholar) were searched until December 2024 without language restriction. From 750 records identified, 35 studies were included after independent screening. Risk of bias was assessed using QUADAS-2 and evidence quality by GRADE. Results and Conclusions: Elevated CA-125 levels were consistently associated with congestion, particularly right-sided, and correlated with clinical, echocardiographic, and natriuretic peptide parameters. Higher CA-125 levels were associated with increased mortality (HR ≈1.68) and HF-related readmissions (HR ≈1.77). Patients with congestion showed significantly higher CA-125 levels (≈54.8 U/mL difference). Cut-off values varied across studies, though levels >35 U/mL were frequently associated with worse outcomes. Combined use with NT-proBNP improved risk stratification and may support therapeutic monitoring. CA-125 is a promising and widely available biomarker for congestion assessment and prognostic stratification in HF. However, variability in cut-off values and lack of standardization limit its routine clinical use. Further studies are needed to validate its integration into clinical practice.

Background/Introduction: Hypereosinophilic Syndrome (HES) is a rare multisystem disorder characterized by persistent hypereosinophilia and eosinophil-mediated organ damage. Cardiac involvement is the main cause of morbidity and mortality, progressing through necrotic, thrombotic, and fibrotic stages, potentially culminating in endomyocardial fibrosis (EMF). Multimodality imaging allows comprehensive evaluation of structural, functional, and tissue abnormalities. Objectives: To characterize cardiac involvement in patients with primary and idiopathic HES using cardiac biomarkers and multimodality imaging. Methods: This retrospective descriptive study included 14 patients with HES who underwent electrocardiography (ECG), 24-hour Holter monitoring, transthoracic echocardiography (TTE), and cardiac magnetic resonance (CMR). Clinical, laboratory, and imaging findings were analyzed descriptively. Results and Conclusions: Fourteen patients were included, predominantly male (71.4%), with a mean age of 47.9 years. Primary HES accounted for 35.7% of cases, whereas idiopathic disease represented 64.3%. Mean eosinophil count was 11,109.9/μL (median 5,684/μL). Cardiovascular involvement occurred in 71.4% of patients, with EMF as the most frequent manifestation (21.4%), followed by eosinophilic myocarditis, restrictive cardiomyopathy, and heart failure. Troponin elevation was observed in 61.5% of patients, while natriuretic peptides were elevated in 35%. ECG demonstrated sinus rhythm in all patients, with a mean heart rate of 73.4 ± 17.3 bpm. Main abnormalities included left atrial enlargement (50%), ventricular repolarization abnormalities (40%), and inactive areas suggestive of fibrosis (30%). Holter monitoring showed low arrhythmic burden, although non-sustained atrial tachycardia occurred in 35% and non-sustained ventricular tachycardia in two cases. TTE showed preserved LVEF (57.3 ± 12.4%), mitral regurgitation in 75%, diastolic dysfunction in 41%, and one intracardiac thrombus. CMR confirmed preserved LVEF (57.7 ± 9.6%), identified intracavitary thrombi in two patients and apical obliteration in three. LGE was absent in only 27.2% of cases, predominantly showing a subendocardial pattern (n=5), followed by mesocardial (n=2) and transmural enhancement (n=2). Patients with primary and idiopathic HES demonstrated high prevalence of cardiac abnormalities, predominantly EMF. LGE on CMR was frequent and associated with elevated biomarkers, electrocardiographic abnormalities, and arrhythmic events.

Table 1. Characteristics of the Study Population (n=14)

Variable	Value
Age (years), Mean ± SD (Median)	47.9 ± SD (47.5)
Sex, n (%)	
Male	10 (71.4%)
Female	4 (28.6%)
HES Etiology, n (%)	
Idiopathic	9 (64.3%)
Primary	5 (35.7%)
Geographic Distribution, n (%)	
Southeastern Region (São Paulo)	8 (57.1%)
Northeastern Region (BA, PE, CE)	6 (42.9%)
Laboratory Data	
Total eosinophils (/μL), Mean ± SD	11,109.9 ± 19,392.8
Total eosinophils (/μL), Median	5,684
Troponin > ULN, n (%) ± SD (% × ULN)	8/13 (61.5%) ± 21.9%
BNP (pg/mL), Mean ± SD	95.6 ± 26.2
BNP (pg/mL), Median	26.0
NT-proBNP (pg/mL), Mean ± SD	120.2 ± 107.9
NT-proBNP (pg/mL), Median	102.9
Cardiovascular Manifestations, n (%)*	
Endomyocardial fibrosis	3 (21.4%)
Restrictive cardiomyopathy	1 (7.1%)
Eosinophilic myocarditis	1 (7.1%)
Asymptomatic	4 (28.6%)
Other cardiac manifestations†	
History of myocardial infarction	3 (21.4%)
Heart failure (HF)	2 (14.2%)

Table 2. Subanalysis of Patients with Late Gadolinium Enhancement on CMR

Finding	LGE Subgroup (N=8)	Total Sample (N=14)
Elevated Troponin	62% (5/8)	61.5% (8/13)
Elevated BNP	75% (6/8)	35.7% (5/14)
Arrhythmias (Holter)	75% (6/8)	42.8% (6/14)
LAE on ECG	62% (5/8)	35.7% (5/14)
Repolarization/Inactive Areas	75% (6/8)	50.0% (7/14)

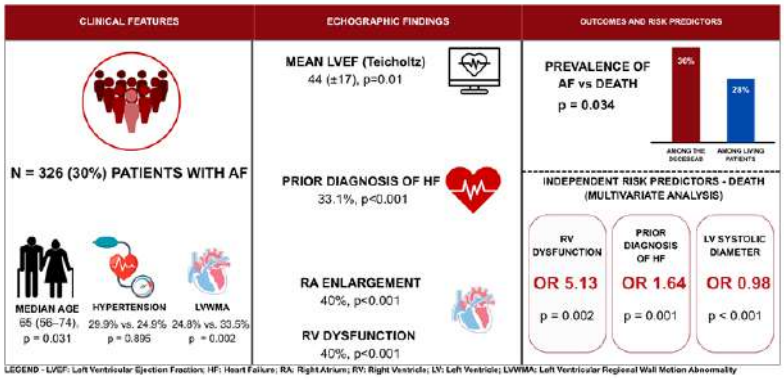
CIRRHOTIC CARDIOMYOPATHY AND MORTALITY IN CIRRHOTIC PATIENTS: A SYSTEMATIC REVIEW

LUCAS COELHO DA SILVA1; RENAN MIRANDA CORREA2; FRANCISCO JOSÉ DE ARAGÃO3; GIOVANNA BARCELOS FONTENELE PEREIRA1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (3) UNIVERSIDADE FEDERAL DO ACRE - RIO BRANCO - AC - BRASIL;



Background/Introduction: Cirrhotic cardiomyopathy (CCM) is a chronic cardiac dysfunction in cirrhotic patients without prior structural heart disease, characterized by diastolic dysfunction, attenuated systolic response under stress, and electrophysiological abnormalities. Redefined by the 2019 Berlin Criteria, CCM has emerged as an independent predictor of major adverse cardiovascular events following high-demand procedures such as TIPS placement and liver transplantation. Objectives: To evaluate whether cirrhotic cardiomyopathy is associated with higher overall mortality in cirrhotic patients compared to those without this diagnosis. Methods: Systematic review following PRISMA 2020 guidelines. Databases: PubMed, LILACS, and Embase. Descriptors: “cirrhotic cardiomyopathy,” “liver cirrhosis,” and “mortality.” Inclusion criteria: studies from 2006–2026 in English or Portuguese addressing CCM outcomes. Exclusion criteria: pediatric populations, unavailable full texts, studies without a control group or defined outcomes. Risk of bias assessed using RoB 2. Protocol registered in PROSPERO prior to data collection. Results and Conclusions: A total of 476 studies were identified; 25 met inclusion criteria, comprising ~8,500 patients. Among these, 18 were cohort studies and 7 were case-control studies. CCM prevalence ranged from 20% to 50% depending on diagnostic criteria. In most studies, CCM was associated with increased all-cause mortality compared to cirrhotic patients without this condition, particularly during TIPS insertion and liver transplantation. CCM was also consistently linked to higher incidence of major adverse cardiovascular events. Risk of bias: 12 studies showed low risk, 9 presented some concerns, and 4 had high risk. Evidence supports an association between CCM and increased mortality, though heterogeneity in study design and diagnostic definitions limits definitive conclusions. Prospective studies applying standardized criteria are warranted.

CLINICAL AND ECHOCARDIOGRAPHIC PREDICTORS OF ATRIAL FIBRILLATION AND ITS ASSOCIATION WITH MORTALITY IN PATIENTS HOSPITALIZED FOR HEART FAILURE: A RETROSPECTIVE COHORT STUDY

RODRIGO RUFINO PEREIRA SILVA1; MARCELA VASCONCELOS MONTENEGRO2; CAROLINA JERÔNIMO MAGALHÃES1; LEONCIO BEM SIDRIM1; LEURIDAN CAVALCANTE TORRES1; CAIO ATANASIO DE MORAIS RAMOS1; JOÃO ROBERTO MACIEL MARTINS1;

(1) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL;

Background/Introduction: Atrial fibrillation (AF) is the most common sustained arrhythmia, affecting approximately 1.5 million Brazilians. This condition is associated with increased morbidity and mortality, making it a major public health problem. Therefore, identifying predictors of AF in the general population is essential for risk stratification and prevention of complications in susceptible individuals. Objectives: To evaluate clinical and echocardiographic variables associated with AF and to investigate their association with in-hospital mortality in the study population. Methods: This retrospective cohort study was approved by the local ethics committee (CAAE 75341723.1.0000.5192) and analyzed patients hospitalized at a tertiary care center for decompensated heart failure (HF), with and without AF. The Mann-Whitney U test was used for quantitative variables, and the chi-square test or Fisher’s exact test was applied for qualitative variables. To identify independent predictors of AF, logistic regression analysis was performed with multicollinearity assessment and stepwise backward selection, with results expressed as odds ratios (OR). A significance level of 5% was adopted. Results and Conclusions: A total of 1,100 patients were evaluated, of whom 326 (30%) had AF, with a mean age of 63±15 years. The most common etiologies were ischemic (26%) and valvular (21%). Compared with patients without AF, those with AF were older (65±14 years; p=0.031), more frequently had a prior diagnosis of HF (33.1% vs. 22.1%; p<0.001), and was not associated with diabetes mellitus or hypertension. In logistic regression, the final model showed a good predictive performance, with a Nagelkerke pseudo-R^2 of 0.702, 85.1% accuracy, 92.1% specificity, and 72.8% sensitivity, and the following remained independently associated with AF: Previous diagnosis of heart failure (OR = 4.71 ; 95% CI 1.83-12.2; p=0.001), right ventricular dysfunction (OR = 5.13; 95%CI 1.80-14.59; p=0.002), and absence of left ventricular diastolic dysfunction (OR = 0.34; 95%CI 0,13-0,87; p=0.025). Regarding prognosis, patients with AF was associated with higher crude mortality (24%; p=0.010). However, in the multivariable analysis for death, AF did not remain an independent predictor, whereas prior diagnosis of heart failure [OR = 1.64 (1.07-2.52); p=0.022], moderate/severe mitral disease [OR 1.93 (1.3-2.8); p<0.001], and left ventricular systolic diameter (OR = 0.98; 95% IC 0.97-0.99; p=0.027) remained associated with the outcome.

COMORBIDITY BURDEN AND FUNCTIONAL CLASS DETERMINE REDUCED SURVIVAL IN PATIENTS WITH HYPERTROPHIC CARDIOMYOPATHY

LUIZA ROCHA SILVA1; PAULO RAFAEL GONÇALVES2; VINICIUS COUTO MABILIA2; FABIO MARIA FERNANDES2; LORAINNY APARECIDA ALENCAR VEIGA3; VIVIANE T HOTTA2; MURILO MARIA ANTUNES2; BARBARA MARIA IANNI2; VAGNER MANDRINI2; LUCIANO NASTARI4; CHARLES MADY2; JULIANO NOVAES CARDOSO2;

(1) HOSPITAL SANTA MARCELINA - SAO PAULO - SP - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (3) FACULDADE SANTA MARCELINA - SÃO PAULO - SP - BRASIL; (4) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - BA - BRASIL;

Background/Introduction: Hypertrophic cardiomyopathy (HCM) presents a heterogeneous clinical course and may progress with heart failure, atrial fibrillation (AF), thromboembolic events, and cardiovascular death. The presence of cardiovascular comorbidities and worsening functional class may act as important prognostic markers. However, national data correlating comorbidity burden, functional class, and survival remain limited. Objectives: To evaluate the association between functional class, clinical comorbidities, and mortality in patients with HCM followed at a Brazilian tertiary care center. Methods: Retrospective study involving patients diagnosed with HCM followed for up to 15 years. Clinical characteristics, comorbidities, New York Heart Association (NYHA) functional class, presence of AF, and clinical outcomes were analyzed. Survival analysis was performed using the Kaplan-Meier method. Results and Conclusions: A total of 732 patients were included, with a mean age of 54±16.5 years, predominantly male (53.7%). Most patients were classified as NYHA I (54.7%) or II (32.2%). A high prevalence of comorbidities was observed, including systemic arterial hypertension (45.1%), dyslipidemia (45.1%), diabetes mellitus (25%), and AF (19.7%). More than 70% of patients were overweight or obese. During follow-up, 110 deaths occurred. Patients with AF had a worse functional profile, with lower prevalence of NYHA I (40.3% vs. 58.3%; p<0.001) and higher frequency of NYHA III (18.1% vs. 10.2%; p=0.009), in addition to higher prevalence of systemic arterial hypertension, diabetes mellitus, and smoking. Kaplan-Meier analysis demonstrated progressive reduction in survival according to worsening functional class, with poorer prognosis among NYHA III-IV patients (log-rank p<0.001). Additionally, AF was associated with a higher risk of stroke/transient ischemic attack (RR 2.96; 95%CI 1.90–4.60; p<0.001). Patients with HCM present a high burden of comorbidities even in less symptomatic stages of the disease, and worsening functional class constitutes an important prognostic marker associated with reduced survival.

COMPARATIVE OUTCOMES OF HYPOTHERMIC OXYGENATED PERFUSION VERSUS STATIC COLD STORAGE IN HEART TRANSPLANTATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

LUCAS RIQUIERI NUNES1; LEONARDO BRAGA GONÇALVES2; ANA CLARA VITORINO DE OLIVEIRA2; MARIANA DA COSTA ROCHA1; VICENTE CASTOR BRITO3; DAVI FREITAS TENÓRIO1;

(1) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE FEDERAL DE UBERLÂNDIA - UBERLÂNDIA - MG - BRASIL; (3) UFCG - CAMPINA GRANDE - PB - BRASIL;

Background/Introduction: Primary graft dysfunction (PGD) is a leading cause of early morbidity after orthotopic heart transplantation, driven by ischaemia-reperfusion injury during ex vivo preservation. Static cold storage (SCS) — the global default for over four decades — provides no continuous metabolic support and limits safe cold ischaemia to approximately four hours, beyond which PGD risk increases sharply. Hypothermic oxygenated perfusion (HOPE) replenishes mitochondrial substrate and washes accumulated reactive oxygen species precursors, potentially attenuating reperfusion injury. A recent network meta-analysis (Kim et al., 2025) identified only two studies directly comparing HOPE with SCS; awareness of a third eligible comparative report not captured in that synthesis motivated a dedicated systematic review, which ultimately identified four eligible studies. Objectives: To provide an updated, prospectively registered synthesis of comparative evidence for HOPE versus SCS in orthotopic heart transplantation, with primary focus on PGD incidence and post-transplant mortality. Methods: PRISMA 2020 systematic review (PROSPERO CRD420251071495). PubMed, Embase, and CENTRAL were searched without restrictions; backward citation searching was performed to minimise risk of missing older reports. Two reviewers independently screened records, extracted data, and assessed risk of bias (RoB-2 for randomised; ROBINS-I for non-randomised studies). Risk ratios (RR) were pooled using a DerSimonian-Laird random-effects model on the log-RR scale. Results and Conclusions: Four studies (one RCT; three non-randomised; N = 423 transplants) met eligibility criteria. HOPE was associated with a significant reduction in any PGD compared with SCS (pooled RR 0.45, 95% CI 0.25–0.80; p = 0.007; I^2 = 0%), representing an approximately 55% relative risk reduction. Pooled estimates for severe LV-PGD (RR 0.63, 95% CI 0.10–3.84), 30-day mortality (RR 1.20, 95% CI 0.25–5.84), and longer-term mortality (RR 1.24, 95% CI 0.57–2.70) were non-significant. ECMO requirement, troponin release, and post-transplant LV function could not be meta-analysed due to data sparsity. HOPE is associated with a consistent, statistically significant reduction in PGD without detected heterogeneity; however, mortality benefit remains inconclusive. Adequately powered trials with standardised reporting of ECMO, biomarker, and DCD outcomes are required before HOPE can be recommended as standard of care.

COMPARATIVE TRANSCRIPTOMIC ANALYSIS OF HUMAN MYOCARDIUM HIGHLIGHTS DISEASE-SPECIFIC MOLECULAR NETWORKS IN ISCHAEMIC AND DILATED CARDIOMYOPATHY

LAURA SCHMITT JURUENA SASSEN1; ULYSSES RAZIA CAVALCANTI1; CAMILA BEATRIZ FACHINI1; GABRIELA CARMINATI LINO1; GABRIEL MELO ROTH DE OLIVEIRA1; LAURA HECK ZETTERMANN1; MARIA LAURA ZSCHORNACK STRELOW1; ROBERTA SCHULTZ MACHADO DOS SANTOS1; NATASHA MALGAREZI2; VINICIUS MOLLING2; MARCELO RAVA DE CAMPOS3; MARCUS VINICIUS SEHL FERREIRA1;

(1) UNISINOS - SÃO LEOPOLDO - RS - BRASIL; (2) UFCSPA - PORTO ALEGRE - RS - BRASIL; (3) HOSPITAL MOINHOS DE VENTO - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: Ischaemic and dilated cardiomyopathies are leading causes of advanced heart failure. Current management relies on polypharmacy without directly addressing underlying molecular mechanisms. Bioinformatic analysis of large-scale genomic datasets (e.g., GSE42955 from GEO) can identify dysregulated molecular pathways and potential pharmacogenetic targets for personalised risk stratification and therapeutic strategies. Objectives: To evaluate the different gene expression patterns in human hearts from patients with ischemic cardiomyopathy, dilated cardiomyopathy and normal controls. Methods: We obtained gene expression data under the identification number GSE42955 from Gene Expression Omnibus (GEO) datasets were analysed using the GEO2R platform in which patients were divided into three groups: (i) ischaemic, (ii) dilated, and (iii) normal. The data were then analysed using Venn diagrams to evaluate the overlap of significantly expressed genes among the groups, and volcano plots to assess statistical significance in relation to the magnitude of change, which are useful for visualising different patterns of gene expression. Results and Conclusions: The Venn Diagram shows that 7 genes overlap (SCN2B, RHOJ, TP53INP2, SNRPB, ETS2, SELM, ELOVL7) when we compare the Normal vs Dilated and Ischemic vs Normal, but no genes overlap when analysing these groups in comparison with the dilated vs ischemic or even when comparing all groups. In the Volcano Plot, when comparing the ischemic with the normal group, 5 genes are underexpressed and 2 genes are overexpressed and when comparing the dilated with normal group, 41 genes are underexpressed and 11 genes are overexpressed. Our findings indicate that dilated cardiac cells exhibited greater changes in gene expression compared with normal cardiac cells. Ischaemic cells also exhibited differences in gene expression, although involving fewer genes. An unexpected finding was that no significantly overlapping genes were identified between dilated and ischaemic cardiac cells. Publicly available datasets enable researchers to use new analytical tools to existing data, thereby generating new conclusions or complementing those already reported in the literature. Overall, this study highlights the potential of bioinformatics-driven genetic analysis as a tool for risk stratification and prevention of disease progression. The identification of key regulatory genes also supports their relevance as pharmacogenetic targets, enabling the development of personalised therapeutic strategies.

DAPA-DECONGEST: DIURETIC EFFICIENCY AND RENAL SAFETY OF DAPAGLIFLOZIN DURING HOSPITALIZATION FOR ACUTELY DECOMPENSATED HEART FAILURE — A REAL-WORLD BEFORE–AFTER OBSERVATIONAL STUDY

CARLOS AURÉLIO SANTOS ARAGÃO1; LUCAS GUIMARÃES DA ROCHA2; LUIZ FLAVIO ANDRADE PRADO1; ROBERTO CINTRA DE AZEVEDO ARAGÃO1; JULIANE DANTAS SEABRA GARCEZ1; MILENA DOS SANTOS BARROS CAMPOS1; WILLIASMIN BATISTA DE SOUZA1; LUÍS AUGUSTO SOUZA DE CARVALHO1; AIRTON SALVIANO DE SOUSA JÚNIOR1; TATIANA BASTOS ALMEIDA1; DOUGLAS NORTON SANTOS ARAGAO3; JOSÉ AUGUSTO SOARES BARRETO FILHO1;

(1) UNIVERSIDADE FEDERAL DE SERGIPE - ARACAJU - SE - BRASIL; (2) CENTRO UNIVERSITARIO TIRADENTES- UNIT - ARACAJU - SE - BRASIL; (3) UNIVERSIDADE TIRADENTES (UNIT) - ARACAJU - SE - BRASIL;

Background/Introduction: In patients hospitalized for acutely decompensated heart failure (ADHF), early and effective decongestion is directly associated with symptomatic improvement and short-term prognosis. Although sodium-glucose cotransporter 2 inhibitors (SGLT2i) reduce long-term clinical outcomes in heart failure, the impact of dapagliflozin on early diuretic efficiency during hospitalization remains to be fully elucidated in real-world clinical practice settings. Objectives: To evaluate the impact of in-hospital dapagliflozin on early diuretic efficiency and renal safety in patients hospitalized for ADHF, comparing consecutive cohorts before and after institutional implementation of inpatient dapagliflozin use. Methods: Retrospective, observational cohort study with a before-after design including consecutive patients hospitalized for ADHF. Primary endpoint: early diuretic efficiency (cumulative urine output within 24 hours per 40 mg furosemide equivalent). Secondary endpoint: worsening renal function (WRF), defined as serum creatinine increase ≥0.3 mg/dL or ≥1.5 times baseline. Continuous variables were compared using non-parametric methods. Results and Conclusions: A total of 234 patients were included: 112 without dapagliflozin and 122 with dapagliflozin. The median 24-hour diuretic efficiency was numerically higher in the dapagliflozin group (564 vs. 452 mL/40 mg furosemide), corresponding to an absolute increase of 112 mL (~25% relative difference); however, this did not reach statistical significance (p=0.08). The proportion of patients achieving diuretic efficiency above the median was similar between groups (42.6% vs. 41.1%; OR 1.07; 95% CI 0.63-1.79; p=0.81). Worsening renal function occurred in 18 patients (14.8%) in the dapagliflozin group and 26 patients (23.2%) in the control group. Despite a lower numerical incidence in the dapagliflozin group, no statistically significant difference was observed (OR 0.57; 95% CI 0.30-1.07; p=0.097). In patients hospitalized for ADHF, the use of in-hospital dapagliflozin was not associated with statistically significant differences in early diuretic efficiency or the occurrence of worsening renal function compared to standard of care. These findings reinforce that the clinical benefits of SGLT2 inhibitors in heart failure are not limited to their diuretic effect but reflect broader cardioprotective mechanisms.

DIGITAL TOOL FOR HEMODYNAMIC DATA RECORDING IN PULMONARY VASOREACTIVITY TESTING: VALIDATION AND WORKFLOW OPTIMIZATION

ERLEI BISPO1; LUÍSA REIS2; HELENA BEZERRA2; CRISTIANO BERARDO1; VERONICA MONTEIRO1;

(1) INSTITUTO DE MEDICINA INTEGRAL PROFESSOR FERNANDO FIGUEIRA - IMIP - RECIFE - PE - BRASIL; (2) FPS - FACULDADE PERNAMBUCANA DE SAUDE - RECIFE - PE - BRASIL;

Background/Introduction: Pulmonary vasoreactivity testing (PVRT) is essential for evaluating cardiac transplant candidates and critically ill patients with pulmonary hypertension. However, hemodynamic data from the Hemosphere® monitor are still recorded manually on paper flowcharts, a process prone to transcription errors, data loss, and delays. Objectives: We developed a mobile app for real-time recording and automatic calculation of hemodynamic variables during PVRT and evaluated its agreement with the standard monitor, reliability, and impact on recording time. Methods: The Pulmonary Vasoreactivity Test App was built on the AppSheets® platform with direct integration to Google Sheets. In the validation phase, we analyzed 42 PVRT forms from patients evaluated for heart transplantation at Recife (2023–2025). Agreement was assessed using absolute percentage error (APE), intraclass correlation coefficient (ICC), and Bland-Altman plots for key variables (TPG, SVR, and PVR). In the prospective phase, 10 experienced ICU physicians completed paired manual and digital flowcharts based on a standardized case, with completion time measured and compared using a paired t-test. The app was registered with INPI (BR512025005898-5). Results and Conclusions: Absolute percentage error was ≤5% in 100% of observations, with a median error of 0%. ICC showed excellent to near-perfect agreement for most variables (0.969–1.000), except initial PVR, which was explained by a single manual transcription error upon reanalysis. Bland-Altman plots confirmed minimal bias and clinically acceptable limits of agreement. Digital flowchart completion was significantly faster than manual recording (mean 116 ± 20 s vs 248 ± 43 s; p < 0.001), representing an average 53% time reduction (approximately 20 minutes saved per completed exam). The app demonstrated high numerical agreement with the Hemosphere® monitor and substantially reduced documentation time. It replaces the vulnerable manual recording step with an automated, standardized, and auditable workflow while also calculating additional hemodynamic parameters not directly provided by the monitor. This tool has strong potential to improve safety and efficiency in pulmonary vasoreactivity testing.

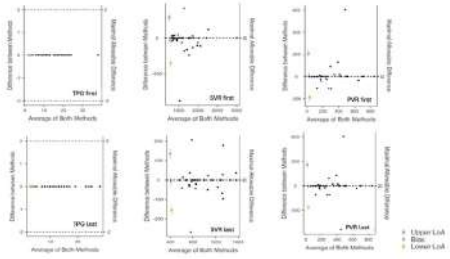

Figure 1. Agreement analysis between derived values obtained from the Hemosphere® monitor and those automatically calculated by the application for TPG, SVR, and PVR at the first and last measurements of the pulmonary vasoreactivity test.

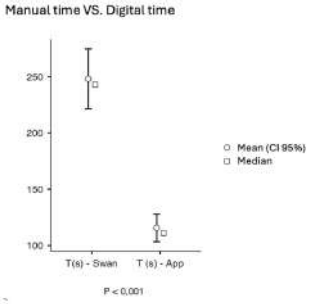

Figure 2. Paired comparison of flowchart completion time between the manual method and the application (n = 10).

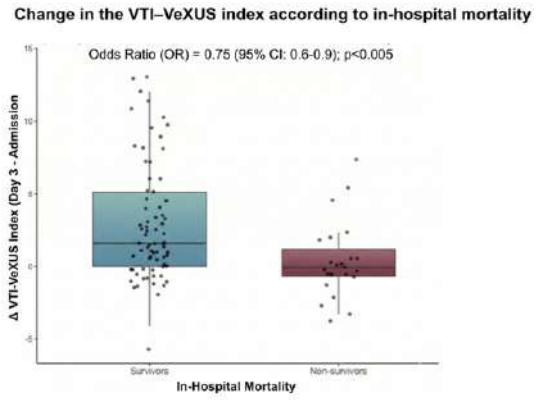
DO DIFFERENCES IN GUIDELINE-DIRECTED MEDICAL THERAPY EXPLAIN EDUCATIONAL INEQUALITIES IN OUTCOMES AFTER ACUTE HEART FAILURE?

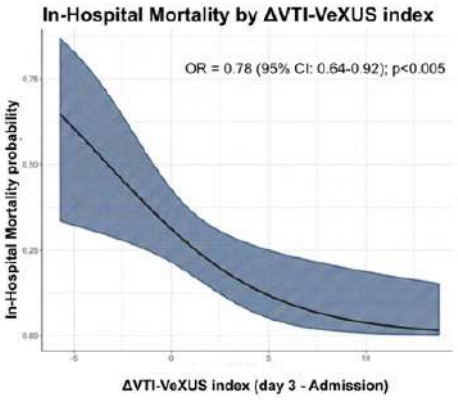
GUSTAVO SAROT PEREIRA DA CUNHA1; RAFAEL MORETTI2; ANA CAROLINA KRACHINSKI DE ANDRADE GAMA2; MATHEUS DUARTE BISSA2; JORGE DAIKUBARA NETO2; KAROLINE VERCKA3; LUCAS MULLER PRADO3; RAPHAEL DEA CIRINO2; WILSON NADRUZ4; FABIO PAPA TANIGUCHI5; ODILSON SILVESTRE6; MIGUEL MORITA FERNANDES-SILVA2;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARANÁ - CURITIBA - PR - BRASIL; (3) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (4) UNICAMP - CAMPINAS - MT - BRASIL; (5) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL; (6) UNIVERSIDADE FEDERAL DO ACRE - RIO BRANCO - AC - BRASIL;

Background/Introduction: Lower educational attainment is consistently associated with worse outcomes after hospitalization for acute heart failure (AHF). Whether disparities in guideline-directed medical therapy (GDMT) prescription and optimization explain these differences remains unclear. Objectives: We aimed to investigate whether disparities in treatment prescription or therapy optimization explain the association between education level and post-discharge mortality following AHF hospitalization. Methods: We conducted a prospective cohort study including patients hospitalized with AHF at 19 public hospitals within the Brazilian Unified Health System (SUS) between 2016 and 2022. GDMT prescription (ACEi/ARB/ARNI, beta-blockers, and mineralocorticoid receptor antagonists) was assessed at discharge and during follow-up at 30 days and 6 months. “Three-drug therapy” was defined as the concurrent use of all three classes. Therapy optimization was defined as dose up-titration, addition of a GDMT class, or switch to ARNI during follow up. The association between education level and 180-day all-cause mortality was assessed using multivariable Cox models. Mediation was evaluated using the four-way decomposition method to quantify the proportion of the association explained by GDMT prescription and early optimization. A sensitivity analysis was performed in patients with LVEF ≤40%. Results and Conclusions: Among 2,425 patients (mean age 60.7±15.0 years; 41% women; LVEF 41±17%), 274 deaths (11.3%) occurred over a median follow-up of 180 days. Lower educational attainment was independently associated with higher mortality (adjusted HR 1.39 per level decrease; 95% CI 1.13–1.73; p=0.002). Patients with lower education were less likely to receive three-drug therapy at discharge (42.9% vs 45.3% vs 61.5% vs 54.7%; p-for-trend=0.001) and less likely to undergo early therapy optimization at 30 days (15.9% vs 20.5% vs 22.4% vs 23.5%; p-for-trend=0.04). However, mediation analysis showed that differences in GDMT prescription and early optimization accounted for only a small and non-significant proportion of the association between education and mortality (2.4%, 95% CI −2.7 to 7.4; p=0.359 and 0.3%, 95% CI −1.3 to 1.8; p=0.757, respectively). Findings were consistent in patients with LVEF ≤40%. Disparities in GDMT prescription and early optimization do not explain the excess mortality observed in patients with lower education in the vulnerable period after acute HF, suggesting that other socioeconomic or care-related factors drive these differences



18055



EARLY IMPROVEMENT IN THE VTI–VEXUS INDEX IDENTIFIES SURVIVAL IN ACUTE DECOMPENSATED HEART FAILURE

MARINA PETERSEN SAADI1; KALEB PINTO SPANNENBERGER1; PHILIPPE ROLA2; GUILHERME HEIDEN TELO1; GUSTAVO PAES SILVANO1; GUILHERME PINHEIRO MACHADO1; RENATO FERRAZ MAULAZ1; HENRIQUE CABRAL SCHERER1; LUIS EDUARDO PAIM ROHDE1; ANDERSON DONELLI SILVEIRA1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL; (2) SANTA CABRINI HOSPITAL, MONTREAL - CANADA;

Background/Introduction: The VTI–VeXUS index integrates arterial flow (LVOT-VTI) and venous congestion (VeXUS score) into a single haemodynamic metric. While proof-of-concept data in septic shock suggest potential prognostic value, its ability to reflect treatment response in acute decompensated heart failure (ADHF) is unknown. Objectives: To evaluate whether early dynamic changes in the VTI–VeXUS index are associated with in-hospital mortality in patients admitted with ADHF. Methods: We analysed a prospective cohort of patients hospitalized for ADHF who underwent echocardiographic assessment of LVOT-VTI and VeXUS at admission and after 72 hours. The VTI–VeXUS index was calculated as VTI/(VeXUS+1). Dynamic change (ΔVTI–VeXUS) was analysed as a continuous variable and in multivariable logistic regression adjusting for clinical severity markers. The primary outcome was in-hospital mortality. Results and Conclusions: Among 114 patients, survivors demonstrated greater improvement in VTI–VeXUS over 72 hours compared with non-survivors. Each unit increase in ΔVTI–VeXUS was associated with a 25% reduction in the odds of in-hospital mortality (OR 0.75, 95% CI 0.60–0.90, p<0.05) and remained independently predictive after adjustment (OR 0.79, 95% CI 0.63–0.94, p=0.01). ROC analysis showed moderate discrimination (AUC≈0.71) for in-hospital mortality, and predicted mortality declined progressively with increasing ΔVTI–VeXUS. Conclusion In ADHF, early trajectory of the VTI–VExUS index identifies effective hemodynamic response and independently predicts survival. Serial assessment may provide an objective bedside target to guide decongestion therapy.

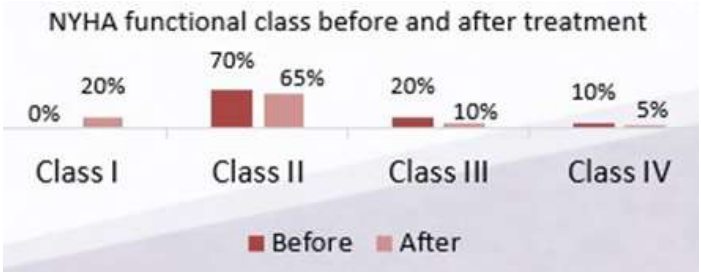
EARLY USE OF SACUBITRIL/VALSARTAN AFTER ACUTE HEART FAILURE STABILIZATION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED TRIALS

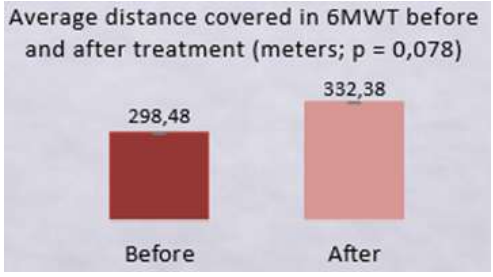
RAFAEL FORTES LOCATELI1; PEDRO HENRIQUE TAVARES FOGAÇA2; CAMILA SALES FAGUNDES2; GABRIEL GRANDO ALVES2; FERNANDA LAVARDA SCHEINPFLUG2; HEITOR FERRARI DA SILVA2; JOÃO CÂNDIDO TAVARES FOGAÇA3; MATEUS DINIZ MARQUES2;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL; (2) UNIVERSIDADE FEDERAL DE SANTA MARIA - SANTA MARIA - RS - BRASIL; (3) UNIVERSIDADE FRANCISCANA - SANTA MARIA - RS - BRASIL;

Background/Introduction: The role of initiating sacubitril/valsartan shortly after stabilization from acute heart failure (AHF) remains to be clearly established. Objectives: This study aimed to evaluate the effects of sacubitril/valsartan on biomarkers and clinical outcomes compared with angiotensin-converting enzyme inhibitors (ACEIs) or angiotensin receptor blockers (ARBs). Methods: A systematic search of PubMed, Embase, and the Cochrane Central Register was performed to identify randomized controlled trials enrolling hemodynamically stabilized patients after AHF. Sacubitril/valsartan was compared with ACEIs or ARBs. The primary outcome was the change in N-terminal pro–B-type natriuretic peptide (NT-proBNP) at 8 weeks. Secondary outcomes included all-cause mortality and adverse events (worsening renal function, hyperkalemia, and symptomatic hypotension). Ratio of change in NT-proBNP and odds ratios (OR) with 95% confidence intervals (CI) were pooled using a random-effects model. The study protocol was registered on PROSPERO (CRD42024599541). Results and Conclusions: Results: Three randomized trials including 1,723 patients were analyzed; 856 (49.7%) received sacubitril/valsartan. Compared with ACEIs/ARBs, sacubitril/valsartan resulted in a significantly greater reduction in NT-proBNP at 8 weeks (ratio of change 0.78; 95% CI 0.69–0.87; p < 0.05). There were no significant differences between groups in worsening renal function (OR 0.85; 95% CI 0.57–1.25; p = 0.40), hyperkalemia (OR 1.12; 95% CI 0.84–1.51; p = 0.44), symptomatic hypotension (OR 1.22; 95% CI 0.73–2.02; p = 0.45), all-cause mortality (OR 0.95; 95% CI 0.53–1.69; p = 0.85), or serious adverse events (OR 1.11; 95% CI 0.90–1.37; p = 0.35). Conclusion: Initiation of sacubitril/valsartan following stabilization from AHF is associated with a greater reduction in NT-proBNP at 8 weeks compared with ACEIs/ARBs, without significant differences in mortality or adverse events.



19901



EFFECT OF INTRAVENOUS REPLETION OF FERRIC HYDROXIDE SUCROSE ON THE FUNCTIONAL CAPACITY OF PACIENTS WITH HEART FAILURE

IZABELE AZEVEDO1; ANNA CAROLINE ULSON COSTA1; EDUARDA NAKOULA1; ISADORA MANSUR CASTRO1; MATHEUS JAREK1; SARAH BERNARD GUTTMAN1; ANA KARYN EHRENFRIED FREITAS1;

(1) UNIVERISADE POSITIVO - CURTIBA - PR - BRASIL;

Background/Introduction: Iron deficiency (ID), in patients with heart failure (HF) is associated with reduced functional capacity and impaired quality of life. Oral iron therapy has limited absorption, whereas intravenous iron is more effective. However, most clinical trials have used ferric carboxymaltose, a high-cost formulation, which limits its use in Brazilian public healthcare settings. In this context, iron hydroxide sucrose emerges as a more affordable alternative, although real-world data on its use are still limited. Objectives: To evaluate the effect of intravenous iron hydroxide sucrose repletion on functional capacity and iron parameters in patients with HF and ID. Methods: This prospective study included stable outpatients with HF who were receiving optimised therapy but remained symptomatic, and who had ID - defined as ferritin <100 ng/mL or ferritin between 100–300 ng/mL with transferrin saturation <20%. Patients received intravenous iron hydroxide sucrose replacement and were evaluated at baseline and 30 days after . Functional capacity was assessed using the six-minute walk test (6MWT) and NYHA functional class. Serum ferritin levels and transferrin saturation were also measured. Results and Conclusions: Twenty patients were included (mean age 65.8 years; 60% female), predominantly with reduced left ventricular ejection fraction. After treatment, ferritin levels increased significantly (Δ +132.2 ng/mL; 95% CI 70.4–193.9; p < 0.001). NYHA functional class improved significantly (p = 0.011), with a shift towards lower functional classes. The six-minute walk distance increased after the intervention, with no statistically significant difference between etiologies. Among patients with ischemic heart failure (n = 12), the mean variation in the 6MWT was 34.9 meters, while among those with non-ischemic etiology (n = 8), the mean variation was 32.5 meters, demonstrating a similar functional response between groups. A clinically relevant gain (≥30 m) in 6MWT distance was observed in 45% of patients. Baseline ferritin levels were not correlated with functional improvement. Conclusions: Intravenous iron hydroxide sucrose repletion was associated with significant improvement in iron stores and functional class, with a clinically meaningful gain in functional capacity in nearly half of patients. These findings support intravenous iron as an effective and safe therapeutic strategy in patients with HF and iron deficiency.

18022

EFFECT OF SACUBITRIL/VALSARTAN ON THE MANAGEMENT OF CLINICAL OUTCOMES IN PATIENTS WITH HEART FAILURE AND RESISTANT ARTERIAL HYPERTENSION

KEVEN GONÇALVES GONÇALVES1; LEONARDO GOUVEA DE OLIVEIRA2; STER MARQUES DE LIMA SILVA2; LUANA KAORI SAKAGUCHI2; RENATO GARCIA LISBOA BORGES2; LUCAS GABRIEL CARDOSO DE SOUZA2; RICARDO ESTEVÃO MATOS SOUTO2; HUGO FEREEIRA MENDES2;

(1) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Background/Introduction: Heart failure with preserved ejection fraction (HFpEF) is a systemic clinical syndrome, caused by structural and functional changes in the heart, caused mainly by resistant arterial hypertension (RAH). However, this syndrome has limited therapeutic options, with few drugs demonstrating a relevant impact. Sacubitril-valsartan is a new therapeutic class that acts by inhibiting angiotensin-neprilisin receptors (ARNI). It has great benefits in the treatment of other groups of heart failure (HF). However, its effectiveness in HFpEF is still questioned. Objectives: To analyze the effectiveness of treatment with Sacubitril-valsartan in reducing mortality, reducing blood pressure and improving quality of life in patients with HFpEF and HAR. Methods: This is a systematic review developed according to the PRISMA protocol. The search considered articles published on the PubMed, Cochrane and EMBASE platforms. The review was guided by the PICO strategy and the DeCS/MeSH descriptors were used. Randomized clinical trials and observational studies published between 2021 and 2026, in Portuguese, English and Spanish, were included. Articles not available in full, studies with a high risk of bias, evaluated by the RoB 2.0 tool, were excluded. Results and Conclusions: 7 studies with 7,006 participants were included, 52% female. Sacubitril/valsartan has reduced vascular mortality, hospitalization for heart failure and new cardiovascular events, in addition to ensuring greater reducing control of blood pressure when compared to ACE inhibitors/ABR. In addition, sacubitril/valsartan obtained more favorable outcomes when compared to ACE inhibitors/ABRs in quality of life scores. These are the NYHA and KCCQ. Therefore, it is concluded that the set of evidence points to sacubitril-valsartan as a promising, safe and effective alternative, especially in individuals with a higher burden of cardiovascular risk.

21871

EFFICACY AND SAFETY OF GLP-1 RECEPTOR AGONISTS AND DUAL GIP/GLP-1 AGONISTS IN PATIENTS WITH OBESITY AND HEART FAILURE WITH PRESERVED EJECTION FRACTION: A SYSTEMATIC REVIEW

ARTHUR CHEDE CHAVES REIS1; FELLIPE DEBACKER LADEIRA1; IVENS MURAD GARCIA MAGALHÃES1; DANIEL TAGLIATE VIDIGAL DE ALMEIDA1;

(1) UFJF - JUIZ DE FORA - MG - Brasil;

Background/Introduction: Heart failure with preserved ejection fraction (HFpEF) associated with obesity is an increasingly prevalent phenotype characterized by high morbidity and limited response to conventional therapies. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) and dual GIP/GLP-1 receptor agonists have emerged as promising therapeutic options in this setting. Objectives: To systematically evaluate the efficacy and safety of GLP-1 RAs and dual GIP/GLP-1 receptor agonists in adults with HFpEF and obesity, focusing on clinical, functional, quality-of-life, and safety outcomes. Methods: This systematic review followed PRISMA 2020 and Cochrane Handbook recommendations. Searches were conducted in PubMed/MEDLINE, Embase, Web of Science, Cochrane Library, and Scopus. Randomized placebo-controlled trials including adults (≥18 years) with HFpEF (LVEF ≥45%) and obesity (BMI ≥30 kg/m²) treated with semaglutide, liraglutide, tirzepatide, dulaglutide, or GLP-1/GIP analogs were eligible. Risk of bias was assessed using the Cochrane RoB 2 tool. Due to heterogeneity, data synthesis was primarily narrative. Results and Conclusions: Of 537 records screened, 22 studies were included, comprising 3 primary RCTs and 19 prespecified or post-hoc secondary analyses. The main RCTs were STEP-HFpEF (semaglutide 2.4 mg; N=529; 52 weeks), STEP-HFpEF DM (semaglutide 2.4 mg in type 2 diabetes; N=616; 52 weeks), and SUMMIT (tirzepatide ≤15 mg; N=731; median follow-up 104 weeks). Semaglutide significantly improved KCCQ-CSS scores (+7.8 and +7.3 points; p<0.001), reduced body weight (−10.7% and −6.4%; p<0.001), and increased 6-minute walk distance (+20.3 m and +14.3 m). A pooled analysis of semaglutide trials demonstrated reduced risk of cardiovascular death or worsening HF (HR 0.69; 95% CI 0.53–0.89; p=0.0045). Tirzepatide also reduced the composite of cardiovascular death or worsening HF (HR 0.62; 95% CI 0.41–0.95; p=0.026), while improving KCCQ-CSS and functional capacity. Gastrointestinal adverse events were more frequent with active treatment but were generally mild, and serious adverse events were numerically lower in treatment groups. Incretin-based therapies, particularly semaglutide and tirzepatide, demonstrate significant benefits in patients with HFpEF and obesity, improving symptoms, quality of life, functional capacity, and HF outcomes with acceptable safety. These agents represent promising therapeutic strategies for this high-risk population.

Table 1 — Characteristics of Included Primary Studies

Study	Reference	Country/ Region	N	Intervention	Comparator	Follow-up	Study Type

EPIDEMIOLOGICAL PROFILE OF IN-HOSPITAL DEATHS AMONG PATIENTS WITH HEART FAILURE IN A TERTIARY CARE CENTER

EDUARDO PIETRE1; RODRIGO SILVA GAMMERDINGER2; PAULO MACHADO PONTES3; BERNARDO BARCELOS FERNANDES FUMAGALLI SILVA3; RAYANE FARIAS AUGUSTO PENNA2; MATIAS BRITO FLORIANI3; MARCOS MORAIS DE MEIS3; ANDRE CASARSA MARQUES4; JEORGIANE DE ASSUMPÇÃO COSTA3; LARISSA FRANCO DE ANDRADE3; FLÁVIO ANDRADE CAMACHO5; MARIA DE FATIMA MARTINS GIL DIAS4;

(1) REDE DOR - RIO DE JANEIRO - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (3) HOSPITAL QUINTA D'OR - RIO DE JANEIRO - RJ - BRASIL; (4) UNIVERSIDADE FEDERAL DO ESTADO DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (5) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL;

Background/Introduction: Heart failure (HF) is a progressive, and highly prevalent condition associated with substantial morbidity and mortality. It significantly impairs functional capacity and quality of life. Furthermore, it is frequently accompanied by psychological and spiritual distress. Objectives: Describe the epidemiological and clinical profile of patients who died during hospitalization with a diagnosis of heart failure in a tertiary care hospital, and to characterize their phenotypes. Methods: Retrospective study with 373 patients hospitalized with heart failure in tertiary care, between September 2022 and July 2025. Demographic, clinical, and phenotypic data were obtained from medical records and analyzed descriptively. Two cases with missing data on dyslipidemia were considered non-dyslipidemic. Analysis and plotting were performed using Python 3.9.6, Pandas 2.3.3, Seaborn 0.13.2, Matplotlib 3.9.4, and Scipy 1.13.1. Results and Conclusions: Twenty in-hospital deaths among patients with heart failure were analyzed (9 women and 11 men), with a mean age of 85.5 years. Hypertension (90%) and diabetes mellitus (75%) were highly prevalent, particularly among men. Atrial fibrillation was present in 55% of cases. Heart failure phenotypes were heterogeneous, with preserved ejection fraction (45%) predominating, followed by reduced ejection fraction (40%). Patients had a high burden of prior healthcare utilization, with a mean of 2.5 hospital admissions in the preceding 12 months. The mean length of stay from admission to death was 29.9 days (standard deviation(SD) 17.5), with longer stays observed in men than in women (32.9 vs. 26.2 days). In conclusion, in-hospital deaths among patients with heart failure occurred predominantly in very elderly individuals with a high prevalence of comorbidities and frequent prior hospitalizations. The distribution of heart failure phenotypes highlights the coexistence of preserved and reduced ejection fraction in fatal cases. These findings reinforce the complexity and advanced stage of disease in this population and the need for further research in the area.It also reinforces the concept that hospital readmissions within a short period increase mortality.

FINE-FUNCTION HF: FINERENONE AND FUNCTIONAL CAPACITY IN HEART FAILURE AFTER SWITCHING FROM SPIRONOLACTONE TO FINERENONE.

GABRIEL LUCAS BÓBBO1; ANDRÉ LUÍS PECCOLO COELHO1; CEZAR HENRIQUE FARAHANI SAGUIER1; FELIPPE DEREK S. SILVA1; GUSTAVO AKIRA TAKAHASHI SANTOS1; RAFIK DAUWD1; ANA KARYN EHRENFRIED FREITAS1;

(1) UNIVERSIDADE POSITIVO - CURITIBA - PR - BRASIL;

Background/Introduction: While finerenone has demonstrated cardiovascular benefits in heart failure with preserved and mild-reduced ejection fraction (HFpEF and HFmrEF), its early effects on functional capacity and patient-reported outcomes in real-world settings remain poorly characterized. Objectives: To evaluate the early and short-term effects of switching from spironolactone to finerenone on functional capacity and patient-reported health status in patients with HFpEF/HFmrEF. Methods: This prospective, single-centre study evaluated consecutive patients with HFpEF/HFmrEF undergoing transition from spironolactone to finerenone in routine clinical practice. Functional capacity was assessed using the 6-minute walk test (6MWT), and health status using the Kansas City Cardiomyopathy Questionnaire (KCCQ). Assessments were performed at baseline, 30 days, and 90 days. Safety endpoints included renal function and serum potassium. Results and Conclusions: A total of 53 patients were included. Functional capacity improved significantly, with 6MWT distance increasing from 274.9 ± 12.9 m to 301.9 ± 13.2 m at 90 days (Δ +27.0 m; p=0.001). KCCQ total score improved from 48.5 ± 3.5 to 67.4 ± 3.2 (Δ +18.9; p<0.001), with consistent improvements across domains. Clinically meaningful improvement (≥30 m in 6MWT) was observed in 53.2% of patients, while 67.4% achieved significant improvement in KCCQ. Benefits were evident at 30 days and sustained at 90 days. Serum potassium remained stable over time (p=0.811), and although a small statistical change in creatinine was observed (p=0.013), median values remained stable, indicating no clinically relevant renal deterioration. CONCLUSIONS In patients with HFpEF/HFmrEF, transition from spironolactone to finerenone was associated with early and sustained improvements in functional capacity and health status, without clinically relevant safety concerns. These findings highlight a meaningful early functional benefit of mineralocorticoid receptor modulation in real-world practice.

FINERENONE VERSUS SPIRONOLACTONE IN PATIENTS WITH CHRONIC KIDNEY DISEASE AND HEART FAILURE

MARIANA GÓES MOREIRA1; THIAGO LUIS SCUDELER1; RAFAEL AMORIM BELO NUNES1; ANA CAROLINA BORSOI1; LEANDRO MENEZES ALVES COSTA1;

(1) HOSPITAL ALEMÃO OSWALDO CRUZ - SÃO PAULO - SP - BRASIL;

Background/Introduction: Mineralocorticoid receptor antagonists (MRA) are well established in heart failure with reduced ejection fraction (HFrEF). However, spironolactone use in patients with concomitant chronic kidney disease is limited by hyperkalaemia and variable benefit. Finerenone, a non-steroidal and more selective MRA, has shown favourable outcomes in cardiorenal populations. Objectives: To compare five-year all-cause mortality between finerenone and spironolactone users in patients with chronic kidney disease and heart failure Methods: We conducted a retrospective cohort analysis using real-world data derived from the global TriNetX research network. The search was conducted on February 6, 2026, including patients diagnosed with heart failure and chronic kidney disease, divided into a finerenone cohort and a spironolactone cohort. Cohort data were subjected to propensity score matching (PSM) for age, sex, ethnicity, medical and medication history. The evaluated endpoint is all-cause mortality mover a five-year follow-up period. Results and Conclusions: A total of 3,103 patients with chronic kidney disease (CKD) and heart failure (HF) receiving finerenone and 427,157 receiving spironolactone were identified. After propensity score matching, 3,100 patients remained in each group, with a mean age of 70 years; approximately 61.2% were male. Coronary artery disease was present in over 60% of patients, while hypertension and diabetes were observed in more than 80% of the cohort. The primary outcome occurred less frequently in the finerenone group compared with the spironolactone group (8.6% vs. 21.5%; RR 0.399; HR 0.519, 95% CI 0.44–0.60; log-rank p<0.001). The absolute risk reduction was 12.9%, corresponding to a number needed to treat (NNT) of approximately 8. In patients with concomitant heart failure and chronic kidney disease, finerenone was associated with a significant reduction in mortality compared with spironolactone, suggesting a potential therapeutic advantage of non-steroidal MRAs in this high-risk population.

GLP-1 RECEPTOR AGONISTS IN HEART FAILURE WITH PRESERVED EJECTION FRACTION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF CLINICAL OUTCOMES

ARTHUR VILAR DE OLIVEIRA MALHEIROS1; ARTHUR HEIMBACH CICUTO2; MARINNA XAVIER DOELER2; THIAGO CASTRO DANTAS2; JULIA GONÇALVES ALONSO2; GABRIEL HENRIQUE SIMONI2; GUILHERME PERINI DURIGAN2; CARLOS ALEXANDRE GOMES FARIAS3; JONATHAN RAMOS NUNES3; PIETRA GRANCIERI PÓ1; THAUANE ÂNGELA SILVA CARDOSO1; NATHALIE DE HOLANDA PANISSI1;

(1) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL; (2) CENTRO UNIVERSITARIO DE VARZEA GRANDE - UNIVAG - CUIABÁ - MT - BRASIL; (3) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL;

Background/Introduction: Heart failure with preserved ejection fraction (HFpEF) accounts for over 50% of heart failure cases and is strongly associated with obesity and cardiometabolic comorbidities, with limited effective pharmacological options. Objectives: To evaluate the effects of glucagon-like peptide-1 receptor agonists (GLP-1 RAs) on HF hospitalization, functional capacity, quality of life, and safety in patients with HFpEF. Methods: Systematic review and meta-analysis following PRISMA guidelines. Three studies were included: two randomized controlled trials (RCTs) and one propensity score-matched retrospective cohort. Primary outcome: HF hospitalization or acute HF exacerbation. Main analysis included only RCTs using hazard ratios and DerSimonian-Laird random-effects model; a sensitivity analysis incorporated all three studies via Generic Inverse Variance. Heterogeneity was assessed by the I^2 statistic. Results and Conclusions: Across 2,594 patients, GLP-1 RAs significantly reduced HF hospitalization or acute HF exacerbation in the primary RCT meta-analysis (pooled HR 0.43; 95% CI 0.20–0.91; p=0.028; I^2=68.1%). Sensitivity analysis confirmed this effect (pooled HR/OR 0.49; 95% CI 0.35–0.68; p<0.001; I^2=36.1%). Descriptively, GLP-1 RAs improved quality of life (KCCQ-CSS mean difference +7.5 points; p<0.001), six-minute walk distance (+17.1m; p<0.001), and body weight (−8.4%; p<0.001). All-cause mortality was reduced in the retrospective cohort (OR 0.34; 95% CI 0.16–0.72; p=0.004). Serious adverse events were consistently lower with GLP-1 RAs. GLP-1 RAs significantly reduce HF-related hospitalizations in HFpEF, with benefits consistent across diabetes status and a favorable safety profile. Substantial heterogeneity in the primary analysis reflects differences in study design, drug formulation, and follow-up duration, underscoring the need for dedicated large-scale outcome trials.

GOLD STANDARD QUADRUPLE THERAPY IN HEART FAILURE AND THE CHALLENGES OF ITS APPLICABILITY IN PRIMARY HEALTH CARE: SYSTEMATIC REVIEW

LARISSA EMANUELA FERNANDES MARINHO1; CAMILA WEHBE2; DAFNE CAROLINE LOPES FERNANDES1; MONIELLY WINNE SOUZA NEIVA ROCHA1; FLAVIA APARECIDA MENEZES CARNEIRO3; ESTHER BRELAZ LIMA GOIS4; MARIANA BUENO GOUVEIA4; ARLINDO GONZAGA BRANCO JUNIOR1;

(1) UNIVERSIDADE FEDERAL DE RONDÔNIA - PORTO VELHO - RO - BRASIL; (2) UNIVERSIDEDADE FEDERAL DE RONDÔNIA - PORTO VELHO - RO - BRASIL; (3) SECRETARIA MUNICIPAL DE SAUDE DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (4) CENTRO UNIVERSITARIO SAO LUCAS (UNISL) - PORTO VELHO - RO - BRASIL;

Background/Introduction: Heart failure (HF) is a clinical syndrome with high prevalence and significant impact on health systems, representing one of the leading causes of hospitalization among adults and the elderly. The combination of renin–angiotensin system inhibitors (ACE inhibitors), beta-blockers, mineralocorticoid receptor antagonists, angiotensin receptor–neprilysin inhibitors (ARNI), and SGLT2 inhibitors, known as Gold Standard Quadruple Therapy, provides additive and early benefits. However, despite its proven efficacy, the implementation of this strategy in clinical practice remains limited, particularly in primary health care (PHC). Objectives: To evaluate, through a systematic review, the impact of Gold Standard Quadruple Therapy on heart failure outcomes and its applicability in primary care. Methods: This is a systematic review with qualitative synthesis, conducted according to PRISMA guidelines. Searches were performed in PubMed, Embase, Cochrane Library, and Scopus to identify randomized controlled trials and meta-analyses on Gold Standard Quadruple Therapy. Studies with relevant clinical outcomes and applicability in PHC were included, while other study designs were excluded. Results and Conclusions: Among the studies analyzed, 18 met the eligibility criteria. Quadruple therapy demonstrated a reduction in mortality with ACE inhibitors (16–27%), beta-blockers (30–35%), mineralocorticoid receptor antagonists (~30%), ARNI (~20%), and SGLT2 inhibitors (25–30%), resulting in an overall mortality reduction of up to 45%. In PHC, the therapy remains underutilized, being fully prescribed in 22% to 35% of patients, while 40% to 60% use one or two classes, and less than 15% achieve target doses. When implemented, it reduces mortality (25–35%), hospitalizations (30–45%), and 30-day readmissions (20–28%). Adherence remains limited, with full adherence around 30%, partial interruption in 45% to 55%, and treatment discontinuation up to 20%. The main barriers include limited access to medications (50%–70%), lack of structured protocols (~60%), therapeutic inertia (~50%), low titration rates (up to 65%), cost (30%–50%), and polypharmacy (>70%). Gold Standard Quadruple Therapy significantly reduces mortality and hospitalizations in HF; however, its effectiveness in real-world settings depends on adequate implementation in primary care, including overcoming structural barriers and improving access to evidence-based therapies.

Background/Introduction: Heart transplantation is a last-line therapy for end-stage heart failure, indicated in both pediatric and elderly populations. The epidemiological analysis of these procedures at the extremes of life may reveal disparities in healthcare delivery and help guide public health policies. Objectives: To analyze the epidemiological profile of hospitalizations for heart transplantation in Brazil (2019–2023), evaluating regional differences in mean cost, length of hospital stay, and mortality rate, with a focus on the extremes of age (children and the elderly). Methods: A retrospective, descriptive, and quantitative epidemiological study was conducted using data from the Brazilian Unified Health System Informatics Department (DATASUS), covering the period from 2019 to 2023. Hospitalizations for heart transplantation (procedure code 0505020041) were analyzed by region, considering the following variables: mean cost per hospitalization, average length of stay, and mortality rate. Results and Conclusions: The national mean cost per hospitalization during the study period was R$ 557,623.14. The Southeast region had the highest mean cost (R$ 578,022.23), while the North region had the lowest (R$ 484,934.03). The average hospital stay was 12.6 days, with longer durations observed in the North (13.6 days) and South (13.2 days) regions. The overall mortality rate was 11.3%, with the highest rate in the Southeast (13.9%) and the lowest in the Midwest (6.87%). Although the data were not stratified by age group, it is well established that pediatric and elderly patients have higher postoperative risks, which may contribute to increased rates in certain regions. Heart transplantation at the extremes of life requires specialized infrastructure and complex clinical management. The observed regional differences may reflect disparities in access to care and variability in healthcare quality. Public policies aimed at improving equity and optimizing outcomes in vulnerable populations are essential.

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL DO ESTADO DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (3) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (4) HOSPITAL QUINTA D'OR - RIO DE JANEIRO - RJ - BRASIL; (5) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (6) REDE DOR - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Heart failure is a major cause of hospitalization worldwide. Depression affects over 30% of patients and is associated with adverse clinical outcomes. Decompensated heart failure represents a period of increased physiological and psychological vulnerability; however, the factors associated with depression in this acute setting remain poorly defined. Identifying predictors of depression in patients with decompensated heart failure may support early recognition and targeted management in this high-risk population. Objectives: To identify independent predictors of depression in hospitalized patients and to evaluate the predictive contribution of spirituality to heart failure phenotypes. Methods: This cross-sectional study included adults hospitalized with decompensated heart failure at a tertiary cardiology center. Depression was assessed using the Patient Health Questionnaire-9 (PHQ-9), and spirituality was measured with the Functional Assessment of Chronic Illness Therapy–Spiritual Well-Being Scale (FACIT-Sp-12). Patients were classified into depressive and non-depressive groups based on PHQ-9 diagnostic criteria. Multivariable logistic regression was used to identify independent predictors of depression The study protocol was conducted in accordance with ethical standards and approved by the Research Ethics Committee. Results and Conclusions: Among the 250 patients included (mean age 71.9 ± 12.7 years; 54% male), 23.6% met criteria for depression.The predominant heart failure phenotype in the group was reduced ejection fraction, 61.2% (n = 153). Multivariable analysis demonstrated that higher spirituality scores were independently associated with a lower likelihood of depression (OR = 0.928; 95% CI = 0.892–0.965), representing the strongest inverse predictor. Spiritually, emerged as a significant protective factor (B = –0.075, SE = 0.020, p < 0.001), such that each 1-point increase in the FACIT–Sp-12 score was associated with a 7.2% decrease in the odds of depression. Older age was also associated with reduced odds of depression (B = –0.038, SE = 0.013, p = 0.002). Depression was highly prevalent among patients hospitalized with decompensated heart failure. Female sex and younger age were independent risk factors, whereas higher spirituality emerged as a protective factor. These findings support the use of psychosocial and spiritual assessments as complementary tools for depression risk stratification in patients with decompensated heart failure regardless of IC phenotype.

IMPACT OF SGLT2 INHIBITORS ON LEFT VENTRICULAR EJECTION FRACTION IN HEART FAILURE: A SYSTEMATIC REVIEW OF RANDOMIZED CLINICAL TRIALS

OTÁVIO DE OLIVEIRA MARQUES1; MATHEUS SACCO GOMES2; MARINA DALL'AGNOL REDEL3; MARIA FERNANDA RONCHETTI GRILLO4; DIMITRIS RUCKS VARVAKI RADOS5; ANDRÉIA BIOLO5;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - SP - BRASIL; (2) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (3) UNISINOS - SÃO LEOPOLDO - RS - BRASIL; (4) HOSPITAL MOINHOS DE VENTO - PORTO ALEGRE - RS - BRASIL; (5) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: Left ventricular ejection fraction (LVEF) is a key parameter for functional assessment and prognostic stratification in heart failure (HF), and is widely used for phenotypic classification and therapeutic decision-making. Although sodium–glucose cotransporter 2 inhibitors (SGLT2i) have demonstrated consistent benefits in reducing mortality and hospitalizations in patients with HF, their direct effects on ventricular systolic function remain incompletely elucidated, particularly across different phenotypes and follow-up durations. Objectives: To evaluate the impact of SGLT2i on LVEF in adult patients with HF. Methods: This systematic review was conducted according to PRISMA guidelines (registered in PROSPERO). A search was performed in PubMed, Embase, and Cochrane, using the terms "heart failure," "SGLT2 inhibitors," and "randomized controlled trials," yielding 2,545 records. After applying eligibility criteria, 85 articles underwent full-text review. Randomized controlled trials comparing SGLT2 inhibitors versus placebo or standard therapy in patients ≥18 years with HF were included. The primary outcome of the main analysis was left atrial diameter and volume assessed by echocardiography or magnetic resonance imaging. For the LVEF subanalysis, a quantitative synthesis was performed using a random-effects model, with results expressed as mean difference (MD) and 95% confidence intervals (CI). Statistical heterogeneity was assessed using the I^2 statistic. Results and Conclusions: Nine randomized controlled trials comprising 658 patients were included in this subanalysis. Follow-up ranged from 1.5 to 12 months. Pooled analysis demonstrated a significant improvement in LVEF favoring SGLT2 inhibitors, with a mean difference (MD) of 0.88% (95% CI 0.15 to 1.62). No heterogeneity was observed among studies (I^2 = 0%), indicating high consistency across trials. The present analysis was restricted to randomized controlled trials in patients with heart failure, providing a more homogeneous and methodologically rigorous estimate. The absence of heterogeneity (I^2 = 0%) further strengthens the reliability of these findings and suggests that the observed effect may reflect the true effect of SGLT2 inhibitors on systolic function. Overall, SGLT2 inhibitors are associated with a consistent and statistically significant improvement in LVEF. These findings reinforce the concept that reverse remodeling may occur, but likely represents only one component of the broader clinical benefit of SGLT2 inhibitors in heart failure.

IMPACT OF THE COVID-19 PANDEMIC ON HEART FAILURE HOSPITALIZATIONS IN MARANHÃO: AN ECOLOGICAL TIME-SERIES STUDY (2018–2024)

SAMUEL VICTOR SOARES DE CARVALHO1; TIAGO CORDEIRO MEDEIROS1;

(1) UFMA - CAMPUS SAO LUIS - SÃO LUÍS - MA - BRASIL;

Background/Introduction: Heart failure (HF) is a leading cause of cardiovascular hospitalization in Brazil, especially in regions with limited specialized care. The COVID-19 pandemic disrupted healthcare delivery, potentially affecting HF management continuity and inpatient outcomes. Data on this impact in the Brazilian Northeast remain scarce. Objectives: To compare HF hospitalizations, in-hospital mortality, and length of stay across pre-pandemic, pandemic, and post-pandemic periods in Maranhão. Methods: Ecological time-series study using data from SIH/SUS (ICD-10 I50) via DATASUS. Monthly records were divided into pre-pandemic (Jan/2018–Dec/2019), pandemic (Jan/2020–Dec/2021), and post-pandemic (Jan/2022–Sep/2024). Variables: monthly hospitalizations, mortality rate (%), and mean length of stay (days). Given the non-normal distribution of monthly data, Kruskal-Wallis was used as the primary test with DSCF pairwise comparisons; one-way ANOVA with Games-Howell post-hoc served as confirmatory analysis. The post-pandemic period (33 vs. 24 months) and DATASUS reporting cutoff at September 2024 are acknowledged limitations; monthly means were used to mitigate temporal asymmetry. Results and Conclusions: Mean monthly hospitalizations fell from 302.5 ± 26.2 (pre) to 233.7 ± 53.6 (pandemic), rising to 372.5 ± 28.2 (post); all pairwise comparisons p < 0.001. In-hospital mortality rose from 10.6% to 14.0% (pandemic) and remained at 14.2% (post); pre vs. pandemic/post p < 0.001, pandemic vs. post p = 0.961 (ANOVA) / 0.867 (Kruskal-Wallis). Length of stay increased progressively: 6.6, 7.5, and 8.3 days (pandemic vs. pre p < 0.001; post vs. pandemic p = 0.004). The pandemic was associated with reduced HF hospitalizations acutely, followed by a rebound exceeding pre-pandemic levels, suggesting unmet demand. Persistently elevated mortality and progressive increase in length of stay indicate lasting disruption of chronic HF care, suggesting increased clinical complexity at admission.

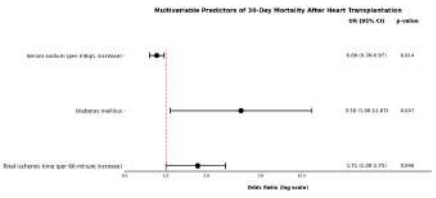
INCOME LEVEL LINKED TO INCREASED IN-HOSPITAL MORTALITY AMONG PATIENTS WITH ACUTE HEART FAILURE IN BRAZIL

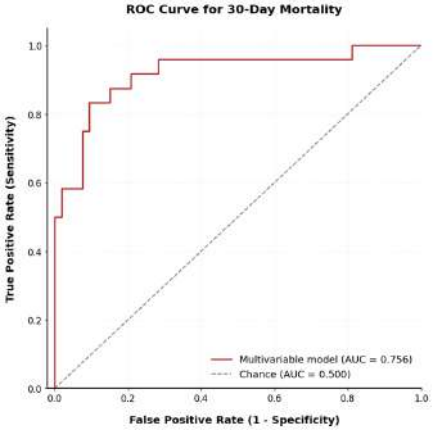
GUSTAVO SAROT PEREIRA DA CUNHA1; MATHEUS BISSA DUARTE2; JORGE TAIDASHI DAIKUBARA NETO2; RAFAEL MORETTI2; KAROLINE CORDEIRO VERCKA3; ANA CAROLINA KRACHINSKI DE ANDRADE GAMA2; JESSICA REICHERT3; RAPHAEL HENRIQUE DÉA CIRINO2; WILSON NADRUZ4; FABIO PAPA TANIGUCHI5; ODILSON MARCOS SILVESTRE6; MIGUEL MORITA FERNANDES-SILVA2;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARANÁ - CURITIBA - PR - BRASIL; (3) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (4) UNICAMP - CAMPINAS - MT - BRASIL; (5) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL; (6) UNIVERSIDADE FEDERAL DO ACRE - RIO BRANCO - AC - BRASIL;

Background/Introduction: Acute heart failure (AHF) continues to be associated with high mortality and morbidity rates; therefore, appropriate risk stratification is essential for the prioritization of patients and the allocation of resources. While socioeconomic factors are linked to worse prognoses in chronic HF, this relationship remains poorly understood in acute HF patients, especially in developing countries with universal healthcare systems, like Brazil. Objectives: Our objetive is to analyze the impact of income and educational attainment in the mortality of patients with AHF in Brazil. Methods: This is a prospective cohort study including patients admitted with a primary diagnosis of AHF at 19 hospitals within the Brazilian Unified Health System (SUS) from February 2016 to November 2022. Patients were classified by monthly household income into the following groups: ≤1 minimum wage (MW), >1 to <2 MW, ≥2 to <5 MW, and ≥5 MW. Educational level was categorized as less than basic, basic, intermediate, and advanced, according to the 2011 International Standard Classification of Education (ISCED) equivalency for Brazil. The impact of income and education on in-hospital mortality was analyzed using logistic regression models additionally adjusted for sociodemographic characteristics (age, sex, race and region of Brazil) (Model 1); HF etiology and ejection fraction (Model 2); and the ADHERE prognostic score, along with non-adherence and infection as causes of decompensation (Model 3). Results and Conclusions: A total of 3,216 patients were included in the analysis (mean age 60.9±14.9 years, 42% women; Figure 1). The mean ejection fraction was 40.7±17.1%; 20,2% had ischemic and 8,4% chagasic etiology. Patients with lower income were more frequently classified as moderate or high risk according to ADHERE (55.8% vs 58.2% vs 49.9% vs 49.1%, p-for-trend=0,015). In-hospital mortality was 11% (n=354), and was more frequent among those with lower income (12,1% vs 12,7% vs 6,8% vs 8,5%, p-for-tend=0,001). Lower income levels remained associated with a higher risk of death after adjustment for Model 1 (OR 1.19, CI95 1.02 - 1.39, p=0.030), Model 2 (OR 1.19, CI95 1.01 - 1.40, p=0.035) and Model 3 (OR 1.20, CI95 1.01 - 1.42, p=0.043; Figure 2). Education levels were not associated with mortality after adjustment for Model 1 to 3. In this large Brazilian cohort of patients with AHF, income level was independently associated with increased risk of in-hospital mortality.



19965



METABOLIC AND PERIOPERATIVE FACTORS ASSOCIATED WITH 30-DAY MORTALITY AFTER HEART TRANSPLANTATION: A MULTIVARIABLE ANALYSIS

RUI PIERI NETO1; LUÍS ALBERTO FRANCO RAMIREZ1; LUANA MONFERDINI1; LEONARDO RUFINO GARCIA1; MARCELLO LANEZA FELICIO1; FLÁVIO DE SOUZA BRITO1; BERTHA FURLAN POLEGATO1;

(1) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL;

Background/Introduction: Early mortality after heart transplantation remains a complex outcome driven by the interaction between recipient characteristics and perioperative factors. Identifying metabolic and perioperative variables associated with early outcomes may improve risk stratification in the early post-transplant period. Objectives: To evaluate metabolic and perioperative variables associated with 30-day mortality after heart transplantation. Methods: This retrospective cohort included 77 consecutive adult patients undergoing heart transplantation between 2019 and 2026. The primary endpoint was 30-day all-cause mortality. A multivariable logistic regression model was constructed including pre-transplant serum sodium, recipient diabetes mellitus, and total ischemic time. Variable selection was based on clinical relevance and univariate screening (p<0.10). Model performance was assessed using the area under the receiver operating characteristic curve (AUC) and Nagelkerke R². Total ischemic time was rescaled to 60-minute increments for clinical interpretability. A sensitivity analysis was performed replacing ischemic time as a continuous variable with a binary cutoff (>300 minutes). Results and Conclusions: Thirty-day mortality was 31.2% (24/77). The multivariable model showed moderate discrimination, with an AUC of 0.756 and Nagelkerke R² of 0.252. On multivariable analysis, lower pre-transplant serum sodium was associated with mortality (odds ratio [OR] 0.86; 95% confidence interval [CI] 0.76–0.97; p=0.014), as well as diabetes mellitus (OR 3.58; 95% CI 1.08–11.87; p=0.037). Total ischemic time was also associated with mortality (OR 1.71 per 60-minute increment; 95% CI 1.00–2.75; p=0.046). In sensitivity analysis (>300 minutes), findings remained consistent, with similar direction of effect for serum sodium (OR 0.85; p=0.005), diabetes mellitus (OR 4.84; p=0.019), and ischemic time (OR 3.49; p=0.055). Model performance remained similar (AUC 0.756 in the main analysis vs 0.752 in the sensitivity analysis). These results should be interpreted in the context of the retrospective single-center design, limited sample size, and potential residual confounding. In this cohort, pre-transplant serum sodium, diabetes mellitus, and total ischemic time were associated with 30-day mortality. These findings support a multifactorial model in which early post-transplant outcomes reflect the interplay between recipient metabolic vulnerability and perioperative ischemic exposure.

METABOLOMIC ALTERATIONS ASSOCIATED WITH EJECTION FRACTION PATTERNS IN HEART FAILURE

JORDANNA CRUZEIRO1; JULIANA SILVA SIQUEIRA1; FABIANE VALENTINI FRANCISQUETI FERRON1; NATÁLIA BITTENCOURT PASQUALINI1; NATHANA ALMEIDA DE LIMA1; MATHEUS ANTÔNIO FILIOL BELIN1; DIJON HENRIQUE SALOMÉ DE CAMPOS1; MAURÍCIO LUÍS SFORÇA1; CAMILA RENATA CORRÊA1; SILMÉIA GARCIA ZANATI BAZAN1;

(1) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL;

Background/Introduction: Introduction: Heart failure (HF) is characterized by structural and functional abnormalities, such as reduced left ventricular ejection fraction (EF). Systemic metabolic alterations play a central role in HF pathophysiology, often preceding and accompanying cardiac dysfunction. Thus, metabolomics emerges as a powerful approach to uncover biochemical signatures associated with HF. Objectives: Objectives: To evaluate the metabolomic profile of patients across different HF phenotypes. Methods: Methods: A cross-sectional study included 60 participants of both sexes, allocated into groups characterized by Doppler echocardiography: HF with preserved EF (HFpEF; n=17), mildly reduced EF (HFmrEF; n=13), reduced EF (HFrEF; n=15), and a control group (C; n=15). Plasma metabolomic profiling was performed using nuclear magnetic resonance spectroscopy. Student's t-test was used for metabolomic comparisons, and one-way ANOVA with Tukey's post hoc test for echocardiographic variables, ($p<0.05$). Results and Conclusions: Results: Metabolomic analysis revealed distinct signatures across HF phenotypes compared to C. In HFpEF, formate was downregulated, while glutamate and choline were upregulated. In HFmrEF, formate, creatine, acetate, and lysine were downregulated, alongside upregulated choline, lactate, and pyruvate. In HFrEF, formate, acetate, and asparagine were downregulated, with no metabolites significantly upregulated. Regarding echocardiography, there was an increase in the values of LVEDD, LVM/BSA, LAV/BSA and septal E/E' in all HF groups vs. C; LVM/BSA showed an increase in the HFrEF vs. HFmrEF; and LVM in the HFpEF and HFrEF groups vs. C. LVESD progressively increased from C to HFpEF, HFmrEF, and HFrEF. LVEF, septal S' and lateral S' progressively decreased from C to HFpEF, HFmrEF, and HFrEF. There was a reduction in the values of E/A, septal E', lateral E', and tricuspid E' in all HF groups vs. C; septal E' and lateral E' also showed a reduction in the HFrEF vs. HFpEF and HFmrEF groups; and TAPSE in the HFrEF group vs. HFpEF, HFmrEF, and C, and in HFpEF vs. C. Conclusion: HF phenotypes exhibit progressive metabolic reprogramming associated with EF patterns. In addition, downregulated formate emerges as a potential biomarker for disease severity, highlighting the utility of metabolomics in the clinical stratification of HF. FAPESP: 2023/08537-5.

PHENOTYPE-SPECIFIC CIRCULATING METABOLOMIC SIGNATURES ASSOCIATED WITH SYSTOLIC AND DIASTOLIC DYSFUNCTION IN HEART FAILURE: AN ECHOCARDIOGRAPHY-INTEGRATED ANALYSIS

JULIANA SILVA SIQUEIRA1; JORDANNA CRUZEIRO1; FABIANE VALENTINI FRANCISQUETI FERRON1; NATÁLIA BITTENCOURT PASQUALINI1; NATHANA ALMEIDA DE LIMA1; MATHEUS ANTÔNIO FILIOL BELIN1; DIJON HENRIQUE SALOMÉ DE CAMPOS1; MAURÍCIO LUÍS SFORÇA1; CAMILA RENATA CORRÊA1; SILMÉIA GARCIA ZANATI BAZAN1;

(1) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL;

Background/Introduction: Introduction: Heart failure (HF) is characterized by the inability of the heart to meet the metabolic demands of tissues and is associated with high morbidity and mortality. Classifying HF based on ejection fraction (EF) as preserved, mildly reduced, or reduced reflects distinct pathophysiological mechanisms, clinical profiles, and therapeutic responses. HF progression involves systemic alterations, including metabolic dysfunction. In this context, metabolomics has emerged as a promising approach to identify metabolic alterations associated with cardiac function and HF heterogeneity. Objectives: Objectives: To evaluate the association between circulating metabolites and echocardiographic parameters in patients with different heart failure phenotypes. Methods: Methods: This cross-sectional study included patients with HF classified as preserved (HFpEF; n=17), mildly reduced (HFmrEF; n=13), and reduced (HFrEF; n=15), as well as a control group (C; n=15) without cardiovascular risk factors. Echocardiography assessed cardiac structure and function, and metabolomic analysis was performed by 1H-NMR. Identified metabolites were correlated with echocardiographic variables by Pearson correlation ($p<0.05$). Additionally, selected significant metabolites were further analyzed using linear regression models to evaluate associations with systolic (EF) and diastolic (E/E' ratio) function, including interaction terms between metabolites and HF groups, adjusted for sex. Results and Conclusions: Results: Metabolomic analysis identified 38 metabolites that showed significant correlations with echocardiographic parameters. Acetate and formate, metabolites related to energy metabolism and one-carbon pathways, were selected for further analysis. In interaction models, acetate was associated with EF in a group-dependent manner (p-interaction = 0.019), with stronger effects in HFrEF patients. Formate was associated with the E/E' ratio in a phenotype-dependent manner (p-interaction = 0.002), showing a positive association with diastolic dysfunction in HFrEF patients. Formate also showed a group-dependent association with EF (p-interaction = 0.004). Conclusion: These findings indicate that specific circulating metabolites are differentially associated with systolic and diastolic dysfunction according to HF phenotype, supporting metabolomics as a tool to characterize HF heterogeneity. Portal vein doppler improvement predicts lower in-hospital mortality in acute decompensated heart failure with right ventricular dysfunction: a prospective cohort study

MARINA PETERSEN SAADI1; KALEB PINTO SPANNENBERGER1; GUILHERME HEIDEN TELO1; GUSTAVO PAES SILVANO1; RENATO FERRAZ MAULAZ1; GUILHERME PINHEIRO MACHADO1; HENRIQUE CABRAL SCHERER1; LUIS EDUARDO PAIM ROHDE1; ANDERSON DONELLI SILVEIRA1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - Brasil;

Background/Introduction: Venous Excess Ultrasound (VExUS) is increasingly used for risk stratification and monitoring decongestion in acute decompensated heart failure (ADHF). However, its validity in patients with right ventricular (RV) dysfunction remains uncertain, as elevated right-sided pressures and compliance may alter Doppler signals. Among VExUS components, portal vein Doppler may be less influenced by right atrial pressure fluctuations than hepatic vein Doppler, potentially offering a pragmatic target for serial congestion assessment. Objectives: To evaluate whether improvement in portal vein Doppler is associated with in-hospital mortality in ADHF patients with RV dysfunction. Methods: We conducted a prospective cohort study including adults (>18 years) admitted to a cardiac intensive care unit with ADHF and RV dysfunction. Venous congestion was assessed on days 1 and 3 using portal vein Doppler grading and other VExUS components. The exposure was an improvement of ≥1 portal Doppler grade. The primary outcome was in-hospital mortality. Associations were assessed using logistic regression. Discrimination was evaluated using ROC curves (AUC) with 95% confidence intervals, and AUCs were compared using DeLong's test. Results and Conclusions: Among 68 patients (median age 61 years; 74% male; median LVEF 20%; median TAPSE 13 mm), complete-case analysis included 63 patients, with 12 deaths (19%). Portal Doppler improvement occurred in 32/63 (51%) and was associated with lower mortality (1/32, 3.1%) versus no improvement (11/31, 35.5%). Portal improvement was independently associated with lower in-hospital mortality (OR 0.06, 95% CI 0.003–0.34; p=0.009). Discrimination was higher for portal improvement (AUC 0.76, 95% CI 0.65–0.85) than hepatic improvement (AUC 0.64, 95% CI 0.53–0.74; DeLong p=0.002), and similar to composite VExUS improvement (AUC 0.72, 95% CI 0.60–0.81; p=0.25). In patients with moderate-to-severe tricuspid regurgitation, no deaths occurred with portal improvement (0/22 vs. 7/19), suggesting identification of a low-risk subgroup, although interaction was not significant. In ADHF patients with RV dysfunction, early improvement in portal vein Doppler was strongly associated with lower in-hospital mortality and showed discrimination comparable to VExUS. Given its simplicity and rapid bedside applicability compared with the full VExUS assessment, serial portal vein Doppler may represent a practical and efficient marker of decongestion response in this high-risk population.

PREDICTORS OF SUDDEN OR ARRHYTHMIC DEATH DURING THE VULNERABLE PERIOD AFTER ACUTE HEART FAILURE

ANA CAROLINA KRACHINSKI DE ANDRADE GAMA1; GUSTAVO SAROT PEREIRA DA CUNHA2; FABIO PAPA TANIGUCHI3; MIGUEL MORITA FERNANDES-SILVA1;

(1) UNIVERSIDADE FEDERAL DO PARANÁ - CURITIBA - PR - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (3) HOSPITAL DO CORACAO - HCOR - SAO PAULO - SP - BRASIL;

Background/Introduction: The post-discharge phase following hospitalization for acute heart failure (AHF) —known as the "vulnerable period"—is associated with increased mortality, including sudden or arrhythmic death; however, predictors of sudden death during this period remain poorly characterized. Objectives: To identify predictors of sudden or arrhythmic death within 180 days after discharge following hospitalization for AHF. Methods: In this prospective cohort, we included patients discharged after hospitalization for AHF from 20 public hospitals participating in the Brazilian Unified Health System (SUS) "Best Practices in Cardiology" program between 2016 and 2022. Patients with an implantable cardioverter-defibrillator were excluded. Fine-Gray competing-risk hazards models were used to identify predictors of sudden or arrhythmic death within 180 days after discharge, with non-arrhythmic death treated as a competing event. Results and Conclusions: Among 1,689 patients (age 61±14 years, ejection fraction 42±17%, 41% women), 98 sudden or arrhythmic deaths and 78 non-arrhythmic deaths occurred within 180 days after discharge. Chagas cardiomyopathy was independently associated with increased risk of sudden or arrhythmic death (SHR 2.60, 95% CI 1.40–4.84, p=0.002), whereas ischemic etiology was not independently associated with mortality. Additional independent predictors included reduced mobility during hospitalization (SHR 2.30, 95% CI 1.37–3.87, p=0.002) and older age (SHR 1.03 per year, 95% CI 1.01–1.05, p=0.002). In contrast, higher systolic blood pressure at discharge (SHR 0.98, 95% CI 0.97–0.99, p=0.008) and higher educational level (SHR 0.68, 95% CI 0.52–0.88, p=0.004) were independently associated with lower risk of sudden or arrhythmic death. In this large cohort of patients with AHF, predictors of sudden or arrhythmic death during the vulnerable post-discharge period included Chagas cardiomyopathy, older age, markers of greater clinical severity and lower educational attainment.

PROGNOSTIC VALUE OF CLINICAL SCORES AND BIOMARKERS IN ADVANCED HEART FAILURE: IMPLICATIONS FOR PALLIATIVE CARE ELIGIBILITY

LEONARDO RIBEIRO PEIXOTO1; GABRIEL NOGUEIRA GAIA2; SANDRYANNE MARIA RODRIGUES PATRIOTA1; ALÉXIA ALVES DE CARVALHO1; KARINE ESPÍNOLA CARDINS GOMES1;

(1) HOSPITAL AGAMENON MAGALHAES - RECIFE - PE - BRASIL; (2) HOSPITAL NOSSA SENHORA DAS GRAÇAS - HOSPITAL ALFA - RECIFE - PE - BRASIL;

Background/Introduction: Advanced heart failure (HF) poses a significant prognostic challenge, especially in low- and middle-income countries (LMICs). Determining the optimal threshold for palliative care (PC) referral relies heavily on accurate risk stratification. While multiparametric clinical scores, such as the MAGGIC (Meta-Analysis Global Group in Chronic Heart Failure) score, and biomarkers like N-terminal pro-B-type natriuretic peptide (NT-proBNP) are well-established for predicting mortality, their specific utility in triggering early PC interventions remains underutilized in clinical practice. Recent epidemiological studies emphasize the need for objective triggers to overcome the current underutilization of PC. Objectives: To systematically evaluate the combined prognostic value of the MAGGIC risk score and natriuretic peptide levels in patients with advanced HF and to define evidence-based thresholds that identify eligibility for early PC integration. Methods: An integrative review of literature (2024-2026) was conducted using PubMed and Cochrane databases. The analysis focused on large-scale validation studies of prognostic models (MAGGIC, SHFM) and biomarkers (NT-proBNP) in advanced HF populations. Outcomes of interest included the area under the curve (AUC) for 1-year mortality prediction and the correlation of high-risk scores with the initiation of PC or advance care planning. Results and Conclusions: Recent real-world validation studies demonstrate that the MAGGIC score remains the most extensively validated prognostic tool for advanced HF, consistently showing an AUC >0.70 for mortality prediction. The integration of MAGGIC scores with elevated NT-proBNP levels significantly enhances prognostic accuracy for near-term mortality. Despite the availability of these robust predictive tools, contemporary observational data reveal a stark clinical gap: fewer than 18% of high-risk HF patients receive a formal PC consultation. The integration of the MAGGIC score with biomarker data provides a robust, objective framework for identifying advanced HF patients at high risk of near-term mortality. Utilizing these validated thresholds as automated triggers for PC referral could bridge the current gap in care, ensuring timely therapeutic adjustments.

RARE COEXISTENCE OF DUAL PATHOGENIC VARIANTS IN THE TTR GENE: A CASE SERIES

PLÍNIO JOSÉ WHITAKER WOLF1; EDILEIDE DE BARROS CORREIA1; LARISSA VENTURA BRUSCKY1; MARCOS OLIVEIRA VASCONCELLOS1; ANA CRISTINA DE SOUZA MURTA1; YONA AFONSO FRANCISCO1; EDUARDO MIKIO SASSAKI1; GABRIELA ESQUERDO ESQUERDO1; THAIS GRECCA ANDRADE1; FERNANDA DE BRITO FORTUNA1; VICTOR BEMFICA1; SARA REGINA1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Background/Introduction: We report a case series of p with dual pathogenic variants in the TTR gene, followed for three years after diagnosis. These cases were identified through the analysis of all p with cardiac amyloidosis and those carrying pathogenic variants in the TTR gene, followed between 2019 and 2025. Objectives: Clinical, echocardiographic, and laboratory characteristics of p with dual pathogenic variants in TTR Methods: We report a case series of p with dual pathogenic variants in the TTR gene, followed for three years after diagnosis. These cases were identified through the analysis of all p with cardiac amyloidosis and those carrying pathogenic variants in the TTR gene, followed between 2019-2025. Results and Conclusions: Among 450 p, four individuals with dual pathogenic variants in TTR were identified; 50% were male, with a mean age of 60±12 years. All carried the Val142Ile variant, three in combination with Val50Met and one with Ser70Arg. All p exhibited a mixed phenotype (cardiac and neurological). Extracardiac manifestations were frequent: dysautonomia in 100%, peripheral polyneuropathy in 75%, carpal tunnel syndrome in 75%, and diarrhea in 50%. Regarding cardiac manifestations, two p required pacemaker implantation due to complete atrioventricular block, and all four developed heart failure—three in NYHA class II and one in class III—with a mean NT-proBNP of 2218±1432 pg/mL. On echocardiography, mean left ventricular ejection fraction (LVEF) was 53±8% (two p with LVEF<50%), global longitudinal strain was 8.5±2.5%, and left atrial volume index was 47±13 mL/m². Mean interventricular septal and posterior wall thicknesses were 18.2±0.9 mm and 15±2.9 mm, respectively. All patients were receiving disease-specific therapy for ATTR with tafamidis 20 mg/day; in one case, treatment also included eplontersen. This case series highlights the rare coexistence of dual pathogenic variants in the TTR gene, a phenomenon scarcely reported in the literature and, to our knowledge, representing the largest series described to date. The presence of both variants was associated with a more severe phenotype, characterized by combined cardiac and neurological involvement in all patients, underscoring the impact of dual genotypic expression and greater clinical burden. Despite this more severe presentation, clinical outcomes were favorable, with survival exceeding three years, surpassing the expected prognosis in the absence of treatment. These findings reinforce the benefit of disease-modifying therapy in ATTR.

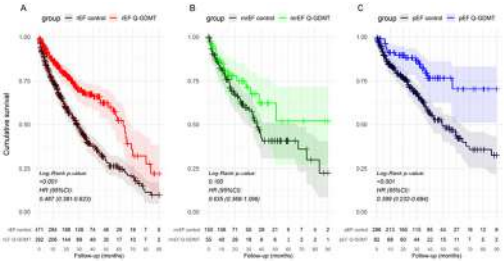
(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RO - BRASIL; (2) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RO - BRASIL; (3) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL; (4) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (5) UNIGRANRIO - RIO DE JANEIRO - RJ - BRASIL; (6) FUNDACAO TECNICO EDUCACIONAL SOUZA MARQUES - RIO DE JANEIRO - RJ - BRASIL; (7) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL; (8) HUAP - RIO DE JANEIRO - RJ - BRASIL;



Background/Introduction: Myocarditis and cardiomyopathies are conditions affecting the myocardium that share pathophysiological mechanisms and can progress to heart failure, which carries a substantial impact on cardiovascular morbidity and mortality. Despite overlapping characteristics, they differ in etiology and clinical presentation, requiring personalized diagnostic and therapeutic approaches. In this regard, establishing a registry to enhance the understanding of these conditions is crucial for developing diagnostic and therapeutic strategies that can improve prognosis and quality of life. Objectives: To analyze epidemiological data and outcomes related to cardiomyopathy and Inflammatory Myopericardial Syndrome among hospitalized patients in the main centers of the Metropolitan Region II of Rio de Janeiro. Methods: This is a cross-sectional, observational and multicenter study. Data collection from November 2025 to May 2026, covering demographic, clinical, laboratory, imaging, and outcome variables obtained from medical records in accordance with national ethical regulations. Results and Conclusions: A total of 52 patients were included (53.8% male). Dilated cardiomyopathy was the predominant phenotype (n=17), followed by myocarditis (n=13), hypertrophic cardiomyopathy (n=8), pericarditis (n=8), left ventricular arrhythmogenic cardiomyopathy (n=3), and infiltrative cardiomyopathy (n=3). Systemic arterial hypertension (55.8%), obesity (28.8%), and diabetes mellitus (23.1%) were the most prevalent comorbidities. One death (1.9%) was recorded due to non-cardiological causes. Initial diagnostic methods included echocardiography (100%), troponin (80.8%), NT-proBNP (67.3%), and ECG (59.6%). For advanced investigation, cardiac MRI (61.5%), genetic testing (7.7%), and endomyocardial biopsy (1.9%) were performed. The partial results of this registry in Metropolitan Region II of Rio de Janeiro demonstrate a predominance of dilated cardiomyopathy and myocarditis, highlighting the relevance of inflammatory and dilated phenotypes in the local hospital setting. The etiological diversity found, including cases of amyloidosis and arrhythmogenic cardiomyopathy, reinforces the need for rigorous differential diagnosis and the use of advanced imaging and genetic technologies. In summary, strengthening clinical registries is fundamental to optimizing risk stratification, enabling personalized therapies, and consequently reducing hospitalization rates and improving the prognosis of patients with myocardial and pericardial diseases.

RESULTS OF QUADRUPLE GUIDELINE-DIRECTED THERAPY ACROSS EJECTION FRACTION CATEGORIES IN HEART FAILURE: REAL-WORLD DATA FROM THE BEAT-HF REGISTRY

VINÍCIUS CARVALHO FIUSA1; GABRIEL CARVALHO FIUSA1; ADRIANA J. B. A. GUIMARÃES2; ANA CLÁUDIA C. NOGUEIRA2; ALEXANDRE ANDERSON S. M. SOARES1; LUIZ SÉRGIO FERNANDES DE CARVALHO1;

(1) UNIVERSIDADE DE BRASILIA - BRASÍLIA - DF - BRASIL; (2) ESCOLA SUPERIOR DE CIENCIAS DA SAUDE - BRASÍLIA - DF - BRASIL;

Background/Introduction: Heart failure (HF) remains a major contributor to cardiovascular morbidity and mortality worldwide. Quadruple guideline-directed medical therapy (Q-GDMT) is a standard strategy in HF with reduced ejection fraction, but current evidence is heterogeneous across other ejection fraction categories. Objectives: To evaluate the results of Q-GDMT across HF ejection fraction categories. Methods: We analyzed data from BEAT-HF (Brasília Evaluation and Tracking of Heart Failure), an observational cohort of 2,314 HF patients who received care between Aug/2010 and Jan/2024 at 6 public hospitals in Brasília, Brazil. Kaplan-Meier curves and Cox proportional hazard regression models were used to asses outcomes stratified by Q-GDMT. The primary outcome was combined hospitalization or death. Results and Conclusions: Our cohort was 56.8% male, with a mean age of 64.5±14.0 years. The population was ethnically-diverse: 53.4% mixed, 20.5% white, 19.5% black, and 6.5% asian. In total, 903 had rEF (56.2%), 241 mrEF (15.0%), and 463 pEF (28.8%). Adherence to GDMT was as follows: ACEI, ARB or ARNI (84.6%), beta-blockers (89.9%), MRA (68.8%), and SGLT2I (41.4%). Only 28,9% received Q-GDMT. Over the median follow-up of 20.8 months [IQR 8.1–36.7], 32.9% were hospitalized at least once, and 22.2% died (mean survival 63.6 months). Q-GDMD was associated with reduced risk for the primary outcome in patients with both rEF (HR 0.487, 95%CI 0.381–0.623, p<0.001) and pEF (HR 0.399, 95%CI 0.232–0.684, p<0.001). In this regionally-representative and ethnically-diverse cohort, Q-GDMT was associated with reduced combined hospitalization or death in HFrEF and HFpEF.

Table 1. Population characteristics, total and stratified by ejection fraction.

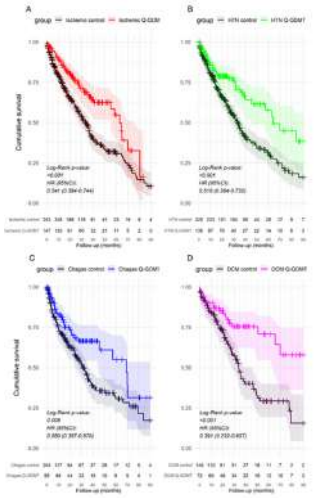
RESULTS OF QUADRUPLE GUIDELINE-DIRECTED THERAPY ACROSS THE MOST PREVALENT HEART FAILURE ETIOLOGIES IN BRAZIL: REAL-WORLD DATA FROM THE BEAT-HF REGISTRY

VINÍCIUS CARVALHO FIUSA1; GABRIEL CARVALHO FIUSA1; ADRIANA J. B. A. GUIMARÃES2; ANA CLÁUDIA CAVALCANTE NOGUEIRA2; ALEXANDRE ANDERSON S M SOARES1; LUIZ SÉRGIO FERNANDES DE CARVALHO1;



(1) UNIVERSIDADE DE BRASILIA - BRASÍLIA - DF - BRASIL; (2) ESCOLA SUPERIOR DE CIENCIAS DA SAUDE - BRASÍLIA - DF - BRASIL;

Background/Introduction: Heart failure (HF) remains a major contributor to cardiovascular morbidity and mortality in Latin America and worldwide. Objectives: To evaluate the results of quadruple guideline-directed medical therapy (Q-GDMT) across the Most Prevalent Heart Failure Etiologies in Brazil. Methods: We analyzed data from BEAT-HF (Brasília Evaluation and Tracking of Heart Failure), an observational cohort of 2,314 HF patients who received care between Aug/2010 and Jan/2024 at 6 public hospitals in Brasília, Brazil. Kaplan-Meier curves and Cox proportional hazard regression models were used to asses outcomes stratified by Q-GDMT. The primary outcome was combined hospitalization or death. Results and Conclusions: Our cohort was 56.8% male, with a mean age of 64.5±14.0 years. The population was ethnically-diverse: 53.4% mixed, 20.5% white, 19.5% black, and 6.5% asian. The most frequent HF etiologies were: ischemic (34.7%), hypertensive (24.7%), chagasic (20.8%), and dilated cardiomyopathy (14.0%). Adherence to guideline-directed medical therapies (GDMT) was as follows: ACEI, ARB or ARNI (84.6%), beta-blockers (89.9%), MRA (68.8%), and SGLT2I (41.4%). Only 28,9% received Q-GDMT. Over the median follow-up of 20.8 months [IQR 8.1–36.7], 32.9% were hospitalized at least once, and 22.2% died (mean survival 63.6 months). Q-GDMD was associated with reduced risk for the primary outcome across all investigated etiologies – ischemic (HR 0.541, 95%CI 0.394–0.744, p<0.001), hypertensive (HR 0.516, 95%CI 0.364–0.732, p>0.001), chagasic (HR 0.580, 95%CI 0.387–0.870, p=0.008), and DCM (HR 0.391, 95%CI 0.232–0.657, p<0.001). Data from this regionally-representative cohort shows that Q-GDMT was associated with reduced combined hospitalization or death across the most prevalent HF etiologies in Brazil.

Table 1. Population characteristics, total and stratified by frequent HF etiologies.

Variable	Ischemic (n=773)	HTN (n=504)	Chagasic (n=428)	DCM (n=285)	p-value

RISK OF INTUBATION IN PATIENTS WITH HEART FAILURE SUBMITS TO HIGH-FLOW NASAL THERAPY VS NONINVASIVE VENTILATION AND CONVENTIONAL OXYGEN THERAPY

LUCAS RODRIGUES ORTIZ SALGADO NASCIMENTO1; TAREK CASTRO FAYYAT1; MARIANA MAINARDES SILVA2; FERNANDA MANFROI GUIMARÃES1; SARA CAMARGO GUEIBER2; MARCELA VASCONCELOS MONTENEGRO3; ANA KARYN EHRENFRIED FREITAS1;

(1) UNIVERISADE POSITIVO - CURTIBA - PR - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARANÁ - CURITIBA - PR - BRASIL; (3) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL;

Background/Introduction: Patients with Heart Failure (HF), especially during acute decompensation, are at high risk of requiring invasive ventilatory support, which is associated with poorer prognosis and adverse clinical outcomes. Therefore, the use of noninvasive respiratory support strategies has become essential. However, current evidence remains insufficient to establish the clinical benefit of high-flow nasal therapy (HFNT) compared with other therapies. Objectives: Quantify the impact of using HFNT in comparison with conventional oxygen therapy and noninvasive ventilation (NIV) in patients with HF. Methods: PubMed, EMBASE, Web of Science, Scopus and Cochrane were searched for this systematic review and meta-analysis of studies comparing HNFT, NIV and conventional oxygen therapy in patients with HF. A total of 568 were triaged, for 15 full text-screenings. The primary outcome was needed for orotracheal intubation. Statistical analysis was performed using relative risk (RR) with corresponding 95% confidence intervals (CIs). All analyses were conducted using Review Manager (RevMan 5.4). Statistical heterogeneity was assessed using the I² statistic. Results and Conclusions: Three studies were included, comprising a total of 265 patients. The primary outcome was the need for orotracheal intubation. Pooled analysis using a random-effects model showed no statistically significant difference between strategies (RR 0.65; 95% CI 0.32–1.30; p=0.24), although the RR favored high-flow nasal therapy (HFNT), with no observed heterogeneity among studies (I²=0%). Secondary outcomes included all-cause mortality, intensive care unit admission, and length of hospital stay; however, reporting of these outcomes was highly heterogeneous, precluding quantitative synthesis. Additional parameters, such as arterial blood gas measurements, suggest improved physiological responses with HFNT. CONCLUSION: In patients with Heart Failure (HF), high-flow nasal therapy (HFNT) did not demonstrate a statistically significant reduction in the need for endotracheal intubation compared with noninvasive ventilation (NIV) or conventional oxygen therapy. The absence of heterogeneity across studies suggests consistency in these findings. However, variability in outcome reporting and the limited number of studies involving this population preclude definitive conclusions. Further well-designed studies are warranted to better define the role and clinical impact of these noninvasive respiratory support strategies in patients with HF.

SAFETY AND EARLY EXPERIENCE WITH VUTRISIRAN IN PATIENTS WITH TRANSTHYRETIN AMYLOID CARDIOMYOPATHY AT A REFERENCE CENTER

LUIZA SEIXAS MANSUR1; LUIZ CLAUDIO DANZMANN1; BRUNA PEDROSO PEREIRA1; MAIARA ANSCHAU FLORIANI1; MARIA CRISTINA COTTA MATTE1; ULYSSES RAZIA CAVALCANTI2; JULIANA MENEZES ZACHER1; GUSTAVO FARIAS PORCIUNCULA1; EDGAR CLOVIS PASA JUNIOR1; CRISTIANE KOPLIN1; MATEUS DE SÁ RÊGO LIMA ALMADA.1; PAULO ERNESTO LEAES1;

(1) UNIVERSIDADE FEDERAL DE CIENCIAS DA SAUDE DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL; (2) UNISINOS - SÃO LEOPOLDO - RS - BRASIL;

Background/Introduction: Cardiac amyloidosis is an increasingly recognized cause of heart failure, particularly in older individuals, and remains frequently underdiagnosed. It is characterized as a restrictive cardiomyopathy with progressive course and poor prognosis. Therapeutic options for transthyretin amyloid cardiomyopathy (ATTR-CM) include transthyretin stabilizers and newer therapies such as vutrisiran, an RNA interference–based treatment that reduces hepatic production of transthyretin (TTR). Recent clinical trials have demonstrated a favorable impact of this therapy on cardiovascular outcomes. Objectives: To evaluate the tolerability of vutrisiran in patients with transthyretin cardiac amyloidosis (ATTR-CM) associated with peripheral neuropathy, based on the initial experience of a reference center in southern Brazil, including different patient profiles—wild-type and hereditary forms—and across both early and advanced stages of the disease. Methods: This is a descriptive case series including three patients diagnosed with ATTR-CM receiving vutrisiran. Baseline clinical data were collected, and patients were monitored after treatment initiation, with emphasis on the identification of adverse events and clinical evolution. Results and Conclusions: Three patients were evaluated. The first patient, carrying the p.Ala101Val genetic variant, was in New York Heart Association (NYHA) functional class II with stage 2 neuropathy and remained clinically stable after 5 months of treatment, with no adverse events. The second patient, with wild-type disease, was in NYHA class I with stage 1 neuropathy and showed significant improvement in neuropathic symptoms after 3 months of treatment, without adverse effects. The third patient, also with wild-type disease, initially presented in NYHA class III with stage 3 neuropathy and improved after 3 months to NYHA class II and stage 2 neuropathy, with no reported adverse events. In this initial series, vutrisiran demonstrated good tolerability and a favorable safety profile, with no adverse reactions observed. Clinical improvement was noted in two of the three patients. Larger studies with longer follow-up are warranted to confirm these findings.

Table 1. Clinical characteristics and evolution of patients treated with vutrisiran

Patient	Disease type	Genetic variant	Baseline NYHA	Baseline neuropathy	Follow-up	Clinical evolution	Adverse events
1	Hereditary	p.Ala101Val	II	Stage 2	5 months	Clinical stability	No
2	Wild-type	—	I	Stage 1	3 months	Improvement in neuropathic symptoms	No
3	Wild-type	—	III	Stage 3	3 months	Clinical improvement (NYHA II; neuropathy stage 2)	No

Abbreviations: NYHA = New York Heart Association.

Note: Clinical improvement was observed in 2 of 3 patients, with no reported adverse events.

18605

Serum 25-hydroxyvitamin D and depressive symptoms across heart failure phenotypes in hospitalized older adults: a cross-sectional study

DÉBORA LEITE FERREIRA1; THALITA VICENTE BRANDÃO2; FLÁVIO ANDRADE CAMACHO2; RAÍLLA KLING DUTRA2; ISABELLA DE MEDEIROS MORAES1; ANA BEATRIZ DOS SANTOS RIBEIRO1; MARIA DE FÁTIMA MARTINS GIL DIAS3; ANDRE CASARSA MARQUES4; LEONARDO ANDRADE FERNANDES DE LUCA3; GABRIELLE DE SOUZA ROCHA2; RENATA FRAUCHES MEDEIROS2; ANDREA CARDOSO DE MATOS2;

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - Brasil; (2) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - Brasil; (3) REDE DOR - RIO DE JANEIRO - RJ - Brasil; (4) UNIVERSIDADE FEDERAL DO ESTADO DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - Brasil;

Background/Introduction: Heart failure is associated with a high prevalence of depressive symptoms, which negatively impact clinical outcomes. Vitamin D deficiency is common in this population and may contribute to mood disorders. Objectives: To investigate the relationship between serum 25-hydroxyvitamin D [25(OH)D] concentrations and depressive symptoms across HF phenotypes in hospitalized older adults. Methods: This cross-sectional study included patients aged ≥60 years hospitalized with heart failure. Serum 25(OH)D levels were measured, and deficiency was defined as <30 ng/mL. Depressive symptoms were assessed using the Patient Health Questionnaire-9 (PHQ-9), defined as a score ≥5 with at least one core symptom (depressed mood or anhedonia). Heart failure phenotypes were classified according to ejection fraction. Logistic regression was used to evaluate the association between 25(OH)D and depressive symptoms. A two-tailed p-value <0.05 was considered statistically significant. Results and Conclusions: A total of 64 patients were included. HF phenotypes differed in NT-proBNP levels (p=0.017), and prevalence of 25(OH)D deficiency (p=0.019), which was observed in 63.6%, 75.0%, and 33.3% of patients with preserved, mildly reduced, and reduced ejection fraction, respectively. Serum 25(OH)D concentrations were not associated with depressive symptoms, and no significant correlations were observed with PHQ-9 scores, either in the overall sample or stratified by ejection fraction. The prevalence of depressive symptoms did not differ between phenotypes (p=0.572). In multivariable logistic regression, only spiritual well-being was independently associated with depressive symptoms (OR=0.771; 95% CI: 0.646–0.920; p=0.004), whereas 25(OH)D, age, sex, and race were not significant predictors. The model was statistically significant (χ^2=15.743; p=0.008) with moderate explanatory power (Nagelkerke R^2=0.367). Although no correlation was found between serum 25(OH)D and depressive symptoms, greater spiritual well-being was associated with a lower occurrence of these symptoms.

THE HIDDEN BURDEN: SOMATIC DEPRESSION IN DECOMPENSATED HEART FAILURE PATIENTS

FLÁVIO ANDRADE CAMACHO1; MARIA DE FATIMA MARTINS GIL DIAS2; ANA BEATRIZ DE SOUZA RIBEIRO3; RAÍLLA KLING DUTRA1; ISABELLA DE MEDEIROS MORAES3; GABRIELLE DE SOUZA ROCHA1; ANDRE CASARSA MARQUES2; LUIS FILIPE AZEVEDO DE CARVALHO4; PEDRO BASTOS DE MEDEIROS5; LEONARDO ANDRADE FERNANDES DE LUCA4; SERGIO LUIS SCHMIDT2; JULIO CESAR TOLENTINO2;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL DO ESTADO DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (3) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (4) HOSPITAL QUINTA D'OR - RIO DE JANEIRO - RJ - BRASIL; (5) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Heart failure is among the leading causes of morbidity and mortality worldwide. Depression, in turn, is a highly prevalent and often underrecognized condition that significantly impacts quality of life and is associated with increased mortality and healthcare costs. In patients with HF, depressive symptoms are common and may worsen clinical outcomes, treatment adherence, and functional status. Depression often presents with a predominance of somatic symptoms, such as fatigue, sleep disturbances, reduced energy, appetite changes, and psychomotor retardation, which may overlap with manifestations of heart failure itself. Objectives: To investigate the association between somatic depression and the different phenotypes of heart failure. Methods: This observational cross-sectional study was conducted in a private hospital. Patients with a previous or new diagnosis of heart failure, according to Brazilian Cardiology Guideline criteria, were included, and those with cognitive disorders were excluded. Depressive symptoms were assessed using the PHQ-9, defined as five or more symptom symptoms including at least one of depressed mood or anhedonia. Somatic symptoms were assessed based on sleep disturbances, fatigue, appetite changes, and psychomotor changes. Statistical analyses included t-test, chi-square test, linear regression, Pearson correlation, and Levene's test. Results and Conclusions: A total of 191 patients were evaluated, of whom 37.9% were women. The mean age was 72 ± 6.2 years. The sample comprised 31.8% with heart failure with reduced ejection fraction and 68.2% with preserved ejection fraction. Depressive symptoms were identified in 74 (59.1%) patients and were more frequent in women, who had approximately twice the prevalence. Somatic symptoms were common but were not significantly associated with heart failure phenotypes (p=0.916, chi-square test). Depressive symptoms were highly prevalent among patients with decompensated heart failure, reinforcing their role as a frequent and clinically relevant comorbidity. Somatic manifestations were particularly prominent; however, they were not associated with different heart failure phenotypes.

U-SHAPED RELATIONSHIP BETWEEN POTASSIUM DYSREGULATION AND IN-HOSPITAL MORTALITY IN DECOMPENSATED HEART FAILURE

PEDRO CASTELLO BRANCO MORAES1; PEDRO PIMENTA DE MELLO SPINETI1; BRUNO REZNIK WAJSBROT1; MARCELO IMBROINISE BITTENCOURT1; ANA LUIZA DO CARMO SOUZA1; ANA LUIZA FERREIRA SALES1; FELIPE NEVES ALBUQUERQUE1; RICARDO MOURILHE-ROCHA1;

(1) HOSPITAL UNIVERSITARIO PEDRO ERNESTO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Potassium homeostasis disorders are frequently observed in patients hospitalized for decompensated heart failure (DHF) and are associated with worse in-hospital (IH) prognosis. Objectives: To evaluate whether potassium disturbances measured at admission or during hospitalization are associated with IH mortality. Methods: A retrospective, longitudinal, observational cohort study was conducted at a quaternary university hospital. Patients admitted with DHF between September 2019 and February 2024 were included. Potassium values at admission, as well as the highest and lowest values recorded during hospitalization, were collected. Hyperkalemia was defined as potassium >5.1 mEq/L and hypokalemia as <3.5 mEq/L, according to the institutional laboratory reference values. Vital status was determined by medical record review. Creatinine clearance was estimated using the 2021 CKD-EPI equation. Statistical analyses were performed using SPSS, with a significance level of 5%. The proportion of missing potassium data was below 10%. Results and Conclusions: A total of 402 patients admitted for DHF were analyzed: 56% male, mean age 64.9 ± 14.2 years. Systolic dysfunction was present in 65.7%; ischemic and valvular etiologies accounted for 30.6% and 11.4%, respectively. Hypertension was present in 67.7%, diabetes in 35.8%, atrial fibrillation or flutter in 32.8%, and CKD (creatinine clearance <60 mL/min) in 58.6%. Mean admission potassium was 4.31 ± 0.74 mEq/L. Hyperkalemia occurred in 9.2% at admission and 44.5% during hospitalization; hypokalemia in 7.1% and 39.6%, respectively. IH mortality was 14.4%. ROC curve analysis identified the lowest in-hospital potassium as the variable most strongly associated with IH mortality (AUC 0.75), with an optimal cut-off of 3.45 mEq/L (sensitivity 69.8%; specificity 74.8%). Given its proximity to the institutional lower reference limit, 3.5 mEq/L was adopted as the operational cut-off. Hypokalemia during hospitalization was associated with higher IH mortality (OR 6.86; 95% CI 3.63–12.95; p<0.001). A U-shaped relationship between admission potassium and IH mortality was observed, with nadir risk at approximately 4.3 mEq/L. Potassium disturbances were frequent in DHF. Hypokalemia during hospitalization was associated with higher IH mortality, and admission potassium exhibited a U-shaped relationship with this outcome.

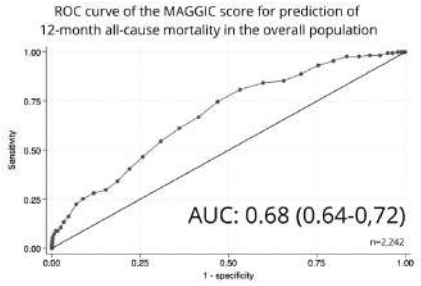
USE OF ARTIFICIAL INTELLIGENCE FOR INDIVIDUALIZATION OF CARDIAC REHABILITATION IN PATIENTS WITH HEART FAILURE

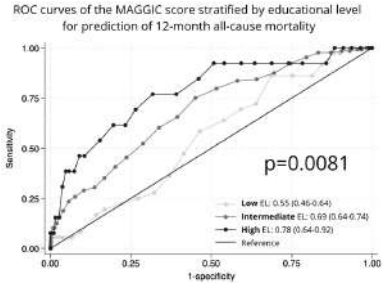
ALINE BRIZOLA OBERDERFER1; BRUNO CESCHIN CHIARATTI1; GABRIELA CARAMORI MENDES1; GUSTAVO PICHEL KAKUDA1; MARIANA MALZONI ROLDAN1; SALIM MUSSI NETO1; FABRICIA DANIELA MARTINS ALMEIDA2; ANA KARYN EHRENFRIED FREITAS1;

(1) UNIVERISADE POSITIVO - CURTIBA - PR - BRASIL; (2) HOSPITAL DE CLINICAS DO PARANÁ - CURITIBA - PR - BRASIL;

Background/Introduction: Heart failure remains a major challenge in cardiology due to its high morbidity and mortality. Although cardiac rehabilitation is a gold-standard intervention for improving functional capacity and reducing hospitalizations, its implementation is limited by geographic barriers, shortage of specialized centers, and low patient adherence. In this context, Artificial Intelligence (AI) may help by processing clinical guidelines to generate personalized exercise protocols, expanding access and optimizing outcomes. Objectives: To evaluate the clinical and functional effectiveness of an AI-individualized cardiac rehabilitation protocol compared with conventional rehabilitation and no structured exercise in patients with heart failure. Methods: Prospective experimental study including 15 clinically stable patients with heart failure with reduced ejection fraction. Participants were randomized into three groups: Group A, AI-individualized rehabilitation protocol (via a bot trained with major national and international heart failure guidelines); Group B, conventional rehabilitation; and Group C, no formal exercise guidance. Follow-up was 8 weeks. Assessments included the Kansas questionnaire, Sit-to-Stand Test, Handgrip Strength, and 6-Minute Walk Test. Results and Conclusions: The sample (mean age 60 years; 80% male) showed relevant benefits with rehabilitation. The AI group demonstrated superior performance in objective outcomes: mean increase of 102 meters in the 6-minute walk test (vs 63 meters in the conventional group and 6 meters in controls) and gain of 5.5 kgf in handgrip strength. The conventional group was superior in the sit-to-stand test, while the control group showed better results in a subjective quality-of-life measure, contrary to the remaining findings. No serious adverse events occurred. Limitations included the small sample size and adherence challenges: follow-up rates were 72% in the AI group, 83% in the conventional group, and 44% in controls. Conclusion AI-guided rehabilitation prescription was safe and effective in heart failure, producing functional gains comparable or superior to conventional methods. This technology may support clinical decision-making and expand access to therapy without replacing human care. Larger studies are needed to confirm these findings.



19416



VALIDATION OF THE MAGGIC SCORE IN BRAZIL AND THE IMPACT OF EDUCATIONAL LEVEL ON ITS PROGNOSIS ACCURACY.

(1) UNIVERSIDADE FEDERAL DO PARANÁ (UFPR) - CURITIBA/PR - CURITIBA - PR - BRASIL; (2) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL; (3) HOSPITAL AGAMENON MAGALHAES - RECIFE - PE - BRASIL; (4) UNIVERSIDADE LUTERANA DO BRASIL- ULBRA - CANOAS - RS - BRASIL; (5) UNIVERSIDADE FEDERAL DO PIAUI - PIAUÍ - PI - BRASIL; (6) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL; (7) UNIVERSIDADE FEDERAL DO ACRE - RIO BRANCO - AC - BRASIL;

Background/Introduction: The Meta-analysis Global Group in Chronic Heart Failure (MAGGIC) score is a widely used prognostic model for mortality risk estimation in chronic heart failure (CHF). It was derived from ~40,000 patients, with limited representation of Latin American populations, and validated mainly in developed countries. Socioeconomic differences in Brazil may limit its external validity. Objectives: To assess the performance of the MAGGIC score in predicting 12-month mortality in Brazilian patients with CHF, and to evaluate the influence of educational level (EL) on its discrimination and calibration. Methods: This prospective, multicenter Brazilian cohort included outpatients with CHF from 30 specialized centers. Patients aged ≥18 years with LVEF ≤50% were enrolled between June 2021 and June 2025 and followed through September 2025. Baseline data for MAGGIC calculation were obtained via standardized questionnaire and medical record review. EL was self-reported and classified as low (illiterate/basic literacy), intermediate (incomplete elementary to high school), and high (college or higher). Follow-up was conducted by telephone to ascertain mortality. Results and Conclusions: A total of 2,389 patients were included (low/intermediate/high EL: n=406/1,757/216; 10 missing). Mean LVEF was 33.6±9.1%, age 61.0±13.5 years, and MAGGIC score 18.6±6.8. Lower EL was associated with higher MAGGIC, older age, higher SBP, more Chagas etiology and COPD, higher NYHA class, and lower use of GDMT at target doses (all p<0.01 for trend). The MAGGIC score showed modest discrimination (AUC 0.68 [0.64–0.72]) and poor calibration (Hosmer-Lemeshow p=0.02). AUCs were 0.55, 0.69, and 0.78 from low to high EL (p=0.008). Calibration was acceptable within strata (p=0.37, 0.20, 0.87). EL modified the association with mortality: compared with low EL, each 10-point increase in MAGGIC was associated with higher odds of death in intermediate (OR 2.16 [1.12–3.92]; p=0.011) and high EL (OR 3.22 [1.21–8.57]; p=0.019). In conclusion, the MAGGIC score showed modest discrimination and inadequate calibration overall. Discrimination was higher in the higher EL groups.

19039

VASOACTIVE SUPPORT IN THE WARD FOR ADVANCED HEART FAILURE: WHEN EXTREME SEVERITY DOES NOT TRANSLATE INTO HIGH MORTALITY

MARIA JULIANA DE ARRUDA QUEIROGA1; THAYNA ALMEIDA BATISTA1; GABRIELA BRITO BEZERRA1; DÉBORA MARQUES MIRANDA SANTANDER2; IGOR RAFAEL MIRANDA FERREIRA SANTANDER2; LARA MARIA MOURA DE SÁ VILLA-CHAN3; DANIEL MOREIRA ALMEIDA1; MARIA ALTINA DE ANDRADE BONILLA3; MARCELA VASCONCELOS MONTENEGRO1; LUIZ DE ALBUQUERQUE PEREIRA DE OLIVEIRA NETO1; HEITOR REGIS SPINELLI1; CARLOS EDUARDO LUCENA MONTENEGRO1;

(1) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL; (2) FAMENE - JOÃO PESSOA - PB - BRASIL; (3) UPE - RECIFE - PE - BRASIL;

Background/Introduction: Advanced heart failure presents high mortality and complex management, with frequent use of vasoactive drugs, even in ward settings, due to structural limitations. Despite its clinical relevance, data on outcomes outside the intensive care unit (ICU) remain scarce. Investigating this practice is essential to guide management, optimize resources, and improve prognosis. Objectives: To evaluate the association between vasoactive support use, length of stay, in-hospital mortality, and 30-day readmission in patients hospitalized for decompensated heart failure. Methods: An observational, retrospective study with analysis of medical records of 252 patients hospitalized in a tertiary hospital between January and December 2024. Results and Conclusions: The use of vasoactive drugs (VAD) was frequent and not exclusive among patients, reflecting the need for therapeutic escalation. Dobutamine had the longest median duration of use (29 days), suggesting greater severity. Nitroglycerin was the most commonly used (n=77), but for a shorter duration (8 days), consistent with acute phases. Milrinone and levosimendan had limited use. Vasoactive support was associated with longer hospital stay, especially with dobutamine (34 vs. 18 days; p=0.002) and nitroglycerin (31 vs. 20 days; p=0.002). In-hospital mortality was 8.3%, higher among vasoactive users, particularly with milrinone (75%; p<0.001). The 30-day readmission rate was 7.2%, occurring exclusively in patients with heart failure with reduced ejection fraction (HFrEF) (p=0.014). The study reveals a profile of advanced heart failure, with frequent and prolonged use of vasoactive drugs, especially dobutamine, reflecting greater severity and hemodynamic instability. The need for these therapies was associated with longer hospital stays and worse outcomes, representing an important risk marker rather than a direct causal effect. Despite this scenario of high complexity, the in-hospital mortality rate was relatively low (8.3%), falling within or below the range described in contemporary registries (7–12%) and lower than more severe cohorts with inotrope use (>20%). This finding reinforces the adequacy of clinical management, even with widespread use of vasoactive support. The 30-day readmission rate was also low (7.2%), concentrated exclusively in patients with HFrEF, highlighting this phenotype as having greater vulnerability in the post-discharge period.

Table 3. Length of stay (in days) on inotropic and vasodilator support.

Medication	n	Median (Minimum – Maximum)	Mean (SD)
Dobutamine	75	29.0 (8–75)	32.0 (±6.6)
Nitroglycerin	77	8.0 (2–22)	10.0 (84.6)
Milrinone	8	7.0 (1–46)	14.6 (18.6)
Levosimedan	4	1.0 (1–1)	1.0 (0.0)

n, number of participants; sd: standard deviation; [1] The drug categories are not mutually exclusive, as the same patient may have used more than one vasoactive therapy during the inpatient period; ^A ^2 The values refer to the length of **hospital stay** (in days) for users of each drug. Source: Research data, 2026.

Table 4. Length of hospital stay (in days) according to the pharmacological support used.

Drug	Median (IQR)	Minimum – Maximum	P
Dobutamine[3]			
Yes (n=75)	34.0 (22 – 63)	3 – 276	0.00[2]
No (n=175)	18 (12 – 18)	4 – 80	
Nitroglycerin[3]			
Yes (n=77)	31.0 (15 – 45)	3 – 276	0.00[2]
No (n=173)	20 (12 – 29)	4 – 225	
Milrinone[3]			
Yes (n=8)	60.5 (20 – 172)	3 – 266	0.57
No (n=242)	22 (13 – 34)	4 – 276	
Levosimedan[3]			
Yes (n=4)	67.0 (26 – 139)	7 – 189	0.148
No (n=246)	22 (13 – 34)	3 – 276	

n, number of participants; iqr, interquartile range; [A1] The values refer to the length of hospital stay (in days) for users of each drug; [A2] Based on the analysis by the Mann–n-Whitney Test, adopting a 95% confidence interval, there was a statistical difference between the groups (p < 0.05); [3] The drug categories are not mutually exclusive, as the same patient may have used more than one vasoactive therapy during the inpatient period. Source: Research data, 2026.

Table 5. Comparison of in-hospital mortality between users and non-users of pharmacological support.

VAD	Death in Users n (%)	Death in Non-Users n (%)	P
Dobutamine	16 (26-23)	5 (2.8)	< 0.001[1]
Nitroglycerin	11 (14.3)	10 (5.7)	0.023[3]
Milrinone	6 (75.0)	15 (6.1)	< 0.001[2]
Levosimedan	1 (25.0)	20 (8.1)	0.295[2]

VAD: Vasoactive Drug; n: number of participants; n number of participants; (%) Percentage within the group; [A1] Pearson's Chisquare Test; [A2] Fisher's Exact Test. Source: Research data, 2026. data, 2026.

Table 6. Distribution of 30-day readmissions according to HF profile.

HF profile	Discharge (n)	Readmission (n)	Rate (%)	P
HFrEF	166	16	9.6%	0.014[1]
HFmrEF	15	0	0.0%	
HFpEF	40	0	0.0%	
Total	**221**	**16**	**7.2%**	

Heart Failure (HF); Heart Failure with reduced Ejection Fraction (HFrEF); Heart Failure with mildly reduced Ejection Fraction (HFmrEF); Heart Failure with **thh** preserved Ejection Fraction (HFpEF); n, number of participants; %, percentage corresponding to the total; [A1] Due to the absence of readmission events **in in** the HFmrEF and HFpEF groups, a dichotomous comparative analysis between the HFrEF profile and the early readmission variable was performed. Based on the analysis by Fisher's Test, adopting a 95% confidence interval between the groups (p < 0.05). Source: Research data, 2026.

ACUTE EFFECTS OF BEETROOT NITRATE SUPPLEMENTATION ON MICROVASCULAR FUNCTION AND NITRIC OXIDE METABOLITES IN RESISTANT HYPERTENSION

STELLA CORRÊA BARRIAS NARA ROCHA1; PATRÍCIA REGINA THOMÉ MARTINS2; ELISA MAIA DOS SANTOS3; VALÉRIA VERRI3; ANDREA ROCHA DE LORENZO2; EDUARDO VERA TIBIRIÇÁ2; GRAZIELLE VILAS BÔAS HUGUENIN1;

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (3) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Hypertension is a major cardiovascular risk factor. Resistant hypertension (RH) is a severe form associated with endothelial dysfunction and reduced nitric oxide (NO) bioavailability. Dietary nitrate (NO_3^-), particularly from beetroot, may enhance NO production, but evidence in RH remains limited. Objectives: Evaluate the acute effects of beetroot extract on microvascular function and plasma nitrite and nitrate levels in patients with RH. Methods: This was a single-blind, randomized, placebo-controlled clinical trial conducted in patients with RH. Participants (≥18 years) attended a single visit after an overnight fast and were randomly to receive either beetroot extract (10g, ~400 mg NO_3^-) or placebo (maltodextrin 10g). Microvascular endothelial function was assessed at baseline and 120 minutes post-intervention using laser speckle contrast imaging (LSCI) (Pericam PSI System, Perimed, Sweden), combined with iontophoresis of acetylcholine (ACh) and sodium nitroprusside (SNP) to evaluate dependent and independent responses, as well as post-occlusive reactive hyperemia (PORH). Plasma NO_3^- and NO_2^- were measured at t0 and t120. Microvascular perfusion was normalised to mean arterial pressure to derive cutaneous vascular conductance (CVC, APU/mmHg). Statistical analysis used Student's t-test ($p<0.05$). Results and Conclusions: A total of 59 participants were included. The BN group showed higher plasma NO_2^- and NO_3^- concentrations at 120 min ($p=0.001$). Area under the curve (AUC) decreased following both ACh and SNP stimuli in both groups ($p=0.001$). Peak CVC decreased within the PLA group at t120 in response to ACh ($p=0.013$); however, no between-group difference was found at this time point ($p=0.826$). No differences between groups were observed for Δpeak CVC (ACh or SNP), and peak CVC in response to SNP was similar between groups. PORH responses showed higher peak CVC in PLA at baseline ($p=0.002$). Peak CVC decreased within the PLA group at t120 ($p=0.001$), with no between-group difference ($p=0.730$). No between-group differences were observed for Δpeak CVC adjusted for HRPO. Despite increased NO_2^- and NO_3^- bioavailability, beetroot extract did not improve microvascular reactivity. This lack of effect may reflect the severe endothelial dysfunction typical of RH, compounded by comorbidities such as obesity, dyslipidemia, and diabetes, and possibly an insufficient dose to elicit endothelial benefits. Further studies are needed to better elucidate the nitrate–nitrite–NO pathway in this population.

BAROREFLEX ACTIVATION IN THE TREATMENT OF RESISTANT HYPERTENSION: A SYSTEMATIC REVIEW.

EMILLY MENDANHA OLIVEIRA1; MATEUS ALFREDO DUARTE1; ARTHUR ALVES CARVALHO E SILVA1; JÚLIA LAMOUNIER ARAÚJO1; MARIA EDUARDA COSTA CORRÊA1; LUANA COSTA PRADO1; LEONARDO LOBATO LEÃO1; RUTH SANTOS ARAÚJO FERREIRA1; GABRIELA MARIA BEZERRA SILVA1; MARIA EDUARDA POSSATO FRANCO1;

(1) UNIVERSIDADE DE RIO VERDE CAMPUS FORMOSA - FORMOSA - GO - BRASIL;

Background/Introduction: Resistant hypertension represents a significant clinical challenge, being associated with high cardiovascular morbidity and mortality and limitations of conventional pharmacological therapies. In this context, baroreflex activation therapy (BAT) emerges as an innovative alternative. Objectives: Analyze the effects of baroreflex activation in resistant hypertension. Methods: This is a systematic literature review following the parameters established by PRISMA-2020. For the search, the terms "Baroreflex activation and resistant hypertension" were used; searches were conducted in PubMed with the filters "last 5 years and clinical studies" and in LILACS with the filters "last 5 years," selecting the complete collection from BVS. Clinical studies in English were included. Results and Conclusions: 31 articles were found, which 2 were deleted for being duplicates, 13 for being tangential to the topic, 2 for being meta-analyses, 5 reviews, 2 animal studies, and 1 case report; 8 articles were included. The applicability of BAT in resistant hypertension (RH) proved to be highly selective. Clinical evaluation revealed that surgical recommendation was feasible for only 17.1% of patients, with implantation effectiveness restricted to 7.8%. Patients undergoing active stimulation exhibited a decrease in 24-hour ambulatory systolic blood pressure at 8 months. Continuous neurological dependence was demonstrated in a crossover trial. Retrospective data confirm that first-generation devices promoted statistically robust reductions in 24-hour and nighttime systolic blood pressure. In contrast, second-generation minimally invasive devices exerted their primary effect through a significant reduction in 24-hour and daytime heart rate, with a less pronounced impact on ambulatory blood pressure in this subgroup. The advantage of the second generation was limited to gains in structural longevity.In 24 patients with a refractory non-dipper phenotypic profile, algorithmic optimization exclusively enhancing nocturnal pulse width converted the physiological pattern, promoting an increase in nocturnal systolic dipping.Baroreflex activation therapy constitutes an effective therapeutic strategy, mainly in patients with a well-defined clinical phenotype and high cardiovascular risk. Its effect in reducing blood pressure in the long term. However, its applicability remains limited, as it requires rigorous clinical evaluation to rule out secondary factors.

DOSE–RESPONSE EFFECT OF SACUBITRIL/VALSARTAN ON OFFICE BLOOD PRESSURE CONTROL IN PREDOMINANTLY AFRO-DESCENDANT PATIENTS WITH RESISTANT HYPERTENSION: A POST HOC ANALYSIS OF A RANDOMIZED CLINICAL TRIAL

YASMIN DE SOUZA LIMA BITAR1; ANDRE RODRIGUES DURAES1; CRISTIANO RICARDO BASTOS DE MACEDO1; MARCELA GORDILHO ARAS2; LEVI CARDOZO SANTOS2; ROGERIO SMITH FREIRE DE ABREU2; ENILSON CARMO BARBOSA DOS SANTOS1; ROQUE ARAS JUNIOR1;

(1) UNIVERSIDADE FEDERAL DA BAHIA - PROGRAMA DE POS GRADUACAO EM MEDICINA E SAUDE - SALVADOR - BA - BRASIL; (2) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL;

Background/Introduction: Resistant hypertension (RH) remains a major therapeutic challenge and is associated with increased cardiovascular risk. Sacubitril/valsartan (Sac/Val) has demonstrated efficacy in blood pressure reduction; however, data regarding its dose-dependent effects in Afro-descendant populations, remain limited. Objectives: To evaluate the dose–response effect of Sac/Val on seated office blood pressure (systolic, diastolic, and pulse pressure), compared with standard therapy, in patients with RH, with emphasis on a predominantly Afro-descendant population, through a post hoc analysis of a randomized clinical trial (RCT). Methods: This post hoc analysis of a prospective, multicenter, open-label, 8-week RCT included 80 predominantly Afro-descendant patients with RH receiving ≥3 antihypertensive agents at maximally tolerated doses. Participants were randomized to standard therapy (enalapril 40 mg/day or losartan 100 mg/day, combined with a calcium channel blocker and a thiazide diuretic) or Sac/Val, up-titrated from 100 to 400 mg/day according to tolerance. The primary endpoint was the proportion of patients achieving seated office systolic blood pressure (SBP) targets ≤140 and ≤130 mmHg and diastolic blood pressure (DBP) targets ≤90 and ≤80 mmHg. Secondary endpoints included mean reductions in office SBP, DBP, and pulse pressure (PP). Proportions were compared using the chi-square test, and continuous variables using analysis of variance (ANOVA) with post hoc analyses. Statistical analyses were performed using SPSS version 25.0, with statistical significance defined as $p < 0.05$. Results and Conclusions: Eighty patients were randomized to Sac/Val (n=40) or standard therapy (n=40), and 75 completed follow-up. After 8 weeks, Sac/Val 100 and 200 mg/day showed the highest blood pressure (BP) target achievement. SBP ≤140 mmHg was achieved in 92.3% and 88.5% of patients, respectively ($p = 0.004$), while SBP ≤130 mmHg was achieved in 76.9% and 84.6% ($p < 0.001$). The 200 mg dose showed the highest DBP control rates for ≤90 mmHg (100%) and ≤80 mmHg (65.4%) ($p = 0.008$ and $p = 0.005$, respectively). Post hoc analyses demonstrated greater SBP reduction with Sac/Val 400 mg versus ACE inhibitor therapy (−20.1 mmHg; 95% CI: −39.4 to −0.9; $p = 0.043$), while the 200 mg dose showed the greatest DBP reduction (−9.1 mmHg; 95% CI: −18.0 to −0.2; $p = 0.044$). No serious adverse events occurred. Sac/Val improved BP control in predominantly Afro-descendant patients with RH, particularly at intermediate doses.

Background/Introduction: Aldosterone dysregulation plays a key role in the pathogenesis of hypertension (HTN). Baxdrostat, a selective aldosterone synthase inhibitor (ASI), is under investigation as a potential treatment option. However, evidence on its efficacy and safety is limited. Objectives: To evaluate the efficacy and safety of baxdrostat in patients with uncontrolled or resistant hypertension through a systematic review and meta-analysis of randomized controlled trials. Methods: This systematic review and meta-analysis was conducted in accordance with PRISMA guidelines. PubMed, Embase, and Cochrane databases were searched for Randomized Controlled Trials (RCTs) comparing Baxdrostat with placebo in patients with uncontrolled or resistant HTN. We pooled risk ratios (RR) and mean differences (MD) with 95% confidence intervals (CI) for binary and continuous endpoints, respectively. The number needed to harm (NNH) was computed as 1/[CER×(RR−1)] using the pooled RR and the pooled control event rate with 95% CI. Results and Conclusions: We included 3 RCTs comprising 1,264 patients, of whom 865 (68%) were randomized to Baxdrostat. Overall, Baxdrostat was associated with reductions in systolic (MD -8.6 mmHg; 95% CI -10.6 to -6.6; p<0.01; Figure 1A) and diastolic blood pressure (BP) (MD -3.5 mmHg; 95% CI -4.8 to -2.2; p<0.01; Figure 1B). Patients treated with Baxdrostat had a higher risk of hyperkalemia (RR 10.2; 95% CI 4.0 to 25.7; p<0.001; Figure 1C), corresponding to an NNH of 10.7 (95% CI 4.0 to 32.2), and overall adverse events (RR 1.2; 95% CI 1.0 to 1.4; p=0.028; Figure 1D). There was no difference in the risk of hypotension (RR 1.8; 95% CI 0.5 to 6.0; p=0.29) or hyponatremia (RR 3.35; 95% CI 0.61 to 18.30; p=0.162). While baxdrostat provides clinically meaningful blood pressure reductions with an increased risk of hyperkalemia, highlighting the need for careful patient selection and monitoring. Larger and longer-term trials are required to define its role in clinical practice.

Figure 1A) There was a significant reduction in systolic blood pressure with the use of Baxdrostat (p<0.01)

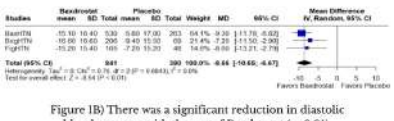

Figure 1C) The use of Baxdrostat was associated with a higher risk of hyperkalemia (p<0.001)

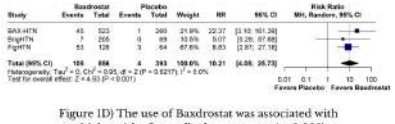

Figure 1B) There was a significant reduction in diastolic blood pressure with the use of Baxdrostat (p<0.01)

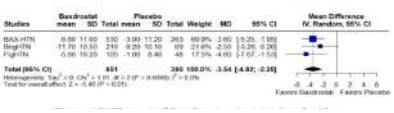

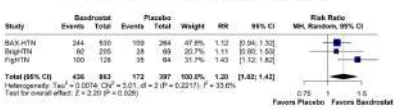

Figure 1D) The use of Baxdrostat was associated with a higher risk of overall adverse events (p=0.028)

IMPACT OF A CARDIORENAL CLINIC ON HEART FAILURE GUIDELINE-DIRECTED MEDICAL THERAPY: INSIGHTS FROM A NATIONAL TERTIARY REFERRAL CENTRE IN AN EMERGING ECONOMY

LUIS ENRIQUE HERNANDEZ-BADILLO1; VICTOR HUGO GOMEZ-JOHNSON2; SALVADOR LOPEZ-GIL2; MAGDALENA MADERO-ROVALO2; ANTONIO JORDAN-RIOS2;

(1) DEPARTMENT OF INTERNAL MEDICINE, DR. BELISARIO DOMÍNGUEZ SPECIALTY HOSPITAL, MEXICO CITY, MEXICO - DF - MEXICO; (2) INCICH - MEXICO;

Background/Introduction: The global burden of cardiorenal disease is rising, prompting integrated care models. Cardiorenal clinics unite cardiologists and nephrologists. This study evaluated GDMT uptitration in severely ill cardiorenal patients. Objectives: To evaluate the impact of a dedicated cardiorenal clinic on the optimization and implementation of guideline-directed medical therapy in patients with heart failure at a national tertiary referral center in an emerging economy. Methods: Between April 2024 and January 2025, 81 patients with heart failure (HFrEF, HFmrEF, or HFpEF) and chronic kidney disease (eGFR <60 ml/min/1.73m²) were prospectively analysed at the National Institute of Cardiology's cardiorenal clinic. All patients were jointly assessed by a cardiologist and a nephrologist to determine optimal treatment based on current evidence and ESC guidelines. The primary outcome was pharmacological optimisation, measured by the modified Heart Failure Collaborative (mHFC) score. A score >60 indicates good optimisation. Renal disease progression was also analysed. Results and Conclusions: Results: In this high-risk cohort, 93.7% had HFrEF, predominantly of ischaemic origin (70.9%). Median LVEF was 32.5%, NT-proBNP 5503 pg/mL, and CA125 12.9. After six months, the mHFC score improved significantly (48.8→78.4; p<0.001), with favourable renal outcomes. Conclusion Our cardiorenal clinic model significantly improved pharmacological optimisation and reduced prognostic markers such as albuminuria. No significant difference in CV mortality was observed, likely due to limited follow-up and sample size. Further analysis is on going guideline-directed medical therapy

THE ASSOCIATION BETWEEN SERUM BIOMARKERS AND CARDIAC REMODELLING IN EARLY STAGES OF CHRONIC KIDNEY DISEASE: A SYSTEMATIC REVIEW

EDUARDA BARANSELLI SESTITO1; RUI MANUEL DE SOUSA SEQUEIRA ANTUNES DE ALMEIDA2;

(1) CENTRO UNIVERSITÁRIO DA FUNDAÇÃO ASSIS GURGACZ - CASCAVEL - PR - BRASIL; (2) CENTRO UNIVERSITARIO DA FUNDAÇÃO ASSIS GURGACZ - CASCAVEL - PR - BRASIL;

Background/Introduction: The main cause of mortality in patients with chronic kidney disease (CKD) is cardiovascular damage. Cardiac remodeling begins silently in the early stages of CKD, and if not treated correctly, may cause severe cardiac compromise. The usual imaging resources can detect left ventricular hypertrophy in severe chronic kidney disease, and it might be too late for any kind of therapy. Therefore, cardiac biomarkers may be a useful screening tool for identifying subclinical cardiac remodeling. Objectives: To evaluate the role of cardiac biomarkers in early detection and risk stratification of subclinical cardiac remodeling. Methods: A systematic review was conducted in accordance with PRISMA guidelines. MEDLINE (via PubMed) and Cochrane Library were searched. Studies including adult patients with CKD stages 1–3a and reporting associations between serum cardiac biomarkers and imaging-defined cardiac remodeling published until August 2025 were included. Study selection was reviewed by an independent reviewer. Risk of bias was assessed using the Joanna Briggs Institute tool. Results and Conclusions: Six studies comprising 9,074 patients were included. NT-proBNP consistently demonstrated a strong association with early cardiac remodeling parameters, particularly left ventricular mass index (LVMI), as it is more closely associated with ventricular wall stress and filling pressure; its synthesis and release occur in response to myocyte distension, volume, and pressure overload. Cardiac troponins were associated with edema and direct damage, including LVMI, left ventricular end-systolic volume (LVESV), and left ventricular end-diastolic volume (LVEDV), but showed no consistent association with left ventricular ejection fraction (LVEF) or left atrial diameter (LAD). Overall, findings across studies were consistent despite methodological heterogeneity. CONCLUSION: NT-proBNP appears to be a promising biomarker for early detection of subclinical cardiac remodeling in patients with CKD. These findings support the potential role of biomarker-based strategies in improving early cardiovascular risk stratification and enabling timely intervention in this high-risk population.

ANGIOGRAPHY-DERIVED FRACTIONAL FLOW RESERVE VERSUS INVASIVE WIRE-BASED FFR IN INTERMEDIATE CORONARY STENOSES: A SYSTEMATIC REVIEW AND META-ANALYSIS OF NON-INFERIORITY

GABRIEL MOURA MACHADO1; MATHEUS ÁVILA MARQUES SANDRE2; LEONARDO DEXHEIMER DA SILVA3; MARIANA MARQUES SEIXAS4; ANA LIVIA LUCATTO BARBIERI5; LUHANDA LEONORA CARDOSO MONTI SOUSA6;

(1) FUNDACAO TECNICO EDUCACIONAL SOUZA MARQUES - RIO DE JANEIRO - RJ - BRASIL; (2) PONTIFICIA UNIVERSIDADE CATOLICA DE GOIAS - GOIÂNIA - GO - BRASIL; (3) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (4) PONTIFICIA UNIVERSIDADE CATOLICA DE SAO PAULO - SÃO PAULO - SP - BRASIL; (5) UNIVERSIDADE DO OESTE PAULISTA - UNOESTE - PRESIDENTE PRUDENTE - SP - BRASIL; (6) INSTITUTO DO CORACAO (INCOR) - HOSPITAL DAS CLINICAS DA FACULDADE DE MEDICINA DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Background/Introduction: Invasive fractional flow reserve (FFR) with a pressure wire during angiography is the gold standard for functional assessment of intermediate coronary stenoses. However, it remains underutilized in clinical practice mostly due to its high cost and invasive nature. In this context, angiography-derived FFR technologies emerged as a less invasive and more clinically accessible alternative. However, whether these technologies are non-inferior to invasive FFR regarding clinical outcomes remains unclear. Thus, this meta-analysis evaluates the comparability of angiography-derived FFR to invasive FFR. Objectives: To compare imaging-based FFR and invasive FFR regarding clinical outcomes, including MACE and hard endpoints, through a systematic review and meta-analysis of available randomized controlled trials. Methods: Following PRISMA standards, we systematically searched MEDLINE and Embase for RCTs comparing imaging-based FFR to invasive FFR. The primary outcome was 1-year MACE, while secondary outcomes included unplanned indicated revascularization, MI, cardiovascular death, and stent thrombosis. Pooled risk ratios (RR) with 95% confidence intervals were calculated using a random-effects model. Results and Conclusions: Three RCTs comprising a total of 6,141 patients (3,089 imaging-based FFR vs. 3,052 invasive FFR) were included. The comparative analysis did not demonstrate statistically significant differences in MACE (RR 1.14; 95% CI 0.85–1.55; I² 57.4%), Unplanned Indicated Revascularization (RR 0.96; 95% CI 0.71–1.29; I² 0%), Any Myocardial Infarction (RR 1.14; 95% CI 0.65–2.00; I² 65.3%), or any other outcome. Although imaging-based FFR showed no significant difference compared to invasive FFR, it is important to highlight that vFFR and FFRangio formally demonstrated non-inferiority and differences may be influenced by distinct algorithms and how each method classified vessel disease severity. Three studies still represent a limited number to establish non-inferiority or a bicaudal difference. Thus, the absence of significant differences suggests the clinical gap between both strategies is probably not large, and imaging-based FFR is likely better than angiography-alone guidance. Furthermore, angio-FFR platforms should not be considered a single therapeutic class, since vFFR and FFRangio demonstrated non-inferiority to invasive FFR outcomes, unlike QFR, which holds a current Class IB guideline recommendation. Further studies are warranted to define the role of imaging-based FFR in clinical practice.

BALLOON PULMONARY ANGIOPLASTY IN CHRONIC THROMBOEMBOLIC PULMONARY HYPERTENSION: INITIAL REGISTRY FROM A TERTIARY HOSPITAL IN SOUTHERN BRAZIL

MILENE FEHLBERG SEHN1; GUILHERME PINHEIRO MACHADO1; PEDRO CASTILHOS DE FREITAS CRIVELARO1; JÚLIA REI PIRES1; JÚLIA BRIGONI MACIEL1; DILLERMANDO O. SCHÄFFER1; JOÃO GABRIEL O. PORTO1; WILLIAM LORENZI1; FELIPE HOMEM VALLE1; MARCO VUGMAN WAINSTEIN1; MARCELO BASSO GAZZANA1; RODRIGO VUGMAN WAINSTEIN1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: Chronic thromboembolic pulmonary hypertension (CTEPH) occurs in up to 5% of cases of pulmonary thromboembolism. Although pulmonary thromboendarterectomy is the treatment of choice, a multimodal management approach including balloon pulmonary angioplasty (BPA) and medications has been gaining ground in non-surgical patients, high-risk surgical candidates, and those with persistent pulmonary hypertension after surgery. BPA may potentially improve functional capacity, reduce pulmonary pressures and pulmonary vascular resistance, and enhance right ventricular performance. Objectives: The present study aims to describe the initial experience from a tertiary hospital in southern Brazil with the use of BPA in patients with CTEPH. Methods: Ambispective cohort including all patients who underwent BPA for CTEPH at the hospital between January 2023 and March 2026. Continuous variables were compared using Student's t-test or the Mann–Whitney test according to the distribution of normality. Results and Conclusions: Twenty-six patients were included and 87 sessions were executed: male sex (27%), mean age 57 years. The mean number of sessions and treated lesions were 3.8 (±1.6) and 13.5 (±5.9), respectively. There was a significant reduction in serum BNP levels: 416 pg/mL pre-procedure vs. 130 pg/mL post-procedure ($p < 0.001$); reduction in mean pulmonary artery pressure: 51.3 mmHg pre vs. 39.5 mmHg post ($p < 0.001$); increase in distance walked in the 6-minute walk test from 303 meters pre to 396 meters post ($p = 0.012$); increase in cardiac output from 3.9 L/min pre to 5.5 L/min post ($p = 0.01$); reduction in total pulmonary vascular resistance from 13.7 Wood units pre to 7.5 Wood units post ($p < 0.001$); increase in mixed venous oxygen saturation from 59.5% pre to 68.5% post ($p < 0.001$); and an increase in pulmonary arterial compliance from 1.29 mL/mmHg pre to 2.5 mL/mmHg post ($p = 0.003$). There were minor complications in 12 cases (7 hemoptysis and 5 reperfusion injury) and no serious complications or deaths. BPA emerges as a promising effective and safe therapeutic alternative for the treatment of patients with CTEPH, with encouraging results in the studied sample. Long-term follow-up and expansion of the sample size will allow more robust conclusions in this context.

CATHETER ABLATION VERSUS STANDARD TREATMENT IN PATIENTS WITH SYMPTOMATIC BRUGADA PATTERN: A SYSTEMATIC REVIEW AND BAYESIAN META-ANALYSIS

VITOR PAIVA DE ALMEIDA1; CHRISTIAN KEN FUKUNAGA2; ANA BEATRIZ VALVERDE RAMOS3; GABRIELI MARANEZI SIPAN4; YOHANA HELOISE MIRALLIA1; TALLES DUARTE BORGES1; ISABELLA MARIA DE PINA OLIVEIRA1; BEATRIZ BENÍCIO VIANA1; KAROLINE MOREIRA COSTA RABÊLO1; BÁRBARA DIAS DOS SANTOS1; DAVI BARBOSA PEREIRA DA SILVA5; RONEY ORISMAR SAMPAIO6;

(1) UNIVERSIDADE FEDERAL DE CATALÃO - CATALÃO - GO - BRASIL; (2) FACULDADE DE MEDICINA ABC - SÃO PAULO - SP - BRASIL; (3) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (4) FACULDADE SANTA MARCELINA - SÃO PAULO - SP - BRASIL; (5) CENTRO UNIVERSITARIO DE MACEIO - UNIMA / AFYA - MACEIO - AL - BRASIL; (6) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Background/Introduction: Brugada syndrome (BrS) is an inherited arrhythmogenic disorder that can cause sudden cardiac arrest and death due to ventricular fibrillation (VF). Conventionally, it is treated with an implantable cardioverter-defibrillator (ICD) and quinidine, but this approach is associated with significant adverse effects and limitations. Catheter ablation (CA) has emerged as a promising therapeutic choice for BrS. Thus, we performed a systematic review and bayesian meta-analysis comparing CA with conventional treatment for BrS. Objectives: Thus, we performed a systematic review and bayesian meta-analysis comparing CA effectiveness with conventional treatment for BrS. Methods: PubMed, Embase, and the Cochrane Library were systematically searched for studies evaluating the effect of CA in patients with symptomatic BrS. Patients undergoing CA were compared with those receiving ICD only, for the primary endpoint of first occurrence of VF or death. We performed a Bayesian random-effects meta-analysis using the bayesmeta R package. Results are expressed as risk ratios with 95% credible intervals (CrI), alongside posterior probabilities of benefit (RR < 1) and harm (RR > 1). The posterior predictive distribution was used to estimate the probable treatment effect in future study populations, accounting for uncertainty in both the pooled effect and between-study heterogeneity. Results and Conclusions: A total of 4 studies, of which 2 are randomized, were included. The study population, comprising 387 patients, was predominantly male (76.5%), with a mean age of approximately 41 years. CA was associated with a significantly lower risk of the primary endpoint compared with standard therapy (RR 0.14, 95% CrI 0.05 to 0.39), with moderate between-study heterogeneity (τ = 0.55, 95% CrI 0.00 to 1.13). The posterior probability of benefit (RR < 1) was 99.98% for the average treatment effect and 98.79% for the predictive distribution, indicating a very high likelihood of consistent treatment benefit across different clinical settings. In patients with symptomatic BrS, CA was associated with a substantially lower risk of VF or death compared with standard therapy. The high posterior probability of benefit, including the predictive framework, supports the consistency of this effect across different clinical settings and indicates the strong effectiveness of therapy.

COLCHICINE AND POST-TAVI CONDUCTION DISTURBANCES: A SYSTEMATIC REVIEW AND META-ANALYSIS

JULIANA FERRAZ DE SOUSA1; EDUARDO GAVAÇA RAMOS2; JOAO PEDRO GARCIA JORGETTI3; HEITOR MALHEIRO OLIVEIRA3; CAMILLA RODRIGUES PEREIRA DA SILVA4; LAYALY AYOUB SILVA5; JULIA GRANATO DE OLIVEIRA6; REBECA LEI FUKAMACHI ZARONI DE PAIVA3;

(1) UNIVERSIDADE ESTADUAL DA REGIÃO TOCANTINA DO MARANHÃO - IMPERATRIZ - MA - BRASIL; (2) UNIVERSIDADE MUNICIPAL DE SAO CAETANO DO SUL - SÃO CAETANO - SP - BRASIL; (3) UNIVERSIDADE MUNICIPAL DE SAO CAETANO DO SUL - SÃO PAULO - SP - BRASIL; (4) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (5) UNIVERSIDADE DE SANTO AMARO - SÃO PAULO - SP - BRASIL; (6) UNIVERSIDADE DE MOGI DAS CRUZES - MOGI DAS CRUZES - SP - BRASIL;

Background/Introduction: Post-procedural inflammatory activation has been implicated in conduction disturbances, leaflet thrombosis, and early adverse clinical events after transcatheter aortic valve implantation (TAVI). Colchicine, a well-established anti-inflammatory agent, has been proposed as an adjunctive strategy to mitigate these complications. Objectives: To assess the efficacy and safety of colchicine after TAVI through a PRISMA-guided systematic review and meta-analysis. Methods: We systematically searched PubMed, Embase, Scopus, and Web of Science for randomized controlled trials and comparative observational studies evaluating colchicine versus control after TAVI. Two independent reviewers performed title/abstract screening, full-text selection, and data extraction. Dichotomous outcomes were pooled as risk ratios (RR) using random-effects models with DerSimonian–Laird estimation. Prespecified harmonized analyses were performed for early permanent pacemaker implantation (PPM) and early mortality combining data across comparable follow-up windows (30 days and 1 month). Statistical heterogeneity was assessed with the I² statistic, and certainty of evidence was evaluated using GRADE methodology. Results and Conclusions: Three study datasets were included — one randomized trial (Co-STAR; n=120), one randomized imaging substudy (n=96), and one propensity score-matched cohort (n=1,404). Colchicine reduced the composite of new-onset atrial fibrillation or PPM-requiring conduction disturbance in the Co-STAR trial (6/60 vs 15/60) and subclinical leaflet thrombosis in the imaging substudy (13/48 vs 26/48). Harmonized pooled analyses showed no significant reduction in early PPM implantation (RR 0.86, 95% CI 0.35–2.10; I²=70.1%) or early mortality (RR 0.78, 95% CI 0.39–1.57; I²=0%), with certainty of evidence rated as low for both outcomes. Although colchicine showed favorable signals for selected mechanistic endpoints, current evidence is insufficient to support its routine use after TAVI, and larger randomized trials are warranted.

DISTAL RADIAL ACCESS VERSUS CONVENTIONAL RADIAL ACCESS FOR CORONARY ANGIOGRAPHY AND INTERVENTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

JÚLIA MARIOTI1; GUSTAVO JOSÉ LUVIZUTTO2; IGOR FACHINI ORIVE1; MARIA EDUARDA SALUM AVEIRO HENRIQUE2; VICTOR SENISE NASCIMENTO1; FÁBIO CARDOSO CARVALHO1; LUIS ALEXANDRE FILIPPI CICCHETTO1; GABRIEL PINHEIRO MODOLO1; RODRIGO BAZAN1; SILMÉIA GARCIA ZANATI BAZAN1;

(1) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL; (2) UNIVERSIDADE FEDERAL DO TRIANGULO MINEIRO - UBERABA - MG - BRASIL;

Background/Introduction: Introduction: Coronary angiography and percutaneous coronary intervention (PCI) are important tools for the diagnosis and treatment of coronary artery disease (CAD). Conventional transradial arterial access (cTRA) is widely used; however, radial artery occlusion remains a complication in this procedure and may prevent future endovascular interventions in the artery. In this context, distal transradial arterial access (dTRA) in the anatomical snuffbox may reduce the incidence of radial artery occlusion and other complication rates. Objectives: Objectives: To evaluate the short- and long-term safety and feasibility of dTRA in patients with CAD undergoing coronary angiography and/or PCI. Methods: Methods: This is a systematic review with meta-analysis, based on the methods described in the Cochrane Handbook for Systematic Reviews of Interventions. Randomized, quasi-randomized, and non-randomized clinical trials were included. The study population consisted of adults with CAD undergoing coronary angiography and/or PCI. The experimental group consisted of those who underwent procedures using dTRA, and the control group used cTRA and/or femoral access. The outcomes evaluated were vascular complications, bleeding, mortality, and clinical outcomes. For study selection, the PubMed, Embase, ClinicalTrials, and Cochrane databases were used, without date or language restrictions. Study selection, data extraction, and risk of bias assessment were performed by two independent, blinded reviewers. The meta-analysis was conducted to obtain a combined effect estimate, using a random-effects model to compare outcomes between the different procedures performed. Results and Conclusions: Results: Safety outcomes (major and minor bleeding, hematomas, aneurysms/pseudoaneurysms, and mortality) did not differ significantly between dTRA and cTRA (OR 1.22; 95% CI 0.88–1.68; I^2=0%). However, the crossover rate was significantly higher in the dTRA (OR 2.39; 95% CI 1.54–3.71; p=0.0001). Conclusion: This meta-analysis demonstrates that the dTRA offers a safety profile comparable to cTRA, though it is associated with a higher probability of crossover, reflecting greater technical challenges at the distal site. Although feasible and safe, the routine adoption of the dTRA should consider operator experience, distal anatomy, and the clinical context of the procedure. Support: FAPESP:2025/15518-2.

GAP BETWEEN GUIDELINES AND CLINICAL PRACTICE IN LDL-C CONTROL IN PATIENTS UNDERGOING MYOCARDIAL REVASCULARIZATION: REAL-WORLD DATA FROM A BRAZILIAN UNIVERSITY HOSPITAL

LAÍSA ALLEN GOMES DE SOUSA1; ITALO COSTA SALES1; IGOR CARDOSO CAMPOS1;

(1) HOSPITAL UNIVERSITARIO DA UNIVERSIDADE FEDERAL DO PIAUI - TERESINA - PI - BRASIL;

Background/Introduction: Coronary atherosclerosis is the leading cause of cardiovascular mortality worldwide. National and international guidelines recommend LDL-cholesterol (LDL-c) < 50 mg/dL for very high cardiovascular risk patients. However, data from global registries demonstrate a wide gap between recommendations and real clinical practice. Objectives: To assess adherence to LDL-c targets in patients undergoing percutaneous coronary intervention (PCI) or coronary artery bypass grafting (CABG) at a Brazilian public university hospital. Methods: Retrospective cohort study including patients who underwent PCI or CABG between January 2019 and December 2022 at Brazilian public university hospital. Demographic variables, comorbidities, type of revascularization, pre- and post-procedure lipid levels, and prescribed therapy were analyzed. Patients without cholesterol records were excluded. SPSS 26 was used for statistical analysis (Mann-Whitney and Wilcoxon; p<0.05). Results and Conclusions: A total of 547 patients were included (265 PCI, 282 CABG); mean age 64.6 years; 61.3% male. Prevalence of hypertension (86%), smoking (63.1%), and diabetes (46.3%). Only 16.1% of PCI patients and 7.2% of CABG patients achieved the LDL-c target < 50 mg/dL post-procedure. Although 97.8% were on statins, 71.3% were using simvastatin (low potency) and only 2.3% received ezetimibe. No patient used PCSK9 inhibitors. In very high cardiovascular risk patients after revascularization, the majority did not achieve recommended lipid targets, highlighting the underutilization of high-efficacy lipid-lowering therapies within the Brazilian public health system.

Chart 1 – Adherence to LDL-c Target < 50 mg/dL Post-Procedure

Group	On Target (LDL-c < 50 mg/dL)	Off Target
PCI (Percutaneous Intervention)	16.1%	83.9%
CABG (Surgical Revascularization)	7.2%	92.8%

Chart 2 – Statins Prescribed Post-Myocardial Revascularization

Statin	% of Patients
Simvastatin (low potency)	71.3%
Rosuvastatin (high potency)	23.8%
Atorvastatin (high potency)	3.3%
Other	~1.6%

⚠ 71.3% of patients received low-potency statin therapy

GENDER DISPARITY IN LIPID CONTROL AFTER MYOCARDIAL REVASCULARIZATION: WOMEN SHOW WORSE ACHIEVEMENT OF LDL-C AND NON-HDL CHOLESTEROL TARGETS

LAÍSA ALLEN GOMES DE SOUSA1; ITALO COSTA SALES1; IGOR CARDOSO CAMPOS1;

(1) HOSPITAL UNIVERSITARIO DA UNIVERSIDADE FEDERAL DO PIAUI - TERESINA - PI - BRASIL;

Background/Introduction: Cardiovascular disease presents pathophysiological differences between sexes. Post-menopausal women exhibit lipid profile changes resulting from estrogen decline, with elevation of LDL-c and non-HDL cholesterol. Despite this, therapeutic intensification in women after myocardial revascularization remains understudied in developing country contexts. Objectives: To analyze sex-based differences in LDL-c and non-HDL cholesterol levels before and after percutaneous or surgical myocardial revascularization, and to investigate possible disparities in lipid-lowering prescription patterns Methods: Sex-based subanalysis of a retrospective cohort (2019–2022) of patients undergoing PCI or CABG. LDL-c, HDL-c, non-HDL-c, and triglyceride levels were compared between men and women at pre- and post-procedure timepoints using the Mann-Whitney U test (p<0.05). Results and Conclusions: The sample included 211 women (38.7%) and 334 men (61.3%). In the post-procedure period, women had significantly higher LDL-c than men (112.7 vs. 86.0 mg/dL; p=0.022), as well as higher non-HDL-c (141.9 vs. 108.8 mg/dL; p=0.006). HDL-c also differed between sexes (p=0.022). No significant difference was observed in pre-procedure values. Women undergoing myocardial revascularization present significantly worse post-procedure lipid control than men, suggesting insufficient therapeutic intensification in this very high cardiovascular risk subgroup.

Chart 3 – LDL-Cholesterol by Sex: Pre- and Post-Revascularization

Timepoint	Female (mg/dL)	Male (mg/dL)
Pre-procedure	79.9	77.0
Post-procedure	112.7 *	86.0 *

** Post-procedure difference: p = 0.022 | Target: 50 mg/dL*

Chart 4 – Non-HDL Cholesterol by Sex: Pre- and Post-Revascularization

Timepoint	Female (mg/dL)	Male (mg/dL)
Pre-procedure	178.8	109.6
Post-procedure	141.9 *	108.8 *

** Post-procedure difference: p = 0.006 | Target Non-HDL-c: 80 mg/dL*

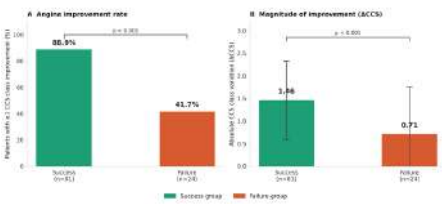
IMPACT OF PERCUTANEOUS CORONARY INTERVENTION FOR CHRONIC TOTAL OCCLUSION ON REFRACTORY ANGINA IMPROVEMENT: COMPARATIVE ANALYSIS BETWEEN TECHNICAL SUCCESS AND FAILURE

GUSTAVO HENRIQUE MENDES FERREIRA1; BERNARDO GAMBORGI SILVEIRA1; OTÁVIO TEIXEIRA MAGALHÃES1; SARAH DIAS FREITAS1; ALANDER NADOTTI1; AMANDA AMABLE MOTTI CHORRES1; JÚLIA FERNANDES AGUIAR1; CARLOS AUGUSTO HOMEM DE MAGALHÃES CAMPOS1; ALEXANDRE ANTÔNIO CUNHA ABIZAID1; LUCIANA OLIVEIRA CASCAES DOURADO1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;



Background/Introduction: Percutaneous coronary intervention for chronic total occlusion (CTO-PCI) is recommended for refractory angina to improve quality of life. However, real-world data directly comparing CCS functional class outcomes between technically successful and unsuccessful CTO-PCI remain scarce, representing a relevant gap in the evidence base for clinical decision-making in this population. Objectives: To evaluate angina improvement in patients undergoing CTO-PCI, comparing outcomes between those with successful recanalization and those with technical failure, and to identify independent predictors of symptomatic improvement. Methods: Single-center retrospective cohort study at a tertiary teaching hospital, including patients >18 years with refractory angina (CCS ≥II) undergoing single-vessel CTO-PCI between 2008 and 2025. Patients were divided by technical outcome: success group (TIMI 3 flow after stent implantation) and failure group. Outcomes were assessed at the first follow-up visit within 6 months post-procedure. The primary endpoint was angina improvement, defined as ≥1 CCS class reduction and absolute ΔCCS. Between-group comparisons used Student's t-test or Mann-Whitney and Fisher's exact tests according to data distribution; within-group comparisons used the Wilcoxon signed-rank test. Independent predictors were identified by multivariate logistic regression (p<0.05). Results and Conclusions: 105 patients were analyzed (success group n=81; failure group n=24). Baseline CCS distribution was similar between groups (p=0.26). The proportion achieving ≥1 CCS class improvement was markedly higher in the success group (88.9% vs. 41.7%, p<0.001), with more than twice the absolute class variation (ΔCCS: 1.46 ± 0.87 vs. 0.71 ± 1.04, p<0.001). No patient in the success group experienced worsening angina, whereas some failure-group patients showed CCS deterioration post-procedure. Regarding antianginal therapy at baseline, the mean number of drug classes in use was similar between groups (2.1 ± 1.0 vs. 2.2 ± 0.9, p=0.80). On multivariate analysis, technical success (OR 9.8; 95% CI 3.2–30.0; p<0.001) and higher baseline CCS class (OR 5.2; 95% CI 1.8–15.0; p=0.007) were the only independent predictors of symptomatic improvement (AUC 0.848; Hosmer-Lemeshow p=0.89). Successful CTO recanalization was associated with greater angina improvement compared to technical failure. The magnitude of benefit was directly related to baseline symptom severity, identifying higher CCS class as a key criterion for patient selection.

Table 1. Baseline clinical and demographic characteristics

Variable	Success group (n=81)	Failure group (n=24)	p-value
DEMOGRAPHIC DATA			
Age (years)	60.3 ± 9.7	57.9 ± 10.1	NS

INSUFFICIENT LONGITUDINAL FOLLOW-UP AND UNDERUSE OF HIGH-POTENCY STATINS AS STRUCTURAL BARRIERS TO LIPID CONTROL IN THE SUS: COHORT ANALYSIS POST-MYOCARDIAL REVASCULARIZATION

LAÍSA ALLEN GOMES DE SOUSA1; ITALO COSTA SALES1; IGOR CARDOSO CAMPOS1;

(1) HOSPITAL UNIVERSITARIO DA UNIVERSIDADE FEDERAL DO PIAUI - TERESINA - PI - BRASIL;

Background/Introduction: Adequate clinical follow-up and the use of high-potency statins are cornerstones of secondary cardiovascular prevention. Within the Brazilian Unified Health System (SUS), structural barriers such as restricted access to medications, bureaucracy in dispensing processes, and deficits in continuity of care may compromise the implementation of best clinical practices. Objectives: To identify structural barriers to LDL-c control in very high cardiovascular risk patients after myocardial revascularization at a public university hospital, and to propose evidence-based strategies to overcome them. Methods: Retrospective cohort (2019–2022) of patients undergoing PCI or CABG. The following were analyzed: type of statin prescribed, use of combination therapies, duration of post-procedure follow-up, and completeness of cholesterol records in medical charts. Data were organized in Excel and analyzed using SPSS 26. Results and Conclusions: Among 547 patients, only 28.1% received a high-potency statin. Ezetimibe was prescribed in 2.3% of cases and no patient used PCSK9 inhibitors. Simvastatin, the lowest-potency statin, was the most frequently prescribed (71.3%). Only 12% of patients had documented LDL-c, and 61.9% had follow-up of less than 6 months. Structural barriers — including restricted access to atorvastatin through the SUS Specialized Component (LME), underreporting in medical records, and insufficient longitudinal follow-up — compromise post-revascularization lipid control. Strategies such as telemedicine, institutional protocols, and streamlined access to high-efficacy lipid-lowering agents are needed.

Chart 5 – Duration of Post-Revascularization Follow-Up

Follow-up Period	Patients (%)
< 6 months	61.9% ⚠
6 months – 1 year	14.2%
1–2 years	12.5%
2–3 years	7.3%
3–4 years	4.1%

Chart 6 – Post-Revascularization Therapeutic Quality Indicators

Indicator	Value
High-potency statin prescribed	28.1%
Ezetimibe prescribed	2.3%
LDL-c documented in medical chart	12.0%

INTRACARDIAC VERSUS TRANSESOPHAGEAL ECHOCARDIOGRAPHY FOR PERCUTANEOUS ATRIAL SEPTAL DEFECT AND PATENT FORAMEN OVALE CLOSURE: A SYSTEMATIC REVIEW, META-ANALYSIS, AND META-REGRESSION

STEPHANIE CHAVES FERREIRA1; GABRIEL CARUSO NOVAES TUDELLA2; LUIZ RICARDO DE SOUSA FERNANDES3; DÁRIO CORREIA NEGREIROS3; HELLEN VITÓRIA ARAUJO FONTENELE3; LETÍCIA BEATRIZ COUTINHO ALVES3; LUIS FELIPE VIEIRA NUNES PORTO3; TAÍNE DE CONTO2; ANDRÉ ALONI JOÃO MANUEL4; VICTOR HUGO PINHEIRO DOS SANTOS5;

(1) UNIVERSIDADE FEDERAL DOS VALES DO JEQUITINHONHA E MUCURI (UFVJM) - TEÓFILO OTONI - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE SANTA MARIA - SANTA MARIA - RS - BRASIL; (3) UNIVERSIDADE FEDERAL DO PIAUI - PIAUÍ - PI - BRASIL; (4) JEAN PIAGET UNIVERSITY OF ANGOLA - ANGOLA; (5) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL;

Background/Introduction: Background: The optimal imaging modality for guiding percutaneous closure of atrial septal defect (ASD) and patent foramen ovale (PFO) remains debated. Intracardiac echocardiography (ICE) may offer procedural and safety advantages over transesophageal echocardiography (TEE), but comparative evidence is inconsistent. Objectives: Objectives: To compare the efficacy, safety, and procedural outcomes of ICE versus TEE in patients undergoing percutaneous ASD/PFO closure, and to explore sources of heterogeneity through meta-regression. Methods: Methods: We conducted a systematic review and meta-analysis in accordance with PRISMA 2020 guidelines. PubMed, Embase, Cochrane Library, and Web of Science were searched through January 2026. Randomized controlled trials and observational studies comparing ICE versus TEE were included. Outcomes included complete closure, procedural success, adverse events, vascular complications, arrhythmias, procedure time, fluoroscopy time, and length of hospitalization. Random-effects models were used to pool effect estimates. Subgroup analyses and meta-regression were performed to investigate heterogeneity. Results and Conclusions: Results: Fifteen studies comprising 45,037 patients were included. ICE demonstrated comparable efficacy to TEE, with no significant differences in complete closure at follow-up (RR 0.99, 95% CI 0.98–1.01), complete closure at discharge (RR 1.02, 95% CI 0.96–1.08), or procedural success (RR 1.00, 95% CI 0.99–1.01). ICE was associated with a significant reduction in vascular complications (RR 0.56, 95% CI 0.32–0.99) and overall adverse events (RR 0.77, 95% CI 0.65–0.91), while no significant difference was observed in arrhythmias. ICE significantly reduced length of hospitalization (MD −0.71 days, 95% CI −1.30 to −0.13), whereas procedure time and fluoroscopy time showed no overall significant differences and substantial heterogeneity. Meta-regression identified publication year as a significant moderator for procedure time and length of hospitalization. Conclusions: ICE provides comparable efficacy to TEE for percutaneous ASD/PFO closure while offering improved safety, with lower rates of vascular complications and adverse events, and shorter hospital stays. These findings support ICE as a safe and effective alternative, particularly in settings prioritizing procedural efficiency and avoidance of general anesthesia. Further randomized studies are warranted to confirm these findings and define optimal patient selection.

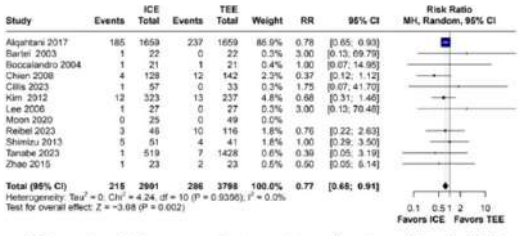

Figure 1. Comparison of adverse events between intracardiac echocardiography (ICE) and transesophageal echocardiography (TEE) in patients with ASD/PFO.

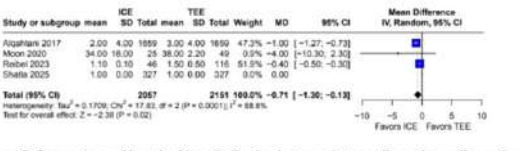

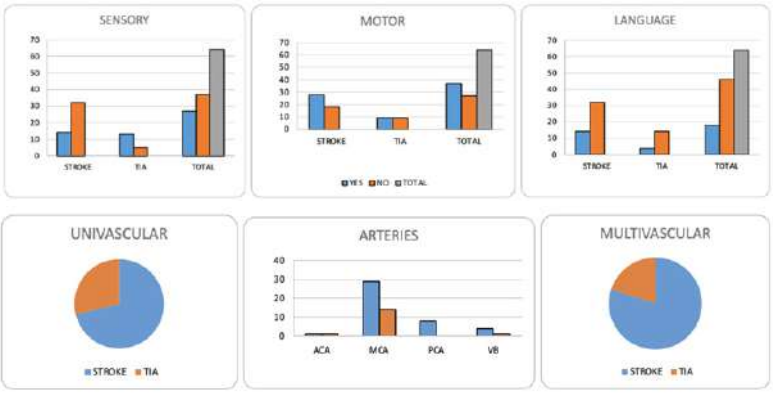

Figure 2. Comparison of length of hospitalization between intracardiac echocardiography (ICE) and transesophageal echocardiography (TEE) in patients with ASD/PFO.

NEUROLOGICAL PHENOTYPES AND VASCULAR PATTERNS IN PATIENTS WITH PATENT FORAMEN OVALE: INSIGHTS FROM A PERCUTANEOUS CLOSURE COHORT IN A TERTIARY HOSPITAL

MARCOS MORAIS DE MEIS1; FELIPE SOUZA MAIA DA SILVA1; ANDRE LUIZ DIAS LIMA BONFIM1; JOSE FABIO ALMIRO1; MAURICIO OLIVEIRA1; CLEVERSON ZUKOWSKI1; LEONARDO ANDRADE FERNANDES DE LUCA1; LUIS FILIPE AZEVEDO DE CARVALHO1; RODRIGO VASCONCELLOS TAVARES BRAVO1; SORAYA PULIER DA SILVA DE FREITAS1; MONICA LUIZA DE ALCANTARA1;

(1) HOSPITAL QUINTA D'OR - RJ - RJ - BRASIL;

Background/Introduction: Patent foramen ovale (PFO) is an atrial septal defect present in 25-30% of the population, recognized as a cause of ischemic stroke and transient ischemic attack (TIA) due to paradoxical embolism. The RESPECT and REDUCE trials demonstrated the benefit of percutaneous PFO closure in preventing recurrent neurological events compared to medical therapy alone. However, Brazilian data are scarce regarding the relationship between neurological phenotype, vascular territory and causal probability of FOP. Characterizing these patterns can improve etiological assessment and patient selection for occlusion. Objectives: To characterize the clinical profile and neurological deficits in patients with closed PFO after an acute neurological event. Methods: Observational, retrospective study from a tertiary hospital in the Brazilian supplementary health network, including 64 patients who underwent percutaneous PFO occlusion after stroke/TIA. The presence of PFO was documented by Transesophageal Echocardiography with microbubble test, performed by an echocardiographer. Patients with atrial fibrillation or other important cardioembolic sources were excluded. Sex, type of event, neurological deficit profile (sensory, motor and language), arterial territory responsible for irrigating the affected region and RoPE score were analyzed. Results and Conclusions: Male predominance was observed (56%vs44%), along with ischemic stroke (72%vs28% TIA), with a mean age of 52.73 ± 12.74 years. Neurological phenotypes varied by event type: ischemic stroke predominantly featured motor deficits (61%) and language deficits (30%), suggesting greater cortical involvement. TIA showed a predominance of sensory symptoms (72%vs30% in ischemic stroke). Univascular involvement predominated (92%), with the middle cerebral artery (MCA) being the most affected territory; multivascular events were rare (~8%). The mean RoPE score was higher in males (6.42vs5.57) and TIA patients (6.22vs5.98). Patients with PFO exhibited distinct clinical patterns: ischemic stroke was associated with structured cortical deficits, whereas TIA predominantly manifested as sensory symptoms, possibly due to transient microembolization. The predominance of univascular involvement and anterior circulation in young patients reinforces paradoxical embolism as the central pathophysiological mechanism. Thus, integrating neurological phenotype, vascular anatomy, and RoPE score may improve attribution of causality to PFO and optimize selection of candidates for percutaneous closure.

RENAL OUTCOMES IN ACUTE CORONARY SYNDROME PATIENTS UNDERGOING CORONARY PROCEDURES: SUBANALYSIS OF THE IDPC RANDOMIZED TRIAL

BEATRICE CONSTANCE FREIRE BELEM SIMAO1; CAMILIA MARIA SOARES DE LIMA1; ALEXANDRE ADAMES JORGE1; LUCAS BLASEK AUADA DE FARIA1; BRUNA GOPP BOTELHO1; AUREA JACOB CHAVES1; MARINELLA P CENTEMERO1; JOSE DE RIBAMAR COSTA JUNIOR1; KLEBER G FRANCHINI1; FAUSTO FERES1; LUIZ F TANAJURA1; RAFAELA ANDRADE PENALVA FREITAS1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Background/Introduction: Contrast-induced nephropathy (CIN) is a clinically relevant complication in patients with acute coronary syndrome (ACS), with direct impact on morbidity and mortality among those undergoing diagnostic or therapeutic percutaneous coronary interventions. Objectives: To determine the incidence of CIN and identify independent predictors of cardiac death and dialysis within 30 days in ACS patients undergoing coronary angiography within the IDPC randomized trial. Methods: Subanalysis of a single-center randomized clinical trial conducted at a tertiary public hospital over two consecutive years, including 882 ACS patients undergoing coronary angiography. Only ioxaglate (low-osmolar) or iodixanol (iso-osmolar) contrast agents were used. Patients on dialysis or exposed to other contrast types were excluded. All received standardized prophylactic hydration with 0.9% saline (0.5–1 mL/kg/h) before and after the procedure. Primary endpoint: CIN, defined as a ≥25% increase or ≥0.5 mg/dL rise in serum creatinine from baseline. Secondary endpoint: composite of cardiac death and dialysis within 30 days. Results and Conclusions: 882 patients were included (mean age 65 years; 35% >70 years; 67% male; 39% diabetic; 25% with prior renal dysfunction, CKD-EPI <60 mL/min/1.73m²). Low-osmolar contrast was used in 50.7% of cases. Mean pre- and post-procedure creatinine: 1.06 vs. 1.12 mg/dL; mean contrast volume: 92 mL. CIN occurred in 15.8% of patients. The composite endpoint at 30 days was observed in 43 patients (4.9%). Multivariate analysis identified independent predictors of death or dialysis: reduced GFR (OR 0.97 per mL/min/1.73m², p=0.009), heart failure (OR 4.81; p=0.013), cardiogenic shock (OR 17.63; p=0.001), CIN (OR 5.45; p<0.001), and contrast type (OR 2.33; p=0.049). Iodixanol use conferred a 2.3-fold higher risk of the composite endpoint compared to ioxaglate — a finding with direct implications for contrast agent selection in this population. CIN incidence was consistent with published literature, and its occurrence, combined with hemodynamic instability and contrast choice, was associated with adverse short-term prognosis.

Background/Introduction: Selecting the optimal prosthesis for TAVI is essential. Despite the availability of several transcatheter heart valve (THV) models, no systematic review with meta-analysis has compared Navitor™ against other contemporary systems in patients with small aortic annuli. Objectives: To compare Navitor™ to other contemporary THVs in patients with severe aortic stenosis and small aortic annuli undergoing TAVI. Methods: We systematically searched literature databases for studies comparing Navitor™ to other THVs in this population. Studies were screened per PRISMA guidelines. Individual patient data (IPD) were extracted from Kaplan-Meier curves using ScanIt (v.2.0.8.0) and reconstructed with IPDfromKM (v.1.2.5.0). A random-effects meta-analysis was performed in R. Results and Conclusions: At 1-year follow-up, two studies were included in the pooled analysis. The random-effects meta-analysis yielded a pooled hazard ratio of 1.04 (95% CI: 0.81–1.34; p=0.76), with no statistically significant difference in overall survival between Navitor™ and comparator platforms. No heterogeneity was detected (I²=0%; p=0.67), supporting the consistency of the pooled estimate. Kaplan-Meier reconstruction confirmed similar survival trajectories among all devices, with 1-year survival ranging from 85% to 90% across groups (log-rank p=0.088). At the 30-day landmark analysis, three studies were included. The pooled hazard ratio was 1.32 (95% CI: 0.76–2.27; p=0.32), likewise non-significant, with no heterogeneity (I²=0%; p=0.59). One estimate carried the smallest weight (6.3%) due to a wide confidence interval (0.33–25.29), reflecting a limited sample size. A borderline trend toward higher early mortality in the EVO group (log-rank p=0.09) did not reach statistical significance. IPD reconstruction yielded consistent estimates across studies, reinforcing the reliability of the survival analysis. No statistically significant difference in overall survival was observed between Navitor™ and contemporary THV platforms at 30 days or 1 year. The absence of heterogeneity supports result consistency. Navitor™ appears safe and effective in patients with small aortic annuli. Larger studies are needed to guide definitive device selection.

CARDIOEMBOLIC STROKE IN CHAGAS CARDIOMYOPATHY: THE INTERPLAY BETWEEN APICAL ANEURYSM, LEFT VENTRICULAR THROMBUS, AND CLINICAL OUTCOMES

JULIA TEIXEIRA TUPINAMBÁS1; JOÃO GABRIEL FRANCISCO RODA1; ANTÔNIO MARCONDES MUTARELLI1; SARA REGINA SILVA CUPERTINO1; VIVIAN BARROSO SANTOS1; HORTÊNCIA MARIA RIBEIRO DE CARVALHO1; KLICIA JARDIM PEREIRA1; MÁRCIA FABRÍCIA ALMEIDA TEIXEIRA1; VICENTE REZENDE SILVA2; WILLIAM ANTÔNIO DE MAGALHÃES ESTEVES2; MARILDES LUIZA DE CASTRO2; MARIA DO CARMO PEREIRA NUNES2;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Chagas cardiomyopathy (CCM) is a major manifestation of a neglected tropical disease, that is an important cause of cardioembolic (CE) stroke. Although left ventricular (LV) apical aneurysm is a common feature of the disease and has been associated with thromboembolic events, its independent contribution to stroke risk is unclear. Objectives: To assess the association between apical aneurysm and CE stroke in CCM, examine the mediating role of LV thrombus, and evaluate the prognostic impact of CE stroke. Methods: This prospective cohort included 518 patients with CCM enrolled from 2007 to 2022 at a tertiary referral center. Diagnosis required two positive serologic tests for Trypanosoma cruzi and evidence of cardiomyopathy. Baseline assessment included clinical evaluation, ECG, and echocardiography with standardized definitions for apical aneurysm and LV thrombus. Stroke events were adjudicated by neurologists using the Causative Classification System. Multivariable logistic regression identified predictors of CE stroke. Age and sex matching estimated the independent effect of apical aneurysm, mediation analysis quantified the indirect effect through LV thrombus, and Cox models assessed predictors of all-cause mortality or heart transplantation. Results and Conclusions: At enrollment, 73 patients (14.1%) had a history of CE stroke. Reduced LV ejection fraction, increased left atrial volume, and LV thrombus were independently associated with CE stroke, whereas apical aneurysm was not after adjustment. However, matched analyses demonstrated an association between apical aneurysm and CE stroke, largely mediated by LV thrombus (63.3%). During a mean follow-up of 4.9 years, 174 patients died and 22 underwent heart transplantation. Mortality was predicted by NYHA III/IV, right-sided heart failure, left atrial enlargement, and LV dysfunction, but not by prior CE stroke or apical aneurysm. Incident CE stroke occurred in 41 patients (9%) and was independently associated with prior CE stroke and LV thrombus. To conclude, in CCM, CE stroke is primarily driven by LV thrombus formation. Apical aneurysm increases embolic risk mainly through thrombus mediation, while prior CE stroke identifies patients at increased risk for recurrence. These findings support targeted stroke prevention strategies focused on thrombus detection and anticoagulation.

EARLY TRYPANOCIDAL THERAPY AFTER ORALLY TRANSMITTED ACUTE CHAGAS DISEASE AND CARDIAC OUTCOMES IN THE AMAZON BASIN: A PRISMA-BASED SYSTEMATIC REVIEW AND META-ANALYSIS

PEDRO HENRIQUE KADOR MAFFI1; MIGUEL LUCAS SILVA MIGUEL VALENTE1; ODILSON MARCOS SILVESTRE2; CLARICE VIUDES DE ABREU1; KEVILYN ASSIS DE ALMEIDA1; ISABELLY DELLA JUSTINA FLORENTINO SILVA1; JOÃO VICTOR BATISTA PIRES1;

(1) UNIVERSIDADE FEDERAL DO ACRE - RIO BRANCO - AC - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Background/Introduction: Oral transmission has reshaped acute Chagas disease epidemiology in the Brazilian Amazon, but cardiac outcomes after early trypanocidal therapy remain insufficiently quantified. Objectives: To estimate post-treatment cardiac abnormalities and serological outcomes after benznidazole-treated acute Chagas disease in oral/Amazonian cohorts. Methods: A PRISMA-based systematic review and meta-analysis of cohort and outbreak studies was performed. Eligible studies included acute Chagas disease acquired in Amazonian or oral-transmission settings and treated with benznidazole. Outcomes were pooled as proportions using logit-transformed random-effects models with Hartung-Knapp adjustment; crude Wilson 95% confidence intervals (CI) were also calculated due to small samples, sparse events and possible overlap. Outcomes included post-treatment cardiac abnormalities, acute-phase cardiac/ECG abnormalities, serological cure, persistent anti-T. cruzi IgG and late gadolinium enhancement (LGE). Results and Conclusions: Ten studies were included; sample sizes ranged from 11 to 179 participants. Post-treatment cardiac abnormalities occurred in 31/375 treated participants in Brazilian cohorts (crude 8.3%; 95% CI 5.9-11.5), with a random-effects estimate of 14.2% (95% CI 1.9-58.9; I^2=91.3%). In Amazon-only cohorts, events occurred in 25/364 participants (crude 6.9%; 95% CI 4.7-9.9; random-effects 9.3%; 95% CI 0.7-58.3; I^2=91.4%). Serological cure occurred in 91/382 participants (crude 23.8%; 95% CI 19.8-28.3; random-effects 23.9%; 95% CI 10.7-45.2; I^2=70.2%), while persistent anti-T. cruzi IgG occurred in 258/382 (crude 67.5%; 95% CI 62.7-72.0; random-effects 67.5%; 95% CI 48.4-82.2; I^2=75.0%). Acute-phase cardiac/ECG abnormalities were frequent (85/252; crude 33.7%; 95% CI 28.2-39.8; random-effects 47.6%; 95% CI 21.5-75.2; I^2=82.8%). Post-treatment LGE was detected in 10/25 patients by cardiac magnetic resonance (40.0%; 95% CI 23.4-59.3; I^2=0.0%). Benznidazole-treated disease after oral/Amazonian transmission showed a low crude frequency of overt post-treatment cardiac disease, but persistent serological/imaging abnormalities were common. High heterogeneity supports standardized, non-overlapping long-term cardiac follow-up.

EPIDEMIOLOGICAL PROFILE OF ACUTE CHAGAS DISEASE IN THE BRAZILIAN LEGAL AMAZON, 2014–2024

MARIA FERNANDA CAMPOS NEVES DOS SANTOS1; GIOVANNI MONTEIRO MATOS1; FABRÍCIO BACELAR MARINHO FILHO1; MELINA CONDE MAUÉS LIMA2; ESTHER ELGRABLY DE MELO E SILVA ZATZ1; HANNAH UNGER1; FABIANA MACHADO ALVES1; GABRIELA CARVALHO DE ASSUNÇÃO1; MARIELLE DE NAZARÉ GONÇALVES DE LIMA E SILVA1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL;

Background/Introduction: Acute Chagas disease remains a significant public health issue in the Brazilian Legal Amazon, exhibiting a distinct epidemiological profile compared to other regions of the country. Transmission is predominantly oral, strongly associated with adverse socioenvironmental and sanitary conditions. The acute phase may involve early cardiac manifestations, including myocarditis, arrhythmias, and heart failure, with potential progression to chronic Chagas cardiomyopathy. Understanding its epidemiological pattern is essential to identify vulnerable populations and strengthen surveillance and control strategies. Objectives: To analyze the epidemiological profile of acute Chagas disease cases in the Brazilian Legal Amazon between 2014 and 2024 according to sociodemographic characteristics and temporal distribution. Methods: A cross-sectional, retrospective, and observational study was conducted using data from the Brazilian Notifiable Diseases Information System (SINAN/DATASUS). Confirmed cases of acute Chagas disease reported in the Legal Amazon from 2014 to 2024 were included. A descriptive analysis was performed considering sociodemographic, temporal, and seasonal variables. Results and Conclusions: Results: A total of 3,824 confirmed cases were recorded, with marked concentration in the Northern region (98.7%), particularly in Pará (83.4%), followed by Amapá (7.7%), Amazonas (3.9%), and Acre (2.5%). Cases outside the region were less frequent, including Maranhão (1.1%) and Mato Grosso (0.2%). An increasing temporal trend was observed, rising from 205 cases in 2014 to a peak of 526 cases in 2023, remaining high in 2024 (505 cases), with a temporary decline in 2020 (162 cases). Seasonal distribution showed higher incidence between July and November, peaking in October (14.0%). Most cases occurred in individuals aged 20–39 years (34.4%), predominantly males (54.0%), individuals of mixed race (86.0%), and those with low educational attainment. Conclusion: Acute Chagas disease remains highly concentrated in the Brazilian Legal Amazon, particularly in Pará, predominantly affecting young adults, males, and socially vulnerable populations. The observed increasing trend and seasonal pattern between July and November suggest predominance of oral transmission, because of the regional food consumption, like açaí . These findings reinforce the need to strengthen epidemiological surveillance, food safety measures, and preventive actions to reduce incidence and related complications.

IS ELECTROCARDIOGRAPHY SUFFICIENT FOR CARDIAC ASSESSMENT IN CHAGAS DISEASE? DISCORDANCE WITH ECHOCARDIOGRAPHY BY HEART FAILURE STATUS

FERNADA ESCARCEGA RAMIREZ1; LUISA FERNANDA AGUILERA MORA1;

(1) SALVANDO LATIDOS A.C - MEXICO;

Background/Introduction: In Chagas disease, electrocardiography (ECG) and transthoracic echocardiography (TTE) assess different aspects of cardiac involvement, and their findings do not always match. In routine practice, especially during initial evaluation or in resource-limited settings, ECG is often the main tool. However, relying on ECG alone may miss relevant structural or functional abnormalities. Although ECG–TTE discordance has been described, little is known about how its direction varies according to heart failure (HF) status. Objectives: To evaluate whether HF is associated with differences in the frequency and direction of discordance between ECG and TTE in patients with Chagas disease, and to assess the implications for the use of ECG as a stand-alone tool. Methods: We conducted an observational, analytical, retrospective, cross-sectional study using a clinical database of patients with Chagas disease, with one record per patient. Patients were grouped by HF status. ECG was considered positive when clinically relevant rhythm, conduction, or repolarization abnormalities were present. TTE was considered positive when relevant structural or functional abnormalities were identified; mild valvular regurgitation was counted only when accompanied by another relevant echocardiographic finding. Discordance was defined as ECG+/TTE− or ECG−/TTE+. Frequency and direction of discordance were compared using chi-square or Fisher's exact test. Results and Conclusions: Results A total of 164 patients were included. Overall ECG–TTE discordance was 25.6% (42/164). Among patients without HF (n=100), discordance was present in 21.0% (21/100), mainly ECG+/TTE− (18/21, 85.7%) rather than ECG−/TTE+ (3/21, 14.3%). Among patients with HF (n=64), discordance was present in 32.8% (21/64), with the opposite pattern: ECG−/TTE+ was more frequent than ECG+/TTE− (14/21, 66.7% vs 7/21, 33.3%). Discordance direction differed significantly between groups (p=0.001), whereas overall discordance frequency did not (p=0.101). Conclusions In Chagas disease, HF was associated with a clear shift in ECG–TTE discordance direction. The predominance of ECG−/TTE+ in patients with HF suggests that ECG alone may be insufficient for comprehensive cardiac assessment and supports the complementary use of echocardiography in this setting.

LOW-COST WEARABLE DEVICE FOR ECG MONITORING IN CHRONIC CHAGAS CARDIOMYOPATHY: PRELIMINARY RESULTS OF AN AGREEMENT STUDY

ENRICO DE FRANCISCO MAGNANI1; IGOR LUCAS GERALDO IZALINO DE ALMEIDA1; BRENO AUGUSTO MAGALHÃES OLIVEIRA1; ELÍS APARECIDA ALVES DOS SANTOS1; JÚLIA NUNES CARDOSO POLICARPO1; MARIA LUÍZA ALVES ROCHA1; BHIANCA LOPES TEIXEIRA1; DEBORAH PEREIRA PRADO2; LILIAN PAULA DE SOUZA2; MARIA DO CARMO PEREIRA NUNES2; DENISE MAYUMI TANAKA1; LUCIANO FONSECA LEMOS DE OLIVEIRA1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Chronic Chagas cardiomyopathy (CCC) is a severe and lethal manifestation of Chagas disease, with high arrhythmogenicity and a significant risk of sudden death. Morbidity and mortality are disproportionately concentrated in low-income regions, where access to specialized cardiac monitoring is restricted by sociodemographic barriers. In this context, the Polar H10 sensor, integrated with a proprietary mobile application, represents a low-cost technological alternative for ambulatory ECG recording, aimed at overcoming these socioeconomic hurdles and democratizing clinical surveillance. Objectives: To preliminarily assess the agreement and reliability of a proprietary mobile application for single-lead electrocardiogram acquisition at rest and under physiological stress, compared with a gold-standard device. Methods: Nine patients with CCC underwent cardiopulmonary exercise testing with simultaneous monitoring using a conventional ECG system (BioAmp) and the Polar H10 + proprietary mobile application. Segments containing 100 consecutive beats, sampled every 10 beats, were analyzed during rest and exercise phases. Temporal ECG metrics (RR, HR, PR, P-wave duration, QRS, QT, QTc, JT, and Tpeak-Tend) were extracted using LabChart Pro, totaling approximately 1,800 analyzed beats. Absolute agreement was assessed using the intraclass correlation coefficient (ICC) and Bland-Altman analysis (B&A). Results and Conclusions: At rest, excellent agreement was observed for RR (ICC=0.998), HR (ICC=0.997), and QT (ICC=0.937), with good agreement for QRS (ICC=0.865), QTc (ICC=0.839), PR (ICC=0.793), JT (ICC=0.786), P-wave duration (ICC=0.778), and Tpeak-Tend (ICC=0.719). Bland-Altman analysis confirmed low systematic bias for RR (-0.001±0.012s; 95%LoA: -0.025 to 0.023s) and QT (-0.004±0.018s; 95%LoA: -0.039 to 0.031s). During exercise, excellent agreement was observed for RR (ICC=0.990), HR (ICC=0.989), PR (ICC=0.962), P-wave duration (ICC=0.924), QRS (ICC=0.911), QT (ICC=0.932), and QTc (ICC=0.900), whereas JT (ICC=0.688) and Tpeak-Tend (ICC=0.744) showed moderate-to-good agreement (all p<0.001). Bland-Altman analysis demonstrated low systematic bias for RR (-0.003±0.016s; 95%LoA: -0.034 to 0.028s) and QT (0.003±0.014s; 95%LoA: -0.024 to 0.030s). The proprietary application + Polar H10 demonstrated high reliability for ECG acquisition in patients with CCC, including under physiological stress, showing potential to expand access to cardiovascular monitoring in resource-limited settings.

PROPORTION AND RISK FACTORS FOR COMPLICATIONS IN PATIENTS WITH RHEUMATIC HEART DISEASE : A HOSPITAL BASED STUDY

TRISHA SHARMA1; MAHESH GURUNG1;

(1) KHESER GYALPO UNIVERSITY OF MEDICAL SCIENCES - BHUTAN;

Background/Introduction: Rheumatic heart disease (RHD) is an irreversible disease of the heart valves that occurs after developing acute or recurrent rheumatic fever that in turn occurs after being infected with group A streptococcus (strep pharyngitis). RHD continues to be more prevalent in developing countries. Despite its significant impact, recent data on the burden of RHD in our population are lacking. Given that RHD is more prevalent in developing countries, it is crucial to identify the disease burden in the country, as well as factors contributing to both the disease and its complication. There is lack of scientific study to evaluate the complications and risk factors associated with RHD, leaving a significant gap in our understanding of its national burden. Objectives: Primary objective: To determine the proportion of complications in RHD patients Secondary objective:To determine the risk factors associated with complications in RHD patients Methods: This is a descriptive cross-sectional study involving 202 patients registered in the RHD registry during the one-year study period. Continuous demographic and clinical variables that followed a normal distribution were compared using the student's t-test. Categorical variables were analyzed using the Chi-square test or Fisher's exact test, depending on the expected cell counts. Results were summarized using frequencies and percentages. All hypothesis testing was two-tailed, and a p-value of less than 0.05 was considered indicative of statistical significance. A multivariable logistic regression analysis was conducted to identify factors independently associated with RHD complications and the occurrence of new RHD. Odds ratios (ORs) with 95% confidence intervals (CIs) were calculated to quantify the strength and direction of associations. Results and Conclusions: Among 202 RHD patients, 60.4% had atleast one complication—most commonly atrial fibrillation (54.9%) and heart failure (36%). Patients with complications were older (45.4 vs. 32.8 years; p<0.001) than those without. Multivariable logistic regression showed that every 10-year increase in age raised odds of complications by 72% (aOR=1.72, p=0.009). Lower-middle income patients had 31 times higher complication odds, and low-income patients 8 times higher odds versus high-income. Among anticoagulated patients, 33% had bleeding manifestations, with majority having poor INR control (mean TTR 36.7%). These findings highlight the need for early detection, awareness, and better healthcare training.

Table1 Socio-demographic characteristics of the patients with RHD at the national referral hospital, 2024-2025 (n=202)

TAKOTSUBO SYNDROME BEYOND THE ACUTE PHASE: HIGH IN-HOSPITAL BURDEN WITH FAVORABLE LONG-TERM OUTCOMES IN A CONTEMPORARY COHORT

PAULA SANTIAGO TEIXEIRA1; GUILHERME BOALENTO FIGUEIREDO1; ANDRÉ KENZO ARAGAKI1; LÍVIA TOSHIKO GONDO1; HELOISA JODAR MATEUS1; KAIO VINICIUS CAMPOS MARQUES1; FRANCISCO SANDRO MENEZES RODRIGUES1; PEDRO IVO DE MARQUI MORAES1; MARIA TERESA NOGUEIRA BOMBIG1; ADRIANO CAIXETA1; HENRIQUE TRIA BIANCO1; ADRIANO H.P. BARBOSA1;

(1) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL;

Background/Introduction: Takotsubo syndrome (TTS) is an acute, stress-induced cardiomyopathy that often mimics myocardial infarction. While short-term complications are well recognized, long-term prognosis and recurrence risk remain incompletely defined. Objectives: To characterize the clinical profile, in-hospital course, and long-term outcomes of patients with TTS in a real-world tertiary care setting. Methods: We conducted a retrospective cohort study including consecutive patients diagnosed with TTS between 2009 and 2026. Clinical, angiographic, in-hospital and long-term follow-up data were systematically collected. Results and Conclusions: Twenty-six patients were included, predominantly female (83%), with a mean age of 62 years. Hypertension (52%) and psychiatric comorbidities (17%) were frequent. Physical stress was the most common identifiable trigger (26%), although more than half of cases had no clear precipitating factor.Apical involvement predominated (90%), with heterogeneous distribution according to InterTAK classification.Despite the transient nature of TTS, the acute phase was marked by substantial clinical burden: 65% required intensive care, 38% vasoactive support, and 15% mechanical ventilation. Mechanical circulatory support was required in one case. One in-hospital death occurred, unrelated to cardiovascular causes.During long-term follow-up, no recurrences of TTS, myocardial infarction, coronary revascularization, or heart failure hospitalizations were observed. One patient developed ischemic stroke, and three died from non-cardiovascular causes.In this contemporary cohort, TTS was associated with high in-hospital morbidity but unexpectedly benign long-term cardiovascular outcomes, with no recurrence observed. These findings challenge the perception of TTS as a condition with significant late risk and underscore the importance of early recognition and supportive management during the acute phase as the key determinant of prognosis.

Clinical Outcomes (n = 26)

Outcome	Events, n/N (%)
MACCE	1/26 (3.8%)
Cardiovascular mortality	0/26 (0%)
Acute myocardial infarction	0/26 (0%)
Repeat revascularization (PCI or CABG)	0/26 (0%)
Stroke / transient ischemic attack	1/26 (3.8%)
Heart failure hospitalization	0/26 (0%)
Non-cardiovascular death	3/26 (11.5%)
All-cause mortality	3/26 (11.5%)
Takotsubo syndrome recurrence	0/26 (0%)

DEVELOPMENT OF AN EDUCATIONAL VIDEO TO PROMOTE SELF-CARE IN PATIENTS WITH HEART FAILURE

ISADORA HAETINGER ANDRIOTTI ALVES1; SIMONI CHIARELLI DA SILVA POKORSKI1; CLAUDIA SEVERGNINI EUGENIO1; LAURA MARIANA FRAGA MERCALI1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: Digital health technologies play an important adjunctive role in the management of patients with heart failure, facilitating information sharing and enhancing patient–professional communication, which may contribute to improved self-care and early recognition of clinical deterioration. Objectives: To develop an educational video to support patients in recognizing the signs and symptoms of heart failure decompensation. Methods: This is a methodological development study guided by the ADDIE instructional design model (Analysis, Design, Development, Implementation, and Evaluation). A structured script and storyboard were developed to ensure content accuracy and facilitate visual planning. The video was produced using the Animaker® platform. The educational content focused on clinically relevant signs and symptoms of heart failure decompensation and incorporated a mnemonic strategy to enhance patient recall of those. This study was approved under the report nº 7.491.021, CAAE 86597825.3.0000.5327. Results and Conclusions: The final educational product is a 2.5-minute animated video designed to promote early recognition of heart failure decompensation. A color-coded mnemonic, “PISCA,” inspired by a traffic light system, was developed to categorize symptom severity and guide patient interpretation. Each letter represents a key clinical manifestation of heart failure. The integration of visual cues and simplified language aimed to improve health literacy and patient engagement. The developed video represents a feasible and potentially effective educational tool to support self-management in patients with heart failure. By facilitating early recognition of warning signs, it may contribute to timely patient-initiated contact with healthcare services and potentially reduce adverse outcomes related to delayed intervention.

EFFECTIVENESS OF HOME-BASED CARDIAC REHABILITATION SUPERVISED BY HEALTHCARE PROFESSIONALS: A SYSTEMATIC REVIEW OF RANDOMIZED CONTROLLED TRIALS

ANNA CAROLINE ANNA SIQUEIRA PENA1; LARYSA SOARES DE OLIVEIRA1; FRANCISCA LIVIA DE ABREU AZEVEDO1; ANA CRISTINA DA SILVA PINTO1;

(1) UNIRIO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Cardiovascular diseases (CVDs) are the leading cause of global mortality, accounting for 17.9 million deaths annually, according to the World Health Organization (WHO). In Brazil, CVD-related expenditures may reach 0.7% of the Gross Domestic Product (GDP). Alignment with the Sustainable Development Goals (SDGs), particularly target 3.4, highlights the need for effective and cost-effective strategies to ensure continuity of care after hospital discharge. Home-based cardiac rehabilitation supervised by healthcare professionals emerges as a promising and accessible approach to expand access and improve adherence; however, its effectiveness compared to traditional models remains uncertain. Objectives: To evaluate the effectiveness of home-based cardiac rehabilitation supervised by healthcare professionals, compared with hospital- or center-based rehabilitation, in improving clinical outcomes and quality of life in patients with cardiovascular diseases. Methods: A systematic review was conducted in accordance with PRISMA guidelines, including randomized controlled trials on home-based cardiac rehabilitation published between 2000 and 2022. The search was systematically performed in MEDLINE/PubMed, Scopus, LILACS, SciELO, and Cochrane Library databases. Study selection was conducted independently by two reviewers, and methodological assessment was based on the PICOTT strategy. Outcomes included quality of life, functional capacity (peak VO□), hospital readmissions, and treatment adherence. Risk of bias was assessed using the RoB 2 tool, and quality of evidence was evaluated using the GRADE approach. Data extraction was also performed independently, and disagreements were resolved by consensus. Results and Conclusions: A total of 278 studies were identified, of which 15 randomized controlled trials were included in the analysis. Home-based cardiac rehabilitation supervised by healthcare professionals was found to be clinically equivalent to hospital-based programs, particularly regarding functional capacity and quality of life. It also showed a trend toward higher treatment adherence, without an increase in hospital readmissions. These findings suggest that the home-based model is a safe and effective alternative, with the potential to expand access to cardiovascular care, particularly in settings with geographic and structural barriers. Furthermore, this approach may contribute to improved quality of care and reduced clinical events, promoting a more comprehensive patient recovery.

FUNCTIONAL DISABILITY AND THERAPEUTIC FOLLOW-UP BETWEEN TWO AND THREE YEARS AFTER ISCHEMIC STROKE

BRENDA SILVA CUNHA1; MARIANA DE ALMEIDA MORAES1; LIANE DE ASSIS CAMPOS MEDEIROS1; BIANCA MOREIRA DE SANTANA1; CARLOS ANTÔNIO DE SOUZA TELES SANTOS1; FERNANDA CARNEIRO MUSSI1;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL;

Background/Introduction: Ischemic stroke (IS) is one of the leading causes of disability worldwide, requiring continuous therapeutic support to minimize sequelae and promote functional recovery. However, gaps remain in long-term follow-up, especially between two and three years after the event. Objectives: To analyze the association between received therapeutic support and the degree of functional disability between two and three years after IS, and to compare functional disability levels between 90 days and two to three years after the event. Methods: This prospective cohort included 155 IS survivors followed at a public hospital. Functional disability was assessed using the Modified Rankin Scale at 90 days and between two and three years, categorized as mild (0–2) and moderate to severe (3–5). Therapeutic support included secondary prevention and follow-up with healthcare professionals. Pearson's chi-square or Fisher's exact tests, odds ratios (OR) with 95% confidence intervals (95% CI), and McNemar's chi-square test were used. Statistical significance was set at 5% ($p<0.05$). Results and Conclusions: Between 90 days and two to three years after IS, transitions in functional disability levels were observed. Among initially asymptomatic individuals, 60.5% remained so, while 39.5% progressed to some degree of disability. Among those without significant disability, 17.6% became asymptomatic and 41.2% remained stable, while 41.2% worsened. Among those with mild disability, 66.7% improved, 22.2% remained unchanged, and 11.1% worsened. In moderate disability cases, 43.2% improved, 32.5% remained stable, and 24.3% worsened. Among those with moderately severe disability, 50% improved, 14.3% remained unchanged, and 35.7% worsened. Finally, among those with severe disability, 56.3% improved and 43.7% remained unchanged. Despite these variations, no statistically significant change in functional disability was observed over time ($p=0.6219$). Access to therapeutic support was limited and unequal: 56.6% had neurologist consultations, 45.8% received physiotherapy, and only 15% had nursing follow-up, while 53.6% reported secondary prevention. The association between therapeutic support and disability showed higher odds of moderate to severe disability among individuals followed by a physiotherapist (OR=3.34; 95% CI 1.63–6.89), with no significant association for other variables, suggesting severity bias in access to care. Gaps in support persist after IS despite disability; continuous multidisciplinary follow-up is essential for recovery

PREVALENCE AND CHARACTERISTICS OF PATIENTS WITH CHRONIC CHAGAS DISEASE AND METABOLIC SYNDROME

MATHAUS HENRIQUE REIS SILVA1; MARIA CECILIA MARQUES DA SILVA1; ANA JULIA TORRES BONFIM ROCHA1; MAYRA DOMINGUES CARDOSO1; MARIA GEOVANIA CARDOSO BATISTA1; ANA CLARA SILVA RODRIGUES PEREIRA1; DARDIANE SANTOS CRUZ1; MARCOS GABRIEL DE JESUS RODRIGUES1; SÂMARA FERNANDES LEITE1; LUCIANO FREITAS FERNANDES1; RENATO SOBRAL MONTEIRO JUNIOR1; ARIELA MOTA FERREIRA1;

(1) CENTRO DE PESQUISA EM SAÚDE - SANTA CASA DE MONTES CLAROS - MONTES CLAROS - MG - BRASIL;

Background/Introduction: Chagas disease (CD) remains an important public health problem, with an estimated 6 to 7 million people infected worldwide, mainly in Latin America. In Brazil, millions of individuals live with the chronic form, whose main manifestation is Chagas cardiomyopathy, responsible for high morbidity and mortality. Metabolic Syndrome (MetS), in turn, has a high global prevalence, affecting approximately 30% to 40% of the adult population. The coexistence between CD and MetS has progressively increased and may worsen cardiovascular prognosis due to shared pathophysiological mechanisms such as chronic inflammation and metabolic dysfunction, although this interaction is not yet fully elucidated. Objectives: To describe the prevalence and characteristics of patients with chronic CD associated with the diagnosis of MetS. Methods: This is an analytical and exploratory cross-sectional study, with retrospective analysis of patients treated at the Chagas Disease Outpatient Clinic located in Montes Claros, MG, an endemic region for CD. MetS was defined according to the NCEP-ATP III criteria. Sociodemographic, clinical, and anthropometric variables were analyzed. Results and Conclusions: A total of 369 individuals with chronic CD were evaluated, of whom 18.4% had MetS. The sample was predominantly composed of women (61.5%), individuals of brown or black race/color (84.6%), and aged up to 59 years (50.7%). Regarding clinical variables, most participants presented overweight/obesity (53.3%), were hypertensive (60.6%), used antihypertensive medications (67.4%), were not diabetic (83.7%), presented the cardiac clinical form (57.5%), reported previous use of benznidazole (65.3%), did not have pacemaker or ICD implantation (91.7%), and had preserved ejection fraction (76.7%). In the bivariate analysis, the variables statistically associated with the presence of MetS were age ($p=0.011$), BMI ($p=0.056$), hypertension ($p=0.003$), and diabetes ($p<0.001$). These findings highlight the interaction between aging and metabolic alterations as determinants of cardiometabolic risk in patients with CD.

20032

TEACHING ELECTROCARDIOGRAPHY TO NURSING RESIDENTS: A QUASI-EXPERIMENTAL STUDY

BRUNO SILVA SANTOS1; KAUE TOGNOLLI1; DANILO DOS SANTOS GOMES1;

(1) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Background/Introduction: The 12-lead electrocardiogram (ECG) is an essential examination in clinical practice, and it is crucial for nurses to develop interpretive skills in order to contribute to the early diagnosis of cardiovascular events. Objectives: The objective of this study was to compare the knowledge gain of nursing residents in adult ECG interpretation using two distinct educational approaches: active methodology and traditional teaching. Methods: This is an interventional, quantitative study with a quasi-experimental, pre- and post-test design, guided by the TREND Statement. Seventeen first-year nursing residents from uni-professional and multi-professional programs participated. Assessment was conducted using the "Questionnaire for Assessing Nurses' Knowledge of Electrocardiography" (QVCEE), validated in Brazil. Nursing residents were divided into two groups (exposure group and control group). In both groups, the QVCEE questionnaire will be administered at two time points: (1) before the intervention (pre-test) and (2) after the intervention (post-test), with the aim of measuring participants' knowledge. In the exposure group, a dialogic expository lecture was conducted, followed by a practical workshop on ECG interpretation. In contrast, the control group received a traditional expository lecture. Results and Conclusions: Analyses were performed using GraphPad Prism software, adopting a significance level of $p < 0.05$. The groups showed no significant difference in the pre-test ($p = 0.139$) or in the delta of correct answers ($p = 0.48$). However, the group exposed to the active methodology achieved a higher mean score in the post-test (19.38 ± 1.4) compared to the traditional group (17.56 ± 1.94), with statistical significance ($p = 0.04$). Overall, both methods resulted in a substantial increase in mean scores, rising from 15.47 ± 1.70 to 18.41 ± 1.91 ($p < 0.0001$). It is concluded that structured educational interventions, regardless of the approach, promote significant improvement in residents' knowledge. However, active methodologies demonstrated a tendency toward superior performance, indicating potential to enhance clinical reasoning and foster more effective learning in ECG education.

Comparison of the Number of Correct Answers After the Class Between Teaching Groups

Group	Total (n = 17)	Mean ± SD
Traditional Methodology	9	17.56 ± 1.94
Active Methodology	8	19.38 ± 1.4
p-value		*0.04*

Paired t-test.
SD: standard deviation.
Significance level adopted: $p < 0.05$.

Comparison of the Number of Correct Answers After the Class Between Teaching Groups

VALIDATION OF AN EDUCATIONAL VIDEO SCRIPT ON SELF-CARE FOR PEOPLE WITH VENOUS ULCERS

ADANY SANTOS DE CASTRO1; ANETE LEDA DE OLIVEIRA1; ELIANA MARQUES GOMES DA SILVA1;

(1) UEA - MANAUS - AM - BRASIL;

Background/Introduction: Venous ulcers represent the most severe manifestation of chronic venous insufficiency and constitute an important public health problem due to their high prevalence, recurrence, and socioeconomic impact. In addition to physical limitations, these lesions negatively affect quality of life, autonomy, and work capacity. In this context, self-care plays a fundamental role in the healing process and prevention of complications, involving adherence to compression therapy, wound care, adequate nutrition, and lifestyle changes. Educational technologies have been increasingly used in health education, promoting patient empowerment and active participation in treatment. However, there is still a scarcity of educational materials specifically designed for individuals with venous ulcers. Objectives: To validate the content of an educational video script on self-care for people with venous ulcers through evaluation by expert judges. Methods: This is a methodological study focused on the content validation stage. The video script was developed based on an integrative literature review and structured into 10 sections related to self-care in venous ulcers. Fourteen expert judges participated in the study, all of whom were nurses with experience in enterostomal therapy and wound care. Validation was conducted virtually using an instrument composed of a Likert scale divided into the following domains: objectives, structure and presentation, relevance, and effectiveness. Quantitative analysis was performed using the Content Validity Index (CVI), considering the material validated when CVI ≥ 80%. Qualitative suggestions provided by the specialists were incorporated into the final version of the script. Results and Conclusions: The script achieved an overall Content Validity Index of 84%, demonstrating a satisfactory level of agreement among the specialists. The main suggestions involved adjustments to technical terminology, reorganization of the content sequence, and simplification of language to improve understanding by the target audience. The validation of the script strengthens the development of educational technologies focused on self-care and may contribute to improved treatment adherence, patient autonomy, and quality of life among individuals with venous ulcers. It is concluded that the script presents valid and appropriate content to support the production of an educational health video.

BEYOND TRADITIONAL RISK STRATIFICATION IN HEART FAILURE: SIMPLE DIETARY MARKERS AS INDEPENDENT PREDICTORS OF ALL-CAUSE AND HEART FAILURE HOSPITALIZATION

ÉDINA CAROLINE TERNUS RIBEIRO1; MARLA DARLENE MACHADO VALE2; DANIELA MEIRELLES DO NASCIMENTO1; ELISA PINEDA3; BEATRIZ D. SCHAAN2; OTAVIO BERWANGER3; NADINE CLAUSELL1; GABRIELA CORRÊA SOUZA1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL; (2) UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL; (3) THE GEORGE INSTITUTE FOR GLOBAL HEALTH/IMPERIAL COLLEGE LONDON - UNITED KINGDOM;

Background/Introduction: Heart failure (HF) is a complex syndrome in which clinical outcomes are influenced by multiple biological and functional domains beyond traditional disease severity measures. Nutritional status and simple dietary behavior indicators are often overlooked in routine HF assessment and their prognostic role in HF remains underexplored. Objectives: To evaluate the association between simple markers of nutritional intake, specifically reduced food intake and daily meal frequency, and the risk of hospitalization (all-cause and HF), as well as their incremental prognostic value in stable HF patients. Methods: This was a prospective cohort study including adult outpatients with stable HF. Reduced food intake was evaluated by self-reported unintentional decrease over the previous 3 months, and the number of meals per day was categorized as 1–2 meals/day vs. >3 meals/day. Outcomes (all-cause and HF hospitalizations) were monitored every six months via structured telephone interviews and confirmed by medical records. Patients were censored at the time of outcome occurrence, heart transplantation or end of follow-up period. Adjusted Cox models estimated HRs (95% CI), with discrimination assessed by the C-statistic (area under the ROC curve). Results and Conclusions: A total of 264 individuals were included (mean age 56.5±12.7 years; 67.4% male; body mass index 28.7±4.9 kg/m²). Most were in New York Heart Association functional class I–II (78.5%), with a mean left ventricular ejection fraction of 33.5±12.8%. Ischemic etiology accounted for 27.2%. Over a median follow-up of 24 months, 89 hospitalizations occurred, 40 of which were due to HF. In multivariable analysis, reduced food intake was independently associated with a 78% increased risk of all-cause hospitalization (HR 1.78; 95% CI 1.09–2.91), increasing the model's C-statistic from 0.679 to 0.695. Similarly, consuming 1–2 meals per day was associated with an approximately three-fold higher risk of HF hospitalization (HR 2.93; 95% CI 1.38–6.20) increasing the C-statistic from 0.702 to 0.756, indicating incremental prognostic value. Simple, easily obtainable markers of nutritional vulnerability, such as reduced intake and low meal frequency, predict hospitalization in stable HF. These findings suggest that incorporating basic dietary screening into routine clinical practice can enhance risk stratification without additional costs.

CARDIOMETABOLIC RISK FACTORS AT BREAST CANCER DIAGNOSIS IS ASSOCIATED WITH MORTALITY IN WOMEN UNDERGOING DOXORUBICIN CHEMOTHERAPY

INGRID MAGS CARVALHO ALMEIDA1; MARCIO DA ROCHA SOUSA2; SARA MARIA MOREIRA LIMA VERDE3; NÁGILA RAQUEL TEIXEIRA DAMASCENO1;

(1) GRADUATE PROGRAM IN CARDIOLOGY, HEART INSTITUTE (INCOR), SCHOOL OF MEDICINE, UNIVERSITY OF SÃO PAULO (FMUSP) - SÃO PAULO - SP - BRASIL; (2) DEPARTMENT OF NUTRITION, SCHOOL OF PUBLIC HEALTH, UNIVERSITY OF SÃO PAULO (FSP/USP) - SÃO PAULO - SP - BRASIL; (3) DEPARTMENT OF NUTRITION, STATE UNIVERSITY OF CEARÁ - FORTALEZA - CE - BRASIL;

Background/Introduction: Treatment with doxorubicin (DOX) is associated with cardiotoxic effects that may increase mortality in breast cancer (BC) patients, related to cumulative dose and pre-existing cardiovascular risk factors. Objectives: To investigate the association between cardiometabolic and lifestyle risk factors at BC diagnosis under DOX treatment and BC mortality in women with a mean follow-up of 646 days. Methods: A total of 129 women with BC without distant metastasis were included, with a mean age of 47.2 years. Of these, 59.4% were premenopausal. Most had T2 tumors (2–5 cm, 38.1%) and N1 lymph node involvement (45.3%). Traditional lipid profile [TC, HDL-c, LDL-c, TG] was assessed enzymatically, and HDL and LDL subfractions were determined using the Lipoprint® system. Results and Conclusions: No differences were observed between the death group (n=9) and survivors (n=120) for obesity (55.6% vs. 40.8%; p=0.49), hypertension (11.1% vs. 26.1%; p=0.45) or diabetes (11.1% vs. 7.6%; p=0.53). None had cardiovascular disease. Traditional lipid parameters were similar: TC (197.6 vs. 194.8 mg/dL; p=0.82), LDL-c (104.2 vs. 97.6 mg/dL; p=0.48), HDL-c (51.6 vs. 47.5 mg/dL; p=0.43), TG (169.6 vs. 144.5 mg/dL; p=0.33). However, large HDL (HDL-2) were reduced in the death group (3.37±1.19 vs. 5.11±2.46 mg/dL; p=0.026). All patients who died had a total large HDL (HDL-1 to HDL-3) below p50 (12.05 mg/dL), while none above this threshold died (p=0.01). Lower total large HDL was associated with reduced survival (median follow-up 949 vs. 1073 days; log-rank p=0.02). Large LDL (LDL-1) levels were also lower in the death group (9.32±4.87 vs. 14.57±7.47 mg/dL; p=0.047). These differences in lipoprotein subfractions suggest a more atherogenic profile, which may contribute to cardiotoxic events. Regarding lifestyle factors, smoking was not associated with outcomes (22.2% vs. 35.8%; p=0.49), but alcohol consumption was more frequent in the death group (100% vs. 58.3%; p=0.01) and associated with lower survival (median follow-up 1006 vs. 1073 days; log-rank p=0.043). These findings suggest that more atherogenic lipoprotein subfractions, beyond the conventional lipid profile and, alcohol consumption, may reduce survival in BC patients treated with DOX. Although preliminary, these data identify potential lipid biomarkers and lifestyle factors that may help in the early identification of vulnerable patients, supporting future investigations.

DHA-ENRICHED KETOGENIC DIET INCREASES AKKERMANSIA AND IS ASSOCIATED WITH ENHANCED POLYUNSATURATED FATTY ACID INCORPORATION IN ERYTHROCYTE MEMBRANES

RIBANNA APARECIDA MARQUES BRAGA1; LETÍCIA ATADEMOS2; BEATRIZ TELES LEAL2; GLAUCIVAN GOMES GURGEL1; LIVIA ALVARENGA3; JÚLIA GALBIATI DE SOUZA1; ERNANI T DE SANTA HELENA4; ANDERSON SANTOS DE FREITAS2; NÁGILA RAQUEL TEIXEIRA DAMASCENO1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (3) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (4) UNIVERSIDADE REGIONAL DE BLUMENAU - BLUMENAU - SC - BRASIL;

Background/Introduction: Background: The gut microbiota plays a key role in lipid metabolism, and dietary fat quality modulates this interaction. The genus Akkermansia has been linked to beneficial metabolic profiles; however, it remains unclear how ketogenic diets differing in lipid composition affect its abundance and its relationship with erythrocyte fatty acid incorporation. Objectives: Objective: To assess the impact of ketogenic diets with different lipid compositions on Akkermansia abundance and its association with erythrocyte fatty acid profiles. Methods: Methods: Male Wistar rats (200–250 g, ~7 weeks old) were assigned for 75 days to standard diet (SD, n=6; AIN-93G), classic ketogenic diet (CKD, n=6; ~90% fat, rich in saturated fatty acids), or modified ketogenic diet (MKD, n=6; ~90% fat, rich in DHA, 1.8 g/kg). Erythrocyte membrane fatty acids were analyzed by gas chromatography. Gut microbiota was assessed from fecal samples using 16S rRNA gene sequencing. Results and Conclusions: Results: α-diversity differed across groups, with higher richness in CKD vs. SD and greater diversity (Shannon) in CKD and MKD vs. SD. β-diversity analysis showed distinct microbial structures ($p<0.05$), with MKD presenting the most distinct profile. Akkermansia was enriched in MKD and exhibited strong positive correlations ($r>0.80$, $p<0.001$) with polyunsaturated fatty acids, particularly omega-3 fatty acids (α-linolenic acid, EPA, DHA) and the omega-3 index in erythrocyte membranes. Positive associations were also observed with omega-6 fatty acids, including linoleic ($r=0.90$) and γ-linolenic acids ($r=0.96$), whereas strong negative correlations were found with arachidonic acid ($r=-0.93$) and the omega-6/omega-3 ratio ($r=-0.91$) (all $p<0.001$). Conclusion: Ketogenic diets modulate Akkermansia in a lipid-dependent manner. A DHA-enriched ketogenic diet increases Akkermansia and is associated with greater incorporation of polyunsaturated fatty acids into erythrocyte membranes, suggesting a link between dietary fat quality, microbiota, and lipid metabolism relevant to cardiometabolic health.

18078

NATTOKINASE SUPPLEMENTATION AS A STRATEGY FOR MANAGING LIPID PROFILE AND INFLAMMATORY LEVELS IN PATIENTS WITH DYSLIPIDEMIA

MARIANA GRANITO PONTE DE OLIVEIRA1; THAYSI RODRIGUES PIMENTEL DE ANDRADE2; KAREN COUTINHO WOLINO3; DENISE MAFRA2; ALINE PEREIRA4; LUDMILA FMF CARDOZO1;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (3) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (4) UNIVERSIDADE ESTADUAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Nattokinase is an enzyme from Natto, a traditional Japanese food made from fermented soybeans, that has been recognized for its direct fibrinolytic, antithrombotic, anticoagulant, and cardioprotective activities, potentially contributing to a reduced risk of certain cardiovascular diseases1. Objectives: This study aimed to evaluate the effects of nattokinase supplementation on inflammatory markers and cardiovascular risk parameters in participants with dyslipidemia Methods: This was a longitudinal, randomized, double-blind clinical trial. Participants received one capsule per day containing 100 mg of nattokinase standardized to 2,000 fibrinolytic units (FU) for 2 months, while the placebo group received an identical capsule containing cornstarch, administered at the same time of day. Dietary intake, blood pressure, and anthropometric parameters, as well as plasma levels of C-reactive protein and fibrinogen, were assessed at baseline and at the end of the intervention. Results and Conclusions: 52 patients completed the study: 27 in the nattokinase group (49.37 ± 14.91 years, 18 women, BMI: 28.80 ± 4.26 kg/m²) and 25 in the placebo group (49.56 ± 13.17 years, 22 women, BMI: 27.32 ± 4.04 kg/m²). The results of the lipid profile are shown in Table 1. The data showed a reduction in LDL levels in the nattokinase group ($p = 0.030$) and a trend toward decreased non-HDL cholesterol levels ($p = 0.087$). In the placebo group, reductions in total cholesterol ($p=0.041$) and HDL cholesterol ($p=0.009$) were observed, with no change in non-HDL cholesterol ($p=0.191$). There was also a trend towards increased levels of fibrinogen (pre: 292.27 ± 74.826; post: 324.00 ± 81.975; $p = 0.09$) and C-reactive protein (CRP) ($p = 0.06$), which was not observed in the nattokinase group ($p = 0.67$). Nattokinase supplementation may be a useful strategy for managing lipid profile and inflammatory status in patients with dyslipidemia.

Table 1: Lipidic profile in patients with dyslipidemia in nattokinase and placebo groups.

Parameters	Nattokinase (n=27)			Placebo (n=25)		
	Baseline	After	*p*-value	Baseline	After	*p*-value
Total Cholesterol (mg/dL)	228.67±39.48	218.00±38.13	0.089	234.96± 41.10	219.00±34.86	**0.041**
LDL (mg/dL)	150.04±35.29	138.78±34.69	**0.030**	148.28±38.10	138.68±31.75	0.181
HDL (mg/dL)	50.85 ± 11.78	49.56±12.55	0.115	56.52±16.49	51.36±14.29	**0.009**
Non-HDL Cholesterol (mg/dL)	177.70 ± 41.17	167.41 ± 42.84	0.087	180.72±44.91	170.08±36.41	0.191
Tryglicerides (mg/dL)	152.04±83.13	167.19±114.90	0.198	170.08±82.35	182.92±99.14	0.232

RELATIONSHIP BETWEEN SERUM MAGNESIUM, BICEPS BRACHII AND RECTUS FEMORIS MUSCLE THICKNESS, AND HANDGRIP STRENGTH IN HOSPITALIZED PATIENTS WITH DECOMPENSATED HEART FAILURE

THALITA VICENTE BRANDÃO1; FLÁVIO ANDRADE CAMACHO1; RAÍLLA KLING DUTRA1; ANA BEATRIZ DOS SANTOS RIBEIRO2; RAYANE FARIAS AUGUSTO PENNA2; RODRIGO SILVA GAMMERDINGER2; MARIA DE FÁTIMA MARTINS GIL DIAS3; LEONARDO ANDRADE FERNANDES DE LUCA3; ANDRÉ CASARSA MARQUES4; ANDRÉA CARDOSO DE MATOS2; GABRIELLE DE SOUZA ROCHA1; RENATA FRAUCHES MEDEIROS1;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (3) REDE DOR - RIO DE JANEIRO - RJ - BRASIL; (4) UNIVERSIDADE FEDERAL DO ESTADO DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Hospitalization for decompensated heart failure (DHF) is associated with muscle wasting, micronutrient deficiencies, and reduced functional capacity. Magnesium is an essential micronutrient involved in muscle metabolism and electrolyte balance and is frequently depleted in cardiac patients. However, its relationship with muscle-related parameters has not been fully elucidated in patients with DHF. Objectives: To investigate the association between serum magnesium levels and muscle-related parameters, including ultrasound-derived muscle thickness of the biceps brachii (BB) and rectus femoris (RF), and handgrip strength (HGS), in patients hospitalized with DHF, stratified by sex. Methods: Cross-sectional study including 44 patients (≥20 years, both sexes) hospitalized for DHF in a private hospital. Muscle thickness and subcutaneous fat were assessed by ultrasound (Vivid S6, GE Healthcare®; linear transducer L6-12-RS) at standardized sites (BB and RF). HGS was measured using a Jamar® dynamometer (dominant hand; three attempts; highest value recorded). Serum magnesium levels were obtained after a 12-hour fast. All assessments were performed within the first 48 hours of hospitalization. Statistical analyses were performed using Kolmogorov-Smirnov or Mann-Whitney tests, and Pearson or Spearman correlation tests, as appropriate ($p<0.05$). The study was approved by the Research Ethics Committees. Results and Conclusions: Of the 44 patients, 29 (65.9%) were male and 15 (34.1%) female. Men had greater RF muscle thickness (2.5 mm; $p=0.013$), less subcutaneous fat at the RF site ($p=0.0005$), and higher HGS (27.6 kgf; $p<0.0001$). Serum magnesium levels were similar between sexes (1.9 mg/dL). In men, BB and RF muscle thickness were positively correlated with HGS ($p=0.008$ and $p=0.001$). In women, BB thickness, RF thickness, and subcutaneous fat were positively correlated with serum magnesium levels ($p=0.015$, $p=0.001$, and $p<0.001$). Serum magnesium was associated with muscle-related parameters in a sex-specific manner in patients with DHF. These findings suggest that magnesium may play a role in muscle composition and function, with potential implications for nutritional and functional assessment in this population.

Background/Introduction: Hypertension is a major global health concern and a leading risk factor for cardiovascular disease, closely associated with chronic inflammation and oxidative stress. The nuclear factor erythroid 2–related factor 2 (Nrf2) is a key regulator of antioxidant defense and redox balance, with an important role in vascular protection. Royal jelly (RJ) has been described as a bioactive compound with antioxidant and anti-inflammatory properties, however, clinical evidence in humans remains limited. Objectives: To evaluate the effects of royal jelly supplementation on oxidative stress and inflammatory markers in patients with hypertension. Methods: This was a preliminary, randomized, double-blind, placebo-controlled clinical trial with hypertensive adult patients. Participants received either royal jelly (300 mg/day) or a placebo for 8 weeks. Clinical, anthropometric, and biochemical parameters were assessed at baseline and post-intervention. Nrf2 mRNA expression was quantified by quantitative real-time PCR (qPCR) in peripheral blood mononuclear cells (PBMCs) and normalized from the GAPDH reference gene using the ΔΔCt method. Lipid peroxidation was assessed by measuring thiobarbituric acid reactive substances (TBARS), including malondialdehyde (MDA). Results and Conclusions: 31 patients completed the study: 18 in the RJ group (62.5 ± 8.3 years, 13 women, BMI: 30.6 ± 6.2 kg/m²) and 13 in the placebo group (58.5 ± 12.3 years, 9 women, BMI: 27.7 ± 5.6 kg/m²). Baseline characteristics were comparable between groups. A significant increase in Nrf2 gene expression was observed in the RJ group ($p = 0.024$), whereas no change was observed in the placebo group. No significant changes were observed in lipid profile, glycemic parameters, inflammatory markers, anthropometric measures, or blood pressure. No differences between groups were found at the end of the intervention (Δ). However, the change in Nrf2 levels tended to be greater in the RJ group compared to placebo ($p = 0.056$). These results suggest that RJ may modulate the expression levels of NRF2 in hypertensive patients.

Table 1: Nrf2 mRNA expression, MDA and plasma levels of CRP of hypertensive patients in royal jelly and placebo groups.

Parameters	Royal Jelly (n=18)			Placebo (n=13)		
	Baseline	After	*p*-value	Baseline	After	*p*-value
Nrf2 (a.u)*	0.9 ± 0.24	1.36 ± 0.49	0.024	1.01 ± 0.19	1.02 ± 0.23	0.935
MDA (nmol/mL)	2.18 ± 1.18	2.94 ± 1.58	0.102	2.8 ± 2.19	3.0 ± 1.57	0.796
hs-CRP (mg/dL)	0.26 ± 0.24	0.31 ± 0.51	0.444	0.25 ± 0.36	0.29 ± 0.46	0.358

*The gene expression analysis included 8 patients in the royal jelly group and 7 patients in the placebo group, Arbitrary unit - a.u.
MDA = malondylaldehyde; hs-CRP = high sensitivity C-reactive protein

ARTIFICIAL INTELLIGENCE-ENABLED ELECTROCARDIOGRAPHY FOR THE DETECTION OF MODERATE-TO-SEVERE TRICUSPID REGURGITATION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF DIAGNOSTIC ACCURACY

ARTHUR HENRIQUE GOHR1; NICOLAS JOSE BERTOLDI2; JULIA DAVID3; GERALDO LUCAS LOPES COSTA4; GUILHERME LOUREIRO FIALHO5;

(1) UNIVERSIDADE FEDERAL DE SANTA CATARINA - FLORIANOPOLIS - SC - BRASIL; (2) UNIVERSIDADE FEDERAL DE SANTA CATARINA - FLORIANÓPOLIS - SC - BRASIL; (3) CENTRO UNIVERSITÁRIO DE BRUSQUE - BRUSQUE - SC - BRASIL; (4) UNIVERSIDADE FEDERAL DE SANTA CATARINA - FLORIANÓPOLIS - FLORIANOPOLIS - SC - BRASIL; (5) HOSPITAL UNIVERSITARIO PROFESSOR POLYDORO ERNANI DE SÃO THIAGO, UNIVERSIDADE FEDERAL DE SANTA CATARINA - FLORIANOPOLIS - SC - BRASIL;

Background/Introduction: Tricuspid regurgitation (TR) is a common valvular heart disease associated with adverse outcomes but frequently remains underdiagnosed, as diagnosis relies on echocardiography, requiring specialized equipment and expertise and typically performed only when disease is clinically suspected. Artificial intelligence–enabled electrocardiography (AI-ECG) has emerged as a potential tool for identifying structural heart disease using widely available data. Objectives: To evaluate the diagnostic accuracy of AI models applied to 12-lead ECG recordings for detecting clinically significant TR. Methods: We performed a systematic review and diagnostic test accuracy meta-analysis in accordance with PRISMA-DTA. PubMed, Embase, and CENTRAL were searched through February 2026 for retrospective studies evaluating deep learning–based 12-lead electrocardiographic models for the detection of clinically significant tricuspid regurgitation, using transthoracic echocardiography as the reference standard. Risk of bias and applicability were assessed with QUADAS-3, and pooled sensitivity and specificity were estimated using a bivariate random-effects model. Results and Conclusions: Five studies comprising 156,432 participants were included, of whom 7,050 had clinically significant tricuspid regurgitation. Across studies, sensitivity ranged from 0.18 to 0.84 and specificity from 0.61 to 0.98. The pooled sensitivity was 0.58 (95% CI, 0.39–0.74) and specificity was 0.91 (95% CI, 0.77–0.97), with an area under the summary receiver operating characteristic curve of 0.82, indicating good overall discriminatory performance. Substantial heterogeneity was observed (I^2 = 99.6% for sensitivity and 100% for specificity), with a strong threshold effect (ρ = 0.89, P = 0.019), suggesting that differences in decision thresholds contributed to variability in diagnostic accuracy. Overall, risk of bias was low, although 1 study showed high risk in the analysis domain due to pair-level rather than participant-level analysis, and 1 study had unclear risk in the index test and target condition domains. These findings indicate that AI-enabled electrocardiography demonstrates high specificity but moderate sensitivity for detecting clinically significant tricuspid regurgitation, supporting its role as an opportunistic risk stratification or pre-echocardiographic triage tool within cardiology workflows rather than as a standalone screening modality.

19948

BEYOND THE SCORE: IMPROVING MORTALITY PREDICTION IN INFECTIVE ENDOCARDITIS

INES MADEIRA SANTOS1; RODRIGO NEVES BRANDÃO1; INES MIRANDA1; MARCO BERINGUILHO1;

(1) ULS AMADORA SINTRA - PORTUGAL;

Background/Introduction: Infective endocarditis (IE) has an increasing incidence despite advances in diagnosis and remains associated with high morbidity and mortality. Several risk scores, including PALSUSE and modified AEPEI, have been developed to predict mortality; however, their performance remains suboptimal. Objectives: To compare the prognostic performance of AEPEI and PALSUSE and assess whether multivariable models improve mortality prediction in IE. Methods: We conducted a retrospective single-center cohort study including patients hospitalized with IE between January 2017 and October 2025. The predictive performance of AEPEI and PALSUSE, and their corresponding multivariable logistic regression models, was evaluated at four time points: in-hospital, 1 month, 6 months, and 12 months. Discrimination was assessed using receiver operating characteristic curves and area under the curve (AUC). Multivariable models incorporated each score with clinical covariates (age, sex, body mass index, immunosuppression, prosthetic material, and diabetes). Results and Conclusions: A total of 184 patients were included; 72.3% were male, with a mean age of 70.2 ± 12.5 years. AEPEI was significantly associated with mortality at all time points (p=0.001), with modest discrimination (AUC 0.678–0.684). PALSUSE was not significant at 6 and 12 months but was associated with in-hospital and 1-month mortality. After multivariable adjustment, discrimination improved for both scores. AEPEI achieved AUCs of 0.787, 0.785, 0.797, and 0.793, while PALSUSE achieved 0.772, 0.764, 0.776, and 0.769, for the respective time points. AEPEI and PALSUSE show limited discrimination when used alone. Integration into multivariable models significantly improves prognostic performance across all time points, supporting the use of combined clinical models over isolated risk scores in IE.

DISTINCT VALVULAR PHENOTYPES IN RHEUMATIC HEART DISEASE WITH AND WITHOUT PRIOR ACUTE RHEUMATIC FEVER DIAGNOSIS

SARA SARY ELDIM CAMPANATI1; VIVIAN BARROSO SANTOS1; DANIELLY RAMOS PEREIRA1; HENRIQUE FAUSTINO VIEIRA DA SILVA1; SILVIO MENDES DE MAGALHÃES1; ANA BEATRIZ DA CRUZ PESSOA1; MÁRCIA FABRÍCIA ALMEIDA TEIXEIRA1; ANA LUISA MIRANDA OLIVEIRA1; NAYANA FLAMINI ARANTES GOMES1; VICENTE REZENDE SILVA1; ADSON PATRIK VIEIRA CARVALHO1; MARIA DO CARMO PEREIRA NUNES1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: A substantial proportion of patients with rheumatic heart disease lack a documented history of acute rheumatic fever, with more than half having no prior diagnosis in childhood. This suggests unrecognized subclinical carditis, which may progress and manifest as distinct patterns of valvular disease in the chronic phase. Objectives: To evaluate whether the absence of a documented history of acute rheumatic fever influences is associated with distinct patterns of valvular involvement in chronic rheumatic heart disease. Methods: This retrospective study included 393 adult patients with rheumatic heart disease from a tertiary referral center. Patients were stratified according to the presence or absence of prior acute rheumatic fever. Significant valvular lesions were defined based on standardized echocardiographic criteria. A phenotypic classification was developed using five mutually exclusive patterns: no significant lesion, isolated mitral stenosis, isolated mitral regurgitation, mixed mitral valve disease, and aortic or multivalvular involvement. Associations between acute rheumatic fever history and phenotypic distribution were analyzed. Results and Conclusions: Among the included patients, 165 (42%) had a history of acute rheumatic fever. Baseline characteristics were similar between groups (table 1). Patients without prior acute rheumatic fever more frequently exhibited isolated mitral stenosis (66.2% vs 47.3%; p < 0.001), (table 2). In contrast, patients with prior acute rheumatic fever demonstrated greater structural complexity, including a higher prevalence of moderate-to-severe mitral regurgitation (16% vs 7%; p = 0.010), aortic regurgitation (10% vs 4%; p = 0.024), and aortic stenosis (19% vs 10%; p = 0.009). The aortic or multivalvular phenotype was significantly more frequent in this group (20.0% vs 8.3%; p = 0.001; OR ≈ 2.75). Overall, phenotypic distribution differed significantly between groups (p = 0.001). These findings suggest that prior acute rheumatic fever is associated with greater valvular complexity, whereas its absence may reflect subclinical carditis with a more indolent disease course. A phenotypic approach may enhance disease characterization and risk stratification and may support earlier echocardiographic surveillance in patients without documented acute rheumatic fever.

Table 1: Baseline characteristics of the study population according to ARF diagnosis

Baselines values		Without (n=228)	With (n=165)	p value
Age (years)		48.8 ± 12.5	46.7 ± 12.1	0.114

INFECTIONS RELATED TO CARDIAC IMPLANTABLE ELECTRONIC DEVICES: CLINICAL AND MICROBIOLOGICAL ANALYSIS IN A TERTIARY CENTER

JAQUELINE DE ANDRADE FONSECA1; CARLOS TADEU DE OLIVEIRA LEONIDIO1; EDUARDO LAMPREA DE ALBUQUERQUE2; ISABEL MOTA VALENÇA RODRIGUES2; JOANA MONTEIRO LEAL3; DIANA PATRÍCIA LAMPREA SEPULVEDA1;

(1) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL; (2) UNIVERSIDADE CATOLICA DE PERNAMBUCO - RECIFE - PE - BRASIL; (3) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL;

Background/Introduction: Infections related to cardiac implantable electronic devices (CIEDs) are significant complications in contemporary cardiology, with increasing incidence due to population aging, a higher comorbidity burden, and growing procedural complexity. These infections are associated with high morbidity and mortality, especially in infective endocarditis. Despite therapeutic advances, the global incidence of CIED infections has increased by more than 200% in the last 16 years, reflecting the complexity of treated cardiac conditions and the risks associated with invasive devices. Objectives: To describe the epidemiological, clinical, and microbiological characteristics of CIED-related infections in a tertiary cardiology center, identifying risk factors and clinical outcomes. Methods: An observational, retrospective, cross-sectional study was conducted at a tertiary cardiology center in Pernambuco, Brazil, between January and November 2024. Patients ≥ 18 years old with CIEDs admitted with infection defined by clinical, microbiological, and imaging criteria were included. Cases were classified as pocket infection or device endocarditis. Epidemiological and clinical variables, device type, and etiological agents were collected. Descriptive analysis was presented in absolute and relative frequencies, and associations with prolonged hospitalization (>42 days) and mortality were analyzed using Fisher's exact test. Results and Conclusions: Seventeen patients were included, with a predominance of males (70.6%) and a mean age of 67.1 ± 15.2 years. Hypertension (70.6%) and renal insufficiency (41.2%) were the most frequent comorbidities. Dual-chamber pacemakers were the most common device (76.4%). Pocket infection occurred in 58.8% and endocarditis in 41.2%. The main antecedents were prior hospitalizations (88.2%) and generator replacement (52.9%). Microbiological analysis (n=16) revealed bacterial growth in 50%, with Staphylococcus aureus (18.8%) and coagulase-negative staphylococci (25%) being the most frequent. Notably, fungal infections were found in 25% of cases, with Candida parapsilosis (18.8%) as the most prevalent agent. Most patients (88.2%) underwent system removal. The mean hospital stay was 52.4 ± 34.8 days, with 41.2% mortality. Endocarditis was the condition most associated with death (71.4% of deaths, p=0.058). The high mortality, particularly in endocarditis cases, highlights the severity of CIED infections and the need for effective prevention, early diagnosis, and timely management.

LATE ONSET PROSTHETIC VALVE ENDOCARDITIS: RISK FACTORS ASSOCIATED WITH MORTALITY

GUILHERME SUAREZ POMPEO1; GIOVANNA IANINI FERRAIUOLI BARBOSA1; RAFAEL QUARESMA GARRIDO1; NICOLAS FEIJÓO1; WILMA FELIX GOLEBIOVSKI1; GUILHERME DALCOL1; TANIA MARA VAREJÃO STRABELLI2; FLAVIO TARASOUTCHI2; RINALDO FOCACCIA SICILIANO2; CRISTIANE CRUZ LAMAS1;

(1) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Background/Introduction: Late prosthetic valve infective endocarditis (LPVIE) is a challenging condition associated with high mortality; however, it remains understudied. This study aimed to assess the epidemiological, clinical, microbiological, imaging features, in-hospital mortality, and associated risk factors of LPVIE. Objectives: This study focused on patients diagnosed with late prosthetic valve infective endocarditis (LPVIE) at two leading Brazilian cardiology centres. It aimed to (1) assess the epidemiological, clinical, microbiological and imaging features and in-hospital outcomes of these patients and (2) describe the factors associated with in-hospital death. Methods: We conducted an observational study of LPVIE cases recorded between 2006 and 2023 at two cardiac surgery centres in Brazil. Data were obtained from prospective databases and medical record reviews. Patients aged ≥ 18 years with a definite diagnosis of LPVIE according to the modified Duke criteria were included. Results and Conclusions: Results: A total of 394 episodes were analysed, 63.2% of which affected males. The mean age was 54.8 ± 17.39 years. Predisposing conditions included poor dental health (55.4%), previous IE (22.6%) and recent vascular access (9.6%). Fever (77.9%) was the most common finding. Embolisation occurred in 20.6% of patients. Vegetations were present in 49.1% and paravalvular abscesses in 20.6% of patients. Blood cultures were negative in 21.12%. Surgery was indicated in 68.5% of cases and performed in 81.9%. The in-hospital mortality rate was 31%. Multivariate analysis demonstrated an association between mortality and acute renal failure, OR 44.65 (95% CI 18.63–106.99; p < 0.01); intracardiac fistulae, OR 11.31 (95% CI 1.26–101.32; p = 0.030); myocardial/paravalvular abscesses, OR 2.90 (95% CI 1.10–7.65; p = 0.031); hospital transfer, OR 3.90 (95% CI 1.43–10.63; p = 0.008); and failure to undergo surgery when indicated, OR 10.21 (95% CI 2.87–36.36; p < 0.001). Conclusion: LPVIE was associated with high in-hospital mortality and complications. Acute kidney injury, structural complications, prior hospital transfer and failure to undergo surgery when indicated were associated with an increased risk of death. These findings highlight the importance of early identification of structural complications and timely surgical assessment.

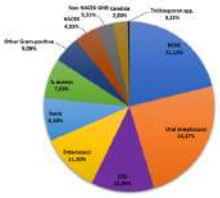

Figure 1 – Etiologic agents in 394 cases of LPVIE in adults, 2006-2023. BCNE: blood culture-negative endocarditis. CNS: coagulase negative staphylococci. *bovis*: group bovis streptococci. *S. aureus*: *Staphylococcus aureus*. PERICARDIAL EFFUSION AFTER VALVULAR HEART SURGERY

JÉSSICA RAÍSA BEZERRA1; RAFAELLA MARIA BEZERRA PINHEIRO CUSTÓDIO1; LUCAS REIS COSTA1; FABIA DANYELA ALENCAR CABRAL BERNARDO1; MARIA JULIA DA CRUZ GOUVEIA NETO DE MENDONÇA1; ELIZABETH DINIZ NÓBREGA1; MARIA EDUARDA OLIVEIRA DE ALBUQUERQUE1; MILENA MOTTA ALMEIDA GOUVEIA1; ERIKA CARDOSO SILVA1; VERÔNICA SOARES MONTEIRO1;

(1) INSTITUTO DE MEDICINA INTEGRAL PROFESSOR FERNANDO FIGUEIRA - IMIP - RECIFE - PE - BRASIL;

Background/Introduction: Valvular heart disease remains a major cause of morbimortality and surgery is the standard of care for symptomatic or hemodynamically significant cases. Pericardial effusion is a common postoperative complication, resulting from inflammatory and hemodynamic mechanisms related to surgical trauma, pericardiotomy, and cardiopulmonary bypass. In the late phase, post-pericardiotomy syndrome may contribute, increasing the risk of adverse outcomes such as cardiac tamponade. Clinical evaluation may be limited, particularly in insidious cases, making transthoracic echocardiography essential for diagnosis and management. This study evaluates the prevalence, clinical and echocardiographic features, and outcomes of postoperative pericardial effusion. Objectives: Evaluate the prevalence, clinical and echocardiographic characteristics, and outcomes of pericardial effusion following valve replacement surgery at a tertiary referral center, and to identify factors associated with its occurrence and complications, including demographic variables, comorbidities, and surgical characteristics, as well as its impact on length of stay, cardiac tamponade, need for pericardiocentesis, and surgical reintervention. Methods: Retrospective observational cohort study including adult patients undergoing valve replacement surgery at a tertiary referral center (2023–2024) with available postoperative transthoracic echocardiography. Clinical, surgical, and laboratory variables were collected, including International Normalized Ratio (INR) and use of anticoagulant and antiplatelet therapy. The primary endpoint was postoperative pericardial effusion; secondary outcomes included cardiac tamponade and need for intervention. Group comparisons used parametric and nonparametric tests. Multivariable logistic regression identified factors associated with outcomes, with adjusted odds ratios and 95% confidence intervals. Discriminative performance of INR ≥1.5 was assessed by receiver operating characteristic curve analysis. Results and Conclusions: Among 360 patients, 324 were analyzed; pericardial effusion occurred in 29.6%, predominantly mild and managed conservatively. Cardiac tamponade was rare (1%). INR ≥1.5 was the only independent predictor (adjusted OR 5.4), while clinical and surgical variables were not associated with the outcome. Pericardial effusion was associated with prolonged hospital stay, supporting systematic echocardiographic surveillance and careful anticoagulation management in the early postoperative period.

RIGHT VENTRICULAR–PULMONARY ARTERIAL COUPLING AS A PROGNOSTIC MARKER IN RHEUMATIC MITRAL STENOSIS

JOSE DIAS DE ASSIS NETO1; DANIELLY RAMOS PEREIRA1; LAURA MUSTAFÁ UMBELINO VIEIRA1; BEATRIZ VELOSO DE ALMEIDA VENUTO1; HORTÊNCIA MARIA RIBEIRO DE CARVALHO1; WILLIAM SILVA BARBOSA1; CAROLINA MADSEN DOS SANTOS1; NAYANA FLAMINI ARANTES GOMES1; ADSON PATRIK VIEIRA CARVALHO1; MARILDES LUIZA DE CASTRO1; WILLIAM ANTÔNIO DE MAGALHÃES ESTEVES1; MARIA DO CARMO PEREIRA NUNES1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Right ventricular-pulmonary arterial coupling, estimated by the TAPSE/PASP ratio (Figure 1), has emerged as a prognostic marker in various heart diseases. However, its role in rheumatic mitral stenosis remains poorly defined. Objectives: To evaluate the prognostic value of right ventricular-pulmonary arterial coupling in patients with mitral stenosis under medical management. Methods: Patients referred for management of mitral stenosis between 2016 and 2024 were included. Those with severe mitral stenosis who were referred for immediate valvular intervention following the initial echocardiographic assessment were excluded. The primary endpoint was a composite of death or need for mitral valve replacement. Impaired ventricular–arterial coupling was defined as TAPSE/PASP < 0.31 mm/mmHg. Results and Conclusions: Results: Of the 819 initially eligible patients, 436 were excluded due to immediate valve intervention, leaving 383 patients for analysis. The age was 47.8 ± 12.4 years, and the mitral valve area was 1.35 ± 0.9 cm²; 67% were in NYHA functional class I/II. The mean TAPSE/PASP ratio was 0.50 ± 0.2, and 63 patients (17%) exhibited impaired ventricular-arterial coupling. After a median follow-up of 3.4 years (IQR: 6 months to 5.9 years), 112 patients underwent surgery for mitral valve replacement and 28 died. In univariate Cox analysis, right ventricular-pulmonary arterial coupling was associated with a higher risk of events (HR: 2.26; 95% CI: 1.44–3.53; p < 0.001) (Figure 2). In multivariate analysis, impaired coupling remained an independent predictor (HR: 1.68; 95% CI: 1.04–2.71; p = 0.032), along with age (HR: 1.02; 95% CI: 1.01–1.04; p = 0.040), mitral stenosis severity (area < 1.5 cm²; HR: 2.47; 95% CI: 1.43–4.24; p = 0.001), and functional class III/IV (HR: 1.90; 95% CI: 1.24–2.91; p = 0.003). Conclusion: Right ventricular-pulmonary arterial coupling, assessed by the TAPSE/PASP ratio, is an independent prognostic marker in patients with rheumatic mitral stenosis under medical treatment, contributing to risk stratification and clinical decision-making.

(1) AMERICAS HOSPITAL COMPLEX – VITORIA AND SAMARITANO BARRA - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Cardiac surgery-associated acute kidney injury (CSA-AKI) is a serious complication. Its incidence can reach 30%, causing a significant impact on care and costs related to hospital admission. We have limited data on these complications in the South American population. Objectives: The primary objective was to describe the incidence and profile of patients with CSA-AKI. The secondary objective was to identify factors associated with the occurrence of CSA-AKI and in-hospital mortality. Methods: This retrospective cohort study included patients aged 18 years or older with data extracted from electronic medical records. All participants had undergone cardiopulmonary bypass(CPB) surgery between December 2023 and June 2025 and were classified according to their AKI stages using the Kidney Disease Improving Global Outcomes criteria. Those with an estimated glomerular filtration rate(eGFR) <15mL/min/1.73 m² or those who underwent renal replacement therapy prior to admission were excluded. Logistic regression was used to identify factors associated with AKI. The association between AKI and mortality was evaluated using Kaplan–Meier(K-M) survival curves and factors associated with mortality were estimated using Cox regression analysis. We used 95% confidence interval and p-value < 0.05. Results and Conclusions: A total of 127 patients. The incidence of CSA-AKI was 40.9% (stage 1 = 65.4%, stage 2 = 11.5%, stage 3 = 21.1%). In the AKI group, we observed a significant difference in age (65.6 [58.8 – 72.7] vs 61.3 [56.3 – 69.3]; p=0.035), lower eGRF (61.1 ± 20.7 vs 84.2 ± 23.7; p<0.001), LVEF (57 [52 – 65] vs 62 [58 – 68]; p=0.019), and higher baseline creatinine (1.37 [1.0 – 1.5] vs 1.0 [0.8– 1.2]), pulmonary arterial systolic pressure (PASP) (33.3 [24 -33] vs 27 [23 – 29]; p=0.026), CPB time (110 [70 – 106] vs 90 [60 –98]; p=0.015) and higher mortality [9 (17.3%) vs 0 (0%); p<0.001]. Logistic regression showed only PASP as a predictor of AKI with OR 1.08 (1.001 - 1.17; p=0.045). The K-M model showed lower 30-day survival in the AKI group (84% [73%-95.9%]), but there were no events in the control group (p=0.0036). The predictors of in-hospital mortality by the Cox model were age (HR 1.21 [1.001 -1.470]; p=0.045) and PASP (HR 1.13 [1.001 - 1.260]; p=0.041). Conclusion: We found a high incidence of CSA-AKI and higher PASP was an independent factor for acute renal dysfunction. AKI was also associated with higher in-hospital mortality; age and PASP were independent factors for its occurrence.

PREOPERATIVE HBA1C ABOVE 7% IDENTIFIES DIABETIC PATIENTS AT HIGHER RISK OF EARLY ADVERSE OUTCOMES AFTER ISOLATED CABG: A PRISMA-GUIDED SYSTEMATIC REVIEW AND META-ANALYSIS

LAIZA SANTOS PIMENTEL HADDAD1; BRUNO FERRAZ DE OLIVEIRA GOMES1; GABRIEL BASTOS COSTA DE ASSIS1; JOÃO VICTOR CORREIA DE SOUZA1; RENATA MEDINA DOS SANTOS1;

(1) INSTITUTO DO CORACAO EDSON SAAD/UFRJ - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Whether preoperative glycemic control influences early outcomes after isolated coronary artery bypass grafting (CABG) in patients with diabetes remains controversial. Objectives: We evaluated the association between elevated preoperative hemoglobin A1c (HbA1c) and short-term postoperative complications after isolated CABG. Methods: This systematic review and meta-analysis was conducted according to PRISMA 2020. PubMed, Embase, and Web of Science were searched for studies including adult patients with diabetes undergoing isolated CABG with available preoperative HbA1c data. Thirteen primary studies were identified as relevant to the review question; 10 met eligibility for qualitative synthesis, and 4 contributed directly to the main quantitative analysis of HbA1c >7% versus ≤7%. Short-term outcomes included postoperative infectious complications, in-hospital mortality, severe renal complications, and length of hospital stay. Pooled estimates were calculated using random-effects models. Results and Conclusions: Results: HbA1c >7% was associated with a markedly higher risk of postoperative infectious complications (OR 3.70, 95% CI 2.54-5.39; I²=0%). This signal remained consistent in sensitivity analysis focused on sternal wound-related outcomes (OR 3.48, 95% CI 1.94-6.24). Elevated HbA1c was also associated with higher crude in-hospital mortality (OR 3.29, 95% CI 1.82-5.92; I²=0%) and longer hospital stay (mean difference 1.28 days, 95% CI 0.48-2.07; I²=65%). Limited data suggested a possible increase in severe postoperative renal complications. Conclusions: In diabetic patients undergoing isolated CABG, preoperative HbA1c >7% identifies a subgroup at substantially higher risk of early postoperative morbidity, particularly wound and sternal infectious complications, and prolonged hospitalization. These findings support HbA1c as a practical perioperative risk stratification tool in candidates for isolated CABG.

PREOPERATIVE PULMONARY FUNCTION AND PERIOPERATIVE FACTORS ASSOCIATED WITH POSTOPERATIVE PULMONARY COMPLICATIONS FOLLOWING CARDIAC SURGERY: A COMPARATIVE ANALYSIS

MICAELE FARIAS NASCIMENTO1; JEFFERSON FELLYPHE RODRIGUES2; DYEGO ANDERSON ALVES DE FARIAS2; RAFAELA FIGUEIRÊDO FERNANDES SOARES2; DANYELLE NÓBREGA DE FARIAS2; PATRÍCIA ANGÉLICA DE MIRANDA SILVA NOGUEIRA1; IVAN DANIEL BEZERRA NOGUEIRA1; RENATA RAMOS TOMAZ BARBOSA3;

(1) UFRN - NATAL - RN - BRASIL; (2) FAMENE - JOÃO PESSOA - PB - BRASIL; (3) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL;

Background/Introduction: Postoperative pulmonary complications (PPC) remain a significant cause of morbidity and mortality following cardiac surgery, contributing to prolonged hospitalization and increased healthcare resource utilization. Early identification of associated risk factors is essential to optimize perioperative management and improve clinical outcomes. Objectives: This study aimed to compare patients who developed PPC with those who did not after cardiac surgery, focusing on preoperative spirometric parameters, the Torrington-Henderson Scale, and perioperative factors associated with PPC occurrence. Methods: This was a documentary, observational, analytical, cross-sectional study including adult patients undergoing cardiac surgery. Sociodemographic, surgical, and preoperative spirometric data were obtained from medical records. Group comparisons were performed using Student's t-test or the Wilcoxon test, according to data distribution, with a significance level set at p<0.05. A total of 34 patients were analyzed. The study was approved by the institutional Research Ethics Committee. Results and Conclusions: Patients who developed PPC had significantly longer cardiopulmonary bypass time (79.67 ±38.44 vs. 55.20 ±25.69; p=0.001) and anoxia time (72.25 ±37.29 vs. 48.05 ±23.95; p=0.001). They also exhibited prolonged hospital length of stay (64.92 ±32.35 vs. 42.65 ±24.70; p=0.001) and longer duration of noninvasive ventilation use (9.58 ±8.91 vs. 5.40 ±2.68; p=0.003). Additionally, patients with PPC demonstrated significantly lower values of vital capacity, forced vital capacity, and forced expiratory volume in one second in the preoperative period. No significant differences were observed in the FEV1/FVC ratio, peak expiratory flow, or Torrington-Henderson score between groups. In conclusion, prolonged intraoperative exposure and reduced preoperative pulmonary function were significantly associated with the development of PPC after cardiac surgery. These findings highlight the importance of preoperative functional assessment as a key strategy for risk stratification and targeted perioperative interventions.

Table 1. Preoperative pulmonary function and postoperative pulmonary complications.

Variable (n=34)	Values
PPC	
Yes	12 (35.3%)
No	22 (64.7%)
Torrington-Henderson score	3.00 ±1.00
Predicted PPC risk (T-H)	
Low	28 (82.4%)
Moderate	6 (17.6%)
Preoperative spirometry (% predicted)	
VC	81.18 ±17.9
FVC	88.62 ±20.9
FEV1	75.35 ±18.58
FEV1/FVC	96.88 ±13.86
PEF	49.88 ±20.38
Obstructive ventilatory disorder	10 (29.4%)
Restrictive ventilatory disorder	6 (17.6%)

Note: Values expressed as mean ± standard deviation or n (%).
VC: vital capacity; FVC: forced vital capacity; FEV1: forced expiratory volume in 1 second; PEF: peak expiratory flow; PPC: postoperative pulmonary complications.

Table 2. Comparative analysis according to the presence of postoperative pulmonary complications (PPC).

Variable	PPC (Yes)	PPC (No)	p-value
Cardiopulmonary bypass time	79.67 ±38.44	55.20 ±25.69	.001
Anoxia time	72.25 ±37.29	48.05 ±23.95	.001
ICU length of stay	11.00 ±10.49	5.45 ±2.60	.004
Preoperative ward stay	32.00 ±26.65	23.10 ±20.08	.002
Postoperative ward stay	21.92 ±19.16	14.10 ±10.34	.002
Total hospital length of stay	64.92 ±32.35	42.65 ±24.70	.001
Days of noninvasive ventilation	9.58 ±8.91	5.40 ±2.68	.003
Spirometry (% predicted)			
Vital capacity (VC)	73.83 ±13.40	86.10 ±19.62	.001
Forced vital capacity (FVC)	80.50 ±19.17	94.15 ±21.61	<.001
Forced expiratory volume in 1 second (FEV1)	69.08 ±18.26	78.80 ±19.01	<.001
FEV1/FVC ratio	98.00 ±11.86	95.05 ±14.33	~0.52
Peak expiratory flow (PEF)	45.50 ±17.33	50.55 ±22.21	~0.47
Torrington-Henderson score	2.75 ± 0.75	2.90 ±0.96	~0.62

Note: Values are expressed as mean ± standard deviation.
PPC: postoperative pulmonary complications; ICU: intensive care unit.

TAKOTSUBO SYNDROME AFTER MITRAL VALVE SURGERY: SYSTEMATIC LITERATURE REVIEW AND INSTITUTIONAL CASE SERIES

MARIANA AIRES DA FONSECA IBRAHIM HAMAD1; ANA CLARA HAJJAR AWAD1; SARA AYRES SOARES ANTUNES1; KASSIA REJANE OLIVEIRA BUENO1; GUILHERME ROSA MARQUES GOMES MELO1; CLAUDIA KLECYANNE RODRIGUES DE BRITO1; VITOR SALVATORE BARZILAI1;

(1) ICTDF - BRASÍLIA - DF - BRASIL;

Background/Introduction: Takotsubo Syndrome (TTS), or stress-induced cardiomyopathy, previously believed to be a benign and self-limiting condition usually associated with emotional triggers, has lately been related with physical stress scenarios, such as the perioperative period. In cardiac surgery, particularly mitral procedures, TTS remains rare and likely underdiagnosed, often mistaken for post-bypass myocardial dysfunction or acute coronary syndromes. Objectives: To analyze the occurrence, clinical profile, and outcomes of TTS in patients undergoing mitral valve surgery through a systematic literature review and a report of three consecutive institutional cases. Methods: A systematic review was conducted in accordance with PRISMA guidelines, using specific descriptors for TTS and mitral surgery via PubMed/MEDLINE. Inclusion criteria focused on case reports, series and systematic literature reviews with confirmed diagnosis and clear temporal association with surgery. Additionally, three institutional cases were analyzed, evaluating variables such as age, sex, procedure type, hemodynamic support, and hospital outcome. Results and Conclusions: Literature indicates a female predominance (80–90%) and mean age of 60–75 years, with early presentation (1st–4th postoperative day) and high incidence of cardiogenic shock (table 1). The institutional series included three mitral repair cases: two early-onset and one late-onset. Two patients required advanced circulatory support (VA-ECMO), resulting in two survivors and one death (table 2). Differential diagnosis was essential to exclude circumflex artery injury or surgical complications. TTS is a rare, but relevant and potentially severe complication after mitral valve surgery. This study reinforces the need for diagnostic vigilance in cases of unexplained hemodynamic instability, especially in women. Early recognition and physiology-guided support are crucial, as the condition carries significant mortality despite the potential for ventricular function recovery.

Table 1 – Characteristics of cases described in the literature

Study	n	Mean age	Procedure	Time to presentation	Shock	Advanced support	Outcome
Chiariello et al. (2016)	review	~65 years	Predominantly mitral	1–3 days	Frequent	Variable	Recovery in most
Devesa et al. (2020)	1	68	Mitral replacement	48h	Yes	Inotropic	Discharge
Gariboldi et al. (2011)	1	64	Mitral replacement	Early	Yes	Clinical support	Discharge
Attisani et al. (2013)	1	70	Minimally invasive mitral	Early	Yes	Inotropic	Discharge
Li et al. (2014)	1	37	Mitral repair	Immediate	Yes	ECMO	Discharge
Systematic review (2023)	81	68	86% mitral/ tricuspid	~4 days	High frequency	Frequent	Mortality present

Table 2 – Clinical cases from the service

Case	Age	Procedure	Timing	Shock	Support	Outcome
1	41	Mitral repair	Early	Yes	Conventional	Discharge
2	74	Mitral repair	Late (D7)	Yes	VA-ECMO	Death
3	74	Mitral repair	Early	Yes	VA-ECMO (7 days)	Discharge

USE OF A PREOPERATIVE EVALUATION PROTOCOL IN LIVER TRANSPLANT CANDIDATES: A PATHWAY TO REDUCING PERIOPERATIVE MYOCARDIAL INFARCTION

ANDRE LUIZ DIAS LIMA BONFIM1; MARCOS MORAIS DE MEIS1; PAULO MACHADO PONTES1; LUIS FILIPE AZEVEDO DE CARVALHO2; LAURA CRISTINA MACHADO PINTO1; LUCIO F PACHECO MOREIRA1; ELIZABETH BALBI1; LEONARDO ANDRADE FERNADES DE LUCA3;

(1) HOSPITAL QUINTA DOR - RIO DE JANEIRO - RJ - BRASIL; (2) HOSPITAL QUINTA DOR - RIO DE JANEIRO - RN - BRASIL; (3) IDOR - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Cardiovascular disease significantly impacts outcomes after liver transplantation, accounting for up to 50% of hospitalizations in the first three months and 40% of deaths within the first month. The multifactorial pathophysiology of cirrhosis increases the risk of false-negative results in functional testing for coronary artery disease (CAD), commonly used in non-cardiac preoperative evaluation. Accurate identification of obstructive CAD is, therefore, essential. Objectives: To evaluate the impact of the CAD-LT score in identifying obstructive CAD in liver transplant candidates. Methods: Observational, retrospective, cross-sectional study conducted at a tertiary private hospital in Brazil. Adult patients who underwent liver transplantation between January and December 2024 were included. Data were obtained from electronic medical records, including demographics, cardiovascular risk factors, clinical data, obstructive CAD, and perioperative myocardial infarction. The primary outcome was perioperative myocardial infarction within 30 days, defined by elevated troponin with clinical, electrocardiographic, or imaging evidence of ischemia. Results and Conclusions: Twenty-nine patients were analyzed (83% male). Main etiologies were NASH (38%) and alcohol (21%), with mean MELD 14. Comorbidities included hypertension (45%), diabetes (59%), and obesity (21%). Intermediate-high and high CAD-LT scores were observed in 80% (n=23); 30% (n=7) underwent coronary angiography, and 57% (n=4) required coronary intervention and dual antiplatelet therapy. CAD-LT showed 100% sensitivity and 48% specificity. A standardized protocol using CAD-LT identified all cases of obstructive CAD, and there was zero events of periprocedural myocardial infarction, supporting its role in improving preoperative risk stratification in liver transplantation.

Background/Introduction: Chronic venous insufficiency (CVI) (CEAP C3-C6) is associated with increased cardiovascular risk and low physical activity levels. Although daily step thresholds (e.g., <4,000 vs. ≥4,000 steps/day) predict mortality and cardiovascular outcomes in the general population, their relevance for patients with CVI remains unknown due to disease-specific functional limitations, including pain, edema, and impaired calf muscle pump function. This knowledge gap limits the applicability of general physical activity guidelines to this clinical population. Objectives: To investigate whether daily step count (categorized as <4,000 vs. ≥4,000 steps/day) is associated with resting systolic blood pressure (SBP), diastolic blood pressure (DBP), heart rate (HR), and heart rate variability (HRV) indices (RR interval, SDNN, RMSSD, LF, HF) in patients with chronic venous insufficiency (CEAP C3-C6). Methods: This cross-sectional study included 112 patients with CVI (median age 59 years; 71.3% women; 54.5% with CEAP C5-C6). Daily step count was measured using waist-mounted triaxial accelerometers (ActiGraph GT3X) over seven consecutive days. Patients were categorized into low (<4,000 steps/day, n=40) and high (≥4,000 steps/day, n=47) step groups. Resting SBP, DBP, and HR were assessed using an automated monitor (Omron HEM-742). HRV was analyzed from 15-minute supine recordings using a Polar H10 chest strap and Kubios software, obtaining time-domain (SDNN, RMSSD) and frequency-domain (LF, HF normalized units) parameters. Linear regression models were applied (crude and adjusted for CEAP classification, sex, age, dyslipidemia, hypertension, diabetes, obesity, smoking, and race). Significance was set at p<0.05. Results and Conclusions: No significant differences between low vs. high step groups for SBP [132(32) vs. 129(19)mmHg; p=0.33], DBP [79(13) vs. 81(13)mmHg; p=0.27], HR [74(11) vs. 72(16)bpm; p=0.24], or HRV indices (RR, SDNN, RMSSD, LF, HF; all p>0.05). Regression models confirmed no associations (all p>0.05). Conclusion: A daily step count ≥4,000 steps is not associated with resting blood pressure, heart rate, or cardiac autonomic modulation in CVI patients, suggesting that step-based thresholds from general populations may not translate to this clinical group.

Table 1. Clinical characteristics of the sample (n = 112)

Variable	Value
Age, years	59.0 (13)
Sex, female (%)	71.3
Weight, kilograms	77.0 (15.8)
Height, meters	157 (0.14)
Body Mass Index, kg/m²	31.0 (6.5)
Disease severity (C5-C6), %	54.5
Time of disease diagnosis, years	17 (15)
Step/day	5957 (4392)
Comorbidities, %	
Hypertension	43.8
Diabetes	20.5
Dyslipidemia	24.1
Obesity	58.9
Medications, %

EFFECT OF ISOMETRIC HANDGRIP TRAINING ON HEART RATE VARIABILITY IN INDIVIDUALS WITH HYPERTENSION: A MULTICENTER RANDOMIZED CONTROLLED TRIAL

EDUARDO BRAGHINI JOHANN1; JULIANA PINTO DA SILVEIRA1; ANTONIO CLEILSON NOBRE BANDEIRA1; ALLANA ANDRADE DE SOUZA1; MARILIA ALMEIDA CORREIA2; BRENO QUINTELLA FARAH3; WAGNER JORGE RIBEIRO DOMINGUES4; GABRIEL GRIZZO CUCATO5; RAPHAEL MENDES RITTI-DIAS2; ALUISIO ANDRADE LIMA6; ALINE MENDES GERAGE1;

(1) UNIVERSIDADE FEDERAL DE SANTA CATARINA (UFSC) - FLORIANÓPOLIS - SC - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (3) UNIVERSIDADE FEDERAL DE SERGIPE - ARACAJU - SE - BRASIL; (4) UNIVERSIDADE DA FORÇA AÉREA (UNIFA) - RIO DE JANEIRO - RJ - BRASIL; (5) NORTHUMBRIA UNIVERSITY - ENGLAND; (6) UNIVERSIDADE FEDERAL RURAL DO PERNAMBUCO - RECIFE - PE - BRASIL;

Background/Introduction: Arterial hypertension (AH) is the main risk factor for deaths from cardiovascular diseases, and its treatment involves medication and lifestyle changes, including physical exercise. Although resistance and aerobic training are effective in controlling blood pressure (BP), adherence to these modalities is still low due to barriers such as fatigue, lack of time, and physical limitations. In this context, isometric handgrip training (IHT) emerges as a promising alternative, as it is simple, fast, safe, and easy to apply. Despite the observed benefits related to this type of training in reducing BP, the mechanisms responsible for these effects are not yet fully understood, highlighting the need for further research on the subject, including assessments such as heart rate variability (HRV). Objectives: To analyze the effect of 12 weeks of IHT on HRV in individuals with hypertension. Methods: This is a multicenter randomized controlled clinical trial, conducted in four different cities in Brazil between April 2019 and September 2024. Participants were individuals with AH, medicated, over 18 years of age, and not participating in a regular physical exercise program. Participants were randomly assigned, by blocks, to two groups: IHT group (four sets, two in each arm with two minutes of isometric contraction at 30% of maximum voluntary contraction and two minutes of rest) and control group (CG, isotonic contractions with an anti-stress ball and stretching). HRV data were collected using a valid heart rate monitor (Vantage V2 - Polar), with R-R intervals exported and evaluated using Kubios HRV software, with analyses performed in the time and frequency domains. Data analysis was performed employing a 2-way analysis of covariance (ANCOVA) for repeated measures, with the baseline values used as covariates. The adopted significance was 0.05. Results and Conclusions: A total of 140 individuals were randomized and 61 completed the intervention (IHT=30; control=31). Baseline characteristics were similar between groups. An isolated time effect was observed for SDNN (IHT: Δ -9.63 vs control: Δ -1.27), RMSSD (IHT: Δ -15.95 vs control: Δ -5.6), and pNN50 (IHT: Δ 2.15 vs control: Δ -1.27). No significant group-by-time interaction was observed for any outcome analyzed. It was concluded that 12 weeks of IHT cannot modify autonomic modulation in individuals with hypertension.

Table 1. HRV analysis pre and post 12 weeks of intervention with adjusted mean by ANCOVA.

	Covariate	Control Group (n=31)		TIH Group (n=30)			p	
Variables	Mean	Mean Post	95% CI	Mean Post	95% CI	g	*t*	g*t

FUNCTIONAL CAPACITY AND MUSCLE ARCHITECTURE IN HYPERTROPHIC CARDIOMYOPATHY: A CROSS-SECTIONAL STUDY

HENRIQUE COSTA MORAES1; MAXIMILIANO ISOPPO SCHAUN1; DANIEL CARLOS GARLIPP2; HELENA ROSETTI QUADROS1; DAVID COHEN2; THIAGO DIPP1;

(1) ICFUC - PORTO ALEGRE - RS - BRASIL; (2) UNIVERSIDADE LUTERANA DO BRASIL- ULBRA - CANOAS - RS - BRASIL;

Background/Introduction: Exercise intolerance in hypertrophic cardiomyopathy (HCM) is primarily driven by central hemodynamic dysfunction. However, the skeletal myopathy hypothesis suggests that functional decline is further aggravated by chronic changes in peripheral muscle architecture (secondary sarcopenia), acting as an additional limiter of submaximal aerobic and daily mechanical performance. Objectives: To analyze the association of peripheral muscle architecture parameters (thickness, pennation angle, and fascicle length) with functional capacity, assessed by the 6-Minute Walk Test (6MWT) and 30-Second Sit-to-Stand Test (30STST), and compare the morphofunctional profile between HCM patients and paired healthy controls. Methods: An observational cross-sectional study evaluated 77 subjects (25-60 years): 43 HCM outpatients and 34 controls. Quadriceps architecture was assessed via B-mode ultrasound. Multiple linear regression ($p<0.05$) quantified the independent predictive effect of morphological variables, clinical diagnosis, and body mass index (BMI) on functional outcomes. Results and Conclusions: Results: The sample comprised 43 HCM patients (46±10 years; BMI 29±5 kg/m²) and 34 controls (40±11 years; BMI 28±3.2 kg/m²). HCM patients exhibited generalized quadriceps atrophy, evidenced by lower total muscle and vastus lateralis (VL) thickness ($p<0.01$). Functionally, the HCM group covered 72 fewer meters in the 6MWT and performed fewer 30STST repetitions ($p<0.001$). VL thickness positively correlated with 6MWT ($\rho=0.383$; $p=0.001$) and 30STST ($\rho=0.421$; $p<0.001$), while pennation angle and fascicle length showed no association ($p>0.05$). Beta-blocker therapy did not influence performance ($p=0.878$). In the multivariable model, HCM diagnosis ($B=-59.03$; $p=0.001$) and BMI ($B=-2.92$; $p=0.044$) emerged as independent predictors of worse performance. Consequently, VL thickness did not retain statistical significance as an independent predictor in the adjusted model ($p=0.075$). Conclusions: HCM imposes severe structural degradation, and reduced muscle thickness is directly associated with functional decline. However, no significant differences occur in pennation angle and fascicle length. Thus, effort intolerance is multifactorial: intrinsic central limiters of the pathology and mechanical overload (BMI) outweigh isolated muscle atrophy as the primary independent predictors of mechanical failure.

INTRADIALYTIC RESISTANCE EXERCISE AS AN ADJUVANT STRATEGY TO REDUCE THE PROPENSITY FOR VASCULAR CALCIFICATION: MODULATION OF FETUIN-A AND BIOCHEMICAL MARKERS OF MINERAL METABOLISM – A PILOT STUDY.

JOSIANO GUILHERME PUHLE1; MATHEUS CHIMELO BIANCHINI2; DÉBORA TAVARES DE RESENDE E SILVA3; VANESSA DA SILVA CORRALO4;

(1) UNIVERSIDADE COMUNITÁRIA DA REGIÃO DE CHAPECÓ - UNOCHAPECÓ - CHAPECÓ - SC - BRASIL; (2) UNIVERSIDADE FEDERAL DA FRONTEIRA SUL - UFFS - CHAPECÓ - SC - BRASIL; (3) UNIVERSIDADE FEDERAL DA FRONTEIRA SUL - UFFS - CHAPECÓ - SC - BRASIL; (4) UNIVERSIDADE COMUNITÁRIA DA REGIÃO DE CHAPECÓ - CHAPECÓ - SC - BRASIL;

Background/Introduction: Chronic kidney disease (CKD) is associated with chronic kidney disease–mineral and bone disorder (CKD-MBD), which contributes to vascular calcification and increased cardiovascular risk in hemodialysis patients. Fetuin-A, an inhibitor of calcium–phosphate crystallization, is inversely associated with these outcomes. However, the effects of intradialytic resistance exercise on fetuin-A and mineral metabolism markers remain unclear. Objectives: Based on this, the present study aims to investigate the effects of intradialytic resistance exercise on circulating fetuin-A levels, gene expression, and mineral metabolism markers associated with a propensity for vascular calcification in hemodialysis patients. Methods: This prospective, interventional pilot study included 30 patients with chronic kidney disease (CKD) undergoing hemodialysis for ≥6 months. Participants underwent a structured resistance exercise program, performed three times a week during the first hour of hemodialysis sessions, for 12 weeks. Exercise intensity was maintained at a moderate level and monitored using the Borg scale (1960). Serum fetuin-A levels were measured by ELISA, and gene expression was assessed by RT-qPCR. Biochemical parameters of MBD-CKD included total calcium (Ca), ionized calcium (Ca^{2}□), phosphorus (P), calcium-phosphorus product (Ca×P), parathyroid hormone (PTH), and 25-hydroxyvitamin D. Statistical analysis included the Shapiro-Wilk test to assess data normality, followed by the paired Student's t-test. Results and Conclusions: Intradialytic resistance exercise significantly increased circulating fetuin-A levels (0.59±0.16 – 1.20±0.41; $p=0.023$), as well as its gene expression (0.59±0.81 – 1.34±0.50; $p=0.011$). Concomitantly, significant reductions were observed in the levels of Ca (10.82±1.28 – 9.61±1.17; $p=0.007$), Ca^{2}□ (2.71±0.31 – 2.40±0.29; $p=0.006$), P (6.38±0.53 – 5.63±0.61; $p=0.005$), Ca×P product (69.15±10.33 – 54.19±8.57; $p=0.012$) and PTH (313.78±203.30 – 239.16±150.16; $p=0.047$). In this context, intradialytic resistance exercise demonstrates potential as a non-pharmacological adjuvant strategy to modulate the fetuin-A axis and mineral metabolism, reducing markers of propensity for vascular calcification. These results reinforce their role by suggesting a possible reduction in cardiovascular risk in hemodialysis patients and indicate the need for confirmation in larger randomized clinical trials, particularly with longer follow-up periods and larger patient populations.

Background/Introduction: Heart failure (HF) is a prevalent clinical condition associated with significant functional impairment. Cardiopulmonary rehabilitation is recommended to improve the physical capacity and quality of life of these patients. In this context, blood flow restriction resistance training (BFRRT) emerges as a low-intensity alternative offering potential functional benefits. Objectives: To compare the effects of blood flow restriction resistance training (BFRRT) and conventional resistance training (CRT) on the cardiorespiratory fitness of patients with heart failure (HF), assessed by cardiopulmonary exercise testing (peak VO_2). Methods: This was a randomized, prospective, parallel-group clinical trial including 20 participants (13 men and 7 women; age: 62.05±13.27 years; weight: 75.00±10.98 kg; height: 1.67±0.12 m; body fat: 24.83±8.88%) classified as NYHA classes II and III. Patients were assigned to one of two groups (n=10 per group): BFRRT (50% BFR + 20–30% 1RM) and CRT (60–80% 1RM). Both groups trained twice a week for 12 weeks, with training loads adjusted based on 1RM. Cardiopulmonary exercise testing using an individualized ramp protocol was conducted pre- and post-training. Data were analyzed using the Wilcoxon signed-rank test for intra-group comparisons and the Mann-Whitney U test to compare relative changes between groups. Results and Conclusions: Data were expressed as median and interquartile range (IQR). In the BFRRT group, peak VO_2 changed from 19.19 (IQR: 13.84–28.45) to 22.91 (IQR: 17.45–26.91) $mL \cdot kg^{-1} \cdot min^{-1}$ (p=0.375). In the CRT group, peak VO_2 changed from 17.70 (IQR: 16.44–20.41) to 18.89 (IQR: 14.90–20.85) $mL \cdot kg^{-1} \cdot min^{-1}$ (p=0.275). Intergroup analysis of relative changes (Δ%) using the Mann-Whitney test showed no significant differences between the two training methods (p=0.791). BFRRT proved to be a viable clinical alternative comparable to CRT in the rehabilitation of patients with HF. Despite the lack of statistical significance—likely associated with the small sample size—BFRRT promoted the maintenance and clinically relevant improvements in cardiorespiratory fitness. Since BFRRT achieves these outcomes using substantially lower mechanical loads, it emerges as a promising strategy to enhance safety and exercise tolerance in functionally limited patients. Future clinical trials with larger sample sizes are warranted to confirm these findings.

Background/Introduction: Chronic Chagas cardiomyopathy (CCC) is associated with reduced functional capacity and exercise intolerance. Although cardiopulmonary exercise testing (CPET) provides objective assessment of aerobic capacity, simpler and low-cost functional measures may be useful in clinical and rehabilitation settings, especially when access to specialized testing is limited. Objectives: To investigate the association between the 1-minute sit-to-stand test, handgrip strength, and CPET-derived variables in patients with CCC. Methods: This cross-sectional observational study was derived from a cohort of patients with CCC and left ventricular ejection fraction >35%. Participants underwent echocardiographic assessment, CPET, the 1-minute sit-to-stand test, and peripheral muscle strength assessment using handgrip dynamometry. Data are presented as median and interquartile range. Associations were analyzed using Spearman's correlation coefficient. Results and Conclusions: Ten individuals were evaluated, with age of 62.0 (52.0–71.0) years, left ventricular ejection fraction of 44.0% (37.3–52.5), and body mass index of 26.3 (23.5–31.0) kg/m². Peak VO_2 was 19.8 (16.0–23.8) mL/kg/min, percentage of predicted VO_2 was 57.1% (44.9–83.6), and oxygen uptake at the anaerobic threshold was 13.2 (11.0–16.5) mL/kg/min. The number of repetitions in the 1-minute sit-to-stand test was 24.0 (20.8–28.5), and handgrip strength was 29.6 (20.4–39.6) kgf. Peak VO_2 showed a strong positive correlation with the number of sit-to-stand repetitions (rho=0.858; p=0.002). Sit-to-stand repetitions were also positively correlated with handgrip strength (rho=0.762; p=0.010). A positive, although not statistically significant, correlation was observed between peak VO_2 and handgrip strength (rho=0.572; p=0.084). In patients with CCC, better performance on the 1-minute sit-to-stand test was strongly associated with higher aerobic capacity assessed by CPET and with greater peripheral muscle strength. These findings suggest that the 1-minute sit-to-stand test may be a practical and accessible complementary tool for functional assessment in this population.

Table 1. Correlations between functional capacity, physical performance, and muscle strength.

ASSOCIATION BETWEEN SEDENTARY BEHAVIOR AND CARDIAC AUTONOMIC MODULATION IN OLDER WOMEN

ANA VITÓRIA BELARDINUCCI DA SILVA1; LUCAS LEONARDO MARCELINO JOIA1; JOÃO PEDRO LUCAS NEVES SILVA1; NATACHA DE LIMA GERVAZONI1; ELOISA ROBLES DE QUEIROZ MACEDO1; MARIANA CARVALHO ARAÚJO1; KEYLA SOUSA OLIVEIRA1; LUCAS AMANCIO DE SOUZA1; LUIZ CARLOS MARQUES VANDERLEI1;

(1) UNIVERSIDADE ESTADUAL PAULISTA (UNESP) - PRESIDENTE PRUDENTE - SP - BRASIL;

Background/Introduction: Aging is associated with an increased risk of cardiovascular diseases. In this context, sedentary behavior (SB) is an important modifiable risk factor. Heart rate variability (HRV) is a relevant marker of cardiac autonomic regulation, a reduction that is more pronounced in postmenopausal women. However, the association between time spent in SB and cardiac autonomic modulation is not yet fully understood in older women, especially when considering objective measures of SB and linear HRV indices. Objectives: To analyze the association between SB and cardiac autonomic modulation, through linear HRV indices, in older women. Methods: This is a cross-sectional observational study including 90 older women (69.31 ± 5.96 years). Initially, data were collected to characterize the sample. Objective assessment of time spent in SB was performed using an accelerometer over seven consecutive days. For the analysis of cardiac autonomic modulation, heart rate was recorded beat-to-beat using a heart rate monitor for 30 minutes, and 1,000 RR intervals from the most stable period of the recording were selected for analysis. The association between SB and linear HRV indices was assessed using Pearson or Spearman correlation coefficients, according to data normality (Shapiro–Wilk test). A significance level of $p < 0.05$ was adopted. Results and Conclusions: A weak negative associationof low magnitude was found between time spent in SB and the LF ($r = -0.23$; $p = 0.023$) and SD2 ($r = -0.212$; $p = 0.045$) indices. No significant associations were observed for the other indices ($p \geq 0.05$). In older women, greater time spent in SB was associated with lower HRV indices reflecting global variability, suggesting worse cardiac autonomic modulation. These findings reinforce the importance of reducing SB as a strategy to improve autonomic modulation in older women.

Table 1. Sample characterization.

Clinical Characteristics	N = 90 Mean ± Standard Deviation
Age (years)	69,31 ± 5,96
Weight (kg)	66,19 ± 10,86

Background/Introduction: Sarcopenia is a common condition in chronic diseases and is associated with impaired functional performance and adverse clinical outcomes. In Chagas disease (CD), musculoskeletal alterations and reduced functional capacity are frequently observed; however, the determinants of sarcopenia in this population remain poorly understood. Identifying simple and clinically applicable markers may improve early detection and risk stratification. Objectives: To evaluate the clinical, functional, and body composition predictors associated with sarcopenia in patients with CD. Methods: This cross-sectional study included 149 patients with confirmed CD. Clinical, echocardiographic, functional, and body composition data were systematically collected. Sarcopenia was defined according to EWGSOP2 criteria. An exploratory analytical approach was performed using univariate logistic regression models including demographic, clinical, echocardiographic, behavioral, and functional variables (age, sex, Body Mass Index [BMI], diabetes, hypertension, NYHA class, clinical form [Clinical form was categorized according to cardiac involvement, with the cardiac form used as the reference category], LVD, LVEF, Human Activity Profile [HAP], Beck Depression Inventory [BDI], and TSL60). Variables achieving statistical significance were entered into a multivariate model using Firth's penalized logistic regression to account for the low event rate and reduce small-sample bias. Results and Conclusions: The sample was predominantly female (61.1%), with a mean age of 64.2±8.5 years, and most patients were classified as NYHA I–II (85.2%). The prevalence of sarcopenia was 11.4%. In univariate analyses, sex, BMI, clinical form of the disease, and TSL60 were associated with sarcopenia. In the multivariate model, BMI (OR = 0.75; 95% CI: 0.62–0.87; p < 0.001) and TSL60 (OR = 0.83; 95% CI: 0.71–0.94; p = 0.004) remained independently associated with the outcome, demonstrating consistent effects after adjustment. Sex (OR = 1.86; 95% CI: 0.58–6.20; p = 0.294) and clinical form (OR = 2.38; 95% CI: 0.65–10.54; p = 0.195) were not significant in the adjusted model. In patients with CD, BMI and TSL60 emerged as independent predictors of sarcopenia. These findings indicate that a simple functional test, combined with an anthropometric measure, may provide clinically relevant information beyond traditional diagnostic components, supporting their use as practical screening tools in this population.

Table 1. Univariate and multivariate Firth logistic regression analysis for predictors of sarcopenia in patients with Chagas disease (n=149).

DUKE ACTIVITY STATUS INDEX REFLECTS OBJECTIVE PHYSICAL PERFORMANCE IN PATIENTS WITH CHAGAS CARDIOMYOPATHY

ANTONIELLY ROCHA DE SOUZA PEREIRA1; MARINA SILVA REIS1; GABRIEL MELO FONSECA1; STEFÂNIA GUIMARÃES NERY1; GUSTAVO REIS MACIEL1; LUCAS FROIS FERNANDES DE OLIVEIRA2; WHESLEY TANOR SILVA3; CHEYENNE ALVES FONSECA1; MARCUS VINÍCIUS ACCETTA VIANNA1; MARTA VALQUÍRIA DA SILVA1; SANNY CRISTINA DE CASTRO FARIA2; HENRIQUE SILVEIRA COSTA1;

(1) UNIVERSIDADE FEDERAL DOS VALES DO JEQUITINHONHA E MUCURI (UFVJM) - DIAMANTINA - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) FUNDAÇÃO OSWALDO CRUZ (FIOCRUZ) - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Functional assessment is a key component of clinical evaluation in patients with Chagas cardiomyopathy, helping estimate physical capacity and guide care strategies. The Duke Activity Status Index (DASI) is a simple, validated questionnaire that assesses self-reported functional capacity through daily activities and reports results in metabolic equivalents. Although widely used in other cardiovascular conditions, its performance in patients with Chagas cardiomyopathy has not been well characterized. Objectives: To describe DASI scores in patients with Chagas cardiomyopathy and examine their association with subjective and objective measures of physical performance. Methods: This study analyzed data from a cohort of 92 patients with Chagas cardiomyopathy (67.5 ± 8.8 years). Participants completed the DASI and the Human Activity Profile (HAP) and underwent handgrip dynamometry, the Short Physical Performance Battery (SPPB), the five-repetition sit-to-stand test, and usual gait speed assessment over 4 meters. Correlations between DASI scores and functional measures were analyzed. Results and Conclusions: The mean DASI score was 26.1 points (SD 12), ranging from 7.25 to 58.2, with a median of 23.45, indicating marked variability in self-reported functional capacity. DASI showed a strong positive correlation with HAP score (r=0.71; p<0.001), supporting convergence between self-reported functional measures. DASI was also positively correlated with SPPB score (r=0.24; p=0.021) and maximal handgrip strength (r=0.20; p=0.049). In addition, inverse correlations were observed with five-repetition sit-to-stand time (r=-0.23; p=0.025) and 4-meter gait time (r=-0.30; p=0.004), indicating that better objective physical performance was associated with higher self-reported functional capacity. These findings support the DASI as a practical and valid tool for functional assessment in patients with Chagas cardiomyopathy. Its significant associations with objective performance measures suggest that it may provide clinically meaningful information in both research and routine care, particularly in settings where rapid, low-cost functional evaluation is needed.

EFFECTS OF A COMBINED PATIENT EDUCATION EXERCISE PROGRAM ON RESTING HEART RATE VARIABILITY OF INDIVIDUALS WITH PREDIABETES OR DIABETES

GABRIELA DE SOUZA MATOS1; LEONARDO HADADE GALDINO1; ANA PAULA DELGADO BOMTEMPO1; ADRIANO LUIZ PEREIRA1; BRUNO DA COSTA MARIANO1; DEYSIANE PERES DA SILVA CLEMENTE DE OLIVEIRA1; LARISSA BARBOSA DE CARVALHO1; MARIANA NUNES CASSIMIRO1; RENATA CRUZEIRO RIBAS2; SILVIA LANZIOTTI AZEVEDO DA SILVA1; PATRICIA FERNANDES TREVIZAN2; LILIAN PINTO DA SILVA1;

(1) UFJF - JUIZ DE FORA - MG - BRASIL; (2) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Individuals with prediabetes or diabetes present reduced heart rate variability (HRV), reflecting worse cardiac autonomic modulation and increased cardiovascular risk. Although physical exercise and patient education are recommended, their combined effects remain underexplored. Objectives: To investigate the effects of patient education combined with a structured exercise program on cardiac autonomic modulation of individuals with prediabetes or diabetes. Methods: This study stems from a secondary outcome of a multicenter randomized clinical trial that involved two parallel groups: an exercise-only program (Ex) and a patient education program associated with exercise (EdEx). The Ex group included aerobic and muscle-strengthening exercises, while the EdEx group combined the exercise program with a patient education program adapted for the Brazilian population. Cardiac autonomic modulation was assessed through linear and nonlinear HRV measures. For heart beat recording, a heart rate monitor (Polar®, model V800) was used. During data collection, participants remained in the supine position and were instructed to maintain a relaxed posture, not to talk, avoid movements, not to sleep, keep their eyes open, and breathe spontaneously. Assessments were carried out in the morning or afternoon periods, without control of environmental conditions, such as temperature, humidity, or external noise. The effects of the interventions were analyzed using a linear mixed model (LMM), considering the group effect (EdEx vs. Ex), time effect (pre vs. post-intervention), and the group × time interaction. The level of significance adopted was P < 0.05. Results and Conclusions: A total of 252 participants were included (Table 1), and all LMM results are presented in Table 2. Overall HRV measures, such as the standard deviation of normal RR intervals (SDNN) and the dispersion of points along the line of identity of the Poincaré plot (SD2), increased significantly at post-intervention (Table 2). However, this improvement in cardiac autonomic control was not influenced by the addition of patient education to the exercise program, as indicated by the absence of a significant group × time interaction (P = 0.150 and P = 0.090).

Table 1. Comparison of sociodemographic and clinical characteristics of the participants.

Variables	EdEx (n = 120)	Ex (n = 132)	*P* value
Demographic Characteristics			
Age (years)	55.5 [43.3-60.8]	52.0 [42.0 -62.8]	0.828

FRAILTY AND FUNCTIONAL STATUS AS PREDICTORS OF CLINICAL OUTCOMES AFTER CARDIOVASCULAR SURGERY: A PRELIMINARY ANALYSIS

JESSICA SECRIERU1; ALINE AREBALO VEPPO1; FERNANDA CECÍLIA DOS SANTOS DE VASCONCELLOS2; MARIA ANGÉLICA JACQUES2; GRACIELE SBRUZZI1;

(1) UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL; (2) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: The physiological stress of open heart surgery (OHS) can lead to a decline in functional status, particularly in frail patients. Assessing these aspects in the postoperative period may help identify a higher risk of readmission and death within 90 days, optimizing clinical management and care transition strategies. Objectives: To investigate the association of functional status and frailty at hospital discharge with clinical outcomes such as falls, hospital readmission, and mortality 90 days after OHS. Methods: This is a prospective cohort study of patients undergoing coronary artery bypass grafting (CABG) and valve replacement surgery (VRS). Functionality was assessed using the Katz Index and frailty was measured via the Clinical Frailty Scale at the time of discharge. A 90-day follow-up was conducted through teleconsultations and medical record reviews to track falls, all-cause readmissions and deaths. Descriptive analysis was performed, and associations between categorical variables were evaluated using Fisher's Exact Test with a 5% significance level. The study was approved (CAAE 79476524.7.0000.5327) by the local Ethics Committee. Results and Conclusions: At the time, 54 participants were included (age 64±10years, 67% male), comprising VRS (52%), CABG (37%) or combined procedures (11%). At discharge, the functionality score was 2±0.8, indicating dependence in two basic activities of daily living. During the 90-day follow-up, 14 readmissions and 2 deaths were recorded. The readmission rate was 30% among functionally dependent patients compared to 14% in independent patients (RR=0.48; 95% CI 0.07-3.41; p=0.657). Furthermore, 4 falls and 2 deaths occurred, all within the functional dependence group. Regarding frailty, 16(29.6%) patients were classified as non-frail, 24(44.4%) as pre-frail, and 14(25.9%) as frail. Two falls were reported in the pre-frail and two in the frail group, with one death occurring in each category. The association of falls and mortality was limited by the low event frequency and the findings were interpreted descriptively. Patients with functional dependence had a higher number of readmissions within 90 days, besides unfavorable outcomes such as falls and death. This suggests the need for targeted rehabilitation and care transition strategies after OHS. The increase of the sample size and the follow-up will allow us to understand the impact of functionality and frailty after hospital discharge.

FUNCTIONAL FRAILTY IN PATIENTS WITH HEART FAILURE WITH PRESERVED EJECTION FRACTION

FELIPE CARDOZO MODESTO1; SERGIO LUIZ SOARES MARCOS DA CUNHA CHERMONT1; CHRISTIANE RODRIGUES ALVES1; LUANA DE DECCO MARCHESE1; MONICA MARIA PENA QUINTAO1; ANTONIO JOSE LAGOEIRO JORGE1;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL;

Background/Introduction: INTRODUCTION: Heart failure (HF) has been a public health problem due to its increasing incidence and high mortality rate. Special attention has been given to HF with preserved ejection fraction (HFpEF), as it has shown a high incidence due to its strong relationship with population aging. Its pathophysiology is complex, multifactorial, and followed by functional decline. Objectives: OBJECTIVE: To evaluate the functional frailty of individuals diagnosed with HFpEF. Methods: METHODS: Cross-sectional study with patients over 40 years of age, referred to a specialized Heart Failure Clinic in Niterói-RJ. Participants underwent laboratory tests, electrocardiogram, and echocardiogram. They were subjected to a battery of functional tests that assess respiratory and peripheral muscle strength and cardiorespiratory fitness. Results and Conclusions: RESULTS: Preliminary results from 12 individuals, predominantly female (75%), with an average age of 67.5 ± 11.1, show a functional decline expressed by a reduction in inspiratory muscle strength (PImax 87.1% ± 37.1 of expected), expiratory flow deficit (Peak flow 56.7% ± 17.6 of expected), and loss of peripheral strength (FPM 76.9% ± 29.4 of expected). CONCLUSION: Results show functional changes with a reduction in respiratory and peripheral muscle strength, highlighting the functional frailty of these participants with HFpEF. Heart failure with preserved ejection fraction; Frailty; Functional status;

GAIT SPEED AS A FUNCTIONAL ASSESSMENT TOOL IN PATIENTS WITH CHAGAS CARDIOMYOPATHY LIVING IN AN ENDEMIC REGION.

MARINA SILVA REIS1; ANTONIELLY ROCHA DE SOUZA PEREIRA1; GABRIEL MELO FONSECA1; STEFÂNIA GUIMARÃES NERY1; GUSTAVO REIS MACIEL1; LUCAS FROIS FERNANDES DE OLIVEIRA2; WHESLEY TANOR SILVA3; CHEYENNE ALVES FONSECA1; MARCUS VINICIUS ACCETTA VIANNA1; MARTA VALQUÍRIA DA SILVA1; SANNY CRISTINA DE CASTRO FARIA2; HENRIQUE SILVEIRA COSTA1;

(1) UNIVERSIDADE FEDERAL DOS VALES DO JEQUITINHONHA E MUCURI - DIAMANTINA - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) FUNDAÇÃO OSWALDO CRUZ - FIOCRUZ RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Chagas disease remains an important cause of cardiomyopathy and heart failure in endemic areas and is increasingly observed among older adults. Functional assessment is essential to guide rehabilitation and clinical management, since physical limitations may emerge early in the course of cardiac involvement. Gait speed is a simple, inexpensive, and feasible measure of mobility and physical performance, particularly useful in aging populations and in settings where less demanding tests are needed. However, its relationship with other functional measures and body composition variables in patients with Chagas cardiomyopathy and cardiac dysfunction has not been sufficiently explored. Objectives: To evaluate the applicability of gait speed in patients with Chagas cardiomyopathy by examining its association with functional and body composition variables. Methods: This cross-sectional study included 57 patients (65.3 ± 7.7 years) with Chagas cardiomyopathy and systolic or diastolic dysfunction, all living in an endemic region. Usual gait speed was assessed by recording the time required to walk 4 meters at a habitual pace. This variable was correlated with the Human Activity Profile (HAP), the five-repetition sit-to-stand test, the 1-minute sit-to-stand test, handgrip strength, and appendicular lean mass index measured by dual-energy X-ray absorptiometry. Correlations were analyzed using Pearson's or Spearman's coefficients, as appropriate. Results and Conclusions: Gait speed showed significant correlations with all evaluated variables, including maximum HAP score (r=-0.371; p=0.008), adjusted HAP score (r=-0.327; p=0.020), five-repetition sit-to-stand time (r=0.363; p=0.014), 1-minute sit-to-stand performance (r=-0.434; p=0.002), handgrip strength (r=0.323; p=0.021), and appendicular lean mass index (r=-0.308; p=0.048). Overall, slower gait performance was associated with poorer self-reported functional status, worse lower-limb performance, reduced muscle strength, and less favorable muscle composition. These findings support gait speed as a relevant marker of functional status in patients with Chagas cardiomyopathy and cardiac dysfunction. Given its simplicity, low cost, and feasibility in older adults, gait speed may be particularly useful for routine assessment in endemic and resource-limited settings, helping detect functional decline and support rehabilitation planning and individualized care.

GLITTRE-ADL TEST FOR FUNCTIONAL ASSESSMENT IN BREAST CANCER SURVIVORS IN CARDIO-ONCOLOGY: PRELIMINARY PILOT DATA

BHIANCA LOPES TEIXEIRA1; ANA CLARA DE OLIVEIRA CAMINI1; ENRICO DE FRANCISCO MAGNANI1; GABRIELLA MOREIRA NEVES RIBEIRO1; LEILA CUNHA DE JESUS1; LÍVIA MARIA ANDRADE RABELO1; MARIANA MAIA DE OLIVEIRA SUNEMI1; LUCIANO FONSECA LEMOS OLIVEIRA1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Background/Introduction: Breast cancer survivors frequently experience functional limitations and reduced capacity for activities of daily living (ADL) due to oncological treatment side effects, negatively affecting quality of life and autonomy. To prevent function decrease, early and accurate physical assessment should be performed, particularly in resource-limited clinical settings. The Glittre-ADL test is a promising tool which simulates multi-dimensional tasks, however its validity has not been established in the breast cancer population. Objectives: This pilot study aim to investigate the association between Glittre-ADL performance and 6MWT distance in breast cancer survivors, exploring the test's potential as a functional assessment tool. Methods: Approved by the ethics committee, this study recruited participants from a physical therapy outpatient service. Inclusion criteria were a diagnosis of breast cancer and completion of chemotherapy at least 3 months before assessment. Assessment included clinical and oncological data, Mini-Mental State Examination (Mini-Mental), cardiovascular risk stratification (SAS and Framingham Score); physical activity levels (IPAQ); and quality of life (EORTC QLQ-C30 and BR23). Exclusion criteria included physical or cognitive impairments hindering test execution. Participants performed the tests in randomized order. Physiological parameters and Modified Borg scores were recorded. Statistical analysis included Shapiro-wilk, and Pearson or Spearman correlation tests ($p<0,05$). Results and Conclusions: The sample (n=7) had mean age of 60.57±10,65 years, BMI of 27,30±3,39 kg/m², and median time since diagnosis of 4,21 years (1,46-43,83). Cardiovascular risk factors and comorbidities were diabetes (71.4%) and hypertension (28.6%), chemotherapy (42.9%), radiotherapy in the left breast (28.6%). Median Glittre-ADL completion time was 176,28 (142,17-233,05) seconds; mean 6MWT distance was 454,25 ± 112,23 meters. A strong inverse correlation was found between Glittre-ADL and 6MWT ($r= −0,786$; $p= 0,036$). Furthermore, Glittre-ADL performance had strongly negatively correlated with Mini Mental scores ($r= -0,954$; $p =0,001$). Preliminary data suggest that Glittre-ADL performance is inversely associated with 6MWT distance, supporting its potential as a feasible, low-cost complementary tool for functional assessment in breast cancer survivors. Larger studies are needed to confirm its validity and to clarify the influence of cognitive function on test performance.

IMPACT OF TRANSITIONAL CARE PROGRAMS AFTER DISCHARGE ON CLINICAL OUTCOMES IN PATIENTS WITH HEART FAILURE: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CLINICAL TRIALS

ALINE AREBALO VEPPO1; VANESSA MENDES KOEHLER1; JESSICA SECRIERU1; GRACIELE SBRUZZI1;

(1) UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: Transitional care programs for patients with Heart Failure (HF) have been proposed to improve clinical outcomes. Although evidence points to a reduction in readmissions and mortality, the effects on functional outcomes and quality of life are not yet fully established. Objectives: To evaluate the effectiveness of post-hospital discharge transitional care programs in patients with HF regarding mortality, hospital readmissions, quality of life, and physical function. Methods: Systematic review and meta-analysis (PROSPERO - CRD420251241032). Randomized clinical trials were included involving adult patients with HF undergoing post-discharge transitional care interventions that assessed all-cause and cardiovascular mortality, hospital readmissions (up to 30 days and after 30 days), quality of life, and physical function (functional capacity and functional status). The search was conducted in the MEDLINE, EMBASE, CENTRAL, and LILACS databases, including grey literature, up to February 2026. The meta-analysis utilized a random-effects model, and the effect size was synthesized using relative risk (RR) and standardized mean difference (SMD). Results and Conclusions: A total of 47 studies (n=15,484 participants) were included, which primarily focused on transitional care programs based on home-visiting, primarily educational, telemonitoring, outpatient clinic–based and structured telephone support. It was observed that interventions reduced all-cause mortality (RR 0.84; 95% CI 0.74–0.95) and hospital readmissions after 30 days discharge (RR 0.83; 95% CI 0.76–0.91), with home-visiting programs being the most effective strategy (RR 0.84; 95% CI 0.74–0.95). Furthermore, an improvement in patients' quality of life was observed (SMD -0.25; 95% CI -0.43 to -0.08). No effect was observed on readmissions within 30 days (RR 0.96; 95% CI 0.80–1.15). Physical function was assessed in three studies, indicating greater variation in functional capacity outcomes, with limited and heterogeneous evidence. Transitional care programs are associated with a reduction in mortality and readmissions, as well as improved quality of life in patients with HF; however, their impact on post-discharge physical function still requires further investigation.

MUSCLE OXYGENATION DURING WALKING IN PERIPHERAL ARTERIAL DISEASE AND TYPE 2 DIABETES

TIAGO DA SILVA NOGUEIRA1; RODRIGO VILLAR2; CAROLINA FELIX1; ISABELLA NASCIMENTO1; GISELA PRYBYSZ1; PATRICIA PAULINO GEISEL1; DANIELLE APARECIDA GOMES PEREIRA1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) UNIVERSITY OF MANITOBA - CANADA;

Background/Introduction: Peripheral arterial disease (PAD) is characterized by impaired blood flow, leading to changes in skeletal muscle oxygenation and reduced functional capacity. Type 2 diabetes mellitus (DM) is a major risk factor for PAD and may compromise microvascular responses during exercise. However, the combined impact of PAD and DM on muscle oxygenation and functional capacity remains unclear. Objectives: To compare muscle oxygenation and functional capacity among individuals with PAD and DM (PADDM), PAD without DM (PADNDM), DM only (DM), and healthy controls (HEALTH). Methods: This cross-sectional study included 96 participants equally allocated into four groups (PADDM, PADNDM, DM, and HEALTH) and matched for age and sex. Functional capacity was assessed using the Incremental Shuttle Walking Test (ISWT), and muscle oxygenation was measured using Near-infrared Spectroscopy (NIRS) during the test. Data normality was assessed using the Shapiro-Wilk test. Group comparisons were performed using one-way ANOVA with Bonferroni post-hoc tests. For statistical significance, an alpha value of 5% was considered ($p<0.05$). Results and Conclusions: All groups had similar mean initial saturation values during the ISWT ($p=0.979$). A reduction in saturation was observed across all groups during the test ($p<0.001$). PADDM and PADNDM groups demonstrated a faster deoxygenation, lower mean saturation and a greater desaturation at the end of the test compared to DM and HEALTH groups ($p<0.001$). Reoxygenation time was significantly longer in PADDM group compared to DM and HEALTH groups ($p<0.001$) and in PADNDM compared to HEALTH ($p=0.034$). In addition, PADDM and PADNDM groups walked shorter distances than DM and HEALTH groups ($p<0.001$). These findings suggests that PAD is associated with impaired muscle oxygenation and reduced functional capacity, regardless of DM status, highlighting its impact on oxygen delivery and recovery, which may contribute to reduced functional capacity.

Table 1. Sample characterization

	PADDM (n=24)	PADNDM (n=24)	DM (n=24)	HEALTH (n=24)	p
Age, years	65 ± 7.64	64.46 ± 8.26	63.50 ± 8.40	63.67±8.69	0.915
Sex, f n (%)	12 (50%) / 12 (50%)	12 (50%) / 12 (50%)	12 (50%) / 12 (50%)	12 (50%)	1.000
BMI, Kg/m²	31.11 ± 8.94	29.01±13.99	29.34 ±4.31	26.75±3.69	0.390
ABI	0.67 ± 0.13*↓	0.65 ± 0.16*↓	1.12 ± 0.09	-	<0.001+

Legend: PADDM: participants with PAD + DM; PADNDM: participants with PAD without DM; DM: participants with DM; HEALTH: healthy participants; BMI: body mass index; ABI: ankle-brachial index; *statistically significant differences compared with the DM group;

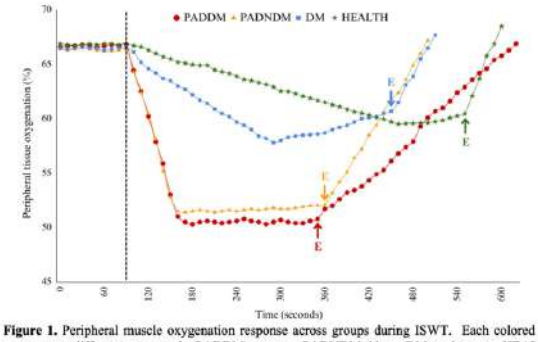

Figure 1. Peripheral muscle oxygenation response across groups during ISWT. Each colored line represents a different group: red - PADDM, orange - PADNDM, blue - DM, and green - HEALTH. The vertical dashed line indicates the start of the test, and colored arrows indicate the end of the test for each group.

PREDICTIVE VALUE OF VENTILATORY VARIABLES ASSESSED AT THE ANAEROBIC THRESHOLD DURING CARDIOPULMONARY EXERCISE TESTING IN PATIENTS WITH CHAGAS CARDIOMYOPATHY

GABRIEL MELO FONSECA1; MARINA SILVA REIS1; ANTONIELLY ROCHA DE SOUZA PEREIRA1; STEFANIA GUIMARÃES NERY1; MARTA VALQUÍRIA DA SILVA1; LUCAS FRÓIS FERNANDES DE OLIVEIRA2; GUSTAVO REIS MACIEL1; WHESLEY TANOR SILVA3; MARCUS VIANNA1; CHEYENNE ALVES FONSECA1; SANNY CRISTINA DE CASTRO FARIA2; HENRIQUE SILVEIRA COSTA1;

(1) UNIVERSIDADE FEDERAL DOS VALES DO JEQUITINHONHA E MUCURI - DIAMANTINA - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) FUNDAÇÃO OSWALDO CRUZ - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Chagas cardiomyopathy has a variable prognosis, and functional assessment using cardiopulmonary exercise testing (CPET) has proven useful for risk stratification. Peak exercise variables such as peak oxygen uptake (VO2peak), VE/VCO2 slope, and end-tidal carbon dioxide pressure (PETCO2) are recognized prognostic markers. However, many patients with Chagas cardiomyopathy do not achieve maximal effort due to functional limitations, making variables obtained at the anaerobic threshold potentially more feasible and clinically relevant. Despite this, data on the prognostic value of submaximal ventilatory variables in this population remain limited. Objectives: To investigate whether ventilatory variables assessed at the anaerobic threshold, including oxygen uptake (VO2 at AT), VE/VCO2 slope at AT, and PETCO2 at AT, predict adverse events in patients with Chagas cardiomyopathy. Methods: This prospective longitudinal study included 44 patients with Chagas cardiomyopathy (50 ± 12 years; NYHA class I–III; left ventricular ejection fraction 40 ± 10%) who underwent CPET. VO2, VE/VCO2 slope, and PETCO2 were analyzed at the anaerobic threshold. Patients were followed for 18 ± 8 months for the occurrence of adverse events, defined as cardiovascular death, heart failure hospitalization, or need for transplantation. Predictive performance was assessed using receiver operating characteristic (ROC) curves, and the association with events was analyzed using Cox regression adjusted for age, NYHA class, and left ventricular ejection fraction. Results and Conclusions: During follow-up, 11 patients (25%) experienced adverse events. The areas under the ROC curve for VO2 at AT, VE/VCO2 slope at AT, and PETCO2 at AT were 0.85, 0.79, and 0.79, respectively. The optimal cutoff values were VO2 at AT <17 mL/kg/min, with 90% sensitivity and 65% specificity; VE/VCO2 slope at AT >30, with 80% sensitivity and 70% specificity; and PETCO2 at AT <34 mmHg, with 90% sensitivity and 70% specificity. In adjusted Cox analysis, only VO2 at AT remained in the final model as an independent predictor of adverse outcomes (HR 0.831; 95% CI 0.72–0.96; $p=0.015$). These findings suggest that ventilatory variables obtained at the anaerobic threshold, particularly VO2 at AT, have relevant prognostic value in patients with Chagas cardiomyopathy. CPET may therefore contribute to risk stratification not only through maximal exercise responses but also through submaximal analysis, which may be especially useful in patients with limited exercise tolerance.

18650

PROBABLE RESPIRATORY SARCOPENIA AND MORTALITY IN PATIENTS WITH HEART FAILURE: A MULTICENTER COHORT ANALYSIS

ISABELLE GEANIZELLE SANTANA DA CRUZ1; CARINA ANA NUNES1; VALERIA GONÇALVES DA SILVA1; MAURO FELIPPE FELIX MEDIANO1; HELENA CRAMER VEIGA REY1; PABLO MARINO CORREA DO NASCIMENTO1; LUIZ FERNANDO RODRIGUES JUNIOR1;

(1) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Heart failure with reduced ejection fraction (HFrEF) is associated with reduced cardiac output, hypoperfusion, and chronic catabolism, leading to muscle wasting. Peripheral sarcopenia is an established predictor of mortality; however, the role of respiratory sarcopenia—affecting ventilatory muscles and respiratory function— is not yet fully understood in patients with HFrEF. Objectives: To evaluate the association between probable respiratory sarcopenia with mortality in patients with HFrEF. Methods: Retrospective multicenter cohort including 125 outpatients (≥18 years) with HFrEF followed at heart failure outpatient clinics, with available data on maximal inspiratory pressure (MIP) and appendicular skeletal muscle mass (ASM). Respiratory muscle weakness was defined as MIP ≥ -80 cmH□O. Low muscle mass was defined by ASM/height² according to EWGSOP2 criteria (<7.0 kg/m² for men and <5.5 kg/m² for women). Probable respiratory sarcopenia was defined as the coexistence of both conditions. The outcome was all-cause mortality within 24 months. Logistic regression was used to estimate odds ratios (OR) with 95% confidence intervals (CI), including adjustment for age and sex. Survival analysis was performed using Kaplan–Meier curves and the log-rank test. Statistical significance was set at $p < 0.05$. The study followed Resolution CNS 466/2012 and was approved by the institutional ethics committee (CEP n° 5.468.501). Results and Conclusions: Mean age was 53.9 ± 11.2 years, and 69.6% were female. The prevalence of respiratory muscle weakness was 52%, and low muscle mass was 24.8%. Probable respiratory sarcopenia was identified in 17.6% of patients, being more frequent in men (55.3% vs. 1.1%). During follow-up, 13 deaths occurred (10.4%). No significant association was found between respiratory sarcopenia and mortality in crude (OR 0.36; 95% CI 0.04–2.93; p=0.341) or adjusted analysis (OR 0.73; 95% CI 0.05–10.98; p=0.821), respectively. Survival analysis showed no difference between groups (log-rank p=0.38). Probable respiratory sarcopenia was not associated with mortality at 24 months in patients with HFrEF.

18713

RECOVERY HEART RATE AS A MARKER OF OFF HEART RATE KINETICS AFTER 6MWT IN HOSPITALIZED CARDIAC PATIENTS.

ERICK CARLOS CONCEICAO SANTOS1; ISADORA SALVADOR ROCCO ROCCO1; LARISSE XAVIER ALMEIDA1; NÍCOLAS MENDES FREIHAT HENRIQUE1; CAROLINE BUBLITZ BARBOSA1; RITA SIMONE LOPES MOREIRA1; WALTER JOSÉ GOMES1; SOLANGE GUIZILINI1; CRISTIANE APARECIDA BETTA1; VERIDIANA SILVA ANDRADE1;

(1) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Background/Introduction: Heart rate (HR) recovery after exercise reflects autonomic regulation, with clinical and prognostic value. Heart rate monitoring during recovery models a physiological parameter of autonomic dynamics (t½ of OFF kinetics). Although recovery HR (HRC), measured by pulse oximetry (PO), is an accessible measure, its association with OFF kinetics is not yet established in hospitalized cardiac patients. Objectives: We evaluated the correlation between HRC measured by PO and the half-recovery time (t½) derived from the OFF kinetics of HR measured by heart rate monitor during the 6MWT, and analyzed possible clinical and physiological predictors obtained during the t½ test of OFF kinetics. Methods: Observational study with hospitalized adult cardiac patients of both sexes undergoing the 6MWT. The HR was monitored using a Polar® H10 heart rate monitor, and HRR was measured using a G-Tech oximeter, defined as the difference between the HR at the end of the 6MWT and at minutes 1, 3, and 5 of recovery. Off-energy kinetics was given by the HR recovery half-life (t½). Peripheral oxygen saturation (SpO□) and the subjective perception of effort using the Borg scale were obtained during the 6MWT and recovery. Associations between parameters were assessed using correlation analyses and a generalized linear model (GzLM). Results and Conclusions: We analyzed 72 patients with a mean age of 74±57.8, who covered 443±114m in the 6MWT, with a half-life (½) of 68s (51.5) and HRR1-min of 15.5±12.3 bpm, 3 min of 21.4±14.5 bpm, and 5 min of 24.5±14.5 bpm. A negative correlation was observed between ½ and HRR1-min ($\rho=-0.309$; p=0.009), but there was no significant association with HRR at 3 and 5 min. There was a significant association ($X2=5.91$; p=0.015) between the presence of slow off-kilometer kinetics (½>105s) and reduced HRR1-minn (≤12 bpm). The independent predictors for t½ were HRR1-min (β=−1.772;IC95%:−2.765 a −0.714;p=0.002)) and the HR achieved at the end of the 6MWT (β=+0.690;IC95%:0.123 a 1.275;p=0.025) and the presence of diabetes (p=0.026) in the GzLM with gamma distribution ($R2=0.19$, $Chi^2/DF=0.286$, residuals p=0.935). The HRR1-min measured by pulse oximetry partially reflected the t½ of the OFF kinetics, serving as a simple marker of chronotropic recovery after the 6MWT. Early recovery of HRR1 and the final HR of the 6MWT are independent predictors of recovery kinetics, reinforcing the potential of HRR1 as a practical tool for estimating autonomic recovery in a hospital setting.

RESPIRATORY DIAGNOSTIC ASSISTANT: AN INNOVATIVE DEVICE FOR CHARACTERIZATION OF THE BREATHING PATTERN IN CHRONIC HEART DISEASE - A PILOT STUDY

TALYSSA BIA SANTOS E SANTOS1; MARIA GEYNA SIQUEIRA GAUDINO1; MAYARA COSTA BARROS1; GERALDO LEITE MAIA1; MARCIO EVARISTO DA CRUZ BRITO1; HERBERT LEITÃO1; MARIA DAS GRAÇAS DE ARRUDA COELHO2; MARIA INÊS REMÍGIO DE AGUIAR1; ARMELE DE FÁTIMA DORNELAS DE ANDRADE1; CYDA MARIA ALBUQUERQUE REINAUX1; SHIRLEY LIMA CAMPOS1; DANIELLA CUNHA BRANDÃO1;

(1) UNIVERSIDADE FEDERAL DE PERNAMBUCO - RECIFE - PE - BRASIL; (2) HOSPITAL DAS CLINICAS - RECIFE - PE - BRASIL;

Background/Introduction: Patients with chronic heart disease may present important alterations in the breathing pattern (BP). However, the assessment of this dysfunction remains predominantly subjective and poorly investigated. Objectives: To evaluate the BP of individuals with chronic heart disease using an innovative prototype named Respiratory Diagnostic Assistant (RDA). Methods: Cross-sectional study (REC n. 6.387.631) conducted with patients with chronic heart disease, of both sexes, aged 18 to 60 years. Data on inspiratory capacity (IC), slow vital capacity (SVC), respiratory rate (RR), tidal volume (TV), minute ventilation (MV), and inspiration–expiration ratio (I:E) were collected using the RDA, in the seated position, at rest. Additionally, qualitative analysis of respiratory curves was performed using the RDA analysis software. Variables were described as mean±standard deviation and frequency, and respiratory measurements were compared with reference values. Results and Conclusions: The sample included 10 individuals, with 8 diagnosed with heart failure (HF), 1 with coronary artery disease (CAD), and 1 in the post–heart transplant period. Six patients were male and four were female, with a mean age of 48.1±14.2 years and mean BMI of 28.5±4.9. Eighty percent of participants presented RR within normal limits; 60% of individuals showed alterations in TV; 100% presented altered MV, exceeding the 5–6 L/min range. The I:E ratio was preserved in 20% of individuals. IC analysis indicated that 50% of participants were within the range considered normal. One hundred percent of individuals presented SVC below reference values. Qualitative analysis demonstrated ventilatory instability at rest, characterized by irregularity of respiratory cycles, variability in volume amplitude, and presence of transient respiratory events. The RDA prototype demonstrated potential to identify relevant alterations in the ventilatory pattern in cardiac patients. This study was funded by: CNPQ (312587/2022-8, 408281/2023-5, 420408/2025-8, and 449721/2025-6); FACEPE (APQ-0679-4.08/25)

IS IT THE PANDEMIC? COMPARISON OF DEPRESSIVE SYMPTOMS IN MEDICINE STUDENTS DURING AND AFTER COVID-19 AND IMPLICATIONS FOR CARDIOVASCULAR HEALTH

ROBERTA PAOLA SANTOS ZONTA1; DARIO MARTIM DANTAS NETO1; IVAN LUCAS PICONE BORGES DOS ANJOS2; LAIS SOUZA RODRIGUES1; ANA CAROLINA PORTO DA HORA3; MARIA APARECIDA DE ALMEIDA SOUZA RODRIGUES1; VERA LUCIA SANTOS ZONTA1; BRUNA PAOLA SANTOS ZONTA1; SIMONE MENEZES MONTENEGRO4; ALEXANDRE AUGUSTUS BRITO DE ARAGAO3; IVANA PICONE BORGES DE ARAGAO1;

(1) UNIVERSIDADE DE VASSOURAS (UNIVASSOURAS) - VASSOURAS - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (3) FACULDADE DE CIENCIAS MEDICAS DE MARICA - MARICÁ - RJ - BRASIL; (4) FACULDADES REUNIDAS DA ASSOCIAÇÃO DE SOLIDARIEDADE À CRIANÇA EXCEPCIONAL (FRASCE) - RIO DE JANEIRO - RJ - BRASIL;

Background/Introduction: Depression is showing significant global growth, affecting approximately 3.8% of the world's population. Along with the COVID-19 pandemic, mental health gained awareness due to it's impact on people. Meanwhile, depression is recognized as a risk factor for cardiovascular diseases, worsening their course and influencing the development of risk factors. Objectives: To compare the prevalence of depressive symptoms in medicine students during and after the COVID-19 pandemic. Methods: An observational, cross-sectional, quantitative study on the self-reporting of symptoms of depression, according to the Diagnostic and Statistical Manual of Mental Disorders (DSM-5), between the per-pandemic (2020) and post-pandemic (2025) periods among medical students. Application of an anonymous questionnaire, after signing an informed consent form. Approved by the Research Ethics Committee. Results and Conclusions: A total of 434 students were interviewed, being 229 in 2020 and 205 in 2025. Significant positive associations were found between the pandemic period and increased prevalence of the following symptoms: decreased interest/pleasure (p=0,039); unintentional weight gain/loss (p<0,001); excessive/inappropriate guilt and feelings of inutility (p<0,001); decreased capacity to think/concentrate (p=0,031); and symptoms's impact on daily life (p<0,001). However, there was no significant correlation when it came to the following symptoms: depressed mood (p=0,143); quality of sleep (p=0,677); psychomotor agitation/retardation (p=0,151); fatigue or lack of energy (p=0,388); and suicidal ideation (p=0,472). The prevalence of self-reported depressive symptoms was significantly higher within the context of the pandemic for a minority of symptoms. Even in those, the difference was no higher than 20% in weight gain/loss and feelings of uselessness/guilt or 10% in lack of interest/pleasure and decreased capacity to think/concentrate. In fact, the percentage of students that reported suicidal ideation post pandemic is higher than per-pandemic. It seems that, while the pandemic probably worsened the prevalence of depressive symptoms in medicine students, it doesn't appear to have been as impactful on that population, considering the prevalence is still high even 3 years past the critical period. Given the profound impact depression can have in the cardiovascular system, it is reasonable to consider medicine students as a possibly vulnerable group for cardiovascular complications.

MIND–BODY INTERVENTIONS IN STRESS MODULATION AND THEIR IMPACT ON CARDIOVASCULAR OUTCOMES: A SYSTEMATIC REVIEW

MATEUS HENRIQUE DE ALMEIDA BUCK1; LETÍCIA GONÇALEZ HERMIDA QUARESMA VAZ1; AMANDA OLIVA SPAZIANI1;

(1) UNIVERSIDADE BRASIL - FERNANDÓPOLIS - SP - BRASIL;

Background/Introduction: Chronic stress and dysregulation of the hypothalamic–pituitary–adrenal axis play a central role in the pathophysiology of cardiovascular diseases, influencing hemodynamic, inflammatory, and behavioral parameters. Mind–body and spirituality-based interventions have been investigated as complementary strategies to modulate these mechanisms. Objectives: To evaluate the impact of mind–body and spirituality-based interventions on stress modulation, considering psychophysiological, neuroendocrine, and behavioral parameters, including cortisol, perceived stress, anxiety, and depressive symptoms, and to analyze their influence on cardiovascular outcomes, functional capacity, quality of life, and associated risk factors, as well as to explore mechanisms linking chronic stress to cardiovascular diseases. Methods: A systematic review was conducted following PRISMA guidelines. Searches were performed in PubMed, SciELO, and Scopus using terms related to “yoga,” “stress,” “spirituality,” and “cardiovascular.” Randomized clinical trials and quasi-experimental studies assessing psychophysiological and cardiovascular outcomes were included. A total of 45 studies were identified, of which 11 met eligibility criteria. For this specific analysis, 6 studies focusing on stress-related outcomes were selected. Study selection was performed by independent reviewers. Results and Conclusions: The included studies (n=6) demonstrated significant reductions in perceived stress (p<0.001), cortisol levels (p<0.001), anxiety (p=0.01), and depressive symptoms (p=0.005), along with improvements in quality of life across different populations. Yoga-based and breathing interventions showed beneficial effects on fatigue and dyspnea in patients with heart failure. Spirituality-based strategies, particularly community interventions, exhibited indirect effects on cardiovascular risk modulation through behavioral changes and improved coping mechanisms. Despite the lack of consistent effects on structural cardiac outcomes, findings suggest that stress modulation is a central pathway in reducing cardiovascular risk. These results support mind–body and spirituality-based interventions as effective complementary approaches in the psychophysiological management of cardiovascular diseases.

SPIRITUALITY AND CLINICAL AND BEHAVIORAL OUTCOMES IN CARDIOVASCULAR DISEASES: A SYSTEMATIC REVIEW

MATEUS HENRIQUE DE ALMEIDA BUCK1; LETICIA GONÇALEZ HERMIDA QUARESMA VAZ1; AMANDA OLIVA SPAZIANI1;

(1) UNIVERSIDADE BRASIL - FERNANDOPOLIS - SP - BRASIL;

Background/Introduction: Cardiovascular diseases remain the leading cause of global mortality and are associated with clinical, behavioral, and psychosocial factors. In this context, spirituality and religiosity have been increasingly investigated as potential modulators of these outcomes, particularly through their influence on stress regulation, therapeutic adherence, and cardiovascular physiological responses. Objectives: To comprehensively evaluate the influence of spirituality and religiosity on clinical, physiological, and behavioral outcomes in patients with cardiovascular diseases, including clinical events, hemodynamic parameters, and cardiometabolic biomarkers. Methods: A systematic review was conducted in accordance with PRISMA guidelines, using a PICO-based strategy. Searches were performed in PubMed, SciELO, and Scopus databases. A total of 19 studies were identified, of which 12 were selected after applying eligibility criteria. Screening was performed in a double-blind manner by independent reviewers through title, abstract, and full-text analysis. Randomized clinical trials and observational studies published within the last 10 years, preferably in English, were included. Eligible studies evaluated spirituality-related interventions, including yoga-based practices and faith-based programs. Results and Conclusions: Among the 12 included studies, approximately 75% demonstrated significant improvements in cardiovascular outcomes. Spirituality-related interventions were associated with reductions in clinical events, including decreased episodes of syncope (up to 72%) and a higher proportion of event-free patients (43.3% vs 16%). Consistent improvements were observed in cardiometabolic parameters, including reductions in blood pressure (up to −8.3 mmHg), body mass index (up to −1.0 kg/m²), and global cardiovascular risk scores (QRISK3 reduction of approximately 29%). Additionally, favorable changes in biomarkers were reported, including reductions in LDL cholesterol (up to −22 mg/dL) and triglycerides, along with increases in HDL cholesterol (up to +6 mg/dL). Physiological benefits were also identified, such as improved vascular function and autonomic modulation. From a behavioral perspective, approximately 66% of studies reported increased treatment adherence and adoption of healthier lifestyles. Overall, spirituality appears to play a relevant role in modulating clinical and physiological outcomes in cardiovascular diseases, supporting its use as a complementary strategy in comprehensive cardiovascular care.

SPIRITUALITY AND MIND–BODY INTERVENTIONS IN REDUCING CARDIOVASCULAR RISK FACTORS: A SYSTEMATIC REVIEW

MATEUS HENRIQUE DE ALMEIDA BUCK1; LETÍCIA GONÇALEZ HERMIDA QUARESMA VAZ2; AMANDA OLIVA SPAZIANI2;

(1) UNIVERSIDADE BRASIL - PARANAÍBA - SP - BRASIL; (2) UNIVERSIDADE BRASIL - FERNANDÓPOLIS - SP - BRASIL;

Background/Introduction: Cardiovascular diseases remain the leading cause of global mortality and are strongly linked to modifiable risk factors such as stress, hypertension, and metabolic syndrome. Mind–body and spirituality-based interventions, particularly yoga, have emerged as adjunct strategies with potential physiological and behavioral benefits in cardiovascular prevention and rehabilitation. Objectives: To assess the effects of spirituality-based and mind–body interventions on cardiovascular risk factors and outcomes, focusing on hemodynamic, metabolic, inflammatory, and psychophysiological parameters, including stress modulation, and their role in cardiovascular prevention and rehabilitation. Methods: A systematic review was conducted following PRISMA guidelines. Searches were performed in PubMed, SciELO, and Scopus using terms related to “yoga,” “spirituality,” and “cardiovascular risk.” Randomized clinical trials and quasi-experimental studies published in the last 10 years were included. From 33 identified records, 15 studies met eligibility criteria after screening. Study selection was performed by independent reviewers. Outcomes included hemodynamic, metabolic, inflammatory, and functional parameters. Results and Conclusions: Included studies (n=15) consistently demonstrated significant reductions in systolic blood pressure ($p<0.05$), waist circumference ($p<0.05$), and cortisol levels ($p<0.001$), alongside improvements in cardiometabolic and inflammatory markers. In individuals with metabolic syndrome, yoga-based interventions achieved higher reversal rates compared to controls (45.4% vs 32.3%). Improvements were also observed in functional capacity, exercise tolerance, and quality of life, particularly among heart failure patients, with significant reductions in anxiety and depressive symptoms. In elderly populations, yoga was associated with improved diastolic function and favorable hemodynamic changes compared to conventional exercise. Additionally, spirituality-based community interventions showed indirect benefits through enhanced behavioral adherence and lifestyle modification. However, no consistent improvements were observed in structural cardiac outcomes, including ejection fraction and echocardiographic parameters. Overall, mind–body and spirituality-based interventions exert beneficial effects primarily through psychophysiological, metabolic, and behavioral pathways, representing a promising complementary approach in cardiovascular risk reduction and rehabilitation.

ACUTE HEMODYNAMIC EFFECT OF CONTINUOUS POSITIVE AIRWAY PRESSURE IN AMBULATORY PATIENTS WITH HEART FAILURE WITH PRESERVED EJECTION FRACTION: A PILOT STUDY.

MARIA CLARA SOARES DE SOUZA DOS SANTOS MURADAS1; EVANDRO TINOCO MESQUITA1; SÉRGIO LUIZ SOARES MARCOS DA CUNHA CHERMONT1; LÚCIA BRANDÃO OLIVEIRA1; LUANA DECCO MARCHESE1; JONATHAN COSTA GOMES1; GUSTAVO DESOUZART SOUZA1; ANTONIO JOSÉ LAGOEIRO JORGE1; WOLNEY ANDRADE MARTINS1; MÓNICA MARIA PENA QUINTÃO1;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL;

Background/Introduction: Heart failure (HF) with preserved ejection fraction (HFpEF) affects 50% of HF patients. Non-invasive ventilation (NIV) has been used as a non-pharmacological treatment in chronic HF by reducing ventricular preload and afterload and improving exercise tolerance in HF with reduced ejection fraction (HFrEF). Little is known about the acute hemodynamic effects of CPAP mode in patients with HFpEF. Objectives: OBJECTIVE: To determine the acute hemodynamic effect of NIV in CPAP mode in patients with HFpEF. Methods: Prospective, randomized, crossover, double-blind study. Five patients with HFpEF (diagnosed more than six months ago) from a HF clinic were evaluated. Na initial consultation (anamnesis/physical examination) was performed. The Berlin Questionnaire was applied. Patients with optimized medication and clinical stability were included. Patients underwent a single session of non-invasive ventilation (NIV) in CPAP or placebo mode (1 cmH2O), on alternate days (30 minutes), in the recumbent position, monitored by impedance cardiography (ICG) – afternoon shift. Data were recorded before, during, and after CPAP (7 cmH2O). Pre- and post-CPAP data were analyzed (therefore, the Student's t-test was used for data analysis). Patients with previous decompensation, COPD, or complex arrhythmias were excluded. The p-value was considered significant if ≤ 0.05. Results and Conclusions: Five patients were evaluated (two males/three females, age 70.6±11 years and LVEF 61.9±3.5%, NYHA Class II/III). A significant increase occurred in the following variables: cardiac output (4.02±1.8 vs 5.04±1.3 l/min; p=0.04), stroke volume (SV; 70.6±18 vs 74.8±19 ml; p=0.01), left ventricular ejection time (LVET; 325.6±32.06 vs 357.4±53.39 ms; p=0.04), left ventricular work (LCW; 5.05±1.6 vs 5.54±1.74 kg/m2; p=0.04) and a reduction in the LV acceleration/Cardiac Index (ACI; 71.4±34.7 vs 61.8±30.2 100/s2; p=0.01), Heather Index (HI 13.14±3.10 vs 11.5±2.55 Ohms/s2; p=0.019) and Systemic Vascular Resistance (SVR; 1383.6±485.1 vs 1324.8±285.8 dynas.s.cm-5; p=0.04) after the CPAP session. This suggests that CPAP mode may improve LV ventricular function in patients with HFpEF. The sample size is small. Therefore, it should be increased to improve the reliability of the results.

BASED-HOME HIGH-RESISTANCE INSPIRATORY MUSCLE STRENGTH TRAINING DECREASES SYMPATHETIC NEURAL DRIVE, IMPROVES ENDOTHELIAL FUNCTION, AND REDUCES EXTRACELLULAR VESICLES IN LONG COVID PATIENTS: A RANDOMIZED, DOUBLE-BLIND, SHAM-CONTROLLED TRIAL

ARTUR OLIVEIRA SALES1; THAIS SILVA RODRIGUES1; JOÃO EDUARDO IZAIAS1; BRUNA EMY ONO1; CAMILA SOUZA NUNES1; GABRIELLY MEL SOARES SILVA1; HELENA NALY MIGUENS ROCHA2; NATALIA GALITO ROCHA2; PEDRO PAULO SILVA SOARES2; MARIA CLAUDIA IRIGOYEN3; RENATA JUNQUEIRA MOLL BERNARDES1; ALLAN ROBSON KLUSER SALES1;

(1) IDOR - RIO DE JANEIRO - RJ - BRASIL; (2) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL; (3) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Background/Introduction: Previous evidence has shown that Long COVID patients have an increased risk of cardiovascular disease, which may be explained, in part, by sympathetic- cardiovascular dysfunction and alterations in the circulating milieu. Therefore, it is vital to propose strategies to restore cardiovascular health in this population. Objectives: To investigate whether inspiratory muscle strength training (IMST) reduces muscle sympathetic neural activity (MSNA), improves endothelial function, lowers blood pressure and reduces extracellular vesicles, and oxidative stress in Long COVID patients. Methods: A randomized, double-blind, sham-controlled clinical trial(NCT06091384) tested the effects of 6 weeks of IMST (30 breaths/day, 6 days/week at 75% PImax) versus SHAM (30 breaths/day, 6 days/week at 15% PImax) on PImax (manovacuometry), MSNA burst frequency (MSNABF, microneurography), brachial artery flow-mediated dilation (FMDBA, ultrasound), systolic and diastolic arterial pressure (SAP and DAP, semiautomated system), platelet and endothelial cell-derived extracellular vesicles (flow-cytometry), and oxidative stress markers. Complementary experiments were conducted on human umbilical vein endothelial cells (HUVEC) cultured with plasma samples from patients. Results and Conclusions: Thirty-seven patients completed the study (21 IMST: 48.4±9.2 yrs; 16 SHAM: 51.9±10.9 yrs). IMST increased PImax and reduced MSNABF, SAP and DAP and improved FMDBA (p<0.05 for all). Also, IMST reduced platelet and endothelial cell-derived VEs and increased SOD and CAT (p<0.05 for all), with no changes in NADPH oxidase or TBARS (p>0.05). HUVEC cultured with patient serum sampled after IMST exhibited lower ROS bioactivity, but there were no changes in NO. No changes were observed in the SHAM. Taken together, our findings indicate that IMST restores the sympathetic-cardiovascular function, suggesting it may be a promising strategy for reducing cardiovascular risk in this population.

CARDIOMETABOLIC AND CARDIOVASCULAR IMAGING PROFILE OF FEMALE ATHLETES: A SPORTS CARDIOLOGY COHORT STUDY

BEATRICE CONSTANCE FREIRE BELEM SIMAO1; KALIANA MARIA NASCIMENTO DIAS DE ALMEIDA1; GABRIELLE SOUZA SILVEIRA TELES1; STEFANY CASARIN MOURA1; JULIA TUPINAMBA DEL REY CRUSOE1; YOLANDA GOMES CAVINI1; MARCOS FERRANTI SMANIOTTO1; RAFAELA ROSSINI BUSO1; RODRIGO OTAVIO BOUGLEUX ALO1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Background/Introduction: The rising participation of women in high-intensity endurance sports contrasts with the paucity of epidemiological data characterizing this population. The cardiometabolic burden, prevalence of cardiovascular disease (CVD), and findings on exercise testing and multimodal imaging in female athletes remain poorly described, limiting sex-specific risk stratification and preventive strategies in sports cardiology. Objectives: To describe the clinical, cardiometabolic, and cardiovascular profile — including exercise testing and imaging findings — of female athletes followed at a specialized sports cardiology outpatient clinic. Methods: Single-center, retrospective observational study of female athletes seen at a sports cardiology clinic in Brazil. Data extracted from electronic medical records comprised demographics, comorbidities, cardiovascular risk factors, type of sport, resting 12-lead EKG, maximal cardiopulmonary or symptom-limited exercise testing, echocardiography, and coronary CT angiography (CCTA) when available. Descriptive statistical analyses were performed. Results and Conclusions: A total of 347 women (age range 13–91 years; mean 57 years) were included, predominantly runners. Functional capacity was excellent in over 90% of participants (>10 METs). The most prevalent cardiovascular risk factors were dyslipidemia (50%), hypertension (34%), smoking (14%), and diabetes mellitus (11%); more than one-third met criteria for high or very high cardiovascular risk. Established CVD was identified in 68 athletes (19.5%): coronary artery disease in 24 — frequently detected by CCTA — and complex arrhythmias in 21. Ventricular dysfunction was present in only one patient. Resting ECG showed left bundle branch block in 8 and right bundle branch block in 9 participants. Echocardiography demonstrated preserved biventricular function in virtually the entire cohort, with low frequency of relevant structural abnormalities. Despite a substantial burden of traditional risk factors, structural heart disease prevalence was low. Female athletes with preserved functional capacity exhibit a favorable structural cardiac phenotype compared to the general population, yet carry a significant cardiometabolic risk burden - underscoring the need for individualized, sex-specific cardiovascular assessment in sports cardiology.

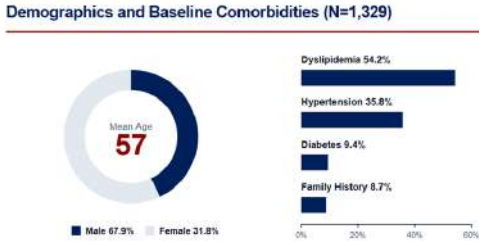
CARDIOVASCULAR STRUCTURAL EFFECTS OF ANABOLIC STEROID USE IN ADULTS: A SYSTEMATIC REVIEW

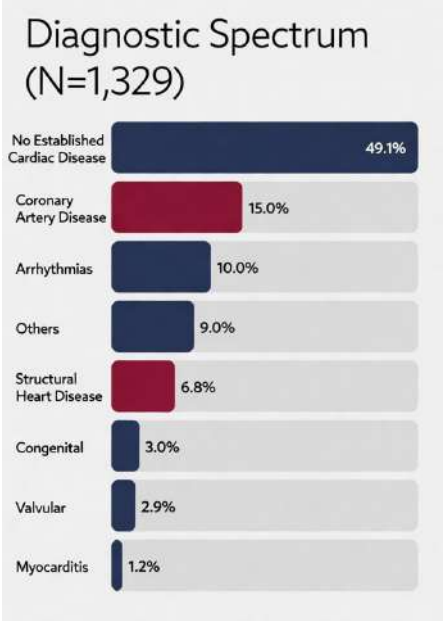
BEATRIZ MARASSATO BERNARDES1; ANA CAROLINA CARVALHO ANTONIO1; JHOSELYN HUAYHUA MAMANI1; JULIA LOSSO FONSECA DE OLIVEIRA1; GIOVANA DURCE CARLINI1; ANNA LUIZA DELGADO SAMPAIO1; LETICIA GALLATI SOARES1; LEONORA GATTO1; JULIA LANG LOPES GAGLIARDI PALERMO1; LUIZA MELLO DA MATA1; ANA FLAVIA MIRANDA LIMA1; IRVING GABRIEL ARAUJO BISPO1;

(1) UNIVERSIDADE MUNICIPAL DE SAO CAETANO DO SUL - SÃO PAULO - SP - BRASIL;

Background/Introduction: Anabolic steroids (AS) increase vascular stiffness and impair endothelial function, raising cardiovascular risk, which may persist even after discontinuation Objectives: This study aimed to evaluate the association between AS use and early cardiovascular dysfunction in adults. Methods: This is a systematic review conducted according to PRISMA guidelines. The research question was structured based on PICO. Searches were performed in PubMed and BVS using descriptors combined with Boolean operators, along with manual reference screening. Observational studies and clinical trials published in the last 10 years, in English, Portuguese, or Spanish, with full text available, were included. Pediatric studies, reviews, and case reports were excluded. Study selection was performed by three independent reviewers using Rayyan, with blinded screening and full-text assessment, resulting in 14 included studies. Data extraction was standardized, including methodological characteristics and outcomes. Results and Conclusions: A total of 1,420 participants were included, predominantly male, aged 30–43 years. AS use was associated with reduced left ventricular systolic function. Chronic users showed significantly lower left ventricular ejection fraction (50% a 63%; P<0,001), with heart failure in 11%. Biventricular global longitudinal strain (P<0.05) and myocardial flow reserve were impaired. Increased left ventricular mass (up to 106 g/m²; P<0.001) and wall thickness were observed, indicating hypertrophy with fibrosis and tricuspid regurgitation (77.1%). Coronary artery disease prevalence ranged from 17% to 25%, with calcifications and endothelial dysfunction. Reduced HDL-c and increased inflammatory biomarkers were observed. Electrophysiological alterations, atrial remodeling, and slowed sodium conduction increased arrhythmia risk. AS use is associated with endothelial dysfunction, increased vascular stiffness, and cardiac remodeling, with reduced function. These alterations may persist after discontinuation, suggesting long-term impact. Findings indicate an early cardiovascular risk factor and reinforce the need for cardiovascular screening in users of these substances.



18060



CLINICAL-EPIDEMIOLOGICAL PROFILE AND SPORTS ELIGIBILITY CRITERIA IN 1,329 PATIENTS OF A TERTIARY SPORTS CARDIOLOGY CLINIC

JOÃO FELIPE TAMIOZZO REIS1; RODRIGO DANTAS FERRAZ1; MATHEUS LORENZETTI PERON1; RAFAEL ENGEL DUCATTI1; RODRIGO OTAVIO BOUGLEUX ALO1; RAFAELA ROSSINI BUSO1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Background/Introduction: Cardiovascular evaluation of athletes and physically active individuals is among the most complex challenges in modern Cardiology, requiring specialized infrastructure for screening, diagnosis, and individualized sports eligibility definition. Large-scale real-world data from tertiary Sports Cardiology referral centers remain scarce in the national literature. Objectives: To describe the clinical-epidemiological profile, diagnostic spectrum, comorbidity burden, electrocardiographic findings, and sports eligibility criteria of patients seen at a tertiary specialized Sports Cardiology outpatient clinic. Methods: Cross-sectional descriptive study based on primary real-world data from a tertiary Sports Cardiology outpatient clinic (2023–2026). All patients with registered records and structured data were included. Variables: sex, age, cardiovascular diagnosis, comorbidities, ECG findings, and sports eligibility. Descriptive statistics: absolute/relative frequencies, mean ± SD, and median with interquartile ranges (IQR). Results and Conclusions: A total of 1,329 patients were analyzed. Male predominance was observed (n=903; 67.9% vs. n=423; 31.8% female), with mean age 57.0 ± 15.5 years (median 59; IQR 49–67; range 12–95). Diagnostic distribution: No Established Cardiac Disease 653 (49.1%), CAD 200 (15.0%), Arrhythmias 133 (10.0%), Other 119 (9.0%), Structural Cardiomyopathy 91 (6.8%), Congenital 40 (3.0%), Valvular 39 (2.9%), and Myocarditis 16 (1.2%). Most prevalent comorbidities: dyslipidemia (54.2%), hypertension (35.8%), diabetes mellitus (9.4%), and positive family history (8.7%). ECG findings: normal (69.2%), athlete pattern (10.6%), and abnormal (20.1%). Sports eligibility: unrestricted clearance (72.4%), restricted clearance (20.8%), and disqualification (3.5%). Notably, among CAD patients (n=199), 51.8% received restricted clearance versus only 7.0% disqualified; a similar pattern was observed in structural cardiomyopathy (55.1% vs. 6.7%). This cohort represents one of the largest primary real-world series from a specialized tertiary Sports Cardiology setting, demonstrating high cardiovascular complexity. Restricted clearance markedly exceeded absolute disqualification, reflecting the modern paradigm of individualized and safe exercise prescription over indiscriminate sports exclusion.

17846

COMPARISON OF ECCENTRIC AND CONCENTRIC CYCLING ON FUNCTIONAL CAPACITY IN POST CORONARY ARTERY BYPASS GRAFTING PATIENTS

SIDRA FAROOQ1; FARZANA AMIR HASHMI1; BASIT ALI ANSARI2;

(1) TABBA HEART INSTITUTE - PAKISTAN; (2) UNIVERSITY OF KARACHI - PAKISTAN;

Background/Introduction: Coronary Artery Bypass Grafting (CABG) results in reduced functional capacity and lower-limb muscle weakness, limiting mobility and delaying recovery. Cardiac Rehabilitation (CR) plays a pivotal role in restoring physical performance; however, optimal exercise modalities remain uncertain. Eccentric (ECC) cycling enables higher force generation with lower metabolic cost compared to traditional concentric (CON) cycling, making it a potentially more suitable option for post-CABG patients with limited cardiopulmonary endurance. Objectives: To compare the effect of Eccentric (ECC) verses Concentric (CON) cycling during CR on functional capacity in post-CABG patients using Six-Minute Walk Test (SMWT) and Short Physical Performance Battery (SPPB) scores. Methods: A randomized controlled trial was conducted at a tertiary cardiac rehabilitation center. Post CABG patients were randomly assigned to either ECC or CON cycling in addition to standard CR protocol. Functional capacity was assessed at baseline and after completion of 6–8 weeks of supervised rehabilitation using 6MWT and SPPB. Participants who completed all prescribed sessions were included in the final analysis. Between-group comparisons were performed for changes from baseline and post-intervention outcomes. Results and Conclusions: Of 133 enrolled patients, 59 (44.3%) completed the rehabilitation program (ECC n=31; CON n=28), with a mean age of approximately 60 years. Baseline functional capacity was comparable between groups. Following intervention, both groups demonstrated improvement; however, gains were greater in the ECC group. Post-rehabilitation 6MWT distance was higher in ECC compared with CON (452 m vs 396 m). ECC participants also showed superior performance in SPPB components, including faster gait speed (2.6 s vs 3.48 s), shorter chair stand time (13.27 s vs 17.75 s), higher chair stand scores (3 vs 1), and better overall SPPB scores (11 vs 9). Eccentric cycling during cardiac rehabilitation resulted in greater improvements in functional capacity and lower-limb performance compared with concentric cycling in post-CABG patients. These findings suggest that integrating eccentric exercise modalities into CR programs may accelerate recovery, improve mobility and optimize physical outcomes after CABG.

COMPARISON OF ELECTROCARDIOGRAPHIC CHARACTERISTICS BETWEEN UNDER-20 AND PROFESSIONAL FOOTBALL ATHLETES AT AN ELITE CLUB

ANTONIO CARLOS AVANZA NETO1; ANTONIO CARLOS AVANZA JÚNIOR1;

(1) UNIVERSIDADE VILA VELHA - VILA VELHA - ES - BRASIL;

Background/Introduction: High-performance athletes, including football players, exhibit increased vagal tone as well as structural and electrical cardiac remodeling, leading to enlargement and increased wall thickness of cardiac chambers, along with changes in rhythm, electrical conduction, and ventricular repolarization. These adaptations may be reflected on the electrocardiogram (ECG). Among other factors, the type of exercise performed, its intensity, and the duration of continuous physical activity may directly influence the ECG characteristics of these athletes. Objectives: To evaluate electrocardiographic changes in high-performance football athletes and to compare these changes between two diferent competitive categories, as well as to assess the influence of training duration and years of physical activity practice on electrocardiographic findings between the two groups. Methods: A total of 57 electrocardiograms were performed in professional athletes and 46 in under-20 category athletes from a professional football club during pre-participation evaluations conducted over two consecutive seasons (2025 and 2026). Data are presented as mean ± standard deviation or standard error of the mean. Tukey's test was used to compare diferences between groups. Results and Conclusions: In the under-20 category, age ranged from 16 to 19 years; ethnicity: 71.8% White and 28.2% Black; BMI: 18.6Kg/m2 to 24.8 kg/m2. In the professional category, age ranged from 21 to 38 years; ethnicity: 68.2% White and 31.8% Black; BMI: 19.1 Kg/m2 to 25.3 kg/m2. The mean duration of continuous training practice was 6 ± 2 years in the under-20 category and 12 ± 5 years in professional athletes. Electrocardiographic parameters — Under-20 athletes: sinus bradycardia: 21 (45.6%); left ventricular hypertrophy: 13 (28.2%); incomplete right bundle branch block: 7 (15.2%); first-degree atrioventricular block: 2 (4.3%); T-wave inversion from V1 to V3: 3 (6.5%); early repolarization: 20 (43.4%). Professional athletes: sinus bradycardia: 30 (52.6%); left ventricular hypertrophy: 24 (42.1%); incomplete right bundle branch block: 7 (12.28%); first-degree atrioventricular block: 3 (5.3%); T-wave inversion from V1 to V3: 4 (7.0%); early repolarization: 34 (59.6%). Early repolarization and sinus bradycardia were the most prevalent findings in both groups. Left ventricular hypertrophy and early repolarization were more prevalent in the professional athlete group, likely secondary to greater training load and cumulative years of practice.

CPAP IMPROVES CARDIAC VAGAL ACTIVITY IN INDIVIDUALS WITH OBSTRUCTIVE SLEEP APNEA

ANA PAULA FERREIRA1; FLÁVIA BAGGIO NERBASS1; MANUELA VITÓRIA MARTINS LOPES1; BIANCA LOUISE CARMONA ROCHA1; DJALMA RABELO RICARDO2; ISABELLE BARRAL MONTESSI2; JULIA MOURA KARL2; THIAGO CASALI ROCHA2; PLINIO DOS SANTOS RAMOS2; LILIANE PATRICIA DE SOUZA MENDES1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL;

Background/Introduction: Obstructive sleep apnea (OSA) is characterized by recurrent upper airway collapse, leading to intermittent hypoxia and sleep fragmentation. This condition imposes continuous stress on the autonomic nervous system, resulting in sympathetic hyperactivity and significantly increasing cardiovascular risk. Continuous positive airway pressure (CPAP) therapy acts mechanically by maintaining upper airway patency and preventing airway collapse during sleep. Previous studies suggest that consistent CPAP use may reduce sympathetic hyperactivity; however, little is known about its effects on cardiac vagal activity (CVA). In this context, the use of methods capable of more specifically assessing the branches of the autonomic nervous system becomes relevant. The 4-second exercise test (4sET), a low-cost tool with good external validity, allows isolated assessment of CVA through the cardiac vagal index, representing a feasible alternative for autonomic evaluation in this population. Objectives: To evaluate CVI in patients with OSA before and after 30 days of CPAP treatment. Methods: This was a longitudinal observational study conducted at a sleep physiotherapy clinic in XXXX. 21 participants with polysomnography-confirmed OSA were included. Cardiac vagal activity was assessed using the CVI, with values expressed as mean ± standard deviation. Paired Student's t-test was used for comparisons before and after treatment. The study was approved by the Research Ethics Committee of XXXXXXX (CAAE: XXXXX). Results and Conclusions: After 30 days of CPAP therapy, a significant increase in CVI was observed (1,24 ± 0,17 vs. 1,32 ± 0,19; p = 0,035). This increase suggests improvement in cardiac vagal activity and favorable modulation of the autonomic nervous system after the intervention, evidenced by greater parasympathetic predominance and possible reduction in sympathovagal imbalance associated with OSA. Conclusion. The findings of the present study suggest that patients with OSA treated with CPAP demonstrate increased cardiac vagal activity after 30 days of treatment, indicating a favorable effect on sympathovagal modulation, with increased parasympathetic predominance and potential relevance for understanding the cardiovascular risk associated with the disease.

EFFECTS OF BLOOD FLOW RESTRICTION TRAINING ON CARDIAC AUTONOMIC FUNCTION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CLINICAL TRIALS

ENRICO VESCOVI SALLES1; AUGUSTO MONTEIRO DE CASTRO XAVIER DE CARVALHO1; JUAN PERES DE OLIVEIRA2; CAROLINE DE OLIVEIRA FISCHER BACCA2;

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (2) UNIDAVI - CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL;

Background/Introduction: Blood flow restriction (BFR) training is a popular technique aimed at enhancing physical performance in athletes. However, its application has recently broadened to a range of clinical populations. Considering the potential applicability of BFR training in cardiac rehabilitation patients, understanding its effects on the cardiac autonomic function is pertinent, as heart rate variability (HRV) can be helpful for cardiovascular risk stratification. While there is inconsistent evidence about cardiovascular adaptations to BFR training, its influence on measures of HRV is yet to be elucidated. Objectives: This systematic review and meta-analysis of randomized clinical trials (RCTs) assessed the effects of exercise training with BFR on sympathovagal balance and time-domain measures of HRV in adults. Methods: CENTRAL, Embase, and PubMed were searched for RCTs comparing the effects of ≥4 weeks of exercise training with versus without BFR on resting HRV in adults. After deduplication, 659 records were screened and seven studies were included. Between-group mean differences (MD) in changes from pre- to post-intervention were calculated for root mean square of successive differences (RMSSD), standard deviation of normal-to-normal intervals (SDNN), and sympathovagal balance (LF/HF) assuming a correlation of 0.5. Random-effects meta-analyses were conducted in RStudio using the DerSimonian and Laird model. Estimates were reported with 95% confidence intervals (CI). Heterogeneity was quantified using I^2. Sensitivity analysis was performed using a leave-one-out analysis. Results and Conclusions: Seven RCTs (n=230) reported RMSSD, a marker of cardiac parasympathetic modulation, showing an increased pooled effect estimate in the BFR group (MD, 2.29 ms; 95% CI, 0.97 to 3.62 ms; P=0.0007; I^2=1.3%). Leave-one-out analysis confirmed robustness. Five RCTs (n=170) reported SDNN, with no significant between-group difference (MD, 1.77 ms; 95% CI, -1.76 to 5.30 ms; P=0.33; I^2=39.5%). Four RCTs (n=100) reported LF/HF, also showing no significant between-group difference (MD, -0.35; 95% CI, -1.25 to 0.55; P=0.45; I^2=94.6%). Key limitations include diversity in demographic characteristics, training protocols, and assessment procedures across studies. The findings of this review suggest BFR training may enhance cardiac parasympathetic modulation in adults, although larger and standardized studies should further evaluate its effects on heart rate variability.

INSTANTANEOUS HEART RATE RESPONSE DURING THE 6-MINUTE WALK TEST IN HOSPITALIZED CARDIAC PATIENTS: FEASIBILITY OF ON AND OFF KINETIC ANALYSIS

GABRIELLE M MARTINIANO1; GABRIELA R CAVALCANTE1; LAIS L RUSSOMANNO1; CAROLINE B BARBOSA1; ISADORA S ROCCO1; ALEXANDRA R MONTE SIÃO1; NELSON HOSSNE JR.1; RITA SIMONE L MOREIRA1; WALTER J GOMES2; VERIDIANA S ANDRADE1; SOLANGE GUIZILINI1;

(1) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL;

Background/Introduction: Heart rate (HR) response to physical exercise is an important marker of cardiovascular function, cardiorespiratory fitness, and prognosis in cardiac patients. Despite its widespread use in tests conducted in controlled environments, evidence on the feasibility of analyzing instantaneous HR responses during submaximal functional tests performed in hospital settings is limited. Objectives: The aim of the study was to analyze the instantaneous HR response during the six-minute walk test (6MWT) in hospitalized cardiac patients, assessing the feasibility of analyzing on- and off-kinetics in the hospital setting. Methods: This was a cross-sectional study including individuals hospitalized for clinical or surgical treatment of cardiovascular conditions. Adults of both sexes were included, with a confirmed clinical diagnosis based on echocardiography, coronary angiography, and clinical history. The 6MWT was performed with continuous HR monitoring using the Polar® H10. HR on-kinetics were analyzed using a monoexponential model, based on the time constant (τ). Off-kinetics were determined by the heart rate recovery half-time ($t½$). Data were described according to the nature of the variables and compared using parametric and non-parametric tests, with a significance level of 5%. Results and Conclusions: A total of 99 patients were evaluated, with a mean age of 57.3±13.6 years and a predominance of females (76.7%), with a left ventricular ejection fraction of 50% (IQR: 25). Patients walked a distance of 442±115 m in the 6MWT, with an HR τ of 67.2±40.2 s, indicating a slow chronotropic response and prolonged recovery, with a $t½$ of 84.5±52.2 s. It was possible to model on-kinetics in 83.8% of cases due to the presence of a steady state, whereas off-kinetics were obtained in 94.9% of individuals. Of the participants, 47.5% were hospitalized for clinical reasons and 52.5% for surgical treatment. There were no statistically significant differences in the acquisition of on- and off-kinetics parameters between hospitalization profiles. The analysis of instantaneous HR response during the 6MWT proved to be feasible, with a high rate of successful estimation of on- and off-kinetics parameters, indicating that HR kinetics assessment can be feasibly incorporated into functional evaluation in the hospital setting, regardless of clinical or surgical hospitalization profile, thereby expanding the potential of the 6MWT as a tool for analyzing cardiovascular response to exercise in this population.

PREDICTORS OF NON-COMPLETION OF CARDIAC REHABILITATION IN A LOW-MIDDLE-INCOME COUNTRY SETTING: A SINGLE-CENTRE OBSERVATIONAL ANALYSIS OF THE INTERNATIONAL CARDIAC REHABILITATION REGISTRY (ICRR)

FARZANA AMIR HASHMI1; SIDRA FAROOQ2; SAQIB SARFARAZ2; SHERRY L. GRACE3;

(1) TABBAHEART INSTITUTE - PAKISTAN; (2) TABBA HEART INSTITUTE - PAKISTAN; (3) YORK UNIVERSITY - CANADA;

Background/Introduction: Cardiac rehabilitation (CR) improves functional capacity, quality of life and cardiovascular outcomes in cardiac patients. Despite of its well-known benefits, a substantial proportion of patients fail to complete the prescribed CR sessions, limiting their potential benefits, particularly In Low-Middle-Income Countries (LMICs). Understanding factors associated with non-completion of CR is critical to identify patients at risk and to develop targeted strategies to improve adherence. Objectives: To identify predictors of non-completion of cardiac rehabilitation in a single-centre program from an LMIC using data from the International Cardiac Rehabilitation Registry (ICRR). Methods: This observational study analyzed registry data from patients enrolled in a single cardiac rehabilitation centre contributing to the ICRR between 2022 and 2025. Baseline variables examined as a predictor includes age, gender, referral diagnosis, referral intervention, education, work status, Body Mass Index, Blood Pressure, functional capacity (Peak METs), diabetes, self-rated Quality of Life (QoL), depression screening (PHQ-2), tobacco use, physical activity status, fruit and vegetable intake and medication adherence. Multivariable logistic regression was performed with adjustment for all clinically relevant covariates. Findings are expressed as adjusted odds ratios (aOR) (95% CI); statistical significance was at $p<0.05$. Results and Conclusions: Among 1,416 participants with complete data, 859 (60.7%) were classified as non-completers (<15 supervised CR sessions). Referral following PCI was associated with higher odds of non-completion compared with CABG (aOR 1.53, 95% CI 1.16–2.00; p=0.002). Greater depressive symptoms independently predicted non-completion (aOR 1.12 per point increase, 95% CI 1.05–1.21; p=0.001). Higher baseline Peak METs was independently protective (aOR 0.80 per SD increase, 95% CI 0.64–0.99; p=0.041), indicating lower functional capacity at baseline may predict non-completion. Higher self-rated QoL was associated with greater odds of non-completion (aOR 1.15 per SD increase, 95% CI 1.02–1.29; p=0.026), suggesting that patients who feel clinically well may be less motivated to continue rehabilitation. No other variables independently predicted non-completion. These findings determine that identifiable baseline characteristics such as referral intervention, depressive symptom burden and functional capacity emerged as modifiable and measurable predictors.

BODY COMPOSITION IN OLDER WOMEN WITH HEART DISEASE FROM A TERTIARY CENTER IN SOUTHERN BRAZIL

RAFAEL VIANNA BEHR1; ANA LAURA ROCHA MACHADO1; PATRICIA AMORIM GROISMAN1; CAUAN TRAMONTINI DIAS1; POLI MARA SPRITZER1; TAYANE MUNIZ FIGHERA1; FERNANDO PIVATTO JÚNIOR1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Background/Introduction: Changes in body composition, particularly increased visceral adiposity, have been associated with higher cardiometabolic and cardiovascular risk. Visceral adipose tissue (VAT) is strongly linked to systemic inflammation, insulin resistance, and the development of cardiovascular disease. However, data on fat distribution in older women with established heart disease remain limited, especially in the Brazilian population. Objectives: To evaluate body composition in older women with established heart disease. Methods: Cross-sectional study including women ≥60 years with a diagnosis of atrial fibrillation, ischemic heart disease, significant valvular disease or prior valve replacement, or heart failure. A control group of women without established heart disease was also included. Body composition was assessed using dual-energy X-ray absorptiometry (DXA). Results and Conclusions: A total of 51 patients were included (31 with heart disease and 20 without), with a median age of 69 (65–73) years; body mass index (BMI) of 31 (28–33) kg/m²; 42 (82.3%) had hypertension; 15 (29.4%) had diabetes; 18 (35.2%) had an estimated glomerular filtration rate <60 mL/min/1.73 m²; and 6 (11.8%) were smokers. There were no differences between groups in the following body composition measures: BMI (30.5 ± 3.9 vs. 30.2 ± 3.3 kg/m²; p = 0.837); weight (76.3 ± 12.6 vs. 75.6 ± 9.3 kg; p = 0.822); total lean mass (39.8 ± 4.8 vs. 38.9 ± 4.7 kg; p = 0.513); appendicular lean mass (17.5 ± 2.7 vs. 17.6 ± 2.5 kg; p = 0.947); appendicular lean mass index (7.02 ± 0.91 vs. 7.05 ± 1.03 kg/m²; p = 0.918); total fat mass (33.8 ± 8.5 vs. 34.4 ± 7.1 kg; p = 0.805); and fat mass index (13.5 ± 3.0 vs. 13.7 ± 2.6 kg/m²; p = 0.738). A significant difference was observed in visceral adipose tissue (VAT) (1,514 ± 618 g vs. 1,187 ± 418 g; p = 0.044). After excluding patients with diabetes mellitus, the difference in VAT between groups remained significant (1,559 ± 696 g vs. 1,124 ± 390 g; p = 0.029). In conclusion, older women with heart disease had higher visceral adipose tissue (VAT) compared with those without heart disease, despite similar values in other body composition parameters, including body weight, BMI, and fat and lean mass indices. These findings suggest that visceral fat accumulation may be associated with the presence of heart disease in this population, even in the absence of differences in overall body composition measures.

CAROTID ULTRASOUND IN THE STRATIFICATION OF SUBCLINICAL ATHEROSCLEROSIS IN YOUNG WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A SYSTEMATIC REVIEW

PEDRO VINÍCIUS SILVA FELIPE1; SAMUEL ROXSANDER1; MARIA EDUARDA DA CUNHA RODRIGUES ARAÚJO1; SERGIO SAMUEL DE ALMEIDA VIEIRA1; EMMANUEL ALMEIDA CARVALHO1; LUIS HENRIQUE DUARTE DE MELO1; ANGELA BEATRIZ DA SILVA1; TUANNY VICTÓRIA FERNANDES MORAIS1; JOÃO VICTOR MATIAS MEDEIROS1; MARIA EDUARDA DANTAS VASCONCELOS1; MARCOS VINICIUS FREIRE PINTO SILVEIRA1; IMARA CORREIA DE QUEIROZ BARBOSA1;

(1) UNIVERSIDADE FEDERAL DE CAMPINA GRANDE - UFCG - CAMPINA GRANDE - PB - BRASIL;

Background/Introduction: Systemic Lupus Erythematosus (SLE) is associated with premature atherosclerosis and subclinical vascular disease, increasing cardiovascular risk even in patients with low apparent risk. Carotid ultrasound (US) stands out as a non-invasive tool for monitoring. However, it is necessary to understand the efficacy of these sonographic markers in risk prediction for specific demographic profiles Objectives: To evaluate the role of carotid US in the diagnosis of subclinical atherosclerosis in young women with SLE. Methods: A systematic review was conducted based on the PRISMA protocol and the PICO acronym ("What is the utility of carotid US in identifying subclinical atherosclerosis in young women with SLE compared to controls?"). Double-blind selection was performed in the first semester of 2026 across PubMed, LILACS, and Scopus databases. The search included clinical trials and case-control studies published in the last 10 years in English, Portuguese, and Spanish Results and Conclusions: Analysis of 11 studies (n=1085; age range 16–45.2 years) revealed a substantially higher atherosclerotic risk in SLE patients. Most studies demonstrated a significant increase in bilateral carotid intima-media thickness (CIMT) ($p < 0.001$) and the presence of plaques in up to 48.1% of young patients—findings underestimated by traditional risk scores. Morphologically, plaques in SLE are predominantly non-calcified and echolucent; higher echogenicity was associated with persistent disease activity (OR=7.9; p=0.010). Prognostically, Total Plaque Area (TPA) > 16 mm² predicted a 6.4-fold higher risk for cardiovascular outcomes (OR=6.44; p=0.028), while plaques in ≥3 bifurcations increased the risk nearly tenfold (OR=9.9; p=0.009). Longitudinal data confirm accelerated progression (IRR=2.26; p=0.002). Lupus nephritis correlated with severe endothelial dysfunction, while sustained clinical remission (DORIS criteria) reduced the risk of new atherosclerosis by 43%. Carotid US is a sensitive tool for the detection and stratification of subclinical atherosclerosis in young women with SLE. Parameters such as TPA possess high prognostic value, surpassing traditional scores and assisting in the prediction of cardiovascular events.

ELEVATED BNP AND NT-PROBNP AS PREDICTORS OF MATERNAL CARDIOVASCULAR EVENTS IN PREGNANT WOMEN WITH CARDIOVASCULAR DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

REBECA MOURA ALVES1; DUSTIN ANDREI MESQUITA BARBOSA1; BÁRBARA CASTRO CARNEIRO1; MARIA DE LOURDES FREITAS REGES1; ANNA JÚLIA ANDRINO SCHNEIDER1; CAIO TEOTÔNIO DE OLIVEIRA1; ARTHUR MENDES BENEVIDES MEDEIROS1; HEITOR GONDIM BRAGA1; RICARDO PEREIRA SILVA1;

(1) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL;

Background/Introduction: Pregnancy imposes substantial hemodynamic stress on women with cardiovascular disease. Brain natriuretic peptide (BNP) and N-terminal pro-B-type natriuretic peptide (NT-proBNP) may help identify patients at increased risk of adverse maternal cardiovascular outcomes, but available evidence remains scattered across heterogeneous cardiac populations. Objectives: To evaluate whether elevated BNP or NT-proBNP levels are associated with maternal cardiovascular events in pregnant women with cardiovascular disease. Methods: We conducted a systematic review and meta-analysis of observational studies by systematically searching PubMed, Embase, and Cochrane databases from inception to April 2026. Eligible studies included pregnant patients with structural heart disease, congenital heart disease, pulmonary hypertension, or mixed cardiovascular disease, and reported maternal cardiovascular outcomes stratified by elevated versus low/normal natriuretic peptide levels. The primary outcome was maternal cardiovascular events, including heart failure, clinically significant arrhythmias, cardiac death, thromboembolic events, urgent cardiovascular intervention, or composite maternal cardiovascular outcomes as defined by each study. When adjusted estimates were not consistently available, crude odds ratios were calculated from extractable 2 × 2 data. Odds ratios were pooled using a random-effects model. Sensitivity analyses included exclusion of studies with extreme or zero-cell distributions, restriction to structural/congenital or acquired heart disease cohorts, and leave-one-out analysis. Results and Conclusions: Six studies comprising 1,077 analyzable pregnancies were included in the primary quantitative analysis. Elevated BNP or NT-proBNP was significantly associated with higher odds of maternal cardiovascular events compared with low/normal biomarker levels (pooled OR 12.78; 95% CI 8.41–19.41; p < 0.0001; I² = 0%). Results were consistent across BNP and NT-proBNP subgroups. Sensitivity analysis excluding studies with extreme or zero-cell distributions yielded similar findings (OR 12.27; 95% CI 8.01–18.81; I² = 0%). In the analysis restricted to structural, congenital, or acquired heart disease cohorts, the association remained robust (OR 8.06; 95% CI 3.35–19.41). Leave-one-out analysis confirmed that no individual study materially changed the overall pooled effect estimate. Elevated BNP or NT-proBNP levels are strongly associated with maternal cardiovascular events in pregnant women with cardiovascular disease.

Background/Introduction: Spontaneous Coronary Artery Dissection (SCAD) causes Acute Myocardial Infarction (AMI), mainly in young to middle-aged women without cardiovascular risk factors. Despite its importance, epidemiological data and outcomes remain limited. Objectives: Characterize the epidemiological, clinical, and angiographic profiles of patients with AMI due to SCAD and identify predictors of combined outcomes during hospitalization and follow-up. Methods: A multicenter cross-sectional study with prospective follow-up included angiographically confirmed SCAD cases from 2013 to 2025 in Rio de Janeiro. Sociodemographic and clinical data were gathered. In-hospital combined outcomes included recurrent ACS, hemodynamic instability, or coronary intervention. Post-discharge outcomes included recurrent chest pain requiring medical care, new ACS episodes, or rehospitalization for ACS with hemodynamic instability, with a follow-up period of up to 10 years. Statistical analysis used descriptive stats, chi-square/Fisher's exact, and Shapiro-Wilk tests; p < 0.05. Results and Conclusions: Seventy SCAD patients were analysed, mostly female (86%), mean age 49.4 ± 12.7 years. Most (64%) were admitted via public healthcare. NSTEMI occured in 70%. The LAD artery was affected in 67%, Type 1 dissection in 41%, and tortuosity in 59%. Moderate to severe left ventricular systolic dysfunction (LVSD) occurred in 24%, segmental wall motion abnormalities in 75%. Conservative treatment was implemented in 87%, including aspirin (96%), clopidogrel (67%), ACE inhibitors/ARBs (53%), beta-blockers (69%), and statins (71%). PCI was performed in 13% initially and 4% after recurrent ACS. In-hospital outcomes occurred in 26%, associated with Type 3 dissection (p=0.032), angioplasty (p<0.0001), and hemodynamic instability (p<0.0001). Among 40 patients followed up to 10 years, 62% had post-discharge combined outcomes associated with impaired TIMI flow (p=0.045) and LVSD (p=0.012). Recurrent chest pain affected 27% in-hospital and 77% post-discharge. No gender association was found. Cardiac rehabilitation rate was 31%. No in-hospital deaths; one cardiovascular death occurred within a year post-discharge. SCAD mainly affects middle-aged women, often as NSTEMI. Conservative management usually leads to favorable outcomes. Hight chest pain recurrence indicate ongoing morbidity and the need for specialized follow-up. Low cardiac rehabilitation referral highlights care gaps. Early diagnosis, risk evaluation, and treatment are crucial to prognosis and prevent recurrence.

Table 1. Baseline Characteristics and Clinical Profile

Variable, n (%)	Total Sample (n=70)	Female (n=60)	Male (n=10)
Age (years), mean ± SD	49.4 ± 12.7	49.6 ± 12.5	48.2 ± 14.5
White Race	38 (62.3%)	33 (63.5%)	5 (55.6%)
Hypertension	35 (50.0%)	29 (48.3%)	6 (60.0%)
Dyslipidemia	18 (25.7%)	14 (23.3%)	4 (40.0%)
Diabetes Mellitus	11 (15.7%)	9 (15.0%)	2 (20.0%)
Smoking (Current/Former)	26 (37.1%)	21 (35.0%)	5 (50.0%)
Obesity (BMI ⩾ 30)	27 (38.6%)	23 (38.3%)	4 (40.0%)
Anxiety	26 (37.1%)	24 (40.0%)	2 (20.0%)
Depression	12 (17.1%)	11 (18.3%)	1 (10.0%)
Migraine	9 (12.9%)	9 (15.0%)	0 (0.0%)
Intense Physical Effort	6 (8.6%)	4 (6.7%)	2 (20.0%)

HOSPITAL OUTCOMES OF ACUTE MYOCARDIAL INFARCTION IN WOMEN IN BRAZIL (2014–2024): A NATIONWIDE DESCRIPTIVE CROSS-SECTIONAL STUDY

ICARO HEICKMEN MELO1; TIAGO NOGUES ALMEIDA1; LUCAS QUEIROZ MENEZES1; ITALO TAVEIRA MELO2; ANDRE JORGE ALMEIDA1; ARTHUR AMORIM FELISARDO1; MIGUEL CHAVES LENZI3; DIEGO NOGUES ALMEIDA4; VICTOR FEITOSA GALDINO5; RAQUEL MEDEIROS QUEIROZ1;

(1) UFRN - NATAL - RN - BRASIL; (2) UNIVERSIDADE FEDERAL DO RECONCAVO DA BAHIA - SANTO ANTONIO DE JESUS - BA - BRASIL; (3) UNIVERSIDADE ESTADUAL DO RIO GRANDE DO NORTE - MOSSORÓ - RN - BRASIL; (4) UNIVERSIDADE FEDERAL DE ALAGOAS - MACEIÓ - AL - BRASIL; (5) FPS - FACULDADE PERNAMBUCANA DE SAUDE - RECIFE - PE - BRASIL;

Background/Introduction: Acute myocardial infarction (AMI) remains a leading cause of morbidity and mortality worldwide, with growing evidence of sex-specific disparities in clinical presentation and outcomes. In Brazil, comprehensive nationwide analyses focusing on women are still limited, particularly regarding temporal trends and regional inequalities. Objectives: To analyze the temporal trends and regional disparities in hospitalization rates and in-hospital mortality due to acute myocardial infarction among women in Brazil, from 2014 to 2024, providing insights into the epidemiology of AMI in this specific population. Methods: This nationwide observational cross-sectional study analyzed secondary data from the Brazilian Unified Health System Hospital Information System (SIH/SUS), accessed via DATASUS. Female patients hospitalized with AMI (ICD-10 code I21) were included. Age-standardized hospitalization rates per 100,000 inhabitants and in-hospital mortality were assessed. Temporal trends were analyzed using Annual Percentage Change (APC) with 95% confidence intervals, and stratified by Brazilian macro-regions. Results and Conclusions: AMI hospitalization rates among women increased significantly over the study period (APC: +5.21%; 95% CI: 4.92–5.50; $p < 0.001$), rising from 45.71 per 100,000 in 2014 to 76.19 in 2024. All regions demonstrated upward trends, with the highest rates observed in the North and Northeast. In contrast, in-hospital mortality declined modestly (APC: −1.46%; $p < 0.001$), decreasing from 11.96% to 10.32%. Marked regional disparities persisted, with consistently higher mortality rates in the Northeast compared to the South. A transient increase in mortality was observed in 2020, coinciding with the COVID-19 pandemic. The burden of AMI among women in Brazil has increased substantially over the past decade, accompanied by only modest improvements in in-hospital mortality. Persistent regional inequalities underscore structural gaps in cardiovascular care delivery. These findings highlight the urgent need for region-specific strategies focused on improving access, early diagnosis, and quality of care for women, particularly in underserved areas.

PROFESSIONAL DETERMINANTS AND GENDER DISPARITIES BETWEEN RECENTLY GRADUATED BRAZILIAN CARDIOLOGISTS.

MARIANA ARAUJO LIMA ELIAS1; RAFAEL HRISTOV TEIXEIRA2; FERNANDA AUGUSTO JUSTO1; AMANDA KAORI ITO1; STELLA AGUIAR TRIGUEIRINHO FERREIRA1; CAROLINE MARTINS FAVERO1; LUIZ APARECIDO BARTOLOTTO1; BRUNO CARAMELLI1;

(1) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE DE BRASILIA - BRASÍLIA - DF - BRASIL;

Background/Introduction: Introduction: Findings on “Medical Demographics in Brazil 2025” (MDB), describe the profile of 20,414 cardiologists in Brazil. In 2019, a study reported the profile of the members of the Brazilian Society of Cardiology (SBC) but the response rate was low (15.6%). This study analyzes the profile of recently graduated cardiologists, highlighting demographic characteristics to identify possible changes in the scenario. Objectives: Objectives: This study aims to establish the profile of cardiologists recently graduated at a reference center (University of São Paulo - USP), identifying predictors of income and structural socioeconomic characteristics. Methods: Methods: A quantitative cross-sectional study was conducted with 376 cardiologists who graduated from USP between 2016 and 2025. Data were collected via a digital questionnaire (30.85% response rate). Analysis employed Chi-square tests (X^2) and Ordinal Logistic Regression Modeling. Findings were compared with data from MDB and a study describing the profile of the members of the SBC. Results and Conclusions:

Logistic regression analysis of income level according to sex and weekly working hours

Predictor	Estimate	Z value	Adjusted Odds Ratio	p value
Weekly Working Hours:				
30 - 40 hours – 20 - 30 hours	0.659	0.610	1.932	0.542
40 - 60 hours – 20 - 30 horas	1.317	1.301	3.731	0.193
60 - 80 hours – 20 - 30 hours	1.710	1.623	5.528	0.105
80 - 100 hours – 20 - 30 hours	2.042	1.748	7.703	0.080
>100 horas – 20 - 30 hours	0.474	0.343	1.607	0.731
Gender:				
Feminino – Masculino	-0.944	-2.198	**0.389**	**0.028**

Results: The sample is mainly young (31-37 years old), with 75.9% lacking postgraduate degrees and 38% practicing exclusively in clinical cardiology; Echocardiography (n=33) is the most prevalent subspecialty. Following the trend shown in MDB, cardiologists were concentrated in the Southeast, followed by the Northeast, South, Central-West, and North regions. Validating the macro-trend, 96.5% of physicians work in private healthcare, which serves as the primary driver for income growth ($p < 0.001$). Respondents were 75% male and 25% female. This gender gap is more pronounced than the national average reported by MDB (64.2% men vs. 35.8% women). Gender inequality was robust, an ordinal regression suggested that gender remains an independent predictor of lower income ($p = 0.028$; OR = 0.389), even after adjusting for weekly workload - which is significantly higher among men; ($p = 0.018$). This inequality aligns with the SBC member’s profile, that shows that 66% of men earn more than R$ 20,000 vs 31% of women. In our study, contrary to expectations, holding a subspecialty title did not provide a significant salary advantage ($p = 0.314$). Conclusion: Despite being performed in one center, our data came from a representative sample from a reference Hospital and suggests that cardiologists’ profile reproduces structural gender barriers and a remuneration model focused on private sector activity, regardless of workload or academic subspecialization.

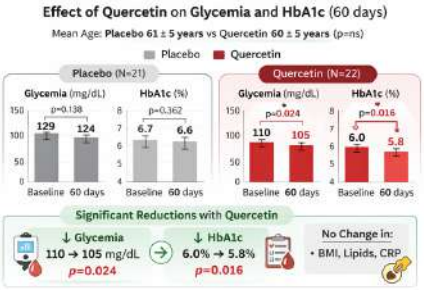
QUERCETIN REDUCES RESIDUAL DYSGLYCEMIA IN POSTMENOPAUSAL WOMEN WITH ESTABLISHED CORONARY ARTERY DISEASE: A RANDOMIZED DOUBLE-BLIND TRIAL.



NATHALIA FERREIRA DE OLIVEIRA FARIA1; JÓSE RAFAEL OLIVEIRA NASCIMENTO,1; KAREN LIKA KUWABARA1; CÉLIA MARIA CASSARO STRUNZ,1; GENI RODRIGUES SAMPAIO2; ELIZABETH APARECIDA FERRAZ DA SILVA TORRES2; ANTONIO DE PADUA MANSUR1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;

Background/Introduction: Postmenopausal women with chronic coronary artery disease (CAD) remain at high residual cardiometabolic risk despite contemporary therapy. Dysglycemia and insulin resistance contribute to endothelial dysfunction, plaque progression, and recurrent events. Although flavonoid-rich diets are associated with metabolic benefits, randomized evidence supporting the use of isolated flavonoid supplementation in secondary prevention is lacking. Quercetin is a bioactive flavonoid with antioxidant and insulin-sensitizing properties. Objectives: To determine whether quercetin supplementation improves glycemic control in postmenopausal women with established atherosclerotic CAD. Methods: In this prospective, randomized, double-blind, placebo-controlled trial, 43 naturally postmenopausal women (<70 years) with angiographically documented CAD (≥70% stenosis in ≥1 major epicardial vessel) were randomized to quercetin 500 mg/day (n=22) or placebo (n=21) for 60 days. All participants completed a 40-day washout of lipid-lowering therapy and maintained their habitual diet. Anthropometric, metabolic, and inflammatory parameters were assessed at baseline and 60 days. Results and Conclusions: Mean age was similar between groups, being 61±5 years in the placebo group and 60±5 years in the quercetin group. At baseline, anthropometric and metabolic parameters were comparable between the groups. In the placebo group, body mass index, glycemia, HbA1c, lipid profile, and C-reactive protein levels remained unchanged after 60 days of follow-up (p>0.05 for all). In contrast, in the quercetin group, glycemia decreased significantly from 110±17 to 105±13 mg/dL (p=0.024) and HbA1c from 6.0±0.70% to 5.8±0.67% (p=0.016). No significant changes were observed in body mass index, triglycerides, total cholesterol, LDL-C, HDL-C, or C-reactive protein levels during the study period (p> 0.05 for all), indicating a glucose-specific metabolic effect independent of weight loss, lipid modulation, or systemic inflammation. No adverse metabolic signals were observed. In postmenopausal women with established CAD, short-term quercetin supplementation significantly improved glycemic control without affecting weight or lipids. These findings provide randomized evidence that a single bioactive flavonoid can directly target residual dysglycemia in secondary prevention.

Table. Body Mass Index (BMI) and Laboratory Parameters in Placebo and Quercetin Groups.

Parameters	Placebo Group (N=21)			Quercetin Group (N=22)		
	Baseline	60 days	p	Baseline	60 days	p
BMI (Kg/m²)	29.69±5.61	29.60±5.44	0.976	28.38±6.12	28.55±5.90	0.325
Glycemia (mg/dL)	129±58	124±60	0.138	110±17	105±13	0.024
HbA1c (%)	6.7±1.8	6.6±1.8	0.362	6.0±0.70	5.8±0.67	0.016
Triglycerides (mg/dL)	154±61	155±54	0.924	155±76	151±86	0.736
Total cholesterol (mg/dL)	231±41	242±54	0.198	235±64	253±61	0.139
LDL-C (mg/dL)	151±36	161±48	0.214	152±53	169±52	0.123
HDL-C (mg/dL)	50±12	51±16	0.476	52±13	53±13	0.118

TYPE OF MENOPAUSE AND HEART FAILURE RISK IN WOMEN: A SYSTEMATIC REVIEW OF OBSERVATIONAL STUDIES

FRANCISCA BEATRIZ DOS SANTOS MAIA BEATRIZ MAIA1;

(1) CENTRO UNIVERSITARIO UNIDOMPEDRO - SALVADOR - BA - BRASIL;

Background/Introduction: Heart failure is a major cause of cardiovascular morbidity and mortality in women. The menopausal transition has been recognized as a period of accelerated cardiovascular risk, and surgical menopause may further modify this risk because of the abrupt decline in ovarian hormone production. This study aimed to synthesize the available evidence on the association between type of menopause, particularly natural versus surgical menopause, and heart failure outcomes in women. Objectives: This study aimed to synthesize the available evidence on the association between type of menopause, particularly natural versus surgical menopause, and heart failure outcomes in women. Methods: A systematic review of observational studies was conducted according to PRISMA 2020. Cohort and case-control studies evaluating natural menopause, surgical menopause, bilateral oophorectomy, or age at menopause in relation to heart failure outcomes were considered. The primary outcome was incident heart failure. Secondary outcomes included heart failure hospitalization and heart failure phenotype, when available. Results and Conclusions: Available evidence suggests that surgical menopause is associated with a less favorable cardiovascular profile than natural menopause, although direct evidence specifically focused on heart failure remains limited. In a recent meta-analysis of cardiovascular outcomes after bilateral oophorectomy, surgical menopause was associated with a higher risk of heart failure compared with controls (pooled HR 2.25, 95% CI 1.15–4.41). In addition, the American Heart Association scientific statement highlights surgical menopause as a relevant reproductive factor in cardiovascular risk assessment. Earlier cohort data also indicate that younger age at menopause, including surgical menopause, is associated with increased incident heart failure risk. However, the literature remains heterogeneous regarding exposure definitions, menopausal subtype, age at surgery, covariate adjustment, and heart failure phenotyping. Current evidence suggests that surgical menopause may be associated with greater heart failure risk than natural menopause, but direct comparative data remain limited. Menopausal history, particularly surgical menopause and age at menopause, may represent relevant sex-specific factors in cardiovascular risk stratification. Further studies are needed to clarify differences according to natural versus surgical menopause and heart failure phenotype.

A NEW MURMUR AFTER INFERIOR STEMI: ATYPICAL VENTRICULAR SEPTAL RUPTURE AND CARDIOGENIC SHOCK FROM RIGHT CORONARY ARTERY OCCLUSION

GUILHERME SILVA MENDES GAIA1; DANIEL BISI DE BORTOLI VALLE1; GABRIELA CALANCA1; LOUISE SALVES DA SILVA1; APARECIDA DE GOUVEA1; MIGUEL TAKAO YAMAWAKI MURATA1; CLARA BERNARDY DOS SANTOS1; WILMA NOIA RIBEIRO1; GABRIEL MANDARINI DOHO1; GABRIEL CAVALCANTE LIMA CHAGAS2; BRUNO ALCOVA NOGUEIRA1; NATHALIA SCHETTINO SAMAD3;

(1) UNIFESP - UNIVERSIDADE FEDERAL DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) CLEVELAND CLINIC FOUNDATION - UNITED STATES; (3) NEW YORK UNIVERSITY - UNITED STATES;

Introduction: Post–myocardial infarction ventricular septal rupture (VSR) is a rare mechanical complication of acute myocardial infarction, with an incidence of 0.1% to 0.4%, reduced in the reperfusion era. Despite this, it remains associated with high mortality, approaching 100% in the absence of intervention. It is classically associated with infarctions involving the left anterior descending artery (LAD); however, cases related to right coronary artery (RCA) occlusion are less frequent. We report a case of VSR secondary to RCA occlusion, highlighting the importance of early recognition of this potentially fatal complication Case Description: A 66-year-old man, a former smoker (47 pack-years), with no known comorbidities or family history of cardiovascular or cerebrovascular disease, was diagnosed with a ST-segment elevation myocardial infarction of the inferior wall. He initially underwent thrombolysis (no angiography feasible) without evidence of reperfusion and was subsequently referred for coronary angiography, which revealed significant lesions in the RCA (80% proximal and 90% distal stenosis) without other obstructive disease. Two drug-eluting stents were successfully implanted. Transthoracic echocardiography (TTE) demonstrated a reduced left ventricular ejection fraction (41%) with akinesia of the inferolateral wall, mid and basal segments of the inferior wall, and the basal inferoseptal segment. The patient was started on guideline-directed medical therapy and discharged a week later. On the following day, he presented with chest pain similar to the initial event, though less intense, associated with nausea. He remained hemodynamically stable, with downtrending troponin levels. On physical examination, a new holosystolic murmur was noted at the lower left sternal border. Repeated TTE revealed a 17 mm ventricular septal rupture in the mid-basal septum with a left-to-right shunt, along with hypokinesia of other ventricular segments. The patient subsequently developed cardiogenic shock, requiring dobutamine and supplemental oxygen, and was referred for urgent surgical repair. Postoperatively, the patient evolved with hemodynamic stability on optimized medical therapy. Follow-up TTE confirmed successful repair, and he remained stable during outpatient follow-up Conclusions: Post–MI ventricular septal rupture is rare but highly lethal. Although typically linked to LAD infarction, it can occur with right coronary occlusion and early recognition and intervention are critical to improve outcomes.

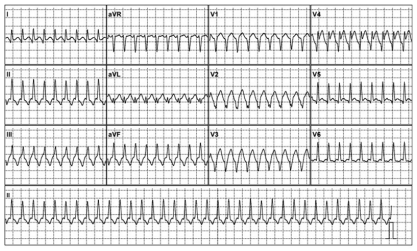
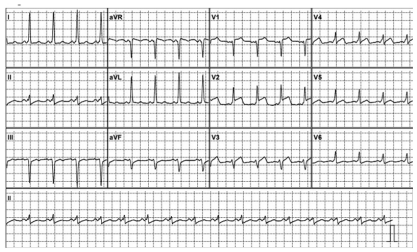
ACUTE CORONARY OCCLUSION MASKED BY SUPRAVENTRICULAR TACHYCARDIA IN A PATIENT WITH WOLFF-PARKINSON-WHITE SYNDROME: A DIAGNOSTIC CHALLENGE



JOÃO FELIPE OLIVEIRA SANTOS1; LAURA MARIA DE SORDI RIGAMONTI1; VILIAN VELOSO DE MOURA FÉ1; MARCELO CUNHA DE FREITAS COSTACURTA1; LUIS FELIPE CHAGA MARONEZI1; MATHEUS ABREU DE SOUSA SANTOS1; VÍTOR CERCAL DE OLIVEIRA1; BARBARA CAPRIOLI PAGAN YEPES PEREIRA1; GUSTAVO BANDONI TRABULSI1; ELTON ANSELMO PURGATO JUNIOR1; PAULO ROGÉRIO SOARES1; JOSÉ ROBERTO DE OLIVEIRA SILVA FILHO1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;



Introduction: The occurrence of Acute Coronary Occlusion (ACO) concomitant with supraventricular tachyarrhythmias is a rarely described entity. While literature reports ST-segment depression and Type 2 myocardial infarction during supraventricular tachycardias (SVT), the manifestation of a Type 1 Infarction (ACO) associated with an accessory pathway is scarce. In Wolff-Parkinson-White (WPW) syndrome, secondary repolarization changes can mimic or mask primary injury currents, requiring a high clinical suspicion to avoid misdiagnosis of non-ischemic injury. Case Description: A 55-year-old male presented with typical chest pain and diaphoresis. The initial ECG showed orthodromic Atrioventricular Reentrant Tachycardia (AVRT) with associated ST-segment elevation. Following adenosine-induced reversal, the baseline ECG revealed persistent ST-segment elevation in the anterior wall, superimposed on a pre-excitation pattern consistent with a right posteroseptal accessory pathway. Fibrinolytic therapy was initiated, and subsequent coronary angiography confirmed a 95% sub-occlusion of the distal left anterior descending artery, treated with a drug-eluting stent (TIMI III). The patient later underwent successful ablation of the posteroseptal pathway. Conclusions: Persistent ST-segment elevation after SVT reversal is a crucial marker of true ischemia, differentiating it from functional tachyarrhythmia changes. In WPW syndrome — analogous to left bundle branch block — the lack of validated algorithms for myocardial infarction diagnosis makes dynamic ECG analysis and clinical correlation determinant. In this case, the prompt identification of ACO, despite the morphological distortions of the accessory pathway, was decisive for the efficacy of reperfusion therapy.

Coronary angiography revealed a 70% stenosis in the proximal segment and a 95% stenosis in the distal third of the left anterior descending artery

Initial ECG showing orthodromic Atrioventricular Reentrant Tachycardia (AVRT) with associated ST-segment elevation

Post-adenosine ECG revealed persistent ST-segment elevation in the anterior leads, superimposed on a pre-excitation pattern consistent with a right posteroseptal accessory pathway

Introduction: The use of anabolic-androgenic steroids (AAS) for aesthetic or performance-enhancing purposes represents a growing public health concern, with an estimated prevalence of 4–6% among resistance training practitioners. AAS users have an approximately three-fold higher risk of acute myocardial infarction (AMI) and up to a nine-fold higher risk of cardiomyopathies. This case series describes the clinical presentation and outcomes of five male patients, AAS users, admitted for AMI at a teaching hospital in São Paulo in 2025. This is a retrospective analysis of clinical, electrocardiographic, laboratory, and angiographic data. Case Description: In this sample, the mean age was 36.8 years (range: 30–47 years), and no high-performance athletes were included. None of the patients had comorbidities. All presented with anginal chest pain, troponin levels above the 99th percentile with a significant delta, and ECG findings meeting criteria for acute coronary occlusion: three cases with ST-segment elevation, one with the De Winter pattern, and one with hyperacute T-waves. Only one patient received thrombolytic therapy in their city of origin. All patients reported using injectable AAS at supraphysiological doses, despite significant imprecision regarding dosages and formulations (testosterone derivatives and trenbolone). Angiography revealed heterogeneous presentations: thrombotic occlusion without atherosclerosis (Figure 1), classic obstructive atherosclerosis (Figure 2), mixed etiology, and coronaries without obstructive lesions, suggesting spasm or prior thrombus lysis. Two patients progressed with left ventricular systolic dysfunction, one moderate and one severe. The latter experienced cardiac arrest due to ventricular fibrillation upon admission, with return of spontaneous circulation after resuscitation, requiring mechanical ventilation, vasoactive drugs, inotropes, and renal replacement therapy. The mean hematocrit was 48.1% (range: 40–61%), with the highest value recorded in the most severe case of the series. The mean LDL was 99 mg/dL. There were no deaths. The absence of comorbidities in this sample reinforces AAS use as the primary etiopathogenic factor. Conclusions: This series highlights the impact of systemic hormonal exposure to AAS—frequently underestimated—as a trigger for a prothrombotic state and coronary instability, predisposing young individuals to severe ischemic events even in the absence of traditional cardiovascular risk factors.

Figure 1: Coronary angiography image demonstrating acute total occlusion of the proximal third of the left anterior descending artery, with a large thrombus burden observed after guidewire passage.

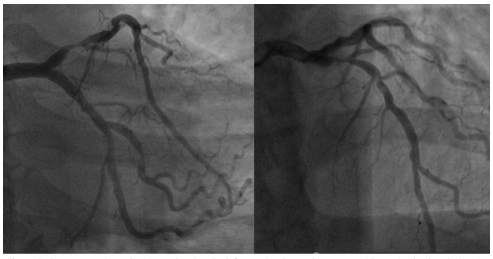

Figure 2: Coronary angiography image showing the left anterior descending artery with proximal subocclusion, in addition to mild/moderate lesions in the remainder of the demonstrated territory.

ACUTE MYOCARDIAL INFARCTION WITH HIGH THROMBOTIC BURDEN IN A PATIENT WITH KLINEFELTER SYNDROME: PATHOPHYSIOLOGICAL IMPLICATIONS AND THE ROLE OF TESTOSTERONE REPLACEMENT THERAPY

MARCELA MENEZES AMARAL1; LORENA DE SOUZA CARVALHO1; FABIO AUGUSTO MARTINS DE ABREU1; LAIS GABRIELLY SILVEIRA DIAS1; HENRIQUE DIAS COELHO CUNHA1; RAFAEL MARCOS ERSE1; BARBARA CAMPOS ABREU MARINO1;

(1) HOSPITAL MADRE TERESA - BELO HORIZONTE - MG - BRASIL;

Introduction: Klinefelter syndrome (47,XXY) is associated with increased thromboembolic risk, possibly related to hypogonadism, endothelial dysfunction, and procoagulant alterations. In acute myocardial infarction, cases with high thrombotic burden and no obstructive coronary disease represent a diagnostic and therapeutic challenge, particularly regarding the role of testosterone replacement therapy. Case Description: A 44-year-old man with hypertension, dyslipidemia, obesity, smoking history, Klinefelter syndrome (47,XXY), and hypogonadism, previously on testosterone replacement therapy, which had been discontinued after a prior myocardial infarction without significant coronary lesions, was admitted with typical chest pain and inferior ST-segment elevation myocardial infarction. Coronary angiography demonstrated the absence of obstructive atherosclerotic disease, but revealed distal right coronary artery occlusion associated with coronary ectasia and a high thrombotic burden. Percutaneous coronary intervention with thrombus aspiration was performed, achieving final TIMI 3 flow, although residual thrombus remained. The patient evolved clinically stable, with preserved left ventricular ejection fraction. The angiographic pattern associated with coronary ectasia suggests a non-atherosclerotic mechanism related to blood stasis and a prothrombotic state. Klinefelter syndrome is recognized as a condition associated with increased thromboembolic risk, possibly mediated by endothelial dysfunction and metabolic abnormalities. Although testosterone replacement therapy raises concerns regarding cardiovascular risk, recent evidence has not demonstrated a consistent increase in thrombotic events and may even improve the metabolic profile. Recurrence of the event despite discontinuation of hormonal therapy reinforces the role of the underlying condition as the main determinant of thrombotic risk. An individualized strategy with clopidogrel for 1 year and anticoagulation was adopted, with favorable clinical evolution and thrombus resolution on follow-up angiography. Conclusions: This case highlights a thrombotic-profile AMI in a patient with Klinefelter syndrome without obstructive coronary artery disease, suggesting a central role of the prothrombotic state associated with the underlying condition. Recurrence of the event regardless of TRT reinforces the need for an individualized approach, including anticoagulation, and for a broader perspective on the impact of hormonal replacement therapy in these patients.

ANOMALOUS RIGHT CORONARY ARTERY WITH INTERARTERIAL COURSE: A MALIGNANT VARIANT PRESENTING WITH SUDDEN CARDIAC ARREST

PEDRO VIANA DINIZ1; JÚLIA MOREIRA DINIZ2; PEDRO HENRIQUE MILAGRES1; BIANCA ITUASSU MAPA NONATO VICENTE GALLO1; JOSÉ HENRIQUE DE OLIVEIRA E OLIVEIRA1; ROCHELLE COPPO MILITÃO RAUSCH1; THAÍS LANY DE OLIVEIRA LEÃO1; GIOVANNI HENRIQUE SOARES DE ARAÚJO1; GABRIEL BRANT MOREIRA FERREIRA2; GUSTAVO CAMPOS SABINO2; MATHEUS FERBER DRUMOND1; GABRIELA ZAMUNARO LOPES RUIZ1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introduction: Coronary artery anomalies are rare and usually benign. However, variants like interarterial course between the aorta and pulmonary artery above the pulmonary valve are considered malignant since they are associated with myocardial ischemia and sudden cardiac death in young individuals. Anomalous origin of the right coronary artery from the left sinus of Valsalva represents a high-risk subtype, especially when associated with features such as acute take-off angle and proximal compression. Case Description: A 22-year-old previously healthy male presented after out-of-hospital sudden cardiac arrest preceded by emotional distress. Initial rhythm was ventricular fibrillation, with return of spontaneous circulation after 26 minutes of cardiopulmonary resuscitation. The patient had a prior history of unexplained syncope seven months earlier and reported use of cocaine, suggesting a possible vasospastic trigger. Upon admission, the patient exhibited impaired level of consciousness consistent with post-resuscitation encephalopathy. Initial electrocardiography showed ST-segment elevation in inferior and lateral leads, which resolved spontaneously. Coronary angiography revealed no obstructive lesions but identified an anomalous right coronary artery (RCA) arising from the left coronary sinus, with suspected proximal extrinsic compression. Coronary computed tomography angiography confirmed an interarterial course of the RCA between the aorta and pulmonary artery, with acute take-off angle and proximal narrowing consistent with suspected extrinsic compression. The patient was admitted to the cardiac intensive care unit and remained hemodynamically stable after initial support. Subsequently, surgical correction with transposition of the RCA, including creation of a neo-ostium in the right coronary sinus was performed. The postoperative course was uneventful, with complete neurological recovery upon hospital discharge 8 days after surgery. Conclusions: Malignant coronary artery anomalies should be considered in young patients presenting with sudden cardiac arrest without evidence of atherosclerotic disease. This case underscores the importance of recognizing warning symptoms, such as unexplained syncope, which may precede life-threatening events. Timely diagnosis and appropriate surgical management are essential to prevent fatal outcomes.

BETWEEN SURGICAL AND THROMBOEMBOLIC RISK: MANAGEMENT OF GIANT CORONARY ARTERY ANEURYSM

THAÍNE INÁCIO DE MENDONÇA1; MATHEUS HENRIQUE DE JESUS LIMA1; ROBERTA ABRÃO PACHECO RODRIGUES DE QUEIROZ1; MATHEUS FERREIRA GONÇALVES1; TAÍS LORRANE MENDES SILVA CRISTOVÃO1; VINICIUS RODRIGUES FRANÇA1; AGUINALDO F FREITAS JUNIOR1;

(1) UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL;

Introduction: Coronary artery aneurysms (CAA) are rare conditions, defined as dilatations exceeding 1,5 times the diameter of the adjacent vessel. In adults, atherosclerosis is the main etiology, although vasculitis and Kawasaki disease should be considered in the differential diagnosis. Clinical management is challenging due to the lack of robust guidelines and randomized clinical trials, particularly when giant aneurysms are associated with obstructive coronary artery disease and clinical frailty. Case Description: A 73-year-old male, former smoker, hypertensive, with stage G3b chronic kidney disease and prior prostate cancer (2023), was evaluated preoperatively for knee arthroplasty. He reported stable angina (CCS II) and dyspnea (NYHA II) for two years. Investigation revealed bilateral popliteal artery aneurysms (19 and 26 mm). Cardiac evaluation showed a 90% proximal lesion in the left anterior descending artery (LAD) and a giant (>20 mm) fusiform aneurysm in the right coronary artery (RCA) with mural thrombi. Despite low surgical risk scores (EuroSCORE II 2.33%; STS 1.01%), he was moderately frail (Clinical Frailty Scale = 6). After Heart Team discussion, surgery was deemed high risk considering age, frailty, and comorbidities. A less invasive strategy was adopted: percutaneous coronary intervention (PCI) of the LAD and conservative management of the RCA aneurysm. Medical therapy included statins, beta-blockers, and dual antithrombotic therapy (low-dose aspirin and warfarin, INR 2.0–3.0). The challenge of choosing between cardiac surgery and long-term anticoagulation in elderly patients lies in balancing thromboembolic risk against bleeding risk. Frailty, fall risk, and multiple comorbidities further complicate anticoagulation management, while surgical risk is also increased in this population, requiring individualized decision-making that considers life expectancy and quality of life. The patient improved clinically, without thrombotic or hemorrhagic events on follow-up. Conclusions: This case highlights the complexity of managing giant coronary artery aneurysm associated with advanced atherosclerotic disease in a frail elderly patient. It underscores the limitations of traditional risk scores and the importance of individualized, Heart Team–based decision-making. In selected cases, percutaneous intervention of the culprit lesion combined with anticoagulation for the aneurysm may represent a safe and effective alternative to conventional surgery.

BEYOND THE MISSING PULSE: CORONARY-SUBCLAVIAN STEAL PRESENTING AS REFRACTORY ANGINA AND PRESYNCOPE IN A POST-CABG PATIENT

ALEXANDRE DINIZ MENDES DA SILVA1; ALICE MONTEIRO SOARES CAJAIBA SOARES1; ANTONIO DOSUALDO NETO1; AMANDA MAGNAGO FACCINI1; EDUARDO JUNIOR PAIVA ARNEZ1; MARCELO HENRIQUE BARBOSA1; ANDRE MELLO GERHARDT1; SORAIA RACHID YOUSSEF DE CAMPOS1; VALERIA MOZETIC DE BARROS1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction: Coronary-subclavian steal syndrome (CSSS) is an underrecognized complication in patients who underwent coronary artery bypass grafting (CABG) using a left internal mammary artery (LIMA) graft. It occurs when proximal left subclavian artery stenosis reverses LIMA graft flow, diverting blood away from the coronary circulation. Clinical manifestations include refractory angina, heart failure decompensation, presyncope, and upper limb ischemia — findings often misattributed to native disease progression or graft failure. Case Description: A 57-year-old woman with hypertension, dyslipidemia, and former smoking presented with refractory angina (CCS II–III), NYHA class III heart failure, presyncope, and absent left upper limb pulse. In 2023, she suffered a non-ST-elevation myocardial infarction and underwent CABG with a LIMA-to-LAD graft and a saphenous vein graft to the marginal branch, subsequently developing ischemic cardiomyopathy with reduced ejection fraction. Echocardiography showed moderate left ventricular systolic dysfunction, diffuse mid-distal akinesia, and an apical aneurysm. Repeat catheterization revealed a patent aorto-marginal venous graft, severe ostial stenosis of the right coronary artery, and significant stenosis at the origin of the left subclavian artery — identified as the cause of CSSS compromising LIMA graft flow. After multidisciplinary discussion, the patient underwent elective percutaneous transluminal angioplasty with stent implantation in the left subclavian artery. Given documented paroxysmal atrial fibrillation and prior rivaroxaban use, dual therapy with oral anticoagulation and clopidogrel was maintained for three months. At follow-up, she demonstrated complete resolution of angina, improvement to NYHA class II, and restoration of the left radial pulse. Conclusions: This case highlights that absent or asymmetric upper limb pulses may be the critical diagnostic clue in post-CABG patients with refractory angina. Bilateral blood pressure measurement and pulse assessment should be part of routine evaluation in this population, ensuring a potentially correctable extracardiac cause is not overlooked. Percutaneous subclavian revascularization proved effective, with outcomes comparable to open surgical repair.

MEDIASTINAL MASS WITH PERICARDIAL EFFUSION AND SEVERE PULMONARY HYPERTENSION AS THE INITIAL MANIFESTATION OF PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA

MÁRYA DUARTE PAGOTTI1; VICTOR BEMFICA DE MELLO MATTOS1; FERNANDA MARTINS HONÓRIO1; ARTHUR FELIPE MACIEL DE LIMA1; ISMAR JUNIOR PEINALDO LJERON1; PEDRO RICARDO UBIRAJARA FRANZON1; MÔNICA FRANCISCHINI1; BÁRBARA DALTRO MARQUES PACKER1; ANTÔNIO CARLOS MUGAYAR BIANCO1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction: Pericardial effusion may be the initial manifestation of severe underlying conditions, particularly in young patients with unexplained hemodynamic instability. Mediastinal masses, especially lymphomas, may present with pericardial effusion, secondary pulmonary hypertension due to extrinsic vascular compression, and cardiopulmonary compromise. Case Description: A 31-year-old man with a history of alcohol use, illicit drug use, and previously treated pulmonary tuberculosis presented with progressive dyspnea, chest pain, and lower-limb edema. Transthoracic echocardiography showed a large pericardial effusion with cardiac tamponade, requiring surgical pericardial drainage. Despite drainage, the patient developed cardiogenic shock, severe pulmonary hypertension, and acute respiratory failure, requiring orotracheal intubation and intensive care support. Chest computed tomography revealed a large mediastinal mass measuring 10 × 6 cm, compressing the pulmonary trunk and its main branches. Pericardiectomy, pericardial biopsy, and mediastinal biopsy were performed. Histopathological analysis confirmed the diagnosis of primary mediastinal large B-cell lymphoma. The patient underwent initial cytoreductive therapy followed by rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone chemotherapy, with an early favorable clinical response. Conclusions: This case highlights the diagnostic and therapeutic complexity of cardiac tamponade associated with severe pulmonary hypertension secondary to extrinsic vascular compression. In this setting, pericardial drainage may paradoxically worsen hemodynamic instability, requiring close monitoring and multidisciplinary management. Early recognition of mediastinal mass syndrome and prompt initiation of specific oncologic therapy are essential to reduce complications and improve outcomes.

RECURRENT ACUTE CORONARY SYNDROME IN A YOUNG PATIENT WITH DIFFUSE CORONARY ECTASIA AND CLOPIDOGREL RESISTANCE

MATEUS COELHO PAIVA1; MARCELO PASQUALI PEIXOTO1;

(1) HOSPITAL REGIONAL DA REGIÃO LESTE - BRASÍLIA - DF - BRASIL;

Introduction: Acute coronary syndrome (ACS) in young patients frequently involves non-atherosclerotic mechanisms. Coronary ectasia, defined as dilation of a coronary segment ≥1.5 times the adjacent vessel diameter, is an uncommon but clinically relevant condition. It significantly alters coronary hemodynamics, leading to reduced flow velocity, turbulence, and blood stasis, which promote platelet activation and intracoronary thrombosis. Additionally, variability in response to antiplatelet therapy, particularly clopidogrel resistance related to impaired metabolic activation, may further increase thrombotic risk and contribute to recurrent ischemic events. Case Description: A 35-year-old male with hypertension, dyslipidemia, obesity, and type 2 diabetes mellitus presented with acute chest pain associated with dyspnea and diaphoresis. Electrocardiogram showed nonspecific repolarization abnormalities, and high-sensitivity troponin was elevated, consistent with non-ST elevation myocardial infarction. Coronary angiography revealed diffuse coronary ectasia with aneurysmal dilation involving the left anterior descending and right coronary arteries, with a large thrombus burden in the proximal left anterior descending artery, without significant stenosis. Initial management included tirofiban infusion, anticoagulation, and dual antiplatelet therapy with aspirin and clopidogrel, with clinical improvement. Ten months later, the patient presented with recurrent chest pain and elevated troponin. Repeat angiography demonstrated recurrent intracoronary thrombosis in the same territory. Platelet function testing revealed high on-treatment platelet reactivity, confirming clopidogrel resistance. Therapy was switched to ticagrelor, resulting in clinical stabilization. Conclusions: Coronary ectasia represents an important non-atherosclerotic cause of ACS in young patients due to its prothrombotic hemodynamic profile. The coexistence of clopidogrel resistance may significantly increase the risk of recurrent events by impairing platelet inhibition. Platelet function testing is a valuable tool for identifying inadequate therapeutic response and guiding treatment optimization. The use of more potent P2Y12 inhibitors, such as ticagrelor, may improve outcomes in selected patients. An individualized approach, integrating anatomical findings and pharmacodynamic response, is essential to reduce recurrence and improve prognosis.

TAKOTSUBO SYNDROME ASSOCIATED WITH SIGNIFICANT CPK ELEVATION AND ADRENAL INSUFFICIENCY: A POSSIBLE SYSTEMIC MANIFESTATION OF A CATECHOLAMINE STORM

LÍLIA MARIA BERSI1; MARIANA PIVA MESQUITA1; VICTOR DE MORAES1; LIVIA CAGLIONI1; MARCELA TANAKA1; LARA AVELAR1; ENRICO SENEME2;

(1) FACULDADE DE MEDICINA DE MARILIA - MARÍLIA - SP - BRASIL; (2) HOSPITAL DAS CLINICAS DA FACULDADE DE MEDICINA DE MARILIA - MARÍLIA - SP - BRASIL;

Introduction: Takotsubo syndrome is a transient cardiomyopathy, triggered by physical or emotional stress, characterized by a reversible left ventricular dysfunction and a clinical presentation similar to acute coronary syndrome. Although it is considered a predominantly cardiac condition, recent evidence suggests systemic inflammatory mechanisms and a catecholamine surge is involved in its pathophysiology. We report a case of Takotsubo syndrome associated with a significant elevation of creatine phosphokinase (CPK) and progression to adrenal insufficiency. Case Description: A 55-year-old female patient with poorly controlled diabetes was admitted with severe lower limb pain for two days, associated with difficulty walking. On admission, she presented sudden retrosternal chest pain. Laboratory tests showed CPK 11,972 U/L, CK-MB 532 U/L, and elevated troponin levels. The electrocardiogram revealed diffuse T-wave inversion, the echocardiography also revealed left ventricular systolic dysfunction with apical akinesia and basal hypercontractility, with an estimated ejection fraction of 38%, and the coronary angiography showed no obstructive coronary artery disease, findings consistent with Takotsubo syndrome. Initially misdiagnosed as rhabdomyolysis, intravenous hydration was iniciated. The patient developed with severe hypoglycemia, hypotension, hyponatremia, requiring vasopressor support. Due to these symptoms, an endocrine investigation was performed, revealing undetectable serum cortisol levels, which confirmed adrenal insufficiency. After intensive treatment and hydrocortisone replacement, the patient achieved clinical stabilization and progressive recovery. Conclusions: Takotsubo syndrome may present systemic manifestations associated with an inflammatory response and a catecholamine surge. The marked elevation of CPK suggests possible systemic muscle injury related to a hypercatecholaminergic state and raises the hypothesis that this enzyme may serve as a marker of poor prognosis, thereby potentially contributing to improved clinical management. The association with adrenal insufficiency is rare and poorly described in the literature, raising the possibility of a pathophysiological interaction between glucocorticoid deficiency and myocardial vulnerability to stress. The recognition of these manifestations may contribute to a better understanding of the pathophysiology and clinical management of this syndrome.

ADDITIONAL LEAD IN THE AZYGOS VEIN: A STRATEGY TO REDUCE DEFIBRILLATION THRESHOLD IN A PATIENT WITH AN IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR.

RAFAELLA BARBOSA DE ASSUNÇÃO ALVES1; LUCAS CARVALHO DIAS1; VITOR BASTOS LOVISI1; ANDRE LUIS PAIS MOREIRA1; MARCELLE PEREIRA DE MENEZES CAMARA1; LEONARDO NANES CORREA DOS SANTOS1; LUIZ EDUARDO MONTENEGRO CAMANHO1;

(1) HOSPITAL PRO CARDIACO - RIO DE JANEIRO - RJ - BRASIL;

Introduction: The implantable cardioverter-defibrillator (ICD) is essential in the prevention of sudden death in patients with structural heart disease. Elevated defibrillation threshold (DFT) represents a challenging condition, associated with increased risk of therapeutic failure and worse prognosis, requiring early identification and appropriate management. Case Description: A 62-year-old male patient with non-ischemic dilated cardiomyopathy secondary to post-myocarditis, with heart failure with reduced ejection fraction (NYHA functional class III), on optimized pharmacological therapy. He had a biventricular ICD implanted for primary prophylaxis of sudden death seven years prior, as well as atrioventricular node ablation due to atrial fibrillation with high ventricular response. Echocardiography revealed severe biventricular systolic dysfunction, with an ejection fraction of 17% (Simpson method). The patient developed recurrent episodes of convulsive syncope and multiple device therapies. ICD analysis demonstrated a ventricular tachycardia episode in the ventricular fibrillation zone, with delivery of seven shocks at maximum energy (41 J), all ineffective, with reversion only after the eighth shock, characterizing an elevated defibrillation threshold. Given the clinical picture and the prospect of cardiac transplantation, additional lead implantation in the azygos vein was performed. Subsequent defibrillation testing demonstrated effective reversion with a 41 J shock. The patient was followed on an outpatient basis for 10 months, without recurrence of arrhythmic events or inappropriate therapies. Conclusions: Elevated defibrillation threshold occurs in a subset of ICD patients and represents a major therapeutic challenge. Factors such as advanced cardiomyopathy, significant ventricular remodeling, and antiarrhythmic drug use may contribute to its occurrence. The addition of leads to the defibrillation system is an effective strategy for modifying the shock vector, increasing the probability of successful reversion of malignant arrhythmias. In this context, azygos vein lead implantation emerges as an uncommon yet potentially useful alternative in selected cases, with a favorable impact on clinical outcomes.

ARRHYTHMIC MITRAL VALVE PROLAPSE IN MARFAN SYNDROME WITH A CONCOMITANT PATHOGENIC LMNA VARIANT: AN OVERLAP SUBSTRATE FOR SUDDEN CARDIAC ARREST

MÁRYA PAGOTTI1; SÁVIA BUENO1; MYLENA IDETA1; BRUNO STEPHAN1; BIANCA LINNENKAMP1; EDUARDA ENGLERT1; BRUNO MOREIRA DOS SANTOS1; NATÁLIA OLIVETTI1; FRANCISCO DARRIEUX1; MAURICIO SCANAVACCA1; JOSÉ EDUARDO KRIEGER1; LUCIANA SACILOTTO1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction: Sudden cardiac arrest (SCA) in young athletes requires evaluation integrating phenotype, imaging, exercise testing, family history, and genetic testing. Arrhythmic mitral valve prolapse (AMVP) is a substrate for malignant ventricular arrhythmias, particularly in female patients with bileaflet prolapse, myocardial fibrosis, and complex complex premature ventricular contractions (PVCs). Overlapping inherited conditions may modify risk. Case Description: A 20-year-old professional volleyball player presented with SCA due to a shockable rhythm while walking between volleyball matches and survived after prolonged resuscitation. An implantable cardioverter-defibrillator was placed for secondary prevention. Her father had exertional sudden cardiac death (SCD) at age 43 and atrial fibrillation (AF). The paternal history included heart failure, SCD, pacemaker, AF, and myocardial fibrosis in relatives with an LMNA-related phenotype; the maternal lineage suggested Marfan syndrome, with several relatives requiring surgery for aortic ectasia. Examination showed marfanoid habitus and a systemic score compatible with Marfan syndrome. ECG showed atrial pacing, mildly prolonged QRS, fragmented low-voltage QRS in lateral leads, and normal QTc. Echocardiography demonstrated bileaflet MVP, moderate mitral regurgitation, and preserved left ventricular function. Cardiac magnetic resonance showed preserved biventricular function, MVP with pseudo-mitral annular disjunction, and extensive ring-like myocardial fibrosis, with anterior/inferolateral subendocardial-transmural involvement and mid-wall basal septal enhancement. Exercise testing induced frequent polymorphic PVCs, including couplets, suggestive of mitral apparatus origin; convex ST-segment depression in inferior and lateral leads, with T-wave inversion, was also observed. Genetic testing identified a pathogenic truncating LMNA variant [c.1560G>A; p.(Trp520*)] and a likely pathogenic FBN1 variant [c.5825G>A; p.(Cys1942Tyr)]. Conclusions: Coexistence of FBN1-related AMVP and a truncating LMNA variant may generate a double-hit phenotype, combining mechanical mitral triggers with inherited myocardial fibrosis and electrical vulnerability. In this patient, SCA was plausibly triggered by AMVP before full age-dependent penetrance of LMNA-related cardiomyopathy. This case highlights the role of genetic testing and precision medicine in refining diagnosis, guiding family screening, and individualizing management.

ARRHYTHMOGENIC PHENOTYPE OF MITRAL VALVE PROLAPSE IN A YOUNG PREGNANT WOMAN PROGRESSING TO ABORTED SUDDEN CARDIAC DEATH: APPROACH WITH SUBCUTANEOUS ICD WITHOUT FLUOROSCOPY

TALITA DÂMARIS OLIVEIRA DA SILVA1; ALAYNE SOUSA MIRANDA ÁVILA1; FILIPE RAMON ANGELO MATIAS1; ANDRES PAULO ANDIA DO NASCIMENTO2; RAFAEL MICHEL DE MACEDO1; VINICIUS NICOLAU WOITOWICZ1; SERGIO GUSTAVO TARBINE1; COSTANTINO COSTANTINI ORTIZ1; MARIA DANNIELLA GIROTO1; LEONARDO IEZZI DE MORAES2; MARCIO MORENO LUIZE1; COSTANTINO ROBERTO COSTANTINI FRACK1;

(1) HOSPITAL CARDIOLÓGICO COSTANTINI - CURITIBA - PR - BRASIL; (2) HOSPITAL COSTANTINI COSTANTINO - CURITIBA - PR - BRASIL;

Introduction: Mitral annular disjunction (MAD) is a structural abnormality characterized by separation of the insertion point of the posterior mitral leaflet from the ventricular wall, allowing systolic displacement of the annulus. It is strongly associated with mitral valve prolapse and malignant ventricular arrhythmias and sudden cardiac death (SCD), composing the spectrum of arrhythmogenic MVP. The pathophysiology involves chronic mechanical stress on papillary muscles and the inferobasal left ventricular wall, leading to fibrosis and formation of a reentry substrate. Risk stratification integrates clinical, electrocardiographic, and imaging findings. High-risk features include syncope, NSVT/complex ventricular ectopy on Holter, inferior T-wave inversion, late gadolinium enhancement on cardiac magnetic resonance (CMR), and, on echocardiography, bileaflet prolapse, valvular redundancy, greater MAD extent, and Pickelhaube sign. Management is risk-guided: in high-risk patients, implantable cardioverter-defibrillator (ICD) is indicated; ablation and mitral valve surgery are options in selected cases. Case Description: A 27-year-old female with MVP since childhood and initially mild mitral regurgitation (MR) was lost to follow-up.She progressed to moderate MR, inferior T-wave inversion, and complex ventricular arrhythmia with NSVT on cardiopulmonary exercise testing, while CMR demonstrated valvular degeneration and excluded late gadolinium enhancement. In early pregnancy, she presented with palpitations, and transthoracic echocardiography showed bileaflet prolapse, moderate-to-severe MR, MAD, and Pickelhaube sign. At 14 weeks of gestation, she was hospitalized after syncope, with worsening ventricular arrhythmia burden on Holter. During hospitalization, she developed aborted SCD, without sequelae. A subcutaneous ICD without fluoroscopy was chosen to protect the mother–fetus dyad, performed without complications, with good evolution associated with optimization of medical therapy, and discharge for follow-up and planning of ablation or valve surgery after pregnancy. Conclusions: MAD may constitute an important arrhythmogenic substrate even in the absence of fibrosis on CMR, being associated with risk of malignant arrhythmias and SCD in young patients. Pregnancy may act as a decompensating factor, limiting therapeutic options. Early recognition is essential to reduce mortality, with systematic use of imaging, allows appropriate risk stratification and implementation of preventive measures, including ICD.

BUNDLE BRANCH REENTRANT VENTRICULAR TACHYCARDIA IN A STRUCTURALLY NORMAL HEART IN A 52-YEAR-OLD WOMAN WITH A PATHOGENIC SCN5A GENE VARIANT IDENTIFIED DURING INVESTIGATION: A CASE REPORT

RAISSA MATIAS LEWINTER1; GABRIELA VIEIRA DA SILVA1; PATRICIA MEI CHEN WANG1; BRUNO MOREIRA DOS SANTOS1; THALES FRAGA FERREIRA DA SILVA1; LUCIANA SACILOTT01; CRISTIANO FARIA PISANI1; FRANCISCO CARLOS DA COSTA DARRIEUX1; JOSÉ EDUARDO KRIEGER1; MAURICIO IBRAHIM SCANAVACCA1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction: Bundle branch reentrant ventricular tachycardia (BBRVT) is a form of ventricular tachycardia (VT) in which both bundle branches of the His-Purkinje system participate in the reentry circuit. This arrhythmia is typically observed in patients with acquired structural heart disease; however, recent reports suggest a potential genetic background in selected cases. We report a case of BBRVT in a structurally normal heart associated with a pathogenic SCN5A variant. Case Description: A 52-year-old woman presented with presyncope and palpitations, with documented monomorphic VT requiring synchronized electrical cardioversion. Baseline electrocardiogram showed first-degree atrioventricular block and left bundle branch block. Transthoracic echocardiography demonstrated a structurally normal heart, and coronary angiography revealed no obstructive coronary artery disease. Cardiac magnetic resonance imaging showed no myocardial edema or late gadolinium enhancement. During follow-up, the patient experienced a new episode of unstable monomorphic VT and was referred for electrophysiological study. No accessory pathways or inducible arrhythmias were initially identified; however, the HV interval was prolonged at 80 ms, leading to implantation of a dual-chamber pacemaker. During subsequent follow-up, recurrent sustained VT and episodes of atrial fibrillation/atrial tachycardia were detected on device telemetry, prompting a repeat electrophysiological study. Bundle branch reentrant ventricular tachycardia was then diagnosed and successfully treated with catheter ablation, with no further VT recurrence during follow-up. Subsequent genetic testing identified a heterozygous pathogenic SCN5A variant (c.673C>T; p.Arg225Trp), affecting the S4 segment of the Nav1.5 sodium channel and resulting in a leftward shift in channel activation and inactivation. Similar variants have previously been associated with ventricular arrhythmias and progressive conduction system disease. Cascade family screening is currently underway. Conclusions: BBRVT is a rare clinical entity and is only infrequently associated with structurally normal hearts. We highlight a case of recurrent monomorphic VT and conduction system disease treated with BBRVT ablation, followed by identification of a pathogenic SCN5A variant associated with Nav1.5 voltage-sensing impairment. This case highlights the importance of genetic testing in apparently idiopathic cases, helping clarify challenging arrhythmic phenotypes.

DANON DISEASE AS A PHENOCOPY OF LEFT VENTRICULAR HYPERTROPHY IN A CHILD WITH VENTRICULAR PRE-EXCITATION: IMPORTANCE OF EARLY DIAGNOSIS

ABNER FERNANDES DA SILVA1; GABRIEL BRANT MOREIRA FERREIRA2; GUSTAVO CAMPOS SABINO2; JÚLIA KROEHLING GIL2; PEDRO MIGUEL VIVAS CASTELO BORGES2; SARAH ALVES PEREIRA DOMINGOS2; ISABELLA MOREIRA GONZALEZ FONSECA1; ANNA TERRA FRANÇA1; GIOVANNI HENRIQUE SOARES DE ARAÚJO1; THAÍS LANY DE OLIVEIRA LEÃO1; RAFAEL RODRIGUES LOPES2; JÚLIA MOREIRA DINIZ2;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introduction: Danon Disease (DD) is a rare X-linked lysosomal condition caused by LAMP2 gene mutations, representing a severe and penetrant form of hereditary cardiomyopathy. In males, it manifests early with an aggressive phenotype, marked by ventricular hypertrophy and high arrhythmic risk. Frequent ECG findings include pre-excitation and conduction disturbances. Skeletal myopathy and cognitive impairment may coexist. Poor prognosis reinforces the need for early diagnosis and timely intervention. Case Description: A 10-year-old male, undergoing treatment with methylphenidate due to cognitive impairment, was referred for evaluation following chest pain, dyspnea, and palpitations. Family history included sudden death in first-degree paternal relatives. Physical examination revealed a grade III systolic ejection murmur, accentuated by the Valsalva maneuver. ECG showed a short PR interval and delta waves (ventricular pre-excitation), and echocardiography revealed obstructive symmetric concentric hypertrophic cardiomyopathy. Treatment with metoprolol was initiated, and the diagnostic workup was extended. Holter monitoring confirmed intermittent Wolff-Parkinson-White (WPW) pre-excitation. Complementary investigation revealed significantly elevated transaminases, creatine phosphokinase (CPK), lactate dehydrogenase (LDH), and NT-proBNP (8,200 pg/mL), suggesting a systemic phenocopy of hypertrophic cardiomyopathy. Cardiac MRI demonstrated diffuse left ventricular wall thickening and heterogeneous mesocardial late gadolinium enhancement, suggesting the presence of fibrosis (not quantified in the exam), suggestive of non-ischemic myocardial injury. Genetic testing identified a pathogenic deletion of exons 1-9 in the LAMP2 gene, confirming DD. Amiodarone was started for arrhythmia prevention, and methylphenidate was discontinued under neurological supervision. Currently, the patient is followed by an arrhythmia specialist, awaiting electrophysiological study, ablation, and genetic screening of first and second-degree relatives. Conclusions: This case illustrates a classic DD presentation and emphasizes clinical suspicion when hypertrophic cardiomyopathy coexists with pre-excitation and systemic signs. Multimodal imaging and genetic testing were decisive for early diagnosis. Timely recognition enables precision medicine, accurate risk stratification, and early referral for emerging therapies.

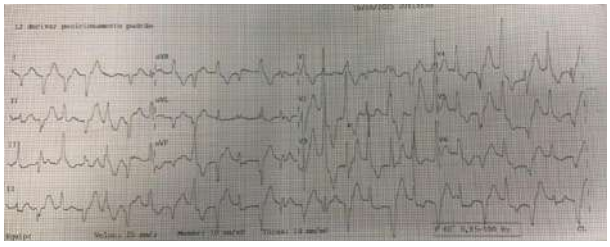
DESMOPLAKIN MUTATION WITH CARVAJAL-LIKE PHENOTYPE: A CASE REPORT OF ARRHYTHMOGENIC LEFT VENTRICULAR CARDIOMYOPATHY IN A YOUNG FEMALE PATIENT

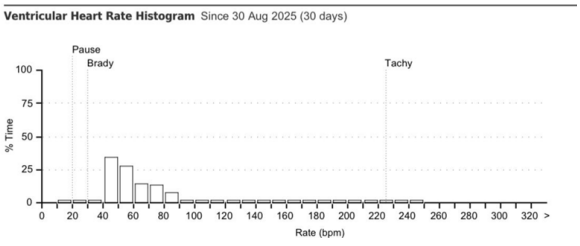
VICTOR BORGES DA SILVA1; DANIELE ALMEIDA SILVA1; GUSTAVO SAAD SILVA TOGHLOBI1; LUCAS PEREIRA VEDOIN1; DOUGLAS NUNES CAVALCANTE1; OLGA FERREIRA DE SOUZA1; ITALO BRUNO DOS SANTOS SOUSA1; VIVIAN DE BIASE1; FLAVIA RENNO TROIANI1; FÁBIO AUGUSTO DE LUCA1;

(1) IDOR - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Desmoplakinopathy is a rare genetic condition caused by heterozygous mutations in the DSP gene, encoding desmoplakin, a key desmosomal protein essential for cardiomyocyte and keratinocyte integrity. Unlike the classic autosomal recessive Carvajal Syndrome, heterozygous DSP mutations follow autosomal dominant inheritance and may present with a Carvajal-like phenotype: woolly hair, palmoplantar keratoderma, and arrhythmogenic left ventricular cardiomyopathy (ALVC). ALVC is characterized by extensive mesial-subepicardial fibrosis, malignant ventricular arrhythmias, and high risk of sudden cardiac death in young patients. Early recognition and timely ICD implantation are critical for prevention of fatal outcomes. Case Description: An 18-year-old female presented with recurrent syncope since age 10, preceded by palpitations, visual darkening and dizziness, occurring predominantly in orthostatic position. Physical examination revealed woolly hair and palmoplantar skin thickening. Family history was notable for maternal arrhythmia with the same DSP mutation. ECG showed intraventricular conduction delay with S-wave notching in V1-V2. Serial Holter monitors demonstrated progressive ventricular ectopic burden: up to 5,370 PVCs with 40 episodes of non-sustained ventricular tachycardia (NSVT). Cardiac MRI revealed moderate LV dilatation with extensive ring-like mesial-subepicardial fibrosis compatible with ALVC. LVEF was 44%. Genetic testing confirmed a heterozygous DSP mutation (p.Cys682Ter), a likely pathogenic variant — establishing the diagnosis of desmoplakinopathy with Carvajal-like phenotype. Given confirmed DSP mutation, recurrent syncope, high NSVT burden and extensive myocardial fibrosis, the patient was classified as high-risk for sudden death and underwent subcutaneous ICD implantation. An appropriate ICD shock for ventricular tachycardia was recorded 20 days post-implant, confirming the arrhythmic risk. Pharmacological therapy was optimized with metoprolol, amiodarone, enalapril, dapagliflozin and sertraline. Conclusions: Desmoplakinopathy with Carvajal-like phenotype is a rare and potentially fatal condition. This case highlights the role of genetic confirmation, cardiac MRI fibrosis pattern, and cutaneous findings in accurate diagnosis. Timely ICD implantation was validated by an appropriate shock for VT. First-degree relative screening is mandatory. Multidisciplinary management is essential in arrhythmogenic cardiomyopathies.



16046



FAMILY-CENTERED AUTOMATED EXTERNAL DEFIBRILLATOR STRATEGY IN HIGH-RISK PEDIATRIC CATECHOLAMINERGIC POLYMORPHIC VENTRICULAR TACHYCARDIA

LETICIA FERRAZ PAMPLONA1; PATRICIA COSTA DE ALMEIDA1; NILSON ARAUJO DE OLIVEIRA JUNIOR1; WALACE MAGALHAES BARBOSA1; PATRICIA MATTOS VIEIRA DO PAÇO1; MARTHA VALERIA TAVARES PINHEIRO1;

(1) REDE DOR - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Catecholaminergic polymorphic ventricular tachycardia (CPVT) is a rare inherited channelopathy characterized by adrenergically mediated ventricular arrhythmias and a high risk of sudden death in structurally normal hearts. Risk stratification in pediatric patients without a clear indication for implantable cardioverter-defibrillator (ICD) remains challenging, with persistent residual risk despite optimized therapy. We report a high-risk pediatric case highlighting an alternative safety strategy based on continuous access to an automated external defibrillator (AED) combined with structured family-centered education. Case Description: A previously healthy 9-year-old girl presented with aborted sudden cardiac death due to ventricular fibrillation, successfully terminated by defibrillation. She had recurrent exertional and emotional syncope and a positive family history of sudden death. Isoproterenol infusion induced bidirectional ventricular tachycardia (Figure 1), supporting the diagnosis of CPVT. Baseline evaluation, including echocardiography and cardiac magnetic resonance, was normal. Holter monitoring showed sinus bradycardia, prominent U waves, normal QTc, and atrial arrhythmias. Genetic testing is ongoing. Propranolol was initiated, and exercise testing with a cycle ergometer and electrophysiological study with isoproterenol failed to induce arrhythmias up to 140 bpm, suggesting adequate beta-blockade. Despite this, given the malignant initial presentation, a portable AED was incorporated as an immediate-response safety strategy, with strict recommendation for continuous availability. Intensive family training focused on early recognition of cardiac arrest and prompt AED use. A multidisciplinary Heart Team ensured close follow-up. Monitoring with an implantable loop recorder showed adequate rate control and no significant arrhythmic events (Figure 2). Conclusions: Non-selective beta-blockers remain the cornerstone of CPVT management, while ICD implantation in children should be individualized. In this setting, a structured AED-based strategy combined with caregiver empowerment may represent a pragmatic and potentially life-saving approach. This case underscores the critical role of early defibrillation access in high-risk pediatric CPVT.

NECK SWELLING FOLLOWING PACEMAKER IMPLANTATION: AN ATYPICAL PRESENTATION OF LEAD-RELATED VENOUS THROMBOSIS

SYED AUN MUHAMMAD1; ANINDYA MUKHERJEE1; SABRA AHMED1;

(1) MID YORKSHIRE NHS FOUNDATION TRUST - UNITED KINGDOM;

Introduction: Neck swelling is an unusual presentation of lead-related venous thrombosis following cardiac device implantation. While pacemaker implantation is a common procedure and thrombosis is not infrequent, this is more often in the form of upper limb redness and swelling. We present an unusual case of a South-Asian gentleman in his late 50s who presented with a painful neck mass twenty-five days following implantation of a Cardiac Resynchronisation Therapy Device (CRT-D). Case Description: A South-Asian gentleman in his late 50's presented to hospital with a swelling in his neck that had been present for approximately two weeks. While initially painless, for one week prior to the patient's admission it had started to cause him mild, tolerable pain and prompted him to self-present to our hospital. The swelling was located at the lateral border of the left anterior triangle, at the base of his left sternocleidomastoid muscle. It was ellipsoid in shape, measuring 2x3 cm. He had undergone implantation of a CRT-D twenty five days prior to his presentation. Past medical history included Ischaemic Cardiomyopathy, Hypertension, Diabetes and Tuberculosis. His CRT-D had been implanted without immediate complication. Venous access had been obtained via the Left Axillary vein, with 3 Axillary vein punctures. A total of three leads were deployed. His blood tests revealed no drop in his Haemoglobin or Platelets. He had normal inflammatory markers. However, his D-dimer was abnormally elevated. He went on to have an Ultrasound Doppler of his neck to better understand the nature of his small, tender neck mass. The Ultrasound Doppler revealed no colour flow across his left external jugular vein, confirming occlusive thrombus. His subclavian vein had partial flow across it as well, demonstrating partial occlusion. These scans confirmed the suspicion of DVT, which was likely as a result of having had a recent implantation of his Cardiac Device. He was treated with a Direct Oral Anticoagulant (DOAC) in the form of Apixaban 5mg twice daily for 3 months duration due to it being a provoked DVT. Earlier follow-up in the Pacing Clinic with closer monitoring was also planned. Since discharge this gentleman has remained well without re-admission to hospital. Conclusions: This case highlights the importance of considering jugular venous thrombosis in patients presenting with neck swelling following ipsilateral cardiac device implantation, even in the absence of limb symptoms.

PRKAG2 SYNDROME: A PHENOCOPY OF HYPERTROPHIC CARDIOMYOPATHY WITH VENTRICULAR PRE-EXCITATION

THAIS LANY DE OLIVEIRA LEAO1; ANNA TERRA FRANÇA1; ISABELLA MOREIRA GONZALEZ FONSECA1; ABNER FERNANDES DA SILVA1; LARISSA FONSECA REIS1; JOSE REINALDO CORREA ROVEDA1; GIOVANNI HENRIQUE SOARES DE ARAUJO1; PEDRO VIANA DINIZ1; GABRIEL BRANT MOREIRA FERREIRA1; GUSTAVO CAMPOS SABINO1; PEDRO MIGUEL VIVAS CASTELO BORGES1; SARAH ALVES PEREIRA DOMINGOS1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introduction: Myocardial hypertrophy is characterized by increased ventricular mass and may arise from hemodynamic, metabolic, or genetic conditions. It encompasses a broad phenotypic spectrum, ranging from sarcomeric hypertrophic cardiomyopathy to phenocopies, including amyloidosis, Fabry disease, PRKAG2 syndrome, and Danon disease. PRKAG2 gene variants are associated with a rare glycogen storage cardiomyopathy characterized by myocardial hypertrophy and prominent conduction system abnormalities, frequently mimicking sarcomeric hypertrophic cardiomyopathy. Accurate etiological differentiation is essential. We report a case of myocardial hypertrophy associated with a PRKAG2 variant. Case Description: A 25-year-old woman was evaluated for ventricular pre-excitation. In 2016, she underwent an electrophysiological study, which identified a low-risk fasciculoventricular accessory pathway. Serial electrocardiograms and 24-hour Holter monitoring confirmed persistent ventricular pre-excitation. Cardiac magnetic resonance imaging (October 2024) demonstrated left ventricular hypertrophy involving the basal and mid segments, with a basal septal thickness of 15 mm and a lateral wall thickness of 14 mm. Genetic testing (July 2025) identified an H401Q variant in the PRKAG2 gene, classified as a variant of uncertain significance (VUS). She has a significant family history of cardiomyopathy: her mother died at age 24 while awaiting heart transplantation; her grandmother had hypertrophic cardiomyopathy in its dilated phase, associated with anteroseptal ventricular pre-excitation and sinus node dysfunction requiring pacemaker implantation; and an aunt had sudden cardiac death. Given the clinical, imaging, and genetic findings suggestive of PRKAG2 syndrome, a repeat electrophysiological study was requested to reassess accessory pathways potentially amenable to ablation. Conclusions: This case highlights a rare phenotypic presentation suggestive of PRKAG2 syndrome, a phenocopy of sarcomeric hypertrophic cardiomyopathy. It emphasizes the importance of a detailed family history and early screening of at-risk relatives. Owing to its rarity, the absence of established criteria for sudden cardiac death risk stratification, and uncertainties regarding cardiac device indication, management remains particularly challenging.

20038

RIGHT ATRIAL APPENDAGE ISOLATION USING THREE PULSED-FIELD ABLATION PLATFORMS DURING REDO ATRIAL FIBRILLATION ABLATION: A MULTIPLATFORM CASE SERIES

GABRIEL ODOZYNSKI1; GURSHARAM SAMRA2; NATHAN KONG2; RONUK MODI2; DANIEL VILLARREAL2; JONATHAN WAKS2; ANDREW LOCKE2; ANDRE D'AVILA2; GREGORY MICHAUD2;

(1) BETH ISRAEL DEACONESS MEDICAL CENTER - FLORIANOPOLIS - SC - BRASIL; (2) BETH ISRAEL DEACONESS MEDICAL CENTER - UNITED STATES;

Introduction: The right atrial appendage (RAA) may be an underrecognized non-pulmonary vein driver of atrial fibrillation (AF). It fires spontaneously in ~7% of cases and can sustain AF. Pulsed-field ablation (PFA) may allow safe, effective lesion delivery in this anatomically complex region. Case Description: Three patients presented for redo AF ablation. All underwent biatrial mapping. RAA isolation was performed when mapping in AF demonstrated complex fractionation and high frequency of firing more prominently in the RAA compared to other atrial regions. Intraprocedural response and arrhythmia recurrence were evaluated. First case (64-year-old): LA mapping showed chronically isolated PVs and PWI. RA mapping identified high-frequency RAA signals. Farapulse ablation of the RAA and SVC achieved complete isolation with immediate AF termination. Second case (74-year-old): LA mapping again demonstrated durable PVI and PWI. During AF, tip and basal RAA fractionation outpaced LA activation. Varipulse lesions resulted in termination during ablation with confirmed block. Third case (54-year-old): LA showed low posterior wall voltage and left-sided reconnection requiring reisolation. In AF, the RAA was the fastest, most disorganized region. Sphere-9 PFA around and within (plus one RF lesion for coronary proximity) produced entrance/exit block after cardioversion. All patients remained free of AF recurrence at ≥6 months with no sinus-node or phrenic-nerve injury. Conclusions: RAA isolation using three distinct PFA platforms was safe and feasible in all cases. AF terminated acutely in two patients despite previously durable PV isolation, implicating the RAA as the operative driver. These cases support prospective investigation of PFA-based RAA isolation as a targeted strategy for non-PV AF triggers in selected patients undergoing redo ablation.

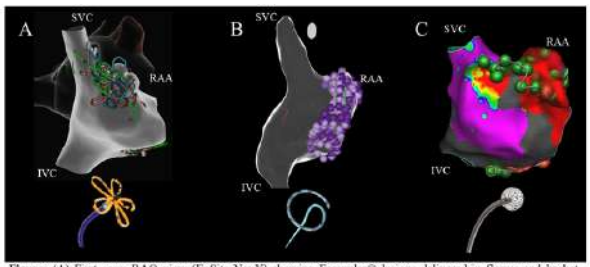

Figure: (A) First case: RAO view (EnSite NavX) showing Farapulse® lesions delivered in flower and basket configurations to isolate the RAA. (B) Second case: RAO view (CARTO) demonstrating Varipulse® lesion set with extension toward the CTI line due to rapid, fractionation activation in the lower anterior RA. (C) Third case: RAO view (Affera) illustrating Sphere-9® lesions encircling/internal the RAA achieving isolation. **Abbreviations:** SVC, superior vena cava; IVC, inferior vena cava; RAA, right atrial appendage.

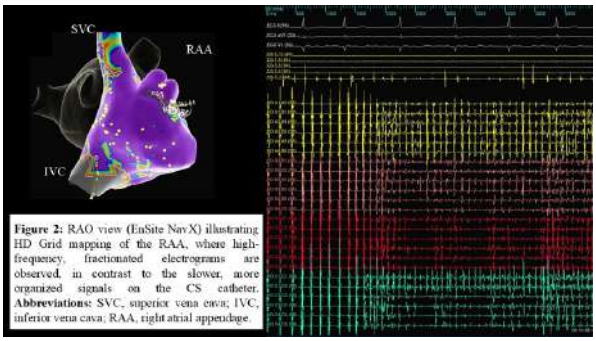

Figure 2: RAO view (EnSite NavX) illustrating HD Grid mapping of the RAA, where high-frequency, fractionated electrograms are observed, in contrast to the slower, more organized signals on the CS catheter. **Abbreviations:** SVC, superior vena cava; IVC, inferior vena cava; RAA, right atrial appendage.

SUCCESSFUL ABLATION OF AN ACCESSORY PATHWAY IN EBSTEIN ANOMALY WITH ABSENCE OF PHYSIOLOGICAL ATRIOVENTRICULAR CONDUCTION: A SEQUENTIAL STRATEGY WITH PERMANENT PACEMAKER IMPLANTATION

ADRIANO RENAN ALMEIDA1; GEORGE PALMEIRA BRAGA1; ANA BEATRIZ ALMEIDA1; AMANDA VIEIRA PIRES1; FABIO MAHAMED RASSI1; VITOR ROSSI SANTOS1; MATHEUS COLEPICOLO BRIANEZI1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction: Ebstein anomaly is a rare congenital heart disease frequently associated with ventricular pre-excitation and atrioventricular accessory pathways. Catheter ablation is challenging because of tricuspid annular distortion, right ventricular atrialization, surgical scars, and possible multiple or decremental pathways. Case Description: An 18-year-old female patient with Ebstein anomaly, severe tricuspid regurgitation, and manifest ventricular pre-excitation underwent cone reconstruction with tricuspid valve repair and surgical accessory pathway ablation on April 25, 2022, with persistent pre-excitation during follow-up. In an electrophysiological study on August 18, 2025, sinus rhythm with pre-excitation was observed. Right septal mapping failed to identify a His potential. Anterograde and retrograde conduction through the accessory pathway were demonstrated, and pre-excited atrial fibrillation was induced, with a shortest RR interval of 196 ms. Fragmented and late potentials in the septal right ventricle suggested scar tissue. As no physiological AV conduction was demonstrated, AV conduction dependent on the accessory pathway was suspected, and ablation was deferred due to the risk of complete AV block. In a subsequent procedure, left posteroseptal ablation was unsuccessful. Remapping of the tricuspid annulus identified the right posteroseptal region as the main target; radiofrequency applications produced intermittent pathway elimination but advanced AV block, supporting absent physiological AV conduction. The procedure was interrupted, and a permanent pacemaker was implanted. On January 5, 2026, after device protection, a new study identified a right posteroseptal accessory pathway with decremental properties. After initial failure with a non-irrigated catheter, an irrigated-tip catheter allowed successful pathway elimination, followed by complete AV block with junctional escape rhythm, persisting after observation and adenosine. The pacemaker was programmed to DDD mode, 60–150 bpm. Conclusions: This case highlights an uncommon scenario in Ebstein anomaly after cone reconstruction: persistent pre-excitation, a right posteroseptal decremental accessory pathway, septal scar substrate, and absence of physiological AV conduction. The sequential strategy — risk recognition, pacemaker implantation, and subsequent ablation — allowed safe treatment, with functional confirmation of complete AV block after accessory pathway elimination.

EXTRINSIC CORONARY COMPRESSION BY PROBABLE SOLITARY FIBROUS TUMOR SIMULATING CHRONIC CORONARY SYNDROME IN A YOUNG PATIENT

ITALO COSTA SALES1; LAISA ALLEN GOMES DE SOUSA2; SERGIO PARENTE LIRA2; GUILHERME PARENTE LIRA2; EDEMIR VERAS DE CARVALHO JUNIOR1; VICTOR LIRA RIBEIRO GONCALVES DE CARVALHO2; NATHAN CANDEIRA COSTA SEIXAS2; ANTONIO JOAQUIM CAVALCANTE DIAS DE OLIVEIRA1; JOSE HUGO ANDRADE SANTOS DANTAS1; ALMIR VIEIRA DE SOUSA NETO1; DANIEL GONCALVES DE SOUSA LOPES1; ALCINO PEREIRA DE SA FILHO1;

(1) HOSPITAL GETULIO VARGAS - TERESINA - PI - BRASIL; (2) HOSPITAL GETÚLIO VARGAS - TERESINA - PI - BRASIL;

Introduction: Coronary artery disease in young adults represents a diagnostic challenge, especially when the underlying etiology is non-atherosclerotic. Unconventional causes of myocardial ischemia, such as extrinsic compression by mediastinal masses, are rare and frequently underdiagnosed. Extra-cardiac Solitary Fibrous Tumor (SFT) is an uncommon mesenchymal neoplasm, predominantly benign, that may affect mediastinal structures with significant hemodynamic impact when adjacent to coronary vessels. Case Description: A 32-year-old male, smoker and hypertensive, presented with progressive anginal syndrome. Initial episodes occurred during exertion with intense precordial pain radiating to the back and dyspnea, evolving to rest angina. A beta-blocker was introduced without symptom relief. Echocardiography showed preserved ejection fraction (62%). Coronary CT angiography revealed zero calcium score with significant luminal reduction of the left main, anterior descending, and circumflex arteries, associated with a 12x10x8mm mediastinal mass causing extrinsic compression. Cardiac MRI identified a well-defined extra-cardiac mass of 20x14x13mm adjacent to the left coronary sinus, with imaging features suggesting probable SFT. Invasive angiography confirmed subocclusive lesions (90-95%) unresponsive to intracoronary vasodilator, supporting extrinsic compression. The patient underwent surgical revascularization and mass resection. Pathology showed atypical lymphomononuclear infiltrate within fibrosis; immunohistochemistry is pending for definitive diagnosis. Conclusions: This case highlights an uncommon cause of severe ischemia in a young adult due to extrinsic coronary compression by a probable mediastinal SFT. Zero calcium score and cardiac MRI were essential diagnostic tools. Non-atherosclerotic etiologies must be considered in young patients with coronary syndrome.

Introduction: Pericardial effusion (PE) results from fluid accumulation in the pericardial space (>50 mL), classified by volume, distribution, and chronicity, and may cause hemodynamic compromise. Although etiologies vary, nearly 50% of cases are idiopathic, and malignancies are a relevant cause of unexplained PE. Such effusions frequently present with negative cytology for malignancy, delaying diagnosis and requiring multimodal investigation. Case Description: A 74-year-old female presented with progressive dyspnea and edema for 7 days. On admission: poor peripheral perfusion, pulmonary congestion, jugular venous distension, atrial fibrillation with rapid ventricular response, hyperlactatemia, and a pro-BNP of 1500 pg/mL. Point-of-care ultrasound demonstrated PE. Urgent echocardiography confirmed significant PE with diastolic filling restriction, a plethoric inferior vena cava, and a dyskinetic right ventricular (RV) free wall. She underwent a pericardial window with drainage of 660 mL of hematic fluid and pericardial biopsy; pathology revealed pericardial thickening and nonspecific chronic inflammatory infiltrate. Cytology and acid-fast bacillus smear were negative, despite an ADA of 122 U/L. Workup for breast, lung, and gastrointestinal malignancies was negative. Cardiac magnetic resonance revealed extensive infiltrative pericardial mass involving the atrioventricular groove, right coronary artery, right atrium, RV outflow tract, tricuspid valve, and aortic root, with diffuse pericardial late gadolinium enhancement and thickening. Positron emission tomography/computed tomography (PET/CT) showed intense hypermetabolism isolated to the heart. Surgical biopsy via sternotomy revealed a thickened pericardium and a friable, fibroelastic mass infiltrating the right atrium with calcified areas. Pathology confirmed Diffuse Large B-Cell Lymphoma. R-CHOP chemotherapy was initiated. The patient remains under multidisciplinary follow-up with a satisfactory initial response to treatment confirmed by follow-up PET/CT. Conclusions: This report reinforces that PE may be both an indicator of occult malignancy and its sentinel manifestation. Hemodynamic compromise demands prompt diagnosis to prevent cardiac tamponade. Although metastatic diseases are common causes of cardiac masses and PE, clinical presentation can be nonspecific and cytology has a low sensitivity. Multimodal imaging is essential for characterizing pericardial infiltration, and surgical assessment may be required for definitive diagnosis and therapy.

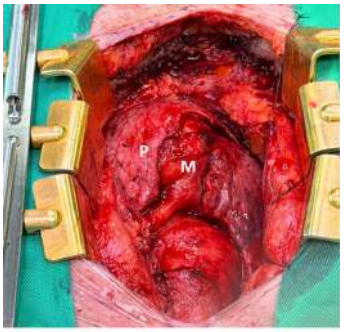

Figure 2: Intraoperative findings during sternotomy showing the thickened pericardium **(P)** and an infiltrative mass **(M)** in close contact with the pericardial layers, invading the right atrium.

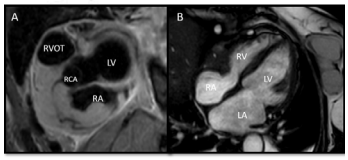

Figure 1: Cardiac magnetic resonance demonstrating an extensive infiltrative mass involving the RVOT and the RA, with perivascular extension and involvement of the RCA, shown in T1-weighted sequence (A) and cine-SSFP images (B). **RVOT**, right ventricular outflow tract; **RCA**, right coronary artery; **RA**, right atrium; **RV**, right ventricle; **LV**, left ventricle; **LA**, left atrium.

ACQUIRED LEFT VENTRICLE–RIGHT ATRIUM SHUNT (GERBODE DEFECT) IN A POST-VALVE SURGERY PATIENT WITH POSSIBLE INDOLENT INFECTIOUS ETIOLOGY

RAQUEL PEREIRA DA SILVA1; ANDRÉ LUIZ LUIZ XAVIER CANEVAROLI1; FERNANDA GARCIA FLEURY1; BRUNA MORENO BARBOSA1; CAROLINE BARRETO CAVALCANTI1; SANDRA DE BARROS COBRA NEGREIROS1; RAFAELA MELO MACEDO1; ANA GIULLIA MARTINS CAPPELE1; SARA MARTINS PEREIRA1; MAGALI MEIRELLES E SILVA1; MONIQUE ALMEIDA VAZ1; ALINE ALINE AKIKO KOMATSU RABELO1;

(1) HOSPITAL DE BASE DO DISTRITO FEDERAL - BRASÍLIA - DF - BRASIL;

Introduction: Background: Left ventricle–right atrium (LV–RA) shunt, or Gerbode defect, is a rare condition that may be congenital or acquired. Acquired forms are typically associated with prior cardiac surgery or infective endocarditis and may present with subacute or indolent progression, particularly in atypical or culture-negative contexts. Case Description: A 58-year-old woman with rheumatic heart disease underwent double valve replacement (aortic and mitral bioprostheses) on February 19, 2024. Over the following months, she developed progressive right-sided heart failure with refractory edema and ascites. Transthoracic and transesophageal echocardiography demonstrated preserved left ventricular ejection fraction, marked right chamber enlargement, torrential tricuspid regurgitation with leaflet malcoaptation and systolic flow reversal in suprahepatic veins, and an aneurysmal formation in the mitral annulus (18×21 mm) associated with a direct LV–RA communication (5–8 mm) with high-velocity systolic flow, consistent with an acquired Gerbode defect. Peripheral stigmata of infective endocarditis were present. Blood cultures during hospitalization and intraoperative samples were negative; however, prior isolation of Burkholderia cepacia on February 22, 2024 had been documented. Empirical antimicrobial therapy included trimethoprim-sulfamethoxazole, levofloxacin, and meropenem; trimethoprim-sulfamethoxazole was discontinued due to sulfonamide-related thrombocytopenia, while levofloxacin was maintained. The regimen remained active against the previously isolated organism. Given the significant left-to-right shunt, severe tricuspid regurgitation, and progressive right-sided volume overload, the patient underwent tricuspid valve replacement and closure of the LV–RA defect and is currently in postoperative recovery. Conclusions: Acquired Gerbode defects should be considered in patients with prior cardiac surgery and unexplained right-sided heart failure. This case suggests a possible indolent infectious process in the context of prior Burkholderia cepacia isolation, an atypical pathogen associated with subacute presentation and limited microbiological confirmation. Multimodal imaging and integrated clinical assessment are essential to guide surgical management.

ISOLATED RIGHT VENTRICULAR ENDOMYOCARDIAL FIBROSIS SECONDARY TO HYPEREOSINOPHILIC SYNDROME: AN UNCOMMON PRESENTATION

TAIS REGINA BISOL1; JOAO ALFREDO REZER BERTÃO1; GUSTAVO KORSSAK GONÇALVES1; MILENE FEHLBERG SEHN1; DORA VERONESI PALOMBINI1; VINICIUS LEITE GONZALEZ1; MURILO FOPPA1; ANGELA BARRETO SANTIAGO SANTOS1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introduction: Endomyocardial fibrosis associated with hypereosinophilic syndrome, also known as Löffler endocarditis, is a rare form of restrictive cardiomyopathy with an unknown exact prevalence. It is characterized by endomyocardial damage mediated by eosinophilic infiltration, leading to necrosis, thrombotic complications, and myocardial fibrosis. The most common pattern of involvement is biventricular disease, followed by isolated left ventricular involvement, while isolated right ventricular (RV) involvement is rare. Case Description: A 21-year-old previously healthy man presented with weight loss, night sweats, and fatigue. Initial laboratory evaluation revealed anemia, thrombocytopenia, and marked leukocytosis with eosinophilia (26,470/mm³), in addition to splenomegaly. The patient was admitted for investigation and management of a myeloproliferative syndrome. Bone marrow examination and immunohistochemistry demonstrated a hypercellular marrow with marked eosinophilia, and immunophenotyping confirmed the diagnosis of hypereosinophilic syndrome associated with the FIP1L1-PDGFRA gene mutation. Assessment of target organ involvement included transthoracic echocardiography (TTE), which showed right chamber dilation with mild right ventricular dysfunction, severe tricuspid regurgitation, and diastolic filling restriction at the RV apex, with no abnormalities in the left-sided chambers. Cardiac magnetic resonance imaging confirmed the TTE findings and demonstrated apical obliteration of the RV by fibrotic material, consistent with endomyocardial fibrosis. Treatment of the underlying disease included corticosteroids, hydroxyurea, and imatinib, along with heart failure management. The patient initially showed an excellent hematologic response, later impaired by poor treatment adherence. At 6-month outpatient follow-up, he was in NYHA functional class I and clinically stable from a cardiovascular standpoint. Conclusions: This case illustrates the association between hypereosinophilic syndrome and endomyocardial fibrosis, with an isolated right ventricular involvement pattern. Cardiac involvement in this syndrome is a major cause of morbidity and mortality, and imaging modalities played a key role in establishing the diagnosis. Early recognition of the underlying etiology allowed the initiation of targeted therapy, potentially modifying the natural history of the disease.

ACUTE GENERALIZED EXANTHEMATOUS PUSTULOSIS FOLLOWING CORONARY ARTERY BYPASS GRAFTING ASSOCIATED WITH AMIODARONE USE: A CASE REPORT

GABRIELE KLEIN DA SILVA1; LUIZA SEIXAS MANSUR1; GULIANO MINOR ZORTEA1;

(1) UFCSPA - PORTO ALEGRE - RS - BRASIL;

Introduction: Acute generalized exanthematous pustulosis (AGEP) is a rare and severe adverse cutaneous reaction, although antibiotics are the most frequent triggers, antiarrhythmic drugs, such as amiodarone, have also been linked to the condition. Case Description: A 64-year-old male patient, a Jehovah's Witness, with a history of hypertension, diabetes, and multi-vessel coronary artery disease, underwent coronary artery bypass grafting on April 23, 2026. The immediate postoperative period was complicated by total atrioventricular block, requiring temporary ventricular pacing, and atrial fibrillation on the first postoperative day with a high ventricular response, treated with high-dose amiodarone infusion (300 mg + 900 mg) over 24 hours.On the second postoperative day, the patient developed erythematous plaques in the bilateral inguinal region, which progressed to extensive and painful erythematous plaques associated with non-follicular micropustules, predominantly involving intertriginous areas, including the abdomen, inguinal folds, gluteal region, and proximal thighs. No fever was associated. The differential diagnosis included AGEP and symmetrical drug-related intertriginous and flexural exanthema (SDRIFE). Relevant recent drug exposures included cefazolin during anesthetic induction, amoxicillin for dental treatment 14 days prior, and amiodarone postoperatively.A dermatological evaluation was requested, and the skin biopsy showed subcorneal pustules associated with superficial dermal edema and a dense perivascular inflammatory infiltrate rich in eosinophils, favoring the diagnosis of AGEP. Amiodarone was promptly discontinued, and systemic corticosteroid therapy with prednisone 40 mg/day was initiated along with topical corticosteroids, resulting in progressive improvement of the lesions, followed by desquamation and resolution of the pustules. Conclusions: AGEP should be considered in the differential diagnosis of acute pustular eruptions in the postoperative period of cardiac surgery, especially in patients exposed to multiple high-risk medications. Although uncommon, amiodarone may act as a potential trigger. Histopathological confirmation and early discontinuation of the suspected agent are essential for favorable clinical outcomes.

COCAINE-INDUCED ANTIPHOSPHOLIPID SYNDROME MIMICRY: TRANSIENT ANTICARDIOLIPIN POSITIVITY ASSOCIATED WITH CATASTROPHIC THROMBOEMBOLIC EVENTS AND FUNCTIONAL RECOVERY

ISABELLA CAROLINE DE FREITAS DOMINGOS1; ÁDHIRA GIOVANNA DE ANDRADE ALVES1; ISABELA CRISTINA BRAZ SANTOS1; CATARINA MATOS DA COSTA1; CLARISSA DE CASTRO FERREIRA1; ADRIANA ABREU RESENDE1;

(1) ESCOLA SUPERIOR DE CIENCIAS DA SAUDE - BRASÍLIA - DF - BRASIL;

Introduction: Antiphospholipid syndrome (APS) is an autoimmune disorder characterized by recurrent thrombotic events associated with persistent antiphospholipid antibodies (aPL), requiring laboratory confirmation on 2 measurements at least 12 weeks apart. However, transient aPL positivity may occur under specific conditions, including infections and illicit drugs exposure, particularly cocaine adulterated with levamisole, potentially mimicking APS and leading to misdiagnosis with important therapeutic implications. Case Description: A 50-year-old man with a 26-year history of chronic cocaine use who presented with ischemic stroke at age 48, followed in the same month by acute myocardial infarction. He subsequently developed severe ventricular dysfunction, with a left ventricular ejection fraction (LVEF) of 22% and a large mobile intracavitary thrombus in the LV detected on echocardiography. During hospitalization, he developed additional systemic thromboembolic events, including critical lower limb ischemia with bilateral popliteal artery occlusion confirmed by Doppler ultrasound, requiring bilateral above-knee amputations. He also presented dyspnea, generalized edema, and cutaneous lesions suggestive of vasculitis. APS was suspected due to the severity and multiplicity of thrombotic events. Immunological testing revealed high-titer anticardiolipin IgM antibodies (107 MPL-U/mL), with negative lupus anticoagulant, antinuclear antibodies, and ANCA. A severe systemic presentation of APS was initially considered. However, repeat testing after 12 weeks demonstrated complete antibody negativation, excluding definite APS according to international criteria. Following cocaine cessation and optimization of medical therapy, LVEF improved significantly (54%), supporting a toxic trigger and partial cardiovascular reversibility. Conclusions: This case illustrates extensive systemic thromboembolic manifestations with transient anticardiolipin positivity in chronic cocaine use, representing APS mimicry. Levamisole exposure may induce immune activation with autoantibody production and vasculopathic manifestations. Recognition of this association is essential to avoid misdiagnosis of definite APS and unnecessary lifelong anticoagulation. Serial aPL testing and systematic investigation of illicit drug exposure are critical in patients with multiple thrombotic events and isolated aPL positivity, allowing individualized management directed toward the underlying cause.

ANOMALOUS ORIGIN OF THE RIGHT CORONARY ARTERY WITH AN INTERARTERIAL COURSE ASSOCIATED WITH THREE-VESSEL CORONARY ARTERY DISEASE: THE ROLE OF COMPUTED TOMOGRAPHY ANGIOGRAPHY AND SURGICAL MANAGEMENT

LUCAS ALBUERNE DINIZ BEZERRA ALBUERNE1; VÍTOR FERRAZ SILVA TACCONI TACCONI1; PABLO HENRIQUE GUEDES SILVA SILVA1; FERNANDA DE QUEIRÓZ ALBUQUERQUE ALBUQUERQUE1; FERNANDO ALBUERNE BEZERRA FERNANDO BEZERRA1; CHARLES SARAIVA GADELHA GADELHA1;

(1) FACULDADE DE MEDICINA NOVA ESPERANCA - JOÃO PESSOA - PB - BRASIL;

Introduction: Anomalous origin of the coronary arteries is a rare condition associated with myocardial ischemia, arrhythmias, and sudden cardiac death. Variants with an interarterial course present a higher risk, especially when associated with atherosclerotic coronary artery disease. Imaging methods, such as coronary CT angiography, are essential for diagnosis and risk stratification. Case Description: A 62-year-old male patient with stable angina and an exercise stress test positive for ischemia at low workload. Cardiac catheterization revealed proximal occlusion of the left anterior descending artery (with an intramyocardial course in the mid segment), a significant lesion in the first marginal branch, and inability to catheterize the right coronary artery. Therefore, coronary CT angiography was requested for further evaluation of coronary anatomy. The exam (coronary CT angiography) demonstrated an anomalous origin of the right coronary artery from the left coronary sinus, with an interarterial course (between the aorta and the pulmonary artery trunk), an intramural segment, and a slit-like ostium (Figure 1), in addition to three-vessel coronary artery disease (Figure 2). Given the presence of symptoms, documented ischemia, and high-risk anatomy, myocardial revascularization surgery was performed using grafts from the Right Internal Thoracic Artery to the Left Anterior Descending Artery, the Great Saphenous Vein to the First Marginal Branch, and the Great Saphenous Vein branch to the posterior interventricular artery. Conclusions: The association between anomalous origin of the coronary arteries with an interarterial course and coronary artery disease represents a high-risk condition for major cardiovascular events. Coronary CT angiography is essential for anatomical definition and therapeutic planning. Myocardial revascularization is an effective strategy in symptomatic patients with evidence of ischemia and unfavorable anatomy.

18020

CARDIAC LEFT VENTRICULAR HEMANGIOMA MIMICKING MYXOMA: A CASE REPORT AND DIAGNOSTIC CHALLENGE

LUIZ GUSTAVO COSTA NEVES1; FERNANDA MOREIRA E LEITE1; JOÃO PEDRO SANTANA VIEIRA1; JORGE SILVEIRA JÚNIOR1; YURI OSMAR DE ARAUJO COSTA1; BRUNO MARQUES ZYNGIER1;

(1) HOSPITAL FELÍCIO ROCHO - BELO HORIZONTE - MG - BRASIL;

Introduction: Primary cardiac tumours are rare, with an estimated prevalence of 0.01% to 0.03% in the general population. Myxomas are the most common type and are predominantly located in the left atrium, whereas their occurrence in the left ventricle is uncommon. More than 90% of these tumours are benign, and both myxomas and hemangiomas are generally treated with surgical resection, with a favourable prognosis. Clinical manifestations vary according to tumour location and characteristics and may include arrhythmias, embolic events, flow obstruction, syncope, and ventricular dysfunction. This case illustrates the diagnostic and therapeutic challenges posed by these uncommon presentations. Case Description: A 51-year-old male Jehovah's Witness with a history of systemic arterial hypertension and dyslipidaemia was being evaluated for non-sustained supraventricular tachycardia detected on an exercise stress test on October 21, 2024. Transthoracic echocardiography revealed an intracavitary left ventricular mass measuring 16 × 10 mm, with a hyperechoic border. Cardiac magnetic resonance imaging confirmed the lesion and showed no impairment of ventricular function. Imaging findings suggested myxoma. The patient underwent surgical resection on February 13, 2025, without the need for blood transfusion. Although the gross appearance of the specimen was also suggestive of myxoma, histopathological examination established the diagnosis of capillary-type cardiac hemangioma. In the postoperative period, the patient developed atrial fibrillation, requiring electrical cardioversion on February 26, 2025. Anticoagulation with apixaban 5 mg twice daily was initiated in association with amiodarone, and the patient had a favourable clinical course. Conclusions: Primary cardiac tumours may have heterogeneous clinical presentations depending on their anatomical location, relationship to the myocardium, and haemodynamic impact. Although many cases are asymptomatic, some patients may present with arrhythmias, embolic events, or signs of intracardiac obstruction. In this case, distinguishing myxoma from cardiac hemangioma was diagnostically challenging, since clinical, surgical, and imaging findings may overlap, making histopathological examination essential for diagnosis. Surgical resection remains the main therapeutic strategy, and recognition of these rare presentations may help guide the management of similar cases.

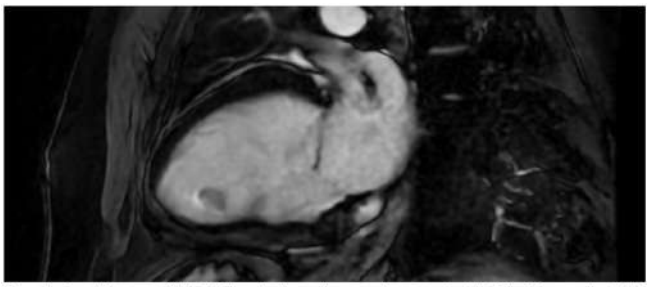

Figure 1. Rounded mass within the left ventricular cavity, measuring approximately 10.4 × 10 mm, attached to the inferoapical segment, pedunculated, mobile, well-circumscribed, and without intrinsic contractility. It is isointense relative to the myocardium on T1-weighted imaging and hyperintense on T2-weighted imaging.

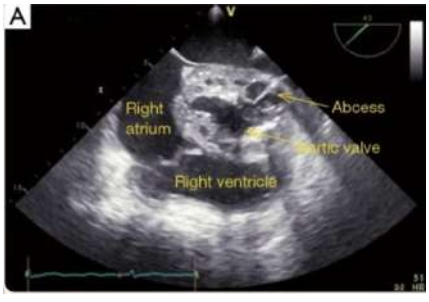
19111

CASE REPORT: ASYMPTOMATIC AORTIC INTUSSUSCEPTION WITH HIGH-RESPONSE ATRIAL FIBRILLATION — INCIDENTAL FINDING AND COMPLEX SURGICAL MANAGEMENT

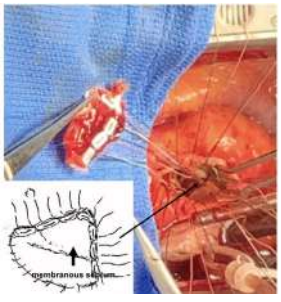
GIOVANNA ZADRA DE MATTOS1; LETICIA ARTILLES MELLO MENDONCA DE ARAUJO1; HERICK LETELBA CARVALHO FERREIRA1; JAMIR DAVIDSON PINTO GONCALVES1; LETICIA BRAGA CAMARGOS1; LETICIA NOLASCO FONSECA MARTINS1; JANIO DE PAULA SANTOS1; JULIANA SERAFIM DA SILVEIRA1; JOSE ROBERTO BERTHOUX MARTINS1; MILTON MANHAES1; CELIO MATHEUS1; EDSON MAGALHAES NUNES1;

(1) HOSPITAL PRO CARDIACO - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Type A aortic dissection is a high-mortality cardiovascular emergency, with rates reaching 1 to 2% per hour in the first 48 hours without surgical intervention. Aortic intussusception is an extremely rare complication, characterized by prolapse of the intimal flap into the vascular lumen, potentially occluding coronary ostia, aortic arch branches, and causing acute severe aortic regurgitation. Its exact incidence remains undefined in the literature, reflecting both its rarity and high pre-diagnosis mortality. Recognition requires strong clinical suspicion and relies on aortic computed tomography angiography for precise anatomical characterization. The association with atypical presentations, such as absence of pain and new-onset arrhythmias, makes diagnosis even more challenging and demands careful structured clinical reasoning. Case Description: A 51-year-old male, with no known comorbidities, presented for a routine outpatient visit completely asymptomatic. High-response atrial fibrillation was identified during cardiological evaluation, prompting referral to the emergency department. Physical examination revealed blood pressure discrepancy between upper limbs. Transthoracic echocardiography showed severe aortic regurgitation and a 64mm aortic aneurysm. Computed tomography angiography demonstrated intussusception of the ascending aorta extending to and obstructing the brachiocephalic trunk, along with an additional flap in the descending aorta. Frozen Elephant Trunk surgery was performed with implantation of an endoprosthesis in the descending aorta, a bifurcated graft in the aortic arch, and a valved conduit with coronary reimplantation, plus closure of the left atrial appendage, which contained an intracavitary thrombus. The procedure totaled 240 minutes of cardiopulmonary bypass, 210 minutes of aortic clamping, and 60 minutes of circulatory arrest. A hemoadsorption cartridge was used to mitigate systemic inflammatory response, and the postoperative course was favorable, with ICU discharge on the fifth day. Conclusions: This case highlights the importance of thorough investigation in new-onset arrhythmias, even in asymptomatic patients. The incidental diagnosis of aortic intussusception reinforces that symptom absence does not exclude life-threatening conditions. The Frozen Elephant Trunk approach, combined with perioperative inflammatory control using emerging biotechnologies, yielded a satisfactory outcome contributing to the literature on management of this condition.



16626



GERBODE'S DISEASE WITH UNUSUAL ANATOMICAL PRESENTATION AND UNCONVENTIONAL SURGICAL CORRECTION: A CASE REPORT

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - Brasil; (22) UFC - FORTALEZA - CE - Brasil;

Introduction: Gerbode's defect is an anomalous communication between the left ventricle and the right atrium, of congenital or acquired etiology, and represents a rare condition in clinical practice. It corresponds to approximately 0.08% of intracardiac shunts and less than 1% of congenital heart diseases. A case of Gerbode's defect is reported below, emphasizing its diagnostic difficulty and therapeutic complexity. Case Description: A 34-year-old male patient was admitted with a history of approximately three months of recurrent fever, predominantly nocturnal, associated with chills, cold sweats, hyporexia, unmeasured weight loss, asthenia, and progressive dyspnea. Initially, infective endocarditis was suspected, and empirical antibiotic therapy was instituted. During the investigation, blood cultures remained negative and the transesophageal echocardiogram did not show vegetations. The echocardiogram revealed a true Gerbode defect, with communication between the left ventricle and right atrium in the region of the atrioventricular membranous septum, associated with a bicuspid aortic valve with significant aortic insufficiency, significant tricuspid insufficiency, aneurysmal deformation of the tricuspid septal leaflet, significant dilation of cardiac chambers, and a left ventricular ejection fraction of 40%. Following discussion within the Heart Team, surgical correction was indicated, consisting of resection of the native aortic valve and implantation of a metallic valve prosthesis, correction of the Valsalva sinus aneurysm, occlusion of the right aorto-atrial fistula, and tricuspid valve repair. Due to the unusual anatomical presentation of the defect, the fistula repair was performed transaortically, during the same surgical procedure as the resection of the native aortic valve and the implantation of the mechanical prosthesis, with the right atrium being addressed only for tricuspid valve repair. In the postoperative period, the echocardiogram showed no residual flow at the level of the membranous septum, and the patient remained under clinical follow-up. Conclusions: The diagnosis of Gerbode's defect can be challenging, especially in unusual presentations and in scenarios initially suggestive of infective endocarditis. This case reinforces the importance of magnetic resonance imaging, echocardiography, and individualized therapeutic planning.

19697

LATE AND UNUSUAL INFECTIOUS COMPLICATION OF THE ASCENDING AORTA AFTER COMPLEX CARDIAC SURGERY: A CASE REPORT

GABRIEL HENRIQUE EFFIO SOLIS1; CAROLINE CAETANO DE SOUZA1; ANNE LOUREIRO XAVIER KISUKURI1; WERLLEY DE ALMIEDA JANUZZI1; ANDRE LUIZ POLO1; LARA GARCIA FERNANDES PEREIRA1; ITALO CARNEIRO DE LIMA1; INGRID VICTORIA SANCHEZ MADRID1; VINISSIUS NASSER DE CARVALHO1; FERNANDO FOCACCIA POVOA1; VINICIUS NASSER DE CARVALHO2; RAMON MOTTA DA SILVA BRITTO1;

(1) INSTITUTO DE ASSISTENCIA MÉDICA AO SERVIDOR PUBLICO ESTADUAL DE SÃO PAULO - SÃO PAULO - SP - BRASIL; (2) INSTITUTO DE ASSISTENCIA MEDICA AO SERVIDOR PUBLICO ESTADUAL DE SÃO PAULO - SÃO PAULO - SP - BRASIL;

Introduction: Late infectious complications of the ascending aorta following cardiac surgery are rare events, yet they are associated with high mortality. Clinical presentation may be nonspecific, delaying diagnosis, and determining the optimal timing for surgical intervention represents a significant challenge, particularly in frail and multimorbid patients. Case Description: 69-year-old male with diabetes mellitus, end-stage renal disease on dialysis, and frailty underwent in July surgical correction of a right coronary artery–to–pulmonary trunk fistula, aortic valve replacement, and coronary artery bypass grafting (CABG). In November, he developed fever and hypotension during dialysis, initially attributed to a probable urinary source. Due to persistent symptoms, further investigation in his hometown revealed a collection at the aortic root, and he was subsequently to our institute for advanced evaluation. Computed tomography demonstrated a large periaortic mediastinal collection containing saccular formations with direct communication with the ascending aorta (AA) at two sites, consistent with infectious pseudoaneurysms and contained rupture of the aortic wall—findings associated with a high risk of imminent rupture, located near the prior aortotomy site. Despite the indication for urgent surgery, the patient was toxemic, with an elevated operative mortality risk. A decision was made to defer surgery, acknowledging the risk of clinical deterioration during this interval, in an attempt to reduce infectious burden and optimize clinical status prior to a complex procedure. After partial stabilization, the patient underwent reoperation. Intraoperatively, an infectious pseudoaneurysm of the AA was confirmed, and reconstruction was performed using a Dacron graft, along with repeat CABG. The aortic valve prosthesis was functioning normally, with no evidence of infectious involvement on PET-CT; therefore, it was preserved to avoid prolonging operative time. The postoperative course was favorable, with discharge from the intensive care unit on postoperative day 5. The patient received six weeks of targeted antibiotic therapy for Pseudomonas aeruginosa, with good clinical response and subsequent hospital discharge in stable condition. Conclusions: Although early surgery is generally recommended due to the high risk of rupture, in highly complex scenarios, determining the optimal surgical timing becomes as critical as the indication itself and should be individualized.

SAVE THE VALVE, REMODEL THE ROOT: HEMI-YACOUB TECHNIQUE - A CASE REPORT

ENZO HENRIQUE OLIVEIRA ZANATTA1; BRUNO FUZARI SILVA2; SALOMÃO MICHEL ABDO FILHO2;

(1) UNINASSAU - CACOAL - RO - BRASIL; (2) INSTITUTO DE CARDIOLOGIA / FUNDAÇÃO UNIVERSITARIA DE CARDIOLOGIA - PORTO ALEGRE - RS - BRASIL;

Introduction: Ruptured sinus of Valsalva aneurysm (SVA) is a rare cardiac anomaly, accounting for less than 1% of congenital heart defects. Although traditional repair focuses on fistula closure, this approach may be insufficient by overlooking that rupture reflects structural failure of the sinus wall rather than a simple fistulous communication. We describe a case of ruptured right SVA treated with localized root remodeling to preserve the native valve and coronary anatomy. Case Description: A 29-year-old male patient presented with a 2-month history of progressive exertional chest pain and dyspnea. Initial echocardiography, subsequently confirmed by computed tomography angiography, demonstrated a ruptured right sinus of Valsalva aneurysm with communication to the right atrium, resulting in a high-gradient left-to-right shunt and volume overload. Intraoperative inspection confirmed localized disease of the right coronary sinus, with a pinpoint rupture and preserved surrounding tissue. Localized valve-sparing root remodeling was performed using the hemi-Yacoub technique, with resection of the diseased sinus, Dacron graft reconstruction to restore the physiologic geometry of the root, and right coronary artery reimplantation, thereby correcting the shunt and restoring sinus morphology. Intraoperative echocardiography demonstrated correction of the communication and preservation of aortic valve function. Conclusions: This case reinforces that the ruptured sinus of Valsalva aneurysm should not be interpreted only as a focal defect to be closed, but as a manifestation of localized aortic root disease. In this setting, in addition to correction of the rupture and the communication, preservation of the physiologic morphology of the sinus through graft reconstruction and reimplantation of the coronary ostium are fundamental components of an anatomically proportionate and functionally more appropriate repair.

SURGICAL REVASCULARIZATION OF A GIANT RIGHT CORONARY ARTERY PSEUDOANEURYSM SECONDARY TO BEHÇET DISEASE AND THE USE OF THE PATIENT BLOOD MANAGEMENT (PBM) STRATEGY

THIAGO JOSE DE OLIVEIRA1; MARCO ANTONIO ARAUJO DE MELLO1; EDUARDO RAFAGA GONÇALVES CALVOSO1; RAFAEL CUNHA MARTINELLI1; SELMA GUIMARÃES FEREIRA MEDEIROS1; RENATA LONDON RODRIGUES NASCIMENTO1; EMERSON GONÇALO PEREIRA FILHO1; KENIO SALGUEIRO OKAMURA1; KAREN ISALBELLE PONTES DURAN1; KAMILLA MORE DA SILVA1; RAFAELA VOLPATO DE FREITAS1; RUBYA TESSER1;

(1) UNIVERSIDADE FEDERAL DE MATO GROSSO DO SUL - CAMPO GRANDE - MS - BRASIL;

Introduction: Behçet disease generally affects young adults between 20 and 40 years of age, with no sex predominance. It is characterized by a recurrent multisystem inflammatory syndrome of unknown etiology. Clinical manifestations include mucocutaneous involvement with oral ulcers, genital ulcers, skin lesions, uveitis, and erythema nodosum. The histopathological features of the disease are vasculitis and thrombosis. Involvement of arteries and veins of all calibers may be observed in 25% of patients, more commonly in men. Arterial vasculitis may involve vessels of any caliber and may be accompanied by aneurysms or occlusions. Case Description: A 26-year-old male patient with a history of pulmonary thromboembolism and recurrent oral aphthous ulcers was hospitalized for endovascular repair of a descending thoracic aortic aneurysm. Two months later, the patient was readmitted with chest pain and underwent coronary angiography, which revealed two giant pseudoaneurysms in the proximal and mid thirds of the right coronary artery. Clinical evaluation showed elevated inflammatory markers and persistent chest pain. Therefore, treatment for the underlying disease was initiated with corticosteroid therapy and cyclophosphamide. Less than 3 months after clinical treatment, the patient required myocardial revascularization with a sequential saphenous vein graft. A PBM strategy was used, including intraoperative and postoperative cell salvage and administration of ferric carboxymaltose on the fourth postoperative day. The patient progressed without the need for transfusion and was discharged on the fifth postoperative day. Conclusions: Suspicion of the diagnosis of Behçet disease arose from the fact that the patient had vascular involvement in multiple territories, including aortic dissection, coronary aneurysm, and a history of venous thromboembolism. After reviewing the literature, it was observed that this clinical case is rare, especially in terms of the clinical presentation of this pathology. Thus, clinical management and surgical treatment aimed to minimize the patient's inflammatory response. The PBM strategy was an additional resource used that contributed to this goal.

TORRENTIAL PRIMARY TRICUSPID REGURGITATION DUE TO MYXOMATOUS DEGENERATION: INNOVATION IN PERCUTANEOUS REPAIR WITH THE PASCAL ACE SYSTEM

RAQUEL BUSANELLO SIPMANN1; RODRIGO PETERSEN SAADI1; RAPHAEL PERCEGONA1; DANIEL SOUTO SILVEIRA1; JORGE LUIS BERNAL DIAZ1; JOÃO PEDRO BARBOSA1; MATEUS SILVA DE CARVALHO1; JULIA GIACOMONI BRAGAGNOLO1; LORRANA CÁTRIA NASCIMENTO DOS REIS1; MARCOS LOPES JÚNIOR1; MAURÍCIO MORETTO SALVARO2; EDUARDO KELLER SAADI1;

(1) HOSPITAL MÃE DE DEUS - PORTO ALEGRE - RS - BRASIL; (2) HOSPITAL MÃE DE DEUS - PORTO ALEGRE - RJ - BRASIL;

Introduction: Significant tricuspid regurgitation has been historically underrecognized, despite its association with increased morbidity and mortality and impaired quality of life. Although the functional form is more prevalent, primary etiologies such as myxomatous degeneration are rare and poorly described in the literature. In recent years, advances in transcatheter therapies have expanded treatment options for patients at high surgical risk, with the PASCAL ACE system emerging as a promising strategy for percutaneous valve repair, showing encouraging early results in regurgitation reduction and clinical improvement. Case Description: Severe primary tricuspid regurgitation is rare and often underdiagnosed, and is associated with worse prognosis. The development of percutaneous approaches, such as the PASCAL ACE system, provides an alternative in selected cases. A 67-year-old female patient with primary tricuspid regurgitation due to myxomatous degeneration presented with mild exertional dyspnea (NYHA II) and bilateral lower limb edema. She was on bisoprolol and indapamide and was admitted for percutaneous tricuspid valve repair. The procedure was performed via right femoral access, with implantation of two PASCAL ACE devices in the anteroseptal and posteroseptal positions, achieving adequate leaflet grasping and significant reduction of the central regurgitant jet. The immediate postoperative course was uneventful, with the patient stable on room air, no access site complications, and normal laboratory tests. She was discharged early and remained under outpatient follow-up. Conclusions: This case highlights that percutaneous tricuspid valve repair using the PASCAL ACE system is safe and effective, providing significant regurgitation reduction and immediate clinical improvement. The presence of primary tricuspid regurgitation due to myxomatous degeneration further underscores the relevance of this report, given the rarity of the condition and the potential of percutaneous techniques in elderly patients with favorable valvular anatomy.

TRANSCATHETER TRICUSPID VALVE REPAIR WITH THE EVOQUE SYSTEM: THE SECOND CASE PERFORMED IN LATIN AMERICA

JORGE LUIS BERNAL DIAZ1; JULIA GIACOMONI BRAGAGNOLO1; RODRIGO PETERSEN SAADI1; CRISTIANO PEDERNEIRAS JAEGER1; DANIEL SOUTO SILVEIRA1; JOÃO PEDRO BARBOSA1; MATEUS SILVA DE CARVALHO1; RAQUEL BUSANELLO SIPMANN1; RAPHAEL PERCEGONA1; DEYMER OROZCO ARROYO1; RONALD DAVINSHI ÂNGULO PALÁCIOS1; EDUARDO KELLER SAADI1;

(1) HOSPITAL MÃE DE DEUS - PORTO ALEGRE - RS - BRASIL;

Introduction: Tricuspid regurgitation (TR), particularly in its severe forms, is associated with significant morbidity and mortality, driven by progressive right-sided heart failure and systemic congestion. Despite its clinical impact, TR remains historically undertreated, largely due to the high surgical risk of affected patients and the limited effectiveness of medical therapy. In recent years, transcatheter therapies have emerged as a transformative alternative for patients deemed inoperable or high risk for surgery. Case Description: A 78-year-old woman with torrential functional tricuspid regurgitation of atrial etiology, permanent atrial fibrillation, and prior anticoagulation with apixaban presented with progressive functional decline (NYHA class II), bilateral lower limb edema, and mild fatigue. Pre-procedural evaluation demonstrated preserved left ventricular ejection fraction (62%), biatrial enlargement, moderate pulmonary hypertension, and massive tricuspid regurgitation, with favorable anatomy for transcatheter intervention using the EVOQUE system. The patient was admitted for transcatheter tricuspid valve repair, which was successfully performed via right femoral venous access, without significant hemodynamic complications. Post-procedurally, she was monitored in the intensive care unit for 24 hours, remaining hemodynamically stable, with adequate respiratory status on low-flow oxygen therapy, no signs of congestion or bleeding, and an intact femoral access site. Chest X-ray and electrocardiogram showed no significant abnormalities, with appropriate device positioning. The patient was discharged 48 hours after the procedure, in good clinical condition, with outpatient follow-up. Conclusions: This report describes only the second case of transcatheter tricuspid valve repair with the EVOQUE system performed in Latin America, reinforcing the feasibility and safety of this cutting-edge approach. In a population historically limited by high surgical risk and few therapeutic options, this strategy provides rapid hemodynamic improvement, early functional recovery, and short hospital stay. This case highlights the evolving role of transcatheter therapies in the management of tricuspid valve disease and supports their use as a transformative and expanding frontier in structural heart interventions.

BMPR2-RELATED HERITABLE PULMONARY ARTERIAL HYPERTENSION IN A CHILD: A CASE WITH CLINICAL INSIGHTS AND EMERGING THERAPEUTIC PERSPECTIVES

EDUARDA FÉLIX PONTE1; YURI OSMAR DE ARAÚJO COSTA2; MONIQUE RODRIGUES TARDIN DE FIGUEIREDO3; DIEGO VIEIRA BARRETO3; APRISCLA MENDES COSTA3; THALES DE MELO MASCI VALADÃO CARDOSO3; TEREZA LÚCIA DE MELO MASCI3; MARIA DA GLÓRIA CRUVINEL HORTA3;

(1) REDE MATER DEI DE SAUDE - BELO HORIZONTE - MG - BRASIL; (2) HOSPITAL FELÍCIO ROCHO - BELO HORIZONTE - MG - BRASIL; (3) SANTA CASA DE MISERICORDIA DE BELO HORIZONTE - BELO HORIZONTE - MG - BRASIL;

Introduction: Heritable pulmonary arterial hypertension (HPAH) is a rare and severe disease, most commonly associated with BMPR2 mutations, present in up to 80% of familial cases. It is characterized by early onset and poor prognosis, making early recognition and family screening essential, particularly in pediatric populations. Case Description: A 7-year-old boy presented with progressive dyspnea (mMRC grade 4), exercise intolerance, chest pain, and perioral cyanosis over six months. Family history was remarkable for pulmonary hypertension in multiple first-degree relatives, including his mother (on ambrisentan and tadalafil, awaiting lung transplantation), as well as his grandmother and aunt, both with early mortality. A sibling died at 2.5 years of age with similar symptoms and no established diagnosis. Physical examination revealed an accentuated P2 and a tricuspid regurgitation murmur. Echocardiography demonstrated severe pulmonary hypertension (estimated systolic pulmonary artery pressure 101 mmHg), right heart enlargement, and moderate right ventricular systolic dysfunction. Right heart catheterization confirmed severe pulmonary arterial hypertension with mean pulmonary artery pressure of 57 mmHg, pulmonary capillary wedge pressure of 18 mmHg, and markedly elevated pulmonary vascular resistance (PVR ~29.6 Wood units). Genetic testing identified a BMPR2 mutation, confirming heritable PAH. Given disease severity, a Potts shunt was performed. Despite intervention, the patient remained with severe pulmonary hypertension, requiring tadalafil and bosentan, with partial stabilization, remaining oxygen-dependent. Conclusions: This case highlights the importance of early recognition of heritable PAH in children with suggestive family history, enabling timely genetic testing and proper management. Symptoms and physical findings may support early suspicion. Management requires a multimodal strategy, including invasive hemodynamic confirmation and early combination therapy targeting the endothelin, nitric oxide, and prostacyclin pathways, with escalation in high-risk patients. In advanced disease, palliative approaches such as Potts shunt and lung transplantation should be considered. Emerging therapies targeting pulmonary arterial remodeling, such as sotatercept, may offer disease-modifying potential by acting on pathways involved in BMPR2-related disease. Early recognition and family screening may be critical to improving outcomes.

GLENN SURGERY AS RESCUE THERAPY IN A PATIENT WITH LATE-CORRECTED EBSTEIN ANOMALY

VICTÓRIA BEATRIZ DA SILVA VITORINO1; GUSTAVO LEITE JACOVELLI1; LUANA FARID GUIMARÃES DE CASTRO1; VICTÓRIA ALONSO RABELO DA SILVA1; JÚLIA EDUARDA NOBREGA DE MELO E CASTRO1; BERNARDO ORPHEU SILVA VITORINO2; VICTOR VARGAS DE OLIVEIRA1; WILFRAN JOHANY FERRER PARRA1; GABRIEL FAIOLI NASCIMENTO ALVES VIEIRA1; LUIS GUSTAVO GALI1; RAFAEL BRÓLIO PAVÃO1; ALFREDO JOSÉ RODRIGUES1;

(1) HOSPITAL DAS CLINICAS DA FACULDADE DE MEDICINA DE RIBEIRAO PRETO - USP - RIBEIRAO PRETO - SP - BRASIL; (2) UNIVERSIDADE DE UBERABA - UBERABA - MG - BRASIL;

Introduction: Ebstein anomaly (EA) is a rare congenital heart disease, characterized by the apical displacement of the tricuspid leaflets, which results in the atrialization of the right ventricle (RV) and a reduction in its functional portion. Clinical presentation and prognosis vary by anatomical severity, with mortality reaching 18% in severe cases untreated during childhood. We report an uncommon severe EA case diagnosed in adulthood with an atypical clinical course. Case Description: A 28-year-old male presented with exertion intolerance, asthenia, a holosystolic murmur at the tricuspid area, and jugular venous distention. Transthoracic echocardiogram (TTE) showed findings consistent with EA: severe right atrial dilation (77 ml/m²), apical displacement of the septal tricuspid leaflet (6 cm from the valvular plane; Carpentier type C), severe tricuspid regurgitation (TR), moderate right ventricular (RV) dysfunction, and a 16x10 mm ostium secundum atrial septal defect (ASD). He underwent tricuspid valve replacement (TVR) with a bioprosthesis, ASD closure, and epicardial pacemaker implantation due to intraoperative third-degree heart block. At one-year follow-up, he developed RV dysfunction symptoms, with anasarca and hepatomegaly. A new TTE revealed bioprosthetic failure, characterized by stenosis due to a large thrombus on its atrial surface (mean gradient 12 mmHg). Despite anticoagulation therapy, he developed hemodynamic instability. Redo-TVR was indicated, combined with a bidirectional Glenn shunt (superior cavopulmonary anastomosis) as a one-and-a-half ventricle repair strategy for hemodynamic rescue of the RV overload. Postoperative follow-up showed a normally functioning prosthesis (mean gradient 6 mmHg), patent Glenn flow, and clinical improvement, with NYHA class reduction and no further hospitalizations. Conclusions: In the setting of EA, the Glenn procedure is typically indicated during childhood as a physiological unloading for severe right ventricular (RV) dysfunction. However, its application in adults remains rare. With the rising prevalence of adults with congenital heart disease, challenges regarding the management of late-stage RV failure become more frequent. This report describes the possibility of applying a bidirectional Glenn shunt as rescue therapy for RV dysfunction after failed isolated valve surgery in an adult with EA, therefore highlighting the applicability of a well-known therapy, in an uncommon scenario.

HEART FAILURE WITH REDUCED EJECTION FRACTION IN AN ADULT PATIENT CAUSED BY ANOMALOUS ORIGIN OF THE LEFT CORONARY ARTERY FROM THE PULMONARY ARTERY.

MARIA CLARA MACHADO1; ANA CAROLINA DE GODOY ARAUJO2; ABDIAS PEREIRA DINIZ NETO1; YAGO AMAZONAS MAGNO1; JULLIE QUEIROGA SANTANA1; ADRIANA MEDEIROS SOUZA QUARESMA1; GABRIELA SENA SANTOS3; CICERO ROBERTO PINHEIRO GRANGEIRO1; FABIANA GOMES ARAGÃO MAGALHÃES1; PAULO ERNANDO FERRAZ CAVALCANTI1; JORGE AUGUSTO NUNES GUIMARÃES1; MONICA CRISTINA REZENDE FIORE1;

(1) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL; (2) HOSPITAL AGAMENON MAGALHAES - RECIFE - PE - BRASIL; (3) FPS - FACULDADE PERNAMBUCANA DE SAUDE - RECIFE - PE - BRASIL;

Introduction: Anomalous left coronary artery originating from the pulmonary artery (ALCAPA), also known as Bland-White-Garland syndrome, is a rare coronary anomaly (1 in 300,000 live births), mainly diagnosed in neonates. Survival into adulthood is uncommon and depends on the development of extensive collateral circulation from the right coronary artery. In the absence of early intervention, mortality may reach 90% during the first year of life. Additionally, cases of sudden cardiac death have been reported in previously undiagnosed patients, and those who survive into adulthood frequently develop heart failure with reduced ejection fraction. Case Description: A 46-year-old woman was admitted to a tertiary cardiology referral center with a 3-year history of progressive dyspnea, now occurring with minimal exertion, associated with orthopnea, paroxysmal nocturnal dyspnea, and lower-limb edema. She also reported occasional exertional angina. On physical examination, she was in good general condition, with a blood pressure of 100/70 mmHg and no signs of congestive heart failure. The electrocardiogram showed sinus rhythm with left bundle branch block. Transthoracic echocardiography demonstrated a dilated left ventricle, left ventricular ejection fraction of 46%, moderate mitral regurgitation, and pulmonary hypertension (estimated pulmonary artery systolic pressure of 53 mmHg). Coronary angiography revealed absence of the left coronary ostium in the aortic sinus, with a dominant and enlarged right coronary artery supplying the left system via collaterals and drainage into the pulmonary artery, consistent with ALCAPA. Hemodynamic assessment showed severe mixed pulmonary hypertension and reduced cardiac index (2.34 L/min/m²). The case was discussed by a multidisciplinary Heart Team, and optimization of medical therapy followed by surgical correction was recommended. Conclusions: ALCAPA is a rare cause of dilated cardiomyopathy in adults and, if left untreated, may progress to severe heart failure and death. Early diagnosis is essential, as surgical correction is the definitive treatment to prevent sudden cardiac death and reverse ventricular dysfunction, even in late presentations.

LEFT VENTRICAL HYPERTRABECULATION IN TWINS: A MIRROR INTO PEDIATRIC CARDIOGENETICS

SABRINA ATTIÉ DE BARROS1; DANIEL SILVA CARVALHO CURI1; MANUELA CAETANO LIMA1; CAMILLA SANTOS AQUINO NUNES1; DIEGO DE ALMEIDA ARAÚJO VITAL1; JULIANA ARAGÃO BARQUETTE ABRAHÃO1; VIVIANE CAMPOS BARBOSA DE SENA1;

(1) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Left ventrical hypertrabeculation is a phenotype of cardiac muscle caused by the failure of myocardial compaction during fetal development, resulting in deep and coarse trabeculations that affect cardiac function. It presents itself with a range of phenotypic manifestations, from asymptomatic adults to children with severe heart failure. The genetics behind this condition are also varied, potentially arising from autosomal dominant mutations (usually encoding sarcomeric protein genes), mitochondrial defects, or complex chromosomal anomalies. With advancements in genomics, more genes have been implicated in the development of this condition, but studies demonstrating a clear correlation between genotype and phenotype of the disease are lacking. This divergence can be observed in the case of monozygotic twins with left ventricle hypertrabelulation and a unknown genotype, with different manifestations of cardiomyopathy and heart failure. Case Description: The twins began follow-up at around 4 months of age, where a diagnosis was made and optimized medical treatment for heart failure was initiated. In the first echocardiogram (ECHO), Twin I had an ejection fraction by the Simpson method of 8%, while Twin II had a fraction of 24%. Twin II remained asymptomatic, while Twin I required an increase in medications, with the first hospitalization for congestive heart failure (CHF) at 3 years old. During this hospitalization, there was a need for inotropes (2 cycles of Levosimendan), followed by re-hospitalization one month post-discharge for a new cycle of inotropes, remaining hospitalized until undergoing orthotopic heart transplant in March 2025 at 3 years and 9 months old. He progressed with graft acceptance and was discharged after 3 months of hospitalization; the first cardiac biopsy showed no signs of rejection. Twin II continues outpatient follow-up with the cardiomyopathy team, with the last ECHO showing an ejection fraction by the Teicholz method of 33.8%, without hospitalizations for CHF. Genetic testing for both patients has been requested but not yet performed. Conclusions: Genetic sequencing of the twins and cardiological exams for family members would be advisable. Left ventricular hypertrabeculation remains an anatomical variant with a wide spectrum of presentations and no clear correlation between genetics and clinical presentation. More studies comparing these characteristics are needed for better elucidation.

RARE ASSOCIATION OF A GIANT NONCORONARY SINUS OF VALSALVA ANEURYSM AND A LEFT CORONARY SINUS ANEURYSM WITH RIGHT VENTRICULAR OUTFLOW TRACT COMPRESSION IN NOONAN SYNDROME.

CYNTHIA SPERANDIO1; MARCIO ANTONIO DOS SANTOS1; ALEXANDRE TAJARA SANTOS1; JULIANA MARIALVA SANTIAGO1; CÍNTIA PERINETTI ALVES MARTINS2; ADIEL CARVALHO JUNIOR3; PAULO GONCALVES MARTIN1; GUILHERME PLACIDO BARBOSA1; MARCELA DIAS AZEM DE FIGUEIREDO1;

(1) FACULDADE DE MEDICINA DE RIO PRETO - FAMERP - SÃO JOSÉ DO RIO PRETO - SP - BRASIL; (2) FACULDADE DE MEDICINA DE SÃO JOSÉ DO RIO PRETO - FAMERP - SÃO JOSÉ DO RIO PRETO - SP - BRASIL; (3) FACULDADE DE MEDICINA DE RIO PRETO - SÃO JOSÉ DO RIO PRETO - SP - BRASIL;

Introduction: Noonan syndrome (NS), an autosomal dominant genetic disorder, is the most common syndromic cause of congenital heart disease after trisomy 21. The most frequent cardiac abnormalities include pulmonary stenosis, hypertrophic cardiomyopathy, and septal defects. We report a rare presentation of this condition associated with a giant noncoronary sinus of Valsalva aneurysm and a left coronary sinus of Valsalva aneurysm, leading to right ventricular outflow tract (RVOT) compression and severe aortic regurgitation. Case Description: A female patient with a history of Noonan syndrome (NS) presented at 56 years of age with progressive dyspnea and palpitations. On physical examination, she was cachectic, with webbed neck, low-set ears, and ptosis. Cardiac rhythm was irregular, with a grade 4/6 systolic–diastolic murmur, most prominent at the accessory aortic area. Bibasilar crackles and lower limb edema were noted. Electrocardiography showed atrial fibrillation. Computed tomography revealed an expansile mediastinal mass. Transthoracic echocardiography demonstrated aneurysmal dilation of the aorta at the level of the sinuses of Valsalva/sinotubular junction measuring 62 mm, resulting in severe aortic regurgitation; a saccular aneurysm of the sinus of Valsalva measuring 3.0 × 3.1 cm; interatrial communication; and severe aortic, mitral, tricuspid, and pulmonary regurgitation. Cardiac magnetic resonance imaging demonstrated external compression of the right atrium and the mid and basal portions of the right ventricle, as well as the right ventricular outflow tract (RVOT), caused by the aneurysm. The patient did not undergo cardiac surgical intervention and, at 67 years of age, developed pulmonary sepsis associated with decompensated heart failure, ultimately resulting in in-hospital death. Conclusions: Sinus of Valsalva aneurysms are uncommon in the general population, with an estimated incidence of approximately 0.1%. The association between Noonan syndrome (NS) and sinus of Valsalva aneurysms is extremely rare, with only a few cases reported in the literature. These aneurysms may remain clinically silent until reaching sizes that lead to compression of adjacent structures, such as the right ventricular outflow tract (RVOT) and coronary ostia, as well as aneurysm rupture. This case report contributes to the recognition of this unusual association and its potential clinical implications.

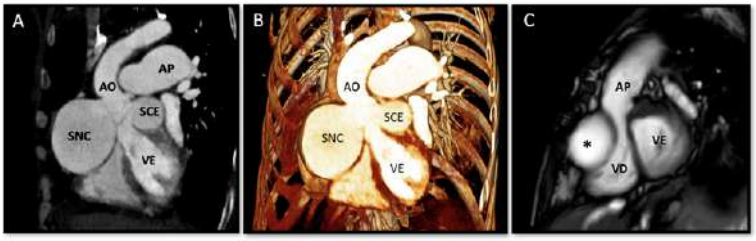

Figure 1. Computed tomography angiography of the thoracic aorta. (A) Multiplanar reconstruction and (B) three-dimensional reconstruction demonstrating a giant noncoronary sinus of Valsalva aneurysm associated with a left coronary sinus aneurysm. (C) Cardiac magnetic resonance imaging showing compression of the right ventricular outflow tract (RVOT) by the giant aneurysm. LV: left ventricle; NCS: noncoronary sinus; LCS: left coronary sinus; AAo: ascending aorta; PA: pulmonary artery; RV: right ventricle.

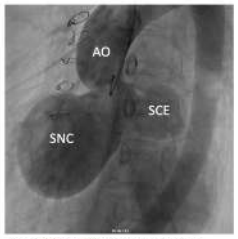

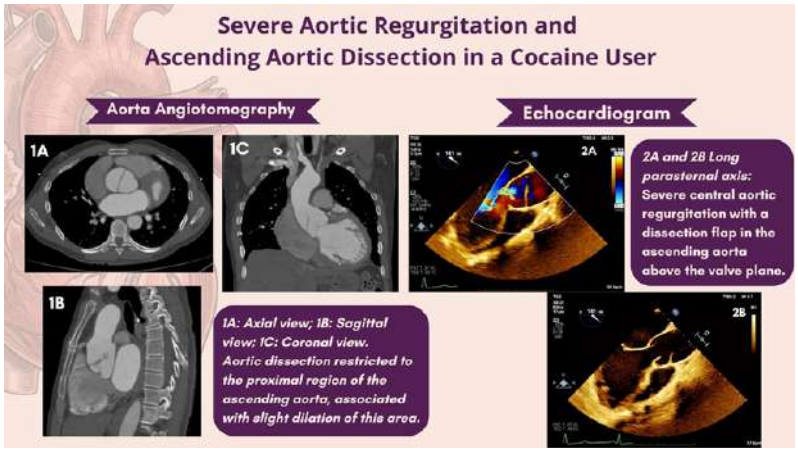

Figure 2. Arteriography in the left anterior oblique (LAO) view. NCS: noncoronary sinus; LCS: left coronary sinus; AAo: ascending aorta.

SEVERE AORTIC REGURGITATION AND ASCENDING AORTIC DISSECTION IN A COCAINE USER: A CASE FOR THE DAVID PROCEDURE

LUISA MARTINS FILGUEIRAS1; FABIO AKIO NISHIJUKA1; LETICIA LIMA DE SOUZA1; MARIA CAROLINA TERRA COLA1; DIEGO SARTY VIANNA1; ELBA SOPHIA THEODORO1; THAÍSSA SANTOS MONTEIRO1;

(1) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Illicit substance abuse presents a significant public health challenge. Cocaine is associated with an increased risk of cardiovascular events. Aortic dissection, a condition associated with high morbidity and mortality, is among the severe cardiovascular complications linked to cocaine use. Case Description: A 50-year-old male, cocaine user with no known comorbidities, presented with progressive dyspnea and chest pain with exertion starting 4 months prior. Transthoracic echocardiography (Echo) revealed severe aortic regurgitation (AR) associated with aortic dissection, with a flap in the ascending aorta just above the aortic valve plane and tubular dilation measuring 46 mm, severe left ventricular systolic dysfunction, with an ejection fraction of 37% by Simpson, left ventricular end-diastolic diameter of 62 mm. Computed tomography (CT) angiography confirmed the diagnosis and he underwent valve-sparing aortic root surgery (David procedure). In the postoperative period, the patient developed bradypsychia, and a brain computed tomography scan revealed a large, old ischemic area. After clinical recovery, a more objective investigation revealed that the patient reported syncope with aphasia 12 months prior to hospitalization. The patient partially recovered, but maintained a condition of alexia, which had not been previously reported. The echocardiogram findings of volume overload with ventricular dilation associated with a stroke 12 months prior to hospitalization led to the conclusion that this was a natural survival of a chronic ascending aortic dissection. Conclusions: This case highlights the catastrophic consequences of cocaine use, including aortic dissection in young patient without significant aortic dilation and without traditional risk factors. The sympathomimetic effects of cocaine—notably hypertensive peaks and increased stress on the aortic wall—likely contributed to the development of the dissection. Left ventricular dysfunction, chamber dilation, and the previous stroke suggest a chronic process. David's procedure is a safe and effective approach, allowing for the preservation of the native valve and avoiding the use of oral anticoagulants in young patients.

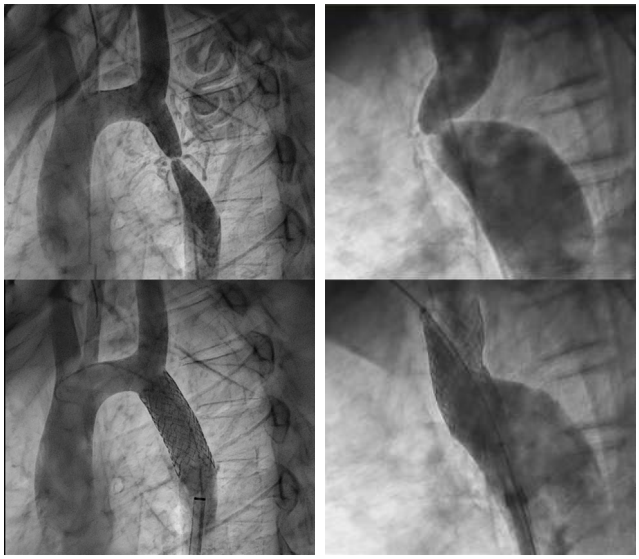
SINGLE-VENTRICLE HEART DISEASE CORRECTED WITH THE FONTAN PROCEDURE PROGRESSING TO COMBINED HEART AND LIVER TRANSPLANTATION: A CASE REPORT

MARIANNA RAMALHO DE SOUSA1; ROBERTO MONTEIRO LEITAO1; NICOLLE CAVALCANTE GAGLIONONE1; GIULIA MUNIZ CUNHA1; ALINE LIMA DA SILVA1; LARA VEIGA SORIA CATULADEIRA1; BRUNO MIRANDA MARQUES1;

(1) REDE DOR - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Univentricular circulation represents one of the rarest and most complex forms of congenital heart disease (CHD), characterized by the presence of a single functional ventricle. The Fontan procedure is crucial for establishing a circulation capable of improving patient survival by separating pulmonary and systemic blood flows; however, in the long term, it may lead to dysfunction in multiple organ systems Case Description: A 25-year-old female patient with a univentricular heart, mitral atresia, double outlet right ventricle with transposed great vessels, right-sided aortic arch, and situs inversus. She underwent bilateral Glenn surgery at 1 year of age and the Fontan procedure with valvuloplasty at 9 years of age. The patient subsequently developed Fontan-associated liver disease (FALD) and end-stage heart failure, requiring combined heart and liver transplantation (CHLT). Cardiac pathology revealed a single valve, a single ventricle, and an incomplete interventricular septum. The hepatic explant revealed two nodules (segments V and VII) of moderately differentiated hepatocellular carcinoma. Conclusions: The Fontan procedure is characterized by increased central venous pressure (CVP), low cardiac output, and lymphatic leakage with obstruction, leading to progressive cardiac and especially hepatic failure, substantially increasing morbidity and mortality in patients with this type of circulation. Hepatocellular carcinoma occurs in approximately 0.18–1.3% of cases of FALD, as observed in the present case. The preferred treatment is combined heart and liver transplantation due to the nearly universal presence of advanced fibrosis in these patients.



17000

SUBARACHNOID HEMORRHAGE AS THE INITIAL MANIFESTATION OF UNDIAGNOSED COARCTATION OF THE AORTA: A TWO-CASE REPORT

MARIANA ALMEIDA PEREIRA1; MAHER MAHMUD KARIM1; KIMBERLY MARIA BENTES VIANA1; MICHELE PELLISARI VIANA GHISI1; JESSICA DE CASSIA DOS SANTOS PELOSO1; INGRID APARECIDA MESQUITA LIMA1; HEIGLON ESTEVÃO BONELLA DENTI1; JUNIOR CHARLY FLORERO PEREIRA1; VICTOR MANUEL OPORTO LOPEZ1; GUSTAVO ROCHA FEITOSA SANTOS1; CAMILA GOMES SILVEIRA1; CÉLIA MARIA CAMELO SILVA1;

(1) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL;

Introduction: Coarctation of the aorta (CoA) is associated with systemic hypertension and an increased prevalence of intracranial aneurysms, resulting in a higher risk of subarachnoid hemorrhage (SAH). SAH as the initial presentation of CoA is uncommon and may reflect under-recognition of classic clinical signs, such as blood pressure discrepancy between upper and lower extremities and diminished femoral pulses. Case Description: Case 1: A 15-year-old previously healthy male presented with sudden-onset severe headache during a soccer match. He was diagnosed with SAH secondary to rupture of a left middle cerebral artery aneurysm and underwent endovascular embolization. Physical examination revealed marked blood pressure discrepancy between upper extremities (147/85 mmHg) and lower extremities (70/40 mmHg), along with diminished femoral pulses. Transthoracic echocardiography demonstrated CoA (peak gradient of 56 mmHg with diastolic runoff), bicuspid aortic valve with mild regurgitation, mild left ventricular hypertrophy, and preserved ejection fraction (73%). Computed tomography angiography confirmed severe CoA, with a 3 mm narrowing of the descending aorta distal to the left subclavian artery and extensive collateral circulation. The patient underwent percutaneous implantation of a covered stent (16×38 mm), resulting in complete resolution of the invasive pressure gradient (34 mmHg to 0 mmHg). Case 2: A 21-year-old male with poorly controlled hypertension had a history of two prior SAH episodes (2020 and 2022) due to ruptured intracranial aneurysms, both treated with surgical clipping. Abdominal ultrasound suggested CoA due to reduced aortic flow, confirmed by computed tomography angiography showing isthmic narrowing of 5 mm and prominent collateral circulation. He underwent percutaneous implantation of a covered stent (16×48 mm), with reduction of the invasive pressure gradient (27 mmHg to 5 mmHg). Conclusions: Subarachnoid Hemorrhage may represent a sentinel event of previously undiagnosed Coarctation of the aorta in young patients. Routine blood pressure measurement in all four extremities and assessment of femoral pulses are simple yet high-yield practices that may facilitate early diagnosis and prevent severe complications. Screening for CoA should be considered in young patients with SAH, particularly in the presence of hypertension or suggestive findings.

TRANSCATHETER TRICUSPID VALVE-IN-VALVE IMPLANTATION IN COMPLEX CONGENITAL HEART DISEASE WITH MULTIPLE PRIOR SURGERIES: FOUR-YEAR CLINICAL AND ECHOCARDIOGRAPHIC FOLLOW-UP

CAMILA MARIA SOARES DE LIMA1; BEATRICE CONSTANCE FREIRE BELEM SIMÃO1; ALEXANDRE ADAMES JORGE1; LUCAS BLASEK AUADA DE FARIA1; BRUNA GOPP BOTELHO1; A. TITO PALADINO1; MARCELO SILVA RIBEIRO1; ANA LUIZA PAULISTA GUERRA1; SIMONE ROLIM FERNANDES FONTES PEDRA1; GISELLE DE MONTALVÃO E ALPOIM LOUZAS1; FAUSTO FERES1; JAIME DA CONCEIÇÃO PADEIRO JÚNIOR1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction: Bioprosthetic tricuspid valve degeneration in patients with multiple prior cardiac surgeries represents a high-risk therapeutic challenge. Transcatheter valve-in-valve implantation in the tricuspid position has emerged as an option for patients with prohibitive reoperation risk, with published experience in this specific anatomical and clinical setting remaining limited. Case Description: A 30-year-old woman with complex congenital heart disease — pulmonary atresia with ventricular and atrial septal defects, Ebstein's anomaly, and patent ductus arteriosus — had undergone seven cardiac surgeries since 1995, including Waterston-Cooley anastomosis, right ventricular outflow tract augmentation with monocuspid patch, right pulmonary artery angioplasty, and two pulmonary valve replacements. In 2017, she underwent concomitant biological tricuspid (31 mm) and pulmonary (23 mm) valve replacement with additional outflow tract reconstruction. She subsequently developed NYHA class III dyspnea and lower-limb edema refractory to optimized medical therapy. Preoperative transesophageal echocardiography demonstrated structural dysfunction of the tricuspid bioprosthesis with a mixed lesion (mean gradient 10 mmHg; moderate-to-severe regurgitation), marked right atrial dilation, and impaired inferior vena cava collapsibility consistent with elevated systemic venous pressure. In 2022, she underwent transcatheter tricuspid valve-in-valve implantation using a 29 mm balloon-expandable prosthesis. At four-year follow-up she was fully asymptomatic, maintained on semiannual specialized cardiology review. Transthoracic echocardiography in 2026 demonstrated a normally functioning prosthesis with thin, mobile leaflets, absent regurgitation on Doppler, mean gradient of 5 mmHg, mild residual right chamber dilation with preserved right ventricular systolic function, and left ventricular ejection fraction of 62%. Pulmonary prosthesis function remained stable without significant regurgitation. Conclusions: Transcatheter tricuspid valve-in-valve implantation was feasible and effective in a patient with complex congenital anatomy and prohibitive surgical risk, yielding complete symptomatic resolution and durable hemodynamic benefit at four-year follow-up, meeting established criteria for procedural success.

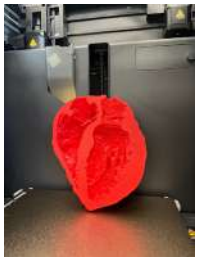
BEYOND THE HYPERTROPHIC PHENOTYPE: 3D CARDIAC PRINTING AS A TOOL FOR CLINICAL REASONING AND FAMILY EDUCATION IN FABRY DISEASE-ASSOCIATED HYPERTROPHIC CARDIOMYOPATHY.



JOSE GREGORIO VALERO RODRIGUEZ1; ANA LUIZA BORGES DE AMORIM2; ANA BEATRIZ COSTA DO COUTO2; LUCAS MATIAS GALVÃO VITÓRIA2; NATHALIA SALIM SAUD2; GUILHERME CESAR FERNANDES DE OLIVEIRA DA COSTA2; ANNA CECÍLIA DE OLIVEIRA MACHADO2; WESLEY RODRIGO NOGUEIRA DIAS2; ANDRÉ CAMARGO MAZZOCCHI2; ISABELA LIRA VIEIRA2; CLAUDIO TINOCO MESQUITA2; EVANDRO TINOCO MESQUITA2;

(1) PROGRAMA DE POS GRADUACAO EM CIENCIAS CARDIOVASCULARES - UFF - NITERÓI - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL;

Introduction: Fabry Disease (FD) is a rare lysosomal storage disorder that requires a high index of clinical suspicion, as it is a major cardiovascular phenocopy. Early diagnosis is currently based on diagnostic multimodality, where Cardiovascular Magnetic Resonance (CMR) and strain Echocardiography (ECG) overcome the limitations of conventional assessment by detecting early lipid accumulation. Additionally, the use of personalized 3D models emerges as a strategic facilitator: beyond assisting multidisciplinary team decisions, these models function as engagement tools for the patient and their family, streamlining cascade screening and the initiation of specific therapy. Case Description: A 42-year-old male amateur athlete presented with progressive headache, muscle spasms, and reduced exercise tolerance with episodes of pre-syncope. Physical examination revealed hypertension (150/90 mmHg). A detailed family history was crucial, revealing relatives diagnosed with FD and cases of early sudden death in male family members. Laboratory tests showed severe renal dysfunction (Cr 11.08 mg/dL) and elevated NT-proBNP. The ECG showed a short PR interval and voltage criteria for Left Ventricular Hypertrophy (LVH). Global longitudinal strain Echocardiography demonstrated reduced deformation in the basal segments, differing from the apical sparing pattern seen in other amyloidoses. CMR confirmed severe LVH (23 mm; mass of 430 g) without Late Gadolinium Enhancement (LGE), suggesting a sphingolipid accumulation phase without extensive fibrosis. Etiological confirmation was achieved via genetic testing, identifying a pathogenic variant in the GLA gene in hemizygosity. Educational Intervention and 3D Printing: To optimize health literacy, a personalized 3D cardiac model was created using the Fused Deposition Modeling technique based on CT angiography. The physical model allowed for tactile visualization of concentric hypertrophy and cavity reduction, facilitating the family's understanding of the pathology. This tool was decisive for engagement in family screening, resulting in the identification of two additional affected family members. Conclusions: FD is a mandatory differential diagnosis in unexplained LVH associated with "red flags" (renal failure and short PR interval). 3D printing emerges as an innovative bridge between advanced cardiovascular imaging and patient-centered education, enhancing genetic counseling and early detection in hereditary cardiomyopathies.

EUGLYCEMIC DIABETIC KETOACIDOSIS IN THE POSTOPERATIVE PERIOD OF CARDIAC SURGERY: THE CHALLENGES OF SGLT2 INHIBITORS

RAYANNE BARROS SPINA1; ERICA SILVA2; ISABELA GALIZZI FAE2; DANILO CASTRO PIRES ALMEIDA2; ANA LUIZA VALLE MARTINS2; FERNANDO FREITAS COUTINHO2;

(1) FACULDADE DE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) REDE MATER DEI DE SAUDE - BELO HORIZONTE - MG - BRASIL;

Introduction: Sodium-glucose cotransporter 2 inhibitors (SGLT2i) are fundamental in the treatment of patients with heart failure, diabetes, and kidney disease, due to their cardiometabolic effects and reduction of cardiovascular events. Euglycemic diabetic ketoacidosis (DKA) is a rare (0.6%) and severe adverse event, attributed to the failure to discontinue the medication during the perioperative period. Glycosuria and reduced insulin levels, associated with increased counter-regulatory hormones, such as glucagon and cortisol, which are already elevated due to surgical stress, lead to severe metabolic imbalance. Diagnosis is challenging, since hyperglycemia is absent, and metabolic acidosis in the postoperative period of complex surgeries may be attributed to tissue hypoperfusion and vasoplegic shock. Case Description: A 74-year-old male patient with diabetes, in regular use of empagliflozin, presented with acute coronary syndrome and indication for coronary artery bypass grafting. In the immediate postoperative period, he developed severe hemodynamic instability, suggestive of vasoplegic shock secondary to cardiopulmonary bypass. Despite the treatment instituted, he persisted with metabolic acidosis: pH 7.24 and bicarbonate 9 mEq/L, associated with an elevated anion gap of 20 mEq/L, normal blood glucose levels, and no proportional lactatemia, with lactate of 2.3 mmol/L. After reviewing the patient's clinical history and identifying recent empagliflozin use, the hypothesis of euglycemic DKA was raised. Confirmation was obtained after urinary investigation, which showed ketonuria 3+ and glycosuria 3+. Intravenous treatment was promptly directed with rigorous hydration, insulin, hypertonic glucose, and potassium replacement. The patient's metabolic condition was stabilized, with rapid clinical improvement. Conclusions: The diagnosis of euglycemic DKA associated with failure to discontinue SGLT2i before cardiac surgery is challenging, since the presence of acidosis in this context may be attributed to other more likely causes, given the systemic inflammatory response. As SGLT2i becomes increasingly common in cardiology practice, it is essential to incorporate their assessment into the preoperative routine. Proper discontinuation and active postoperative suspicion are fundamental measures to prevent diagnostic delay and reduce morbidity and mortality. Discontinuation of SGLT2i at least 72 hours before elective procedures is essential to prevent this potentially lethal complication.

A RARE ASSOCIATION BETWEEN YAMAGUCHI SYNDROME AND CORONARY ARTERY FISTULA DRAINING INTO THE LEFT VENTRICLE AS A CAUSE OF SYNCOPE: A CASE REPORT

DANIELA GALON CARNIEL1; CRISTIANE DE OLIVEIRA SOUZA1; LEONARDO DE MOURA LEAL1; VITOR BONIATTI NEVES1; PEDRO TERRA CALIL MACEDO1; RAFAEL MIRANDA DE MARCO1; MATHEUS CRIPPA PETRILLO1; ARTHUR MENEZES SCHMITZ1; ANNA BEATRIZ DE SOUZA SOUSA1; AMANDA RIVA ROHERS1; ISABELLA PAGLIOLI CANALI1; MARIA CLAUDIA DUTRA BARCELLOS GUTERRES DA COSTA1;

(1) PUCRS - PORTO ALEGRE - RS - BRASIL;

Introduction: Yamaguchi syndrome is a rare variant of hypertrophic cardiomyopathy linked to MYH7 and MYBPC3 mutations. It features left ventricular apical hypertrophy (≥15 mm) and the classic “ace of spades” sign. Patients are often asymptomatic but may have fatigue, dyspnea, angina, arrhythmias, or syncope. Complications include myocardial infarction, stroke, and sudden cardiac death. Coronary abnormalities, such as fistulas draining into Thebesian veins, can worsen oxygen supply–demand imbalance. When significant, they may intensify the coronary steal phenomenon, aggravating ischemia and requiring surgical or catheter-based treatment. Case Description: An 81-year-old woman, with a history of hypertension, previous coronary artery bypass grafting and pulmonary fibrosis, was admitted for evaluation after falling from standing height, associated with transient loss of consciousness while walking. The episode occurred abruptly, without prodromal symptoms, and the patient was unable to recall the event afterward. On cardiovascular examination, heart rhythm was regular, heart sounds were normal, and a grade 3/6 systolic murmur was heard at the aortic area. Transthoracic echocardiography showed normal left ventricular dimensions, preserved systolic function, grade I diastolic dysfunction, mild biatrial enlargement, mild aortic regurgitation, and mild mitral regurgitation. In addition, there was marked asymmetric hypertrophy of the apical left ventricular segments, a pattern consistent with apical hypertrophic cardiomyopathy, also known as Yamaguchi syndrome. Coronary angiography demonstrated the absence of significant obstructive coronary stenoses, but disclosed extensive coronary venous drainage into the left ventricle through the Thebesian venous plexus, resulting in a high-flow coronary pattern. Taken together, the findings supported the diagnosis of a rare association between apical hypertrophic cardiomyopathy and anomalous coronary fistulous drainage to the left ventricle, identified during the investigation of unexplained syncope. Conclusions: This case highlights the rare association between Yamaguchi Syndrome and anomalous coronary drainage through Thebesian veins. Even without obstructive coronary disease, severe ischemia can occur; thus, identifying such vascular anomalies is essential for accurate risk stratification and clinical management in patients with apical hypertrophy.

20162

DILATED CARDIOMYOPATHY ASSOCIATED WITH DMD GENE MUTATION PRESENTING AS AN ISOLATED CARDIAC PHENOTYPE IN ADULTHOOD: A RARE PRESENTATION

ANA LUÍSA MALTA DÓRIA1; PEDRO DAVI DA FONSECA CARVALHO TENÓRIO1; ANA PAULA MACHADO SOARES1; JULLIE DE QUEIROGA SANTANA1; HEITOR RÉGIS SPINELLI1; CAMILA TERESA NÓBREGA1; EDUARDO DAMASCENO MOTA1; ARTHUR LOPES FEITOSA MARIZ1; ANTONIO TIAGO GUERRA DE ALBUQUERQUE NETO1; FRANCISCO DIOGO ALMEIDA SILVA1; ANDREA DE FREITAS PIMENTEL TOSCANO1; CARLOS EDUARDO LUCENA MONTENEGRO1;

(1) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL;

Introduction: Dilated cardiomyopathy associated with the dystrophin gene (DMD) is classically linked to Duchenne and Becker muscular dystrophies. Presentation as an isolated cardiac phenotype, also referred to as Duchenne type 3, particularly in adults and in the absence of skeletal muscle involvement, is rare and often underdiagnosed. Case Description: A 41-year-old male has been under follow-up since 2015 due to heart failure and palpitations. Initial echocardiography demonstrated dilated cardiomyopathy with diffuse left ventricular (LV) hypokinesia, progressing to a left ventricular ejection fraction (LVEF) of 26% in 2022. Investigation excluded ischemic (normal coronary arteries) and infectious etiologies. Serial evaluations showed progressive LV dilation (LV end-diastolic diameter up to 60 mm), systolic dysfunction with inferolateral akinesia and diffuse hypokinesia, as well as diastolic dysfunction and mild left atrial enlargement. Cardiac magnetic resonance imaging was not performed due to limited availability at the institution. A 24-hour Holter monitor in 2024 revealed a high burden of ventricular ectopy (~1300/24 h) and an episode of non-sustained ventricular tachycardia, with similar findings documented since 2015. Genetic testing (January 2024) identified a hemizygous c.5794C>T (p.Gln1932Ter) variant in the DMD gene, classified as likely pathogenic. Family history was positive for cardiomyopathy in siblings, suggesting X-linked inheritance, without reported skeletal muscle involvement. The patient is currently on enalapril, bisoprolol, digoxin, and furosemide. He showed improvement in LVEF to 45%, remains in New York Heart Association functional class I, and is not receiving SGLT2 inhibitor therapy. Conclusions: This case illustrates a rare presentation of DMD gene–associated cardiomyopathy with an isolated cardiac phenotype in an adult, without skeletal muscle involvement. This pattern may delay diagnosis when initially classified as idiopathic. The combination of non-ischemic echocardiographic findings and a positive family history was key to raising suspicion, later confirmed by genetic testing. This report highlights the importance of genetic investigation in apparently idiopathic dilated cardiomyopathies, with implications for family screening and clinical management.

GENETICS CLARIFIES INTRAUTERINE BRADYCARDIA: HOMOZYGOUS CACNA1D + TTR V50M IN SEVERE CONDUCTION SYSTEM DISEASE

JOÃO ANCELMO DOS REIS NETO1; FLÁVIA RENNÓ TROIANI2; GABRIELA FERNANDA ESQUERDO SAMPAIO3; CAROLINE CORDEIRO BARROSO BRAGA4; LARISSA VENTURA RIBEIRO BRUSCKY3; PLINIO JOSE WHITAKER WOLF3; EDUARDO MIKIO SASSAKI3; SARA REGINA ALCADE DOMINGOS3; EDILEIDE DE BARROS CORREIA3;

(1) BENEFICENCIA PORTUGUESA - SAO PAULO - SP - BRASIL; (2) HOSPITAL SÃO LUIZ MORUMBI - SÃO PAULO - SP - BRASIL; (3) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (4) PONTIFÍCIA UNIVERSIDADE CATÓLICA DE CAMPINAS - CAMPINAS - SP - BRASIL;

Introduction: Hereditary transthyretin amyloidosis (ATTRv), particularly associated with the V50M variant of the TTR gene, is characterized by variable penetrance and a broad phenotypic spectrum, including neuropathic and cardiac involvement. Although cardiac manifestations typically occur later in life, early electrical abnormalities may precede overt structural disease. In parallel, the CACNA1D gene encodes the Cav1.3 L-type calcium channel, which plays a critical role in sinoatrial node automaticity and atrioventricular conduction. Pathogenic variants in CACNA1D have been associated with severe, early-onset conduction system disorders, including fetal and childhood bradyarrhythmias. Increasing evidence suggests that the interaction between variants in distinct genes may underlie oligogenic inheritance models, contributing to atypical or more severe phenotypes. In this context, the coexistence of TTR and CACNA1D variants may represent a combined genetic substrate influencing early conduction disease and long-term cardiovascular risk. Case Description: A 29-year-old obese female presented with significant bradycardia since intrauterine life, prompting consideration of pregnancy termination. She required atrial pacemaker implantation at 3 years of age. Mild hearing impairment was also present, expanding the extracardiac phenotype. Born to consanguineous parents (third-degree cousins), she was referred for cardiomyopathy evaluation after identification of the pathogenic V50M variant in the TTR gene (2023). A homozygous variant of uncertain significance (VUS) in CACNA1D was also identified. Both parents were heterozygous for CACNA1D, with sinus bradycardia; the father also carried the V50M variant without clinical amyloidosis. The combination of early conduction disease and hearing impairment suggests an expanded phenotype related to Cav1.3 dysfunction, supporting the pathogenic role of the homozygous CACNA1D variant. Conclusions: This case supports a potential oligogenic model involving CACNA1D and TTR, in which the homozygous CACNA1D variant may explain the severe and very early-onset conduction system dysfunction, present since fetal life, while the ATTR V50M variant represents an additional risk for future infiltrative cardiomyopathy. These findings highlight the importance of comprehensive genetic evaluation in patients with unexplained early conduction disease, not only for etiological clarification but also for prognostic stratification and familial risk assessment.

HOT PHASES CARDIOMYOPATHY DUE TO DESMOPLAKIN PHATOGENIC GENE MUTATION

HENRIQUE AMARAL BRASIL1; GABRIEL LEONARDO A NETO1; YURI OSMAR COSTA1; RODRIGO MENDES FREITAS2; LETICIA POLI FONSECA2; ANDRÉ SILVA RODRIGUES2; MARCELO FONSECA GUIMARÃES2; EDUARDO BELISARIO FALCHETTO BELISARIO FALCHETTO2; MARIA CONSOLAÇÃO VIEIRA MOREIRA2;

(1) HOSPITAL FELICIO ROCHO - BELO HORIZONTE - MG - BRASIL; (2) HOSPITAL FELÍCIO ROCHO - BELO HORIZONTE - MG - BRASIL;

Introduction: Introdution: Hot phases are a challenging clinical presentation in some genetic cardiomyopathies, among them a Desmoplakin (DSP) cardiomyopathy . Hot phase is marked by acute chest pain and elevated cardiac troponins. Case Description: Case report: A 18 - year- old fit and health male presented with chest pain and dyspneia. Physical examination was normal. ECG: sinus rhythm, small Q waves in leads II, III and aVF. Laboratory markers were normal, except troponin and NT proBNP. Echocardiogram:Left ventricular ejection fraction (LVEF) of 66% and CMR showed LVEF of 44%, myocardial edema assessed using T2-weighted Imaging and extensive subepicardial fibrosis, detected via late gadolinium enhancement (LGE). Coronary angiography: normal coronary arteries. Heart failure (HF) therapy was started. Ten months later: No cardiac symptoms; troponin, NT proBNP and LVEF of 62%. CMR:LVEF of 46%, no edema; presence of subepicardial fibrosis. 24 hour Holter monitor: Sinus rhythm and 1588 ventricular extrasistoles. Sixteen months later he presented with severe chest pain e dyspneia at rest. A new CMR showed LVEF of 26%, RVEF of 29%, no edema, but extensive subepicardial LGE. Endomyocardial Biopsy: No signs of inflammatory cardiomyopathy or acute myocarditis, no giant cell myocarditis, no sarcoidosis. No infiltration with lymphocytes (CD3, LFA-1, CD45R0), cytotoxic cells (perforin) and macrophages (Mac-1), no enhanced endothelial expression of cell adhesion molecules (HLADR). No signs of storage disease. Negative PCR results for enteroviruses (Cox), herpesvirus type 6 A/B, cytomegalievirus, Epstein Barr virus, and parvoviruses. Normal PET Scan. Genetic test demonstrated a pathogenic variant in the DSP gene. An ICD was implanted. HF treatment optimized. LVEF improved to 49%. Follow up 27 months later:He presented, again, with severe chest pain e dyspneia at rest. He was hospitalized and the CMR showed a LVEF of 42%, presence of edema and extensive subepicardial LGE. Troponin:12970 ng/mL and NT proBNP: 16640 pg/mL. Despite the treatment of DSP- myocarditis is still unknown, we treated him with 1,000 mg intravenous methylprednisolone for 3 days with a taper to oral steroids over a 2- to 3-week period. The patient was discharged home and 14 days later, a new Echocardiogram showed a LVEF of 50%. He improved symptoms, troponin and NT proBNP were normal. Conclusions: Conclusion: This case suggests a possible involvement of DSP pathogenic mutation in a hot phases cardiomyopathy.

ANGINA AS A MARKER OF LATE CARDIAC REINNERVATION AFTER TRANSPLANTATION: A CASE REPORT WITH 24-YEAR SURVIVAL

PLÍNIO JOSÉ WHITAKER WOLF1; EDILEIDE DE BARROS CORREIA1; MARCOS OLIVEIRA VASCONCELLOS1; ANA CRISTINA MURTA1; YONA AFONSO FRANCISCO1; LARISSA VENTURA BRUSCKY1; SARA REGINA ALCALDE DOMINGOS1; EDUARDO MIKIO SASSAKI1; GABRIELA ESQUERDO1; THAIS GRECCA ANDRADE1; FERNANDA DE BRITO FORTUNA1; VICTOR BEMFICA1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction: Heart transplantation (HTx) is the definitive, gold-standard therapy for patients with advanced, refractory heart failure, significantly improving survival, with a mean post-transplant survival of approximately 7–12 years. However, one of the main factors limiting long-term survival is cardiac allograft vasculopathy (CAV), which leads to ischemia, fibrosis, and ventricular dysfunction, often presenting with minimal or atypical symptoms due to post-transplant cardiac denervation. We describe a case of a transplant recipient with survival beyond the international average who developed symptomatic CAV. Case Description: A 68-year-old man, with a history of hypothyroidism prior to HTx, underwent bicaval orthotopic heart transplantation 24 years ago (donor aged 19 years) for advanced valvular heart disease, without perioperative complications. He had an uneventful post-transplant course, developing dyslipidemia but no major complications, including cellular or antibody-mediated rejection, malignancy, or cytomegalovirus infection. Over the past 10 years, he has been treated with simvastatin, levothyroxine, and aspirin, along with immunosuppressive therapy consisting of cyclosporine and mycophenolate sodium. During follow-up, the patient remained asymptomatic, with echocardiography demonstrating preserved biventricular function, and coronary CT angiography at 17 years post-transplant showing no obstructive coronary lesions. At 24 years post-HTx, the patient developed progressive, typical angina (CCS class III), associated with exertional dyspnea. Echocardiography showed a left ventricular ejection fraction of 67%, global longitudinal strain of 23%, normal chamber dimensions and contractility, and no valvular disease or pulmonary hypertension. Coronary angiography revealed a subocclusive lesion in the mid right coronary artery, which was successfully treated with percutaneous coronary intervention. The patient subsequently remained asymptomatic. Conclusions: Post-transplant survival is primarily limited by CAV. This case highlights that optimal control of comorbidities, appropriate immunosuppression, and favorable donor/graft characteristics may delay the onset of CAV, contributing to survival beyond the international average. Moreover, the presence of typical angina suggests cardiac reinnervation (particularly sympathetic), which may facilitate the clinical recognition of CAV and could be associated with the favorable prognosis observed in this patient.

Figure 1. Coronary angiography before (A) and after (B) percutaneous coronary intervention.

A: Coronary angiography in the left anterior oblique projection demonstrating a subocclusive lesion in the mid right coronary artery (red arrow). **B:** Coronary angiography in the left anterior oblique projection following percutaneous coronary intervention of the mid right coronary artery lesion (yellow arrow).

ELECTRICAL STORM ASSOCIATED WITH REACTIVATION OF CARDIAC SARCOIDOSIS FOLLOWING OXANDROLONE USE

MATHEUS SACCO GOMES1; AMANDA RAQUEL COSTA CRUZ1; BRUNO LEAL MARTINS1; MARIO HENRIQUE CALIANO1; PATRICIA DE SOUZA MAGALHAES1; CECILIA MONTEIRO BOYA BARCELLOS1; DALMO ANTONIO RIBEIRO MOREIRA1; LARISSA VENTURA RIBEIRO BRUSCKY1; IBRAIM MASCIARELLI FRANCISCO PINTO1; PLINIO JOSE WHITAKER WOLF1; EDILEIDE DE BARROS CORREIA1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction: Sarcoidosis is a multisystem granulomatous disease of unknown etiology, characterized by non-caseating inflammation. Clinically manifest cardiac involvement occurs in 5% of cases, although advanced imaging and autopsy studies suggest an underdiagnosed prevalence of up to 25–30%. Cardiac Sarcoidosis (CS) is an important cause of atrioventricular blocks, cardiomyopathy, and malignant ventricular arrhythmias, which frequently occur due to reentry involving fibrotic scars interspersed with active granulomatous inflammatory foci. We report a case of electrical storm (ES) in a patient with CS in metabolic remission, presenting isolated inflammatory reactivation in the context of recent oxandrolone use. Case Description: A 46-year-old male patient started follow-up in 2022 due to dyspnea and complete atrioventricular block (CAVB), undergoing permanent pacemaker implantation. In 2023, he presented with sustained ventricular tachycardia (VT) and reduced ejection fraction (LVEF 37%). Cardiac Magnetic Resonance revealed extensive mid-wall and epicardial late gadolinium enhancement with a non-ischemic fibrosis pattern (Figure 1). Ablation of the arrhythmogenic substrate and upgrade to an Implantable Cardioverter-Defibrillator (ICD) were performed. Screening for secondary etiologies and exome sequencing were negative. Given the findings, an 18F-FDG PET/CT was performed in April 2024, confirming systemic sarcoidosis with cardiac uptake (SUVmax 11.4). Following immunosuppression (prednisone and methotrexate), a new PET/CT in November 2024 demonstrated complete remission. In January 2026, the patient was admitted with an ES (>20 episodes of VT/VF) after oxandrolone use in the past 3 months and alcohol consumption. Management included deep sedation, amiodarone, lidocaine, magnesium sulfate, and left stellate ganglion block. A new PET/CT in January 2026 confirmed isolated reactivation of CS (SUVmax 6.6 in the LV), without systemic foci. Pulse therapy was initiated, followed by an Adalimumab and Methotrexate regimen. He was discharged on optimized immunosuppression and referred for heart transplant evaluation due to the severity and refractoriness of the disease. Conclusions: Electrical storm can be the sole manifestation of isolated cardiac sarcoidosis reactivation, despite systemic remission. This case highlights the risk of exogenous triggers, such as oxandrolone, in vulnerable myocardium. Following clinical stabilization, PET/CT is essential for patient follow-up and to guide immunosuppressive therapy.

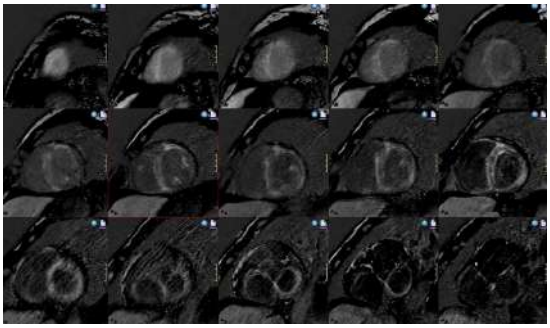
EVANS SYNDROME FOLLOWING INOTERSEN THERAPY IN HEREDITARY ATTR AMYLOIDOSIS WITH CARDIAC INVOLVEMENT: A RARE HEMATOLOGIC COMPLICATION

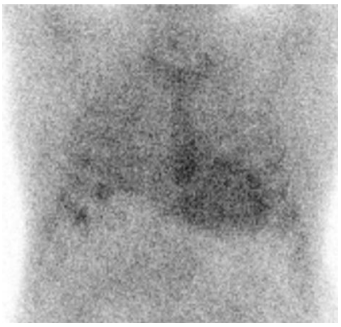
ANA BEATRIZ NEPOMUCENO CUNHA1; JULIANA CORRÊA DE OLIVEIRA CAIED1; GABRIEL MOSTARO FONSECA1; ALINE SABRINA HOLANDA TEIXEIRA MORAES SABRINA HOLANDA TEIXEIRA MORAES1; RÔMULO FONSECA DE MORAES1; MARCELO CAPITO CASTILHO1; MOYSÉS ANTÔNIO PORTO SOARES1; BRUNA GONÇALVES GUSTINELLI1; YASMIN TRINDADE MEIRELES1; RIANE RODRIGUES MARTION1; RODRIGO NORONHA CAMPOS1;

(1) BENEFICENCIA PORTUGUESA - SAO PAULO - SP - BRASIL;

Introduction: Hereditary transthyretin amyloidosis (ATTRv) is an autosomal dominant condition marked by systemic amyloid deposition, mainly affecting peripheral nerves and the myocardium. Inotersen, an antisense oligonucleotide that suppresses hepatic transthyretin synthesis, is an established treatment option, although it may lead to hematologic toxicity. Autoimmune hemolytic anemia related to this therapy is exceptionally uncommon and remains poorly described in the literature. Case Description: A 70-year-old man with a history of hypertension and diabetes presented with progressive distal paresthesia, proximal muscle weakness, and fatigue over two years, initially attributed to polyneuropathy. His condition evolved with weight loss and gait impairment, leading to a diagnosis of stage II familial amyloid polyneuropathy. Tafamidis 20 mg/day was initiated, and inotersen was added four years later. Cardiac involvement was confirmed by bone scintigraphy and cardiac magnetic resonance imaging, both consistent with amyloid cardiomyopathy. Genetic testing identified a Val50Met mutation in the transthyretin gene, confirming ATTRv. During follow-up, the patient developed clinical worsening and required hospitalization due to severe anemia (hemoglobin 6 g/dL), thrombocytopenia, and elevated NT-proBNP levels (2,068 pg/mL). Further investigation revealed autoimmune hemolytic anemia with associated thrombocytopenia, including microspherocytes on peripheral smear, consistent with Evans syndrome and strongly suggestive of a drug-induced mechanism. Inotersen was discontinued, and treatment was subsequently adjusted. Conclusions: While thrombocytopenia and systemic reactions are recognized adverse effects of inotersen, this case highlights a rare occurrence of Evans syndrome potentially related to its use. It underscores the need for close hematologic surveillance and a high index of suspicion when unexplained cytopenias arise during antisense therapy, enabling timely diagnosis and management of this unusual complication.



16886



NON-INVASIVE DIAGNOSIS OF HEREDITARY TRANSTHYRETIN CARDIAC AMYLOIDOSIS: APPLICATION OF THE DIAGNOSTIC ALGORITHM IN A PATIENT WITH VAL122ILE VARIANT

ADIEL CARVALHO JUNIOR1; THIAGO BACCILI CURY MEGID1; ANNA CLARA DE MELO SOUSA FERRO1; JOÃO VITOR MIRANDA SOUTO FERREIRA1; LUCAS ITALO FERRARI SANTOS1; CYNTHIA SPERANDIO1; RENATO DE FARIAS VIGOLO1; LORENA MOREIRA LAVOYER1; LIVIA MARIANA LIMA GAVA1; CAROLINA BERTININI BONINI1; CAMILA CALDEIRA UBIDA1;

(1) FACULDADE DE MEDICINA DE SÃO JOSÉ DO RIO PRETO - SÃO JOSÉ DO RIO PRETO - SP - BRASIL;

Introduction: Hereditary transthyretin cardiac amyloidosis (ATTRv-CM) is a progressive disease caused by TTR gene variants that promote transthyretin protein misfolding, resulting in myocardial amyloid deposition. The Val122Ile variant is the most prevalent in the United States, present in 3.4% of African Americans, manifesting as cardiomyopathy after age 60. The modern diagnostic approach allows non-invasive diagnosis through monoclonal protein screening, technetium-99m pyrophosphate scintigraphy, and TTR gene sequencing. This report describes a case of ATTRv-CM with the Val122Ile variant, demonstrating the practical application of the contemporary non-invasive diagnostic algorithm. Case Description: A 71-year-old male presented with progressive dyspnea evolving to functional class IV. Electrocardiogram showed atrial fibrillation with diffusely low QRS voltage. Echocardiogram revealed biventricular dysfunction (LVEF 34.6%), septal thickening with hyperrefringence, and valvular disease. The discordance between low voltage and myocardial thickening raised suspicion of infiltrative disease. Cardiac MRI showed diffuse transmural late enhancement suggestive of storage disease (Figure 1). Following the diagnostic algorithm, AL amyloidosis was excluded through normal serum and urine immunofixation and light chain assays. Technetium-99m pyrophosphate scintigraphy demonstrated grade 2 uptake, confirming ATTR-CM (Figure 2). Genetic testing identified the pathogenic Val122Ile mutation, establishing hereditary transthyretin cardiac amyloidosis diagnosis. Conclusions: This case demonstrates the systematic application of the non-invasive diagnostic algorithm for ATTRv-CM, achieving diagnosis without endomyocardial biopsy. Identification of the Val122Ile variant has important implications for family screening and genetic counseling of asymptomatic carriers at risk.The voltage-mass discordance remains a key clinical clue for infiltrative cardiomyopathy suspicion. Early recognition is essential, as TTR stabilizer therapy reduces mortality and hospitalizations.

21854

PHENOTYPIC PROGRESSION FROM HYPERTROPHIC CARDIOMYOPATHY TO DILATED AND ARRHYTHMOGENIC PHENOTYPE IN A PATIENT CARRYING A TPM1 VARIANT

HENRIQUE MOTOKI OLIVEIRA1; MARIA LUIZA RODRIGUES TAMBORINI1; ISABELLA CABRAL MARINHO PLENS1; EDUARDO ALBANSKE RABONI1; MYLENA MIKI LOPES IDETA1; VIVIANE TIEMI HOTTA1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction: Hypertrophic cardiomyopathy (HCM) is a primary myocardial disease characterized by left ventricular hypertrophy resulting from pathogenic variants in genes encoding sarcomeric proteins. Progression to dilated cardiomyopathy (DCM) is observed in only 3–5% of cases and is considered a marker of worse prognosis. Variants in the TPM1 gene, which encodes alpha-tropomyosin, account for 1–5% of HCM cases and present heterogeneous phenotypes, including hypertrophic, dilated, or arrhythmogenic forms. Case Description: A 66-year-old hypertensive woman presented with a 20-year history of progressive dyspnea associated with atypical chest pain, dizziness, and syncope. There was no family history of cardiomyopathy or sudden cardiac death. Initial investigation with transthoracic echocardiography (TTE) demonstrated interventricular septum (IVS) thickness of 14 mm, a maximum left ventricular outflow tract gradient of 51 mmHg, and preserved left ventricular ejection fraction (LVEF). Subsequent cardiac magnetic resonance (CMR) revealed IVS thickness of 26 mm and multifocal diffuse midwall late gadolinium enhancement with a non-ischemic pattern, without ventricular dysfunction despite 40% myocardial fibrosis. Coronary angiography showed no obstructive lesions. Twenty-four-hour Holter monitoring demonstrated first-degree atrioventricular block (AVB), with episodes of complete AVB and atrial fibrillation, leading to pacemaker and implantable cardioverter-defibrillator (ICD) implantation and anticoagulation. Genetic testing identified a pathogenic heterozygous TPM1 variant. After 9 years of follow-up, the patient developed progressive ventricular dysfunction (LVEF: 24%), requiring upgrade to CRT-D. Despite optimized heart failure medical therapy, the patient progressed to NYHA functional class III. Conclusions: This case illustrates the progression of hypertrophic cardiomyopathy to a dilated phenotype in a patient carrying the p.Arg21Leu TPM1 variant. Extensive myocardial fibrosis identified by cardiac magnetic resonance, involving 40% of the myocardium, had already suggested a higher risk of adverse progression associated with this genetic variant. This report reinforces the phenotypic heterogeneity of variants related to hypertrophic cardiomyopathy and highlights the importance of early surveillance for markers of poor prognosis in patients carrying pathogenic TPM1 variants.

PHENOTYPIC TRANSITION FROM DANON DISEASE–RELATED HYPERTROPHIC CARDIOMYOPATHY TO BIVENTRICULAR ARRHYTHMOGENIC CARDIOMYOPATHY REQUIRING HEART TRANSPLANTATION

GIOVANA PEREIRA BELITARDO1; NATÁLIA QUINTELLA SANGIORGI OLIVETTI1; FELIPE CERQUEIRA1; DEBORAH BELFORT1; LUIZ ALBERTO1; GIOVANNA NAPOLITANO1; DERNIVAL DANTAS DIAS JUNIOR1; LUCIANA SACILOTTO1; EDIMAR ALCIDES BOCCHI1; BRUNO BISELLI1; JOSÉ EDUARDO KRIEGER1; SILVIA MOREIRA AYUB FERREIRA2;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introduction: Danon disease is an X-linked lysosomal storage disorder caused by LAMP2 variants, classically associated with hypertrophic cardiomyopathy. In women, the phenotype is variable and often atypical. Arrhythmogenic cardiomyopathy (ACM) is characterized by fibrofatty myocardial replacement and ventricular arrhythmias. We report a case of genetically confirmed Danon disease with evolution to a phenotype consistent with ACM across clinical, imaging, and histopathological findings. Case Description: A 43-year-old woman with a hypertrophic phenotype at age 30 (short PR interval and preserved left ventricular function) showed progressive electrical and structural remodeling over 10 years, including low QRS voltages, ventricular arrhythmias, and severe biventricular dysfunction. Cardiac magnetic resonance demonstrated extensive ring-like mid-myocardial and subepicardial late gadolinium enhancement, fulfilling criteria for biventricular ACM. Genetic testing identified a pathogenic LAMP2 variant, confirming Danon disease. The patient progressed to advanced heart failure requiring inotropes, intra-aortic balloon pump support, and heart transplantation. Pathological examination of the explanted heart demonstrated extensive fibrofatty myocardial replacement, along with multiple foci of enlarged, vacuolated cardiomyocytes showing strong periodic acid–Schiff (PAS) positivity. Conclusions: This case demonstrates a rare phenotypic transition from hypertrophic cardiomyopathy to an arrhythmogenic phenotype in Danon disease. Multimodality evaluation and histopathology supported a genuine arrhythmogenic remodeling process, highlighting the importance of serial phenotypic reassessment in genetic cardiomyopathies

Figure 1: Electrocardiogram showing sinus rhythm, a short PR interval and repolarization abnormalities.

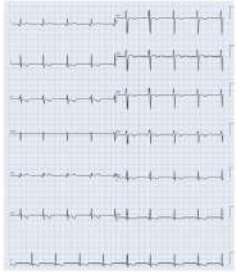

Figure 2: Echocardiogram showing mild ventricular thickening

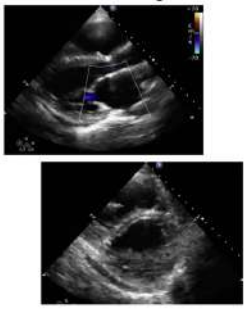

Figure 3: Pathological microscopy showing multiple foci of enlarged, vacuolated cardiomyocytes strongly stained by periodic acid-Schiff (PAS).

PRE-EXCITED ATRIAL FIBRILLATION AND LEFT VENTRICULAR HYPERTROPHY: FABRY DISEASE

MATHEUS SACCO GOMES1; PATRICIA DE SOUZA MAGALHÃES1; BRUNO LEAL MARTINS1; MARIO HENRIQUE CALIANO1; AMANDA RAQUEL COSTA CRUZ1; BEATRIZ FLORIAM FOLTRAN1; GABRIELA FERNANDA ESQUERDO SAMPAIO1; PLINIO JOSE WHITAKER WOLG1; KELIN CHEN1; EDILEDE DE BARROS CORREIA1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introduction: Fabry Disease (FD) is an X-linked inborn error of metabolism causing lysosomal glycosphingolipid accumulation. Myocardial involvement often mimics Hypertrophic Cardiomyopathy (HCM). Integrating clinical reasoning and multimodal imaging is crucial for etiological distinction and the complex challenge of reclassifying Variants of Uncertain Significance (VUS) in the GLA gene. Case Description: A 62-year-old woman with a history of ischemic stroke at age 41 (mild facial sequela) and familial sudden death (brother at 25) reported dyspnea and palpitations since 2024. In July 2025, during external follow-up, she presented pre-excited atrial fibrillation with rapid ventricular response. Coronary angiography ruled out severe obstructive disease (40% LAD lesion). After stabilization, she was referred for accessory pathway ablation. Echocardiography showed biatrial enlargement and severe asymmetric left ventricular hypertrophy (LVH) (septum 19 mm). The clinical triad of LVH, accessory pathway, and premature stroke raised FD suspicion. Cardiovascular magnetic resonance (CMR) confirmed left chamber dilation, systolic dysfunction (LVEF 44%), asymmetric inferoseptal thickening (17 mm), and reduced native T1 mapping (846 ms). Subendocardial late gadolinium enhancement (LGE) and myocardial edema (T2 hyperintensity) in the mid-inferolateral and mid-anterolateral segments suggested inflammation and microvascular dysfunction—findings highly suggestive of FD. Genetic testing detected the heterozygous missense variant c.280T>G; p.(Cys94Gly) in GLA. Despite absence in gnomAD/literature, in silico deleterious predictors, and other pathogenic variants at the Cys94 residue, it was formally classified as VUS (ACMG criteria). Given the compatible phenotype, alpha-galactosidase A and Lyso-Gb3 levels were requested aiming to reclassify this “hot” VUS to pathogenic based on new robust evidence, confirming the definitive diagnosis. In Feb 2026, she underwent successful pathway ablation. Conclusions: Coexistence of LVH, anomalous atrioventricular conduction, and premature stroke mandates storage cardiomyopathy suspicion. CMR tissue mapping (native T1) provides a robust substrate to correlate phenotype to genotype, supporting future pathogenic reclassification of this VUS. This pheno-genotypic correlation warrants FD biochemical confirmation, enabling specific therapy, arrhythmia management, and cascade screening.

REVERSIBLE LEFT VENTRICULAR DYSFUNCTION IN TYPE II MIXED CRYOGLOBULINEMIA: EVIDENCE OF INFLAMMATORY CARDIAC INVOLVEMENT

ANA BEATRIZ NEPOMUCENO CUNHA1; GABRIEL MOSTARO FONSECA1; KOODY ANDRE HASSEMI KITAWARA1; ALINE SABRINA HOLANDA TEIXEIRA MORAES1; JULIANA CORRÊA DE OLIVEIRA CAIED1; JOÃO CARLOS DOMICIANO DA SILVA1; YASMIN TRINDADE MEIRELES1; RÔMULO FONSECA DE MORAES1; MARCELO CAPITO CASTILHO1; RIANE RODRIGUES MARTION1; BRUNA GONÇALVES GUSTINELLI1; RODRIGO NORONHA CAMPOS1;

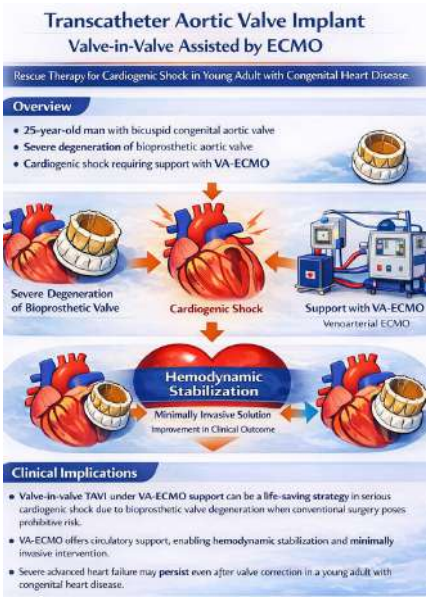
Introduction: Cryoglobulinemia is a systemic immune complex–mediated vasculitis with heterogeneous organ involvement. Type II mixed cryoglobulinemia is frequently linked to previous hepatitis C virus infection or monoclonal B-cell expansion, promoting complement activation and vascular injury. Although extra-cardiac manifestations are well recognized, cardiac involvement is rare and may arise from inflammatory myocardial injury, coronary microvascular dysfunction, or systemic inflammatory burden. Case Description: An 86-year-old man with hypertension, former smoking history, arrhythmia, and previously treated hepatitis C presented with dyspnea, peripheral edema, and decompensated heart failure accompanied by renal impairment. Laboratory tests revealed significantly elevated NT-proBNP (9,595 pg/mL) and mild elevation of high-sensitivity troponin. Cardiac magnetic resonance imaging showed dilation of left-sided chambers and reduced left ventricular ejection fraction (LVEF) of 39%, without late gadolinium enhancement. During hospitalization, he developed acute kidney injury with proteinuria and hematuria; renal biopsy demonstrated immune complex–mediated membranoproliferative glomerulonephritis. Further workup identified IgM kappa monoclonal gammopathy, reduced complement levels, and monoclonal B-cell lymphocytosis without evidence of malignancy on PET-CT. These findings established the diagnosis of type II mixed cryoglobulinemia related to prior hepatitis C infection and B-cell clonal expansion. Treatment with corticosteroids and rituximab led to clinical improvement and recovery of LVEF to 56%. Conclusions: This report describes an uncommon presentation of type II mixed cryoglobulinemia with heart failure due to left ventricular systolic dysfunction in the absence of obstructive coronary disease or infiltrative cardiomyopathy. The absence of myocardial fibrosis and subsequent improvement in ventricular function suggest a predominantly inflammatory and reversible process, likely mediated by coronary microvascular involvement and immune complex deposition. Early recognition of this mechanism is crucial, particularly in patients with systemic vasculitis features, as targeted immunosuppressive therapy may significantly improve outcomes.



17679

VALVE-IN-VALVE TAVI UNDER VA-ECMO SUPPORT AS A BRIDGE-TO-DECISION IN REFRACTORY CARDIOGENIC SHOCK IN A YOUNG ADULT WITH CONGENITAL HEART DISEASE.

(1) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL; (2) HOSPITAL UNIVERSITARIO PEDRO ERNESTO - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Early structural degeneration of bioprosthetic valves in adults with congenital heart disease is a major cause of clinical deterioration, potentially leading to advanced heart failure and cardiogenic shock. In this setting, redo surgery often carries prohibitive risk, particularly in the presence of severe ventricular dysfunction and hemodynamic instability. Valve-in-valve TAVI has emerged as a less invasive therapeutic alternative, while venoarterial extracorporeal membrane oxygenation (VA-ECMO) may provide hemodynamic stabilization and enable structural interventions in critically ill patients. Case Description: A 25-year-old male with bicuspid aortic valve and congenital stenosis, previously treated with three percutaneous valvuloplasties followed by surgical aortic valve replacement with a bioprosthesis. He developed complete atrioventricular block requiring permanent pacing, later upgraded to cardiac resynchronization therapy with defibrillator due to progression to advanced heart failure. Left ventricular ejection fraction was 12%, with severe functional tricuspid regurgitation and moderate mitral regurgitation. Echocardiography revealed severe structural degeneration of the bioprosthesis with critical stenosis (mean gradient 46 mmHg; peak velocity 4.3 m/s) and pulmonary hypertension (PASP 70 mmHg). Cardiopulmonary exercise testing showed marked functional impairment (peak VO□ 9 mL/kg/min; VE/VCO□ slope 48.3). The patient progressed to refractory cardiogenic shock and cardiorenal syndrome, requiring inotropic support, renal replacement therapy, and VA-ECMO. Under circulatory support, transfemoral valve-in-valve TAVI (Navitor Vision 27 mm) was successfully performed, with optimal positioning and immediate reduction of the transvalvular gradient to 10 mmHg. ECMO was weaned after 48 hours. Follow-up demonstrated a well-functioning prosthesis and improvement in LVEF to 20%. Conclusions: Valve-in-valve TAVI under VA-ECMO support represents an effective rescue strategy in hemodynamic collapse due to bioprosthetic degeneration, promoting immediate afterload reduction and clinical stabilization. In selected young patients with congenital heart disease and prohibitive surgical risk, it may serve as a bridge-to-decision, allowing reassessment for definitive therapies such as heart transplantation or durable mechanical circulatory support.

ANGINA AS A MARKER OF LATE CARDIAC REINNERVATION AFTER TRANSPLANTATION: A CASE REPORT WITH 24-YEAR SURVIVAL

PLÍNIO JOSÉ WHITAKER WOLF1; EDILEIDE DE BARROS CORREIA1; MARCOS OLIVEIRA VASCONCELLOS1; ANA CRISTINA MURTA1; YONA AFONSO FRANCISCO1; LARISSA VENTURA BRUSCKY1; SARA REGINA ALCALDE DOMINGOS1; EDUARDO MIKIO SASSAKI1; GABRIELA ESQUERDO1; THAIS GRECCA ANDRADE1; FERNANDA DE BRITO FORTUNA1; VICTOR BEMFICA1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introdução: Heart transplantation (HTx) is the definitive, gold-standard therapy for patients with advanced, refractory heart failure, significantly improving survival, with a mean post-transplant survival of approximately 7–12 years. However, one of the main factors limiting long-term survival is cardiac allograft vasculopathy (CAV), which leads to ischemia, fibrosis, and ventricular dysfunction, often presenting with minimal or atypical symptoms due to post-transplant cardiac denervation. We describe a case of a transplant recipient with survival beyond the international average who developed symptomatic CAV. Descrição do Caso: A 68-year-old man, with a history of hypothyroidism prior to HTx, underwent bicaval orthotopic heart transplantation 24 years ago (donor aged 19 years) for advanced valvular heart disease, without perioperative complications. He had an uneventful post-transplant course, developing dyslipidemia but no major complications, including cellular or antibody-mediated rejection, malignancy, or cytomegalovirus infection. Over the past 10 years, he has been treated with simvastatin, levothyroxine, and aspirin, along with immunosuppressive therapy consisting of cyclosporine and mycophenolate sodium. During follow-up, the patient remained asymptomatic, with echocardiography demonstrating preserved biventricular function, and coronary CT angiography at 17 years post-transplant showing no obstructive coronary lesions. At 24 years post-HTx, the patient developed progressive, typical angina (CCS class III), associated with exertional dyspnea. Echocardiography showed a left ventricular ejection fraction of 67%, global longitudinal strain of 23%, normal chamber dimensions and contractility, and no valvular disease or pulmonary hypertension. Coronary angiography revealed a subocclusive lesion in the mid right coronary artery, which was successfully treated with percutaneous coronary intervention. The patient subsequently remained asymptomatic. Conclusões: Post-transplant survival is primarily limited by CAV. This case highlights that optimal control of comorbidities, appropriate immunosuppression, and favorable donor/graft characteristics may delay the onset of CAV, contributing to survival beyond the international average. Moreover, the presence of typical angina suggests cardiac reinnervation (particularly sympathetic), which may facilitate the clinical recognition of CAV and could be associated with the favorable prognosis observed in this patient.

CARDIOVASCULAR MANAGEMENT CHALLENGES IN MOYAMOYA DISEASE: A CASE REPORT

NATHALIA SALIM SAUD1; NOEMI ROCIO ANDRADE ALBAN2; WOLNEY DE ANDRADE MARTINS1; MARCOS MERULA DE ALMEIDA1;

(1) HOSPITAL UNIVERSITARIO ANTONIO PEDRO - NITEROI - RJ - BRASIL; (2) UNIVERSIDAD DE AMBATO - ECUADOR;

Introduction: Moyamoya Disease (MMD) is a rare, chronic occlusive cerebrovascular disorder characterized by progressive stenosis of the terminal internal carotid arteries and their branches. While primarily a neurological entity, its frequent association with systemic vascular involvement—such as renal artery stenosis, severe hypertension, and coronary artery disease (Moyamoya Syndrome)—imposes significant challenges for the cardiologist, particularly regarding hemodynamic stability and stroke prevention. Case Description: A 34-year-old female presented with a history of refractory hypertension and recurrent transient ischemic attacks (TIAs). Diagnostic workup via digital subtraction angiography (DSA) revealed bilateral stenosis of the supraclinoid internal carotid arteries with the pathognomonic “puff of smoke” collateral network, confirming MMD. Cardiology was consulted for blood pressure (BP) optimization and preoperative risk assessment for encephaloduroarteriosynangiosis (EDAS). Echocardiography showed moderate concentric left ventricular hypertrophy (mass index 115 g/m2). Screening for secondary hypertension identified significant right proximal renal artery stenosis. Treatment was initiated with calcium channel blockers, cautiously avoiding rapid BP drops to preserve cerebral collateral perfusion. The patient achieved neurological stability and satisfactory BP control prior to successful revascularization surgery. Cardiovascular management in MMD is a delicate balancing act. Maintaining Mean Arterial Pressure (MAP) is critical; extreme hypertension risks hemorrhagic stroke from fragile collateral vessels, while hypotension triggers cerebral infarction due to hypoperfusion. Literature suggests that MMD can coexist with fibromuscular dysplasia and stenosis of medium-sized arteries (renal and coronary). The cardiologist’s role is vital in identifying these extracranial stenoses and tailoring antiplatelet therapy, weighing ischemic risks against the hemorrhagic potential of neovessels Conclusions: Moyamoya Disease requires a multidisciplinary approach where the cardiologist is essential for hemodynamic stabilization and screening for associated systemic vasculopathies. BP targets must be individualized to ensure adequate cerebral perfusion reserve, thereby reducing perioperative morbidity and mortality.

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction: Hypertension (HTN) is a multisystemic disease characterized by elevated blood pressure (BP) and complex pathophysiology. Genetic, environmental, and behavioral factors contribute to its development. Among the secondary causes, Takayasu arteritis (TAK) is a large-vessel vasculitis that involves the aorta and its major branches. HTN in TAK is commonly associated with renal artery stenosis or aortic coarctation-like physiology; however, mechanisms such as sympathetic activation and baroreceptor dysfunction may also contribute. This case series illustrates the spectrum of TAK presentation and the challenges in HTN management. Case Description: Case 1: AMS, female, 45 years old, diagnosed with TAK at 27 years old after systemic symptoms and upper-limb claudication. Pulses were absent in both arms. Imaging demonstrated inflammation of the aortic arch, sparing the descending aorta and renal arteries. BP could initially only be measured in the thighs when HTN was first identified. After immunosuppressive and antihypertensive therapy, pulses gradually returned and BP became measurable in both arms. Initial measurements were misleading, with systolic differences >80 mmHg between limbs. Despite restored flow, the patient remained hypertensive, requiring six antihypertensive drugs. Case 2: EGRL, male, 19 years old, referred without a previous TAK diagnosis despite multiple arterial revascularization procedures since early childhood. BP was controlled with two medications and renal function was preserved. He had reduced lower-limb pulses and pressure without symptoms. Investigation revealed bilateral renal artery and infrarenal aortic stenosis and established the diagnosis of TAK. Case 3: ERS, female, 49 years old, with HTN since pregnancy at 20 years old, was referred after developing heart failure. She complains of NYHA III dyspnea and lower-limb claudication. Investigation identified significant stenosis of the descending aorta and renal arteries, leading to TAK diagnosis and refractory HTN. Renal and aortic angioplasty resulted in symptom improvement and reduction of two antihypertensive drug classes. Conclusions: HTN is a major challenge in TAK. Aortic and subclavian disease may falsely lower BP values, delaying diagnosis and treatment. Inter-limb pressure differences can also limit ABPM. HTN in TAK is multifactorial and not solely related to renal artery stenosis, requiring multidisciplinary follow-up for better vascular and BP control.

Introduction: Pickering syndrome is a rare, underrecognized phenotype of renovascular disease, classically linking recurrent flash pulmonary edema, refractory hypertension, renal dysfunction and bilateral renal artery stenosis. Its recognition is decisive because it identifies a potentially reversible mechanism of cardiorenal collapse. Case Description: An 81-year-old woman with long-standing hypertension, type 2 diabetes, chronic kidney disease and reported atrial fibrillation was admitted with acute dyspnea, hypoxemia and severe hypertensive crisis, requiring noninvasive ventilation, intravenous vasodilators and loop diuretics. She initially improved, but blood pressure remained difficult to control despite escalation to amlodipine, carvedilol, losartan, spironolactone, hydralazine, isosorbide, clonidine and furosemide, with nitroprusside during decompensations. Echocardiography showed LVEF 44%, diffuse hypokinesia and grade II diastolic dysfunction. Renal Doppler and computed tomography angiography demonstrated critical bilateral ostial atherosclerotic renovascular lesions greater than 90%, with a reduced left kidney. During hospitalization, she developed recurrent episodes of flash pulmonary edema, repeatedly associated with systolic blood pressure over 200 mmHg and no evident infectious trigger, requiring intensive care, noninvasive ventilation, nitroprusside and furosemide. This recurrence despite intensive antihypertensive therapy, together with fluctuating renal dysfunction and bilateral critical renovascular disease, established Pickering syndrome. Bilateral renal angioplasty with stent implantation was performed. After revascularization, congestion resolved, nitroprusside was withdrawn, renal function recovered, with creatinine decreasing from 3.56 to 1.35 mg/dL, and antihypertensive therapy was markedly de-escalated. At follow-up, she remains on carvedilol and low-dose hydralazine only. Conclusions: This case highlights Pickering syndrome as a rare but actionable diagnosis. Although renal revascularization is not broadly beneficial in unselected atherosclerotic disease, recurrent flash pulmonary edema with refractory hypertension and renal dysfunction defines a high-risk phenotype in which intervention may restore cardiorenal stability and reduce antihypertensive burden.

COMBINED PERCUTANEOUS TREATMENT OF GIANT ARTERIOVENOUS MALFORMATION AND COMPLEX CORONARY LESIONS IN A HIGH-RISK SURGICAL PATIENT: A CASE REPORT.

VICTOR TAVARES TRINDADE1; NUBIA ANDRADE SILVA1; NASSANDRO JUNIOR MACHADO GARCIA1; GUILHERME DINIZ PRUDENTE1; MAURICIO LOPES PRUDENTE1; GIULLIANO GARDENGHI1;

(1) HOSPITAL ENCORE - APARECIDA DE GOIANIA - GO - BRASIL;

Introduction: Coronary artery fistulas (CAF) are congenital anomalies characterized by direct communications between one or more coronary arteries and cardiac chambers or adjacent great vessels. The prevalence is estimated to be between 0.2% and 0.4% of all congenital heart defects. The etiology is attributed to deviations in embryonic development. The clinical presentation is variable. Symptoms may include fatigue, dyspnea, palpitations, chest pain (resulting from the "coronary steal" phenomenon), and syncope. The diagnosis is established by imaging modalities. Coronary cineangiography is the gold standard for diagnostic confirmation and anatomical delineation of CAF. There are no standardized therapeutic guidelines for the management of CAF. The objective of this article is to report the case of a patient with complex obstructive coronary artery disease and multiple coronary fistulas to the pulmonary trunk treated with concomitant coronary angioplasty and fistula embolization. Case Description: A 66-year-old female with history of systemic arterial hypertension (SAH), insulin-dependent diabetes mellitus, dyslipidemia, stage IV chronic kidney disease (CKD), and pulmonary hypertension (PH). Initial evaluation with myocardial perfusion scintigraphy (MPS) revealed significant ischemia (approximately 21%), with hypoperfusion of the anterior, septal, and apical regions. She underwent cardiac catheterization (CATH), which demonstrated calcified lesions and critical obstructions in the following coronary segments: RCA: 90% proximal stenosis; LAD: 95% proximal stenosis and 90% mid-segment stenosis; left circumflex artery (LCx): 90% proximal stenosis; posterior descending artery (PDA): 80% stenosis in the mid segment. In addition, large high-flow fistulas originating from the proximal segments of the LAD and RCA draining into the pulmonary trunk (PT) were identified. Given the patient's high surgical risk, the heart team opted for percutaneous treatment with stent and fistula embolization. Conclusions: CAPF may be considered a differential diagnosis in patients presenting with acute or chronic coronary syndromes, primarily due to the phenomenon of coronary flow steal, especially when associated with significant atherosclerotic disease. Mastery of multiple percutaneous interventional techniques (used in endovascular surgery and neurointervention) allows, in selected cases, complete resolution of both the vascular malformation and the atherosclerotic disease, particularly in patients at high surgical risk.

COMBINED TRANSCAVAL ACCESS AND BASILICA TECHNIQUE IN TRANSCATHETER AORTIC VALVE REPLACEMENT (TAVR): A CASE REPORT

MIGUEL PISANI LEME FERREIRA1; EULER DE AZEVEDO NETO1; MARCO ANTONIO FICHTNER BELLIZZE1; ALEXANDRE ANTÔNIO CUNHA ABIZAID1; FABIO SANDOLI DE BRITO JUNIOR1; SANTIAGO A GARCIA2; ADAM GREENBAUM3; PAULA CAROLINE COSTA GONÇALVES1; TALLISON RENAN TENORIO DE LIMA1; JONATAN RINALDI1; FLÁVIO TARASOUTCHI1; TARSO AUGUSTO DUENHAS ACCORSI1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) THE CHRIST HOSPITAL - UNITED STATES; (3) EMORY UNIVERSITY HOSPITAL - UNITED STATES;

Introduction: Transcatheter aortic valve replacement (TAVR) is a well-established minimally invasive alternative to surgical valve replacement for severe symptomatic aortic stenosis. The transfemoral route is the preferred access; however, it may be unfeasible in individuals with small or diseased iliofemoral arteries, increasing the risk of vascular complications. Alternative approaches, such as transapical or transaortic access, are more invasive and associated with higher morbidity. In this context, transcaval TAVR has emerged as a fully percutaneous option, enabling access to the abdominal aorta via the inferior vena cava, thereby avoiding diseased arterial pathways. Additionally, the BASILICA technique, which involves intentional leaflet laceration prior to valve deployment, has been developed to prevent iatrogenic coronary obstruction, a rare but potentially fatal complication of TAVR. Case Description: An 83-year-old woman with diabetes mellitus, coronary artery disease, and chronic obstructive pulmonary disease presented with progressive dyspnea, now at rest, requiring long-term oxygen therapy. Transthoracic echocardiography revealed severe low-flow, low-gradient aortic stenosis (area 0.9cm², mean gradient 27mmHg, stroke volume index 32mL/m², left ventricular ejection fraction 36%). The stress echocardiogram showed preserved contractile reserve with maintenance of the valve area. Computed tomography angiography showed a small aortic annulus (392mm²), low left coronary height (8mm) and narrow sinus of Valsalva (27mm), indicating high risk of coronary obstruction. Iliofemoral arteries were bilaterally small and diffusely atherosclerotic. Coronary angiography demonstrated moderate-to-severe lesions in the right and circumflex territories. The Society of Thoracic Surgeons score predicted mortality was 29.9%. Given the high surgical risk and unfavorable transfemoral access, a transcaval approach with BASILICA was performed under general anesthesia with transesophageal guidance. The procedure was successful, with no coronary obstruction or complications. Valve implantation was adequate and the aortic port was closed with a nitinol occluder. The patient was discharged on day 11 and remained stable at follow-up, no longer requiring oxygen therapy. Conclusions: This case demonstrates that combining transcaval access with the BASILICA technique is a feasible and effective fully percutaneous strategy for high-risk patients who are unsuitable for transfemoral TAVR and at increased risk of coronary obstruction.

Picture 1 – Successful crossing. The guidewire is advanced from the inferior vena cava into the aorta.

EARLY PERCUTANEOUS CLOSURE OF POST-INFARCTION VENTRICULAR SEPTAL DEFECT: A CASE FOR RETHINKING INTERVENTION TIMING

ALBERT DICKSON DE LIMA FILHO1; GUILHERME BORGES DE MORAIS1; DANIELLE CAVALCANTE MONTEIRO1; BRUNA LISBOA VEGARA1; JOSÉ HUMBERTO RODRIGUES JUNIOR1; TARCISIO MARIZ MAIA FILHO2; ANDRÉ FRANCISCO DE PAULA ANTONANGELO2; WANGLES JOTÃO GERALDO2; GERSON BARBOSA DO NASCIMENTO2; MARIA SANALI MOURA DE OLIVEIRA PAIVA2;

(1) UFRN - NATAL - RN - BRASIL; (2) INSTITUTO ATENA - NATAL - RN - BRASIL;

Introduction: Post–myocardial infarction ventricular septal defect (VSD) is a rare but potentially fatal mechanical complication, even in the era of early reperfusion. Its incidence ranges from 0.17% to 0.31%, with mortality exceeding 80% in untreated cases. It results from septal rupture, creating a left-to-right shunt that leads to left ventricular volume overload, reduced cardiac output, and rapid hemodynamic deterioration, often progressing to acute heart failure or cardiogenic shock. Management is challenging and involves hemodynamic stabilization and individualized decision-making between surgical repair—the gold standard—and percutaneous closure, a viable alternative in selected patients. Case Description: A 59-year-old woman with no prior cardiovascular disease or traditional risk factors presented with typical chest pain at rest. She was diagnosed with ST-segment elevation myocardial infarction after 12 hours of symptoms and underwent thrombolysis with initial improvement. After 24 hours of hospitalization, she developed hypotension, tachycardia, and a new systolic murmur at the left sternal border. Echocardiography showed a left ventricular ejection fraction of 36%, extensive wall motion abnormalities, and a VSD with a left-to-right shunt of approximately 1.5 cm, along with pulmonary hypertension. The case was evaluated by the Heart Team. Given the initial hemodynamic instability, the size of the defect, and the acute phase context, an early percutaneous approach was chosen with device implantation, Amplatzer 16mm. The procedure was successfully performed, with immediate hemodynamic improvement. The patient stabilized and was discharged 48 hours later. At follow-up, she remained in NYHA class I–II on optimized therapy. Conclusions: This case challenges the paradigm of delaying intervention in post–myocardial infarction VSD, showing that, in selected cases, an early percutaneous approach may be not only feasible but decisive in halting hemodynamic deterioration. More than an alternative to surgery, it may become a leading strategy when time is the main prognostic determinant. This report highlights that decision-making guided by clinical dynamics and Heart Team assessment—rather than static recommendations—may redefine intervention thresholds, enabling a more assertive and potentially transformative approach to these catastrophic complications.

ENDOVASCULAR APPROACH IN STANFORD TYPE A–EQUIVALENT AORTIC DISSECTION WITH COMPLEX ARTERIAL ANATOMY: CASE REPORT AND FAVORABLE AORTIC REMODELING

LETÍCIA BRAGA CAMARGOS1; LUIZ ANTONIO DE ALMEIDA CAMPOS1; NEY DUARTE NETO1; GIOVANNA ZADRA DE MATTOS1; LETICIA NOLASCO FONSECA MARTINS1; RAFAELLA BARBOSA DE ASSUNCÇÃO ALVES1; THAISA EODRIGUES GARCIA1; BRUNNO BASTOS KNOPLOCH1; GAUDENCIO ESPINOSA LOPES1;

(1) HOSPITAL PRO CARDIACO - RIO DE JANEIRO - RJ - BRASIL;

Introduction: Acute Stanford type A aortic dissection is traditionally managed with emergent open surgery due to its high mortality. However, advances in endovascular techniques have expanded therapeutic possibilities in selected cases, particularly when the entry tear is not located in the ascending aorta. We report a case of a Stanford type A-equivalent dissection treated with a fully endovascular strategy, achieving favorable aortic remodeling. Case Description: ACS, a 65-year-old hypertensive woman, presented with mild chest pain and nausea. She had positive troponin and underwent coronary angiography, which revealed no obstructive lesions. Cardiac magnetic resonance imaging demonstrated an intramural hematoma in the ascending aorta. Computed tomography angiography showed a dissection with probable origin in an aberrant right subclavian artery, associated with retrograde intramural hematoma involving the ascending aorta, consistent with a Stanford type A–equivalent dissection. A bovine arch variant (left common carotid artery originating from the brachiocephalic trunk) and a retroesophageal right subclavian artery were identified, with extension of the dissection flap to the right external iliac artery. After hemodynamic stabilization with nitroprusside and esmolol, an endovascular strategy was chosen, with implantation of a thoracic endograft with a branch to the left subclavian artery and occlusion of the aberrant right subclavian artery. Follow-up computed tomography angiography demonstrated complete resolution of the intramural hematoma in the ascending aorta and arch, appropriate endograft positioning, and obliteration of the false lumen in the adjacent thoracic segment, with preserved flow in the left subclavian artery through a patent stent. The patient remains hemodynamically stable and asymptomatic. Conclusions: Endovascular treatment may be an effective alternative in selected cases of Stanford type A–equivalent dissection with a distal entry tear, particularly in complex anatomical settings. The favorable outcome and aortic remodeling highlight the importance of individualized, multidisciplinary decision-making in acute aortic disease.

Introduction: Left atrial appendage occlusion (LAAO) is an effective alternative to reduce the risk of stroke in patients with non-valvular atrial fibrillation (AF) who have contraindications to oral anticoagulation. However, device-related thrombosis (DRT), although uncommon, is associated with an increased risk of thromboembolic events. In oncologic patients, management is particularly challenging due to the prothrombotic state and higher bleeding risk, with limited data on the influence of active malignancy on DRT formation. Case Description: A 71-year-old male patient with permanent AF, CHA□DS□-VA score of 3 and HAS-BLED score of 2, previously on apixaban, developed recurrent hematuria of unknown origin, even after investigation and exclusion of glomerular and urological causes, leading to a functional contraindication to oral anticoagulation. He underwent percutaneous LAAO with implantation of a Watchman FLX® device, with adequate positioning and no residual leak. Despite a shortened antiplatelet strategy, hematuria persisted. Subsequent urological investigation revealed high-grade urothelial carcinoma of the bladder. During oncologic staging, a giant thrombus adherent to the atrial surface of the device was identified, extending to the Coumadin ridge, measuring approximately 5.6 × 1.5 cm (area of 6.77 cm²). The diagnosis was confirmed by transesophageal echocardiography and cardiac computed tomography angiography, with no significant peridevice leak. Given the high thromboembolic risk, full anticoagulation with warfarin was initiated regardless of the prior contraindication, considering that the thrombotic risk outweighed the bleeding risk at that time, resulting in progressive thrombus reduction. After surgical treatment of the bladder cancer, complete thrombus regression was observed after six months of anticoagulation. Warfarin was discontinued, and apixaban was reintroduced, with no recurrence of bleeding or new DRT. Conclusions: The interaction between AF, active malignancy with bladder bleeding, and thrombosis related to intracardiac devices can be highly challenging. LAAO does not eliminate thrombotic risk associated with hypercoagulable states. This case highlights the importance of late surveillance through multimodal assessment and the recognition of cancer as a risk factor for DRT. Thrombus regression following oncologic treatment and anticoagulation adjustment demonstrates that management should be continuous, individualized, and conducted in a multidisciplinary manner.

Figure 1: Cardiac computed tomography angiography (Fig. A) and 2D and 3D transesophageal echocardiography (Figs. B and C, respectively) 6 months after left atrial appendage occlusion. The occlusion device is visualized, well positioned, with a giant thrombus adherent to the atrial surface of the prosthesis.

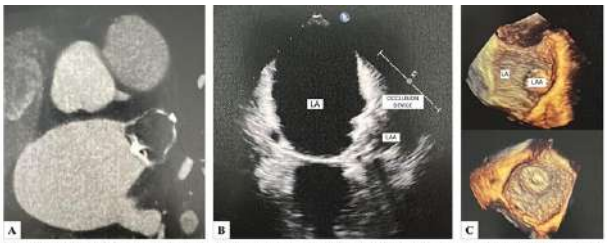

Figure 2: Cardiac computed tomography angiography (Fig. A) and 2D and 3D transesophageal echocardiography (Figs. B and C, respectively) after oncologic treatment and 6 months of full anticoagulation. The left atrium is visualized with a well-positioned occlusion device in the left atrial appendage, with complete thrombus regression.

MITRAL VALVE-IN-VALVE: FROM GOOD HEMODYNAMIC RESULT TO HIDDEN EMBOLIC RISK

YASMIN TRINDADE1; FERNANDO AUGUSTO ALVES DA COSTA1; MOHAMAD SAID GHANDOUR SAID GHANDOUR1; GABRIELA CHAVES SANTANA1; JHONY LUCAS INÁCIO DE ALMEIDA1; ALESSANDRA JOSLIN OLIVEIRA1; RAFAEL BONAFIM PIVETA1; MIGUEL OSMAN DIAS AGUIAR1;

Introduction: Structural degeneration of mitral bioprostheses is a relevant late complication. In elderly patients at high surgical risk, transcatheter valve-in-valve (ViV) implantation has become a well-established alternative therapy. Despite favorable technical results, thromboembolic complications remain a concern, since in the presence of significant mitral regurgitation, the regurgitant jet may exert a “washing” effect on the left atrium, reducing local blood stasis. Therefore, its abrupt correction may significantly alter left atrial hemodynamics, favoring the appearance of spontaneous echo contrast and potential thrombus formation. Case Description: A 78-year-old woman with previous surgical mitral valve replacement with a bioprosthesis in 2013 evolved during follow-up with NYHA functional class III symptoms. Echocardiography showed structural degeneration of the bioprosthesis, with leaflet rupture and severe mitral regurgitation. Given the high surgical risk, the Heart Team indicated transcatheter mitral valve-in-valve implantation. After the procedure, transesophageal echocardiography showed a well-positioned prosthesis, with no paravalvular leak, satisfactory transmitral gradient, and no significant residual mitral regurgitation. However, intense spontaneous echo contrast was observed in the left atrium and left atrial appendage, not evident at baseline assessment. It was assumed that the abrupt interruption of the large regurgitant jet, previously responsible for a “washing” effect on the left atrium, associated with left atrial enlargement and possible transient reduction in cardiac output under anesthesia, favored blood stasis. Full anticoagulation was initiated, followed by transition to oral anticoagulation. The patient evolved without clinical embolic events, and follow-up echocardiography demonstrated complete disappearance of spontaneous echo contrast, absence of thrombi, and adequate function of the transcatheter prosthesis. Conclusions: Transcatheter mitral valve-in-valve implantation is an effective option for degenerated mitral bioprostheses in patients at high surgical risk. This case shows that, even with an excellent immediate hemodynamic result, abrupt correction of severe mitral regurgitation may favor left atrial stasis and increase thromboembolic risk. Early echocardiographic recognition and prompt anticoagulation were essential for a favorable outcome.

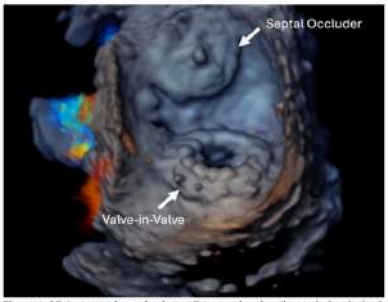

Figure 1: 3D transesophageal echocardiogram showing the occluder device in the interatrial septum and the prosthesis in mitral position (Valve-in-Valve).

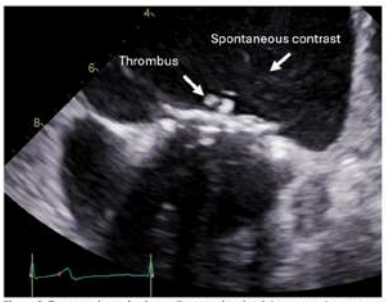

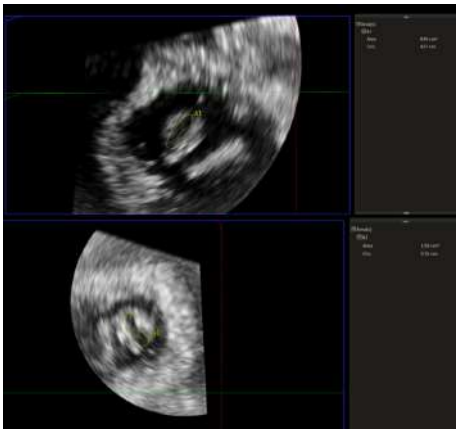

Figure 2: Transesophageal echocardiogram showing intense spontaneous contrast in the left atrium and a small thrombus on the left atrial surface of the occluder device in the interatrial septum.

MITRAL VALVULOPLASTY WITH BALLOON CATHETER IN A PREGNANT WOMAN WITH RHEUMATIC MITRAL STENOSIS AND CARPENTIER RING WITH UNFAVORABLE WILKINS SCORE.

ANDEILE ALBUQUERQUE GALHARDO1; RENATO PALADINO NEMOTO1; NEIVA ANGELINA BOLONHIN BELTRÃO1; EDUARDO LUIS CUKIERKORN1; VITOR EMER EGYPTO ROSA1; HENRIQUE RIBEIRO1; TARSO AUGUSTO DUENHAS ACCORSI1; FLAVIA POTSCH CAMARA MATTOS GIRARD1; WALKIRIA SAMUEL AVILA1; FLAVIO TARASOUTCHI1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction: The treatment of choice for rheumatic mitral stenosis is balloon mitral valvuloplasty (BMV) when the Wilkins score is favorable. However, this score has limited performance in the assessment of mitral valves previously repaired with a Carpentier ring, as it was developed for evaluation of the native valve. Valve-in-ring is a percutaneous treatment alternative, but it carries a risk of left ventricular outflow tract obstruction in some cases. Multidisciplinary Heart Team discussion with specialists is essential to define the therapeutic strategy in complex cases. Case Description: A 43-year-old female patient with severe rheumatic mixed mitral valve disease underwent mitral valve repair with a rigid Carpentier ring (size 30) and commissurotomy in 2015. She had an unplanned pregnancy requiring hospitalization during the first trimester due to dyspnea on minimal exertion. Transthoracic echocardiography showed commissural fusion, a mitral valve area of 0.9 cm² (planimetry), a mean left atrium–left ventricle gradient of 21 mmHg, a pulmonary artery systolic pressure of 89 mmHg, and a Wilkins–Block score of 10 points (subvalvular involvement: 3 points), unfavorable for BMV. The case was discussed with the interventional cardiology team to assess the feasibility of a valve-in-ring procedure. Cardiac computed tomography angiography demonstrated a high risk of left ventricular outflow tract obstruction (mitral annulus–septum distance of 16 mm and a predicted neo-LVOT area of 150 mm²). Given the complexity, the case was reviewed by the Heart Team, and BMV in the presence of the ring was considered. The procedure was performed in the operating room without complications, resulting in an increase in mitral valve area to 1.54 cm², with a reduction in the mean gradient to 8 mmHg and in pulmonary artery systolic pressure to 59 mmHg. Conclusions: BMV in the presence of a Carpentier ring is a practice rarely reported in the literature. The risks include possible ring dehiscence with acute mitral regurgitation and interference with balloon expansion, which may limit the gain in valve area. Another particular feature of this case is that the procedure was performed despite an unfavorable Wilkins score. This case highlights the importance of longitudinal follow-up, family counseling, and the role of the Heart Team. Performing BMV in the presence of a Carpentier ring with an unfavorable Wilkins score is uncommon, but it may represent a lower-morbidity alternative in high-risk situations.

PERCUTANEOUS TRANSFEMORAL IMPLANTATION OF AN EVOQUE PROSTHESIS IN A PATIENT WITH SEVERE TRICUSPID REGURGITATION AFTER RESECTION OF A CARDIAC LIPOMA

JULIA LASSERRE MOREIRA1; HUGO VINICIUS NEVES MORAIS1; RAFAEL ROCHA MOL SILVA1; JAIRO ALVES PINHEIRO JUNIOR1; FABIO CONEJO1; RENATA DE SA CASSAR1; RAFAELA DA SILVA FERREIRA1; MARINA BAHIA RIBEIRO1; FELIPE AMBROSIO FONTES1; GABRIEL NOVAES DOS SANTOS1; HENRIQUE BARBOSA RIBEIRO1;

(1) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introduction: The main indication for surgical intervention for tricuspid regurgitation (TR) is in the setting of correction of concomitant left-sided valve disease, but the surgical procedure is still associated with high morbidity and mortality. Transcatheter tricuspid valve replacement (TTVR) with the Evoque system has emerged as an effective treatment in this scenario. Multimodality imaging is essential for procedural planning and success. We describe a successful TTVR in a patient with severe TR after surgical resection of a cardiac lipoma. Case Description: We present a case of a previously healthy female patient, asymptomatic, with evidence of a cardiac tumor on a routine echocardiogram performed at age 43. The investigation was complemented with magnetic resonance imaging, which revealed a mass in the anterior and anteroseptal basal wall of the left ventricle (LV), measuring approximately 5.0 x 2.1 x 3.4 cm, not obstructing LV outflow tract but projecting towards the right ventricle (RV), suggestive of a lipoma. The patient remained asymptomatic but subsequent examination showed the mass was increasing. A surgical resection of the lesion was performed in the year of diagnosis. The procedure required detachment of the tricuspid valve to access the interventricular septum and opening of the pulmonary trunk to complete the dissection. The histopathological examination confirmed lipoma. In the postoperative period, torrential TR was evident, which over the years led to dilation of the right ventricle and congestive symptoms. Surgery was ruled out by the multidisciplinary team and transcatheter edge-to-edge repair was not possible due to anatomic characteristics. The correction was possible three years after diagnosis via percutaneous transfemoral implantation of an EVOQUE prosthesis. The procedure was uneventful. Post-procedure echocardiography showed a well-located tricuspid prosthesis with good leaflet mobility and minimal regurgitation, with a maximum right atrium-ventricular diastolic gradient of 9 mmHg and a mean gradient of 5 mmHg. The patient remained in the ICU for 24 hours for hemodynamic monitoring. She remained asymptomatic throughout the postoperative period and was discharged 4 days after the procedure for outpatient follow-up. Conclusions: A TTVR with the Evoque system was successfully performed in a patient who was not a candidate for surgical or transcatheter edge-to-edge repair of severe symptomatic TR. Despite its recent development, the procedure seems promising and effective.

GIANT CHAGASIC MEGACOLON AS A RARE CAUSE OF CARDIAC COMPRESSION DUE TO MEDIASTINAL SHIFT

GUILHERME VENDRAMINI VASCONCELOS1; GRACIELLE FERNANDA DOS REIS SILVA2; DÊNIO DUTRA BARBOSA JUNIOR2; SANZIO DUPIM SOARES2; FLÁVIA BITTAR BRITTO ARANTES1;

(1) UNIVERSIDADE FEDERAL DE UBERLÂNDIA - UBERLÂNDIA - MG - BRASIL; (2) UBERLANDIA MEDICAL CENTER - UBERLANDIA - MG - BRASIL;

Introduction: Chagas disease is a chronic condition, often presenting with cardiac and gastrointestinal involvement. While Chagasic cardiomyopathy is a leading cause of heart failure in Latin America, the mechanical impact of a giant megacolon on the heart is a rare find, therefore frequently being overlooked. This anatomical distortion can cause significant mediastinal shift, leading to direct compression of cardiac chambers and impairment of venous return. In the context of simultaneous electrolyte imbalances and mechanical compression, the heart is subjected to a dual threat: impaired pumping mechanism and a high fatal arrhythmia risk. Case Description: An 81-year-old male with Chagas disease and metastatic prostate cancer presented with laboratory findings of a critical arrhythmogenic state: hypokalemia (1.90 mmol/L) and hypocalcemia (0.95 mmol/L), associated with severe prostration and hypoxemia (SpO2 88% on room air). Chronic use of laxatives was reported. Imaging studies demonstrated a massive gas-filled megacolon causing dramatic left-to-right mediastinal shift due to diaphragmatic compression, leading to displacement of the heart against the right thoracic wall, restricting cardiac filling and contraction, in addition to bilateral basal atelectasis. 12 lead electrocardiogram presented with right axis deviation. The patient was managed in the Intensive Care Unit with electrolyte replacement, introduction of a rectal tube and continuous cardiac monitoring. Electrolyte stabilization was achieved after 3 days of continuous intravenous replacement, and the colonic decompression led to improvement of respiratory parameters , mitigating the immediate risk of sudden cardiac death from either mechanical collapse or malignant arrhythmias. A colostomy was indicated due to high recurrence risk. Conclusions: This case reports a rare but critical cardiopulmonary complication of Chagasic megacolon. Severe anatomical displacement of the heart, when combined with metabolic disarray, significantly amplifies the risk of cardiovascular collapse. Physicians must maintain high suspicion for mechanical causes of mediastinal shift in Chagasic patients, as the synergy between cardiac compression, potential cardiomyopathy and electrolyte instability represents a high-risk scenario for lethal electrical and hemodynamic outcomes. The use of the patient's data and imaging studies was authorized by the patient and its family. The case was submitted for approval by the research ethics committee.

Introduction: Acute Chagas cardiomyopathy remains a severe manifestation of Trypanosoma cruzi infection and may progress rapidly to conduction abnormalities and advanced heart failure. The association with systemic autoimmune diseases requiring immunosuppression is rare and may worsen myocardial injury and clinical outcomes. Case Description: A 23-year-old woman was admitted to the intensive care unit with severe decompensated heart failure (left ventricular ejection fraction 32%) five months after treatment for acute Chagas disease. During outpatient investigation of serositis, systemic lupus erythematosus was diagnosed and hydroxychloroquine was initiated. Four days later, she developed complete atrioventricular block requiring permanent pacemaker implantation. Her clinical condition rapidly deteriorated with acute pulmonary edema and respiratory failure requiring invasive mechanical ventilation and vasopressor support. She was transferred to a tertiary care center presenting systemic congestion and acute kidney injury. After initial stabilization and withdrawal of vasopressors, pulse methylprednisolone therapy was repeated and mycophenolate mofetil was introduced due to lupus activity. Despite optimized heart failure therapy, progressive hemodynamic deterioration occurred and she was considered ineligible for heart transplantation. She subsequently developed recurrent cardiogenic shock characterized by metabolic acidosis, oliguria, and peripheral hypoperfusion requiring inotropic support. Despite maximal medical therapy, refractory shock persisted and the patient died 25 days after admission. Conclusions: Acute Chagas cardiomyopathy associated with systemic immunosuppression may lead to rapid progression to advanced heart failure, conduction system disease, and refractory cardiogenic shock even in young patients. Early cardiac monitoring is essential in patients with acure Chagas disease receiving immunosuppressive therapy in endemic regions

ACUTE MYOCARDIAL INFARCTION DUE TO EXTRINSIC COMPRESSION OF THE RIGHT CORONARY ARTERY SECONDARY TO SINUS OF VALSALVA PSEUDOANEURYSM IN PROSTHETIC VALVE ENDOCARDITIS

ANNIE CHINEYE UZÔMA ARÊDA OSHAI1; TEREZA COSTA AMOROSO LIMA E PIVA1; THAIS LANY DE OLIVEIRA LEÃO1; FELLIPE DE CAMPOS BORGES1; MONICA MARIA COSTA CALDAS1; CHRISTIANO GONÇALVES DE ARAUJO1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introduction: Prosthetic valve infective endocarditis may present with atypical manifestations and severe periannular complications, such as abscesses and pseudoaneurysms. The occurrence of acute coronary syndrome in this setting is rare and is usually related to embolic phenomena. Case Description: A 77-year-old female with a history of surgical aortic valve replacement with a bioprosthesis eleven years earlier due to severe aortic stenosis was initially admitted with a four-day history of fever of unknown origin. Given the suspicion of infective endocarditis, empirical antibiotic therapy was initiated, and the patient was transferred between different healthcare facilities. Serial transthoracic echocardiograms showed prosthetic valve dysfunction, with moderate regurgitation and severe stenosis (mean gradient of 45 mmHg and valve area of 0.9 cm²), without initial evidence of vegetations, abscesses, or other perivalvular complications. All blood cultures remained negative. The patient subsequently developed sudden chest pain associated with ST-segment elevation and elevated serum troponin levels. Coronary angiography revealed occlusion at the ostium of the right coronary artery, suggestive of extrinsic compression, with no possibility for percutaneous intervention. Computed tomography angiography of the thoracic aorta demonstrated a saccular aneurysmal dilation of the right coronary cusp of the sinus of Valsalva (4 × 3.6 cm), adjacent to the origin of the right coronary artery, causing extrinsic compression of the vessel. A repeat echocardiogram revealed vegetations on the prosthetic valve. After multidisciplinary discussion by the Heart Team, an initial conservative approach was chosen, with optimization of antibiotic therapy and planned reassessment with imaging after at least fourteen days, maintaining a strategy for subsequent surgical intervention. Conclusions: Prosthetic valve infective endocarditis may present with atypical manifestations and severe complications. This case illustrates a rare presentation of blood culture-negative prosthetic valve endocarditis complicated by sinus of Valsalva pseudoaneurysm and acute myocardial infarction due to extrinsic compression of the right coronary artery. It highlights the importance of clinical suspicion and the use of multimodality imaging in the diagnostic evaluation and therapeutic planning of such uncommon complications

CATASTROPHIC PRESENTATION OF A MYCOTIC ABDOMINAL AORTIC ANEURYSM IN A PATIENT WITH MULTIMORBIDITY: A CASE STUDY

NATHALIA SALIM SAUD1; NOEMI ROCIO ANDRADE ALBAN2; LEONARDO ANDRADE CACERES2; ARIEL IVAN MENA AMALUIZA2; WOLNEY DE ANDRADE MARTINS1; MARCOS MERULA DE ALMEIDA1;

(1) HOSPITAL UNIVERSITARIO ANTONIO PEDRO - NITEROI - RJ - BRASIL; (2) UNIVERSIDAD DE AMBATO - ECUADOR;

Introduction: Infectious aortitis is a rare but life-threatening condition, often associated with significant morbidity and mortality. Among its etiologies, Salmonella species are notable pathogens, particularly in patients with underlying atherosclerosis or immunocompromising conditions. Its clinical presentation is frequently nonspecific, mimicking other inflammatory or autoimmune diseases, which can delay diagnosis. Early recognition and prompt multidisciplinary management are essential to improve outcomes. Case Description: A 55-year-old male was admitted to the Emergency Department presenting with acute, intense abdominal pain in the left hypochondrium, without irradiation, associated with nausea and vomiting. The patient's medical history was significant for severe cardiovascular disease: previous coronary artery disease with ischaemic heart failure (Left Ventricular Ejection Fraction of 36%). He also presented with systemic hypertension, insulin-dependent type 2 diabetes mellitus, dyslipidaemia, and obstructive peripheral arterial disease. He was a former smoker.Laboratory tests revealed a heightened inflammatory state, with an Erythrocyte Sedimentation Rate (ESR) of 110 mm/h. An abdominal Computed Tomography (CT) scan demonstrated aortitis with an ulcer in the distal abdominal aorta, near the bifurcation of the left iliac artery, accompanied by significant adjacent inflammation.A definitive diagnosis was established after blood cultures returned positive for Salmonella sp., at which point the antibiotic regimen was escalated to meropenem. A follow-up Doppler ultrasound revealed dissection of the abdominal aorta with true lumen thrombosis and ectasia. Conclusions: Mycotic aneurysms caused by Salmonella are associated with high morbidity and mortality rates. Rupture and dissection are catastrophic complications that carry a guarded prognosis, even with appropriate surgical and antibiotic treatment, particularly in patients with multiple cardiovascular comorbidities. The diagnostic challenge lies in the fact that infectious aortitis can mimic autoimmune diseases. Screening with blood cultures and early clinical suspicion are essential, especially in diabetic and atherosclerotic patients. A multidisciplinary approach is of paramount importance for a prompt and accurate diagnosis, thereby optimising effective patient treatment.

CHRONIC CONTAINED RUPTURE OF THORACOABDOMINAL AORTIC ANEURYSM WITH ADJACENT INVASION: DIAGNOSTIC CHALLENGE AND COMPLEX ENDOVASCULAR MANAGEMENT

ANDREZA RIBEIRO PINHO1; MARCELO GUSTAVO LOPES1;

(1) UNICAMP - CAMPINAS - MT - BRASIL;

Introduction: Chronic contained rupture of thoracoabdominal aortic aneurysm is a rare vascular condition. This presentation is estimated to account for only 2.7% to 4% of all ruptured abdominal aortic aneurysms, particularly when it manifests with extra-abdominal symptoms and an insidious course. The association with lumbar vertebral body erosion is even more uncommon: since the first reported case in 1962, fewer than 100 similar cases have been documented in the world literature. Case Description: Case Report: A 75-year-old male patient with hypertension, diabetes, and a smoking history, who had undergone open repair of an abdominal aortic aneurysm (AAA) in 1998 (bifurcated polyester graft), presented 27 years after the index procedure with late aneurysmal degeneration of the graft, chronic contained posterior rupture, and extensive vertebral body erosion. The clinical picture manifested as progressive low back pain over a six-year course, initially attributed to neoplastic and infectious etiologies; however, bone biopsies ruled out neoplasia, revealing only chronic inflammatory infiltrate. Hypotheses of spondylodiscitis and mycotic pseudoaneurysm led to prolonged courses of antibiotic therapy without success. In 2024, the patient developed incapacitating pain, lower limb weakness, and episodes of spontaneous scrotal hematomas (a sign of retroperitoneal hemorrhagic dissection). Computed tomography angiography (2025) revealed a 12.9 cm expansive lesion involving vertebral bodies T12 through L4, with marked bone destruction. Upon admission to a tertiary care center, active infectious etiology was excluded based on negative blood cultures and the absence of systemic signs of infection, establishing the diagnosis of late aneurysmal graft degeneration with chronic contained posterior rupture and secondary vertebral erosion. Due to surgical risk, endovascular treatment was chosen using a branched thoracoabdominal endograft with visceral revascularization using stents for the celiac trunk, superior mesenteric artery, and renal arteries, along with aorto-biiliac stent extension, aiming to exclude the rupture area and depressurize the compromised segment. Conclusions: This case is relevant not only for the rarity of the condition but also for illustrating an uncommon presentation of high diagnostic difficulty, and for reinforcing the importance of long-term surveillance after AAA repairs and the role of complex endovascular therapy as an alternative in high-risk patients with huge bone erosion.

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL; (3) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (4) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL;

Introduction: Eosinophilic Granulomatosis with Polyangiitis (EGPA) belongs to the group of ANCA-associated systemic vasculitides (antibody positive in 30-40% of the cases) that affect small to medium-sized vessels, characterized by granulomatous inflammation and vascular necrosis. Despite its low prevalence, the disease presents high morbidity and mortality and can be underdiagnosed, especially in atypical cardiac presentations. Given the rarity of its presentation and the relevance of the involvement, this work describes a case of perimyocarditis associated with EGPA, emphasizing its diagnostic and therapeutic challenges. Case Description: A 36-year-old woman, 30 weeks pregnant, was admitted with dyspnea, chest pain, headache, scotomas, and lower limb edema. She had a history of chronic rhinosinusitis. Upon examination, she was hypertensive, tachycardic, tachypneic, and presented with diffuse wheezing. Initially, the condition was managed in the ICU as an asthma exacerbation and HELLP syndrome, culminating in an emergency cesarean section. After clinical stabilization and transfer, the patient continued to have pleuritic chest pain. The echocardiogram revealed a large pericardial effusion (21 mm). Following the initial therapeutic failure for pericarditis with ibuprofen and colchicine, new exams detected an increase in the pericardial effusion (34 mm), leukocytosis with marked eosinophilia (5,343/mm3), and elevated troponin (3,363 ng/mL), indicating myocardial damage. Investigations for autoantibodies (including ANCA), viruses, parasites, and neoplasms were negative. The patient underwent a pericardial biopsy to investigate the effusion, which revealed fluid with a predominance of eosinophils. The histopathology showed an eosinophilic inflammatory infiltrate, granuloma formation, and necrosis in fibroadipose tissue, confirming the diagnosis of EGPA. Induction therapy with methylprednisolone and cyclophosphamide was instituted, resulting in significant clinical improvement and hospital discharge. However, the newborn from the emergency cesarean section passed away in the neonatal ICU due to pulmonary sepsis. Conclusions: Perimyocarditis associated with eosinophilia is a rare condition with grave potential, and early recognition of the condition is a major determinant for the patient's outcome. This case report has limitations, such as the absence of long-term follow-up for the patient, which makes it difficult to characterize possible chronic cardiac sequelae or the occurrence of relapses.

16890

INCIDENTALLY IDENTIFIED KOMMERELL DIVERTICULUM IN A PATIENT WITH ASYMMETRIC SEPTAL HYPERTROPHY: CONSERVATIVE MANAGEMENT IN AN ASYMPTOMATIC ADULT

YASMIN TRINDADE1; FERNANDO AUGUSTO ALVES DA COSTA1; GABRIELA CHAVES SANTANA1; JHONY LUCAS INACIO DE ALMEIDA1;

(1) BENEFICENCIA PORTUGUESA - SAO PAULO - SP - BRASIL;

Introduction: Kommerell diverticulum (KD) is a rare congenital aortic arch anomaly, characterized by a saccular dilation at the origin of an aberrant subclavian artery, often associated with a right-sided aortic arch. It may remain asymptomatic and be detected incidentally, but it can also cause compressive symptoms, such as dysphagia, cough, and dyspnea, and may be associated with dissection or rupture when aneurysmal. In adults, management and intervention thresholds remain controversial, and small asymptomatic cases may be followed with serial imaging. Case Description: An adult woman was followed in the outpatient setting for asymmetric septal hypertrophy and was receiving disopyramide and diltiazem, with clinical improvement and reduction of the intraventricular gradient; beta-blockers were avoided due to a history of severe bronchospasm. During routine evaluation, chest imaging was requested because of pulmonary comorbidity and showed a mediastinal opacity, prompting further investigation. Computed tomography characterized an aortic arch anomaly with an aberrant subclavian artery and the presence of Kommerell diverticulum, without signs of dissection. The patient denied dysphagia, odynophagia, dyspnea, or chest pain, and there was no clinical evidence of compression of adjacent structures; therefore, conservative management was chosen. After one year of follow-up, repeat imaging showed no progressive changes. Given the anatomic stability and persistent absence of symptoms, conservative treatment with clinical and imaging surveillance was maintained. Conclusions: Kommerell diverticulum may mimic a mediastinal mass and be incidentally diagnosed on routine imaging studies. In asymptomatic adults, anatomic characterization by computed tomography is essential for diagnostic confirmation and management planning. In this case, the absence of compressive symptoms and stability during follow-up supported conservative management with imaging surveillance, reserving intervention for symptom development, progressive enlargement, or aneurysmal complications.

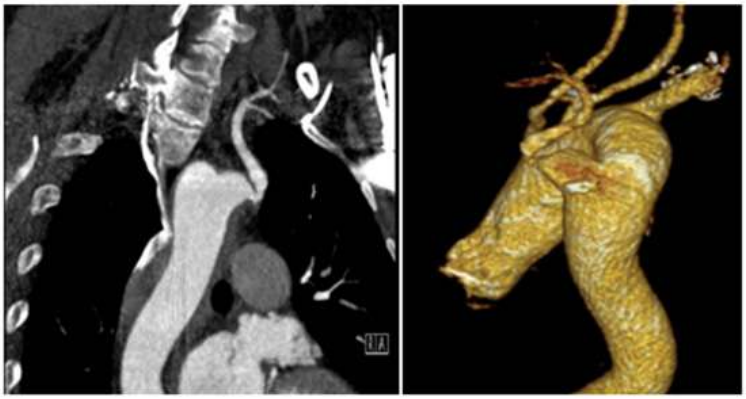

Figure 1. Aortic arch anomaly with an aberrant subclavian artery and presence of Kommerell diverticulum, with no signs of dissection.

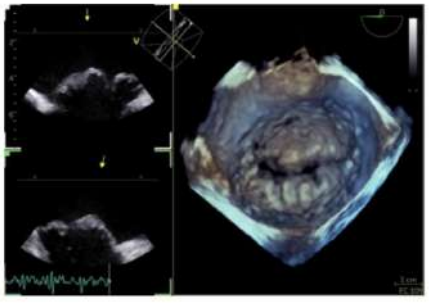
17285

MITRAL ANNULAR DISJUNCTION AS AN OCCULT RISK FACTOR FOR SUDDEN CARDIAC DEATH IN ASYMPTOMATIC INDIVIDUALS: A CASE REPORT

THAYNA ALMEIDA BATISTA1; MARIA JULIANA DE ARRUDA QEUIROGA1; GABRIELA BRITO BEZERRA1; LUCAS IAN SOUSA QUEIROZ1; ICARO CESAR SOARES DE MENEZES1; DAVISON NOELY SALVINO DE OLIVEIRA1; LORENNA ANDRESSA BATISTA ZACARIAS1; MARIA CLARA DE SOUZA VIEIRA1; LUIZ DE ALBUQUERQUE PEREIRA DE OLIVEIRA NETO1; EUGÊNIO SOARES DE ALBUQUERQUE1; DIANA PATRÍCIA LAMPREA SEPULVEDA1;



(1) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL;

Introduction: Mitral annular disjunction (MAD) is a structural abnormality associated with mitral valve prolapse (MVP) and ventricular arrhythmias, constituting an important substrate for sudden cardiac death (SCD). Case Description: A 32-year-old male patient previously assymptomatic suffered an out-of-hospital cardiopulmonary arrest (CPA) in a shockable rhythm, with 36 minutes of resuscitation. After the return of circulation, he suffered another CPA during transport. During the investigation, resting ECG revealed sinus rhythm, normal axis, and criteria for left ventricular hypertrophy (LVH). 24-hour Holter monitoring showed baseline sinus rhythm and low ventricular arrhythmia burden (31 isolated premature ventricular complexes, 14 in bigeminy, with no sustained or non-sustained ventricular tachycardia). Echocardiography, however, revealed severe mitral annulus disjunction (20 mm) associated with myxomatous prolapse and moderate regurgitation. The detailed transesophageal echocardiogram confirmed and characterized the valvular disease: thickened, redundant mitral leaflets with marked prolapse into the left atrium and mitral annular disjunction measuring 20 mm (Figure 1). Doppler study identified severe to moderate mitral regurgitation. Tissue Doppler imaging of the lateral mitral annulus showed a prominent S' wave (22.5 cm/s), consistent with the Pickelhaube sign, an echocardiographic marker of MAD. Three-dimensional echocardiographic image reconstruction also allowed morphological assessment of the valve, suggesting Barlow's disease as the etiology in this case (Figure 2). Cardiac magnetic resonance imaging could not be performed due to unavailability at the service. Material for genetic testing was collected, and the result is pending. After 60 days in the intensive care unit with severe complications (hypoxic-ischemic encephalopathy, status epilepticus, pulmonary infection, and renal dysfunction), the patient was stabilized. He received an implantable cardioverter-defibrillator (ICD) for secondary prevention and is awaiting mitral valve surgery for definitive correction. Conclusions: Mitral annulus disjunction is a high-risk anatomical marker for malignant arrhythmias and sudden cardiac death, especially when associated with mitral valve prolapse. Its diagnosis requires targeted echocardiographic investigation. Management should be multimodal, including ICD for secondary prevention and evaluation for surgical valve repair, essential to modify the prognosis of these patients.

Figure 1 – Transthoracic echocardiogram, parasternal long-axis view, revealing mitral annular disjunction of 20 mm.

Figure 2 - Three-dimensional reconstructed transesophageal echocardiographic image revealing myxomatous degeneration involving both valvular leaflets, associated with mitral annular disjunction.

Introduction: Aortic stenosis is the most prevalent valvular disease in Western countries, and aortic valve replacement is a common procedure. It is estimated that more than 400,000 aortic valve replacements are performed annually worldwide. Over the decades, the technological evolution of biological prostheses has represented significant advances in hemodynamics, tissue preservation techniques, and anticalcification treatments. Despite these advances, limited durability remains the main disadvantage of bioprostheses. The deterioration of bioprostheses within two decades of implantation is widely recognized, and data beyond that period are scarce and heterogeneous. Case Description: A 63-year-old male patient with a history of aortic valve disease and aortic coarctation, previously treated surgically with aortic valve replacement using a biological prosthesis in 1978, presented after 48 years of being asymptomatic and with well-controlled comorbidities. He developed dyspnea, and on physical examination, a holosystolic ejection murmur was detected in the aortic area, radiating to the mitral and tricuspid areas, suggestive of bioprosthesis dysfunction. A preoperative echocardiogram demonstrated a biological aortic prosthesis with fibrocalcific changes, an aortic valve area (AVA) of 0.7 cm², an estimated peak LV–Ao systolic gradient of 107 mmHg, and a mean gradient of 70 mmHg. Peak velocity was estimated at 5.2 m/s. The acceleration time (AT) was 140 ms. The patient underwent surgery, during which the old biological prosthesis was found to have a calcified and ruptured leaflet. It was replaced with a new biological prosthesis (N°. 23). The postoperative echocardiogram showed a normally functioning aortic bioprosthesis, without significant regurgitation on Doppler evaluation. The estimated peak LV–Ao systolic gradient was 16 mmHg, with a mean gradient of 8 mmHg. The effective orifice area was estimated at 2.1 cm² based on the continuity equation and planimetry. Following surgery, the patient had a favorable postoperative course and was discharged from the hospital 15 days after the procedure. Conclusions: Structural valve deterioration is an active, multifactorial process driven by calcification, inflammation, and mechanical stress, with freedom from degeneration of approximately 50% at 20 years. The continuous function of an aortic bioprosthesis over four decades, more than doubling the expected lifespan, represents one of the longest such reports in the literature.

TROPHOBLASTIC EMBOLIZATION OF THE TRICUSPID VALVE: A MIMIC OF CULTURE-NEGATIVE ENDOCARDITIS

PAULA CAROLINE COSTA GONCALVES1; TARSO AUGUSTO DUENHAS ACCORSI1; MIGUEL PISANI LEME FERREIRA1; TALLISON RENAN TENORIO DE LIMA1; ELIAS DAVID GUAMAN CHARCO1; JONATAN RINALDI1; FLÁVIO TARASOUTCHI1;

Introduction: Culture-negative endocarditis remains a major diagnostic challenge, traditionally attributed to fastidious pathogens or prior antimicrobial exposure. However, non-infectious mechanisms are increasingly recognized. In the postpartum setting, trophoblastic embolization represents an exceptionally rare and underrecognized entity capable of mimicking this condition. Case Description: A 19-year-old woman developed persistent fever, weight loss, and recurrent pulmonary embolic events following multiple uterine curettages for retained placental tissue after premature delivery. Transesophageal echocardiography revealed a progressively enlarging tricuspid vegetation, evolving to leaflet perforation and severe regurgitation. Despite prolonged broad-spectrum antimicrobial therapy, repeated blood cultures, serological, and molecular investigations remained negative. Multimodality imaging confirmed pulmonary embolism and persistent metabolic activity at the tricuspid valve. In the setting of progressive valvular destruction and ongoing embolization, surgical intervention was undertaken. Intraoperative findings confirmed a large vegetation (Figure 1), which was surgically excised (Figure 2), and valve repair was successfully achieved. Histopathological analysis demonstrated necrotic cellular aggregates consistent with degraded villous-trophoblastic material, with no evidence of infection. Conclusions: This case challenges the conventional infection-centered paradigm of endocarditis by highlighting trophoblastic embolization as a non-infectious substrate capable of mimicking culture-negative disease and driving progressive valvular injury. In postpartum patients with negative microbiological workup, alternative etiologies should be systematically considered. Histopathology is critical for diagnosis, and early surgical intervention may be required. Recognition of this mechanism has direct implications for clinical decision-making, particularly in distinguishing patients who may benefit from early surgical intervention rather than prolonged empirical antimicrobial therapy.

WHEN CARDIAC MYXOMAS RECUR: A CASE OF CARNEY COMPLEX

FELIPE CERQUEIRA MATHEUS1; FABIO FERNANDES1; ANA PAULA BARROS1; VERA DEMARCHI AIELLO1; IZADORA RADUAN BRIGO1; CAMILE GUIMARÃES VESCHI1; CAMILE GUIMARÃES VESCHI1; EDNARA TARDIOLI SOARES1; EDNARA TARDIOLI SOARES1; VIVIANE TIEMI HOTTA1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction: Carney Complex is a rare autosomal dominant syndrome characterized by pigmented skin lesions, myxoid tumors, and endocrine abnormalities. Cardiac myxomas are the leading cause of mortality, typically presenting early in life, with multicentric involvement and a high recurrence rate. Pathogenic variants in PRKAR1A are central to diagnostic confirmation and disease characterization. Case Description: A 27-year-old woman presented with progressive dyspnea (now at minimal exertion), recurrent fever, and a 5kg weight loss over 5 months. She had undergone 3 prior cardiac surgeries for myxoma resection, involving distinct cardiac chambers over time: the left atrium at age 11, the right atrium 5 years later, and the right ventricle at age 21 (figure 1). Transthoracic echocardiography revealed a new right ventricular mass (figure 2) suggestive of tumor recurrence. She underwent surgical resection without complications, and histopathology confirmed a recurrent myxoma. Multidisciplinary evaluation identified extracardiac manifestations, including cutaneous lentiginosis and superficial angiomyxomas. Endocrine assessment demonstrated cyclic Cushing syndrome, hyperprolactinemia, and galactorrhea, refractory to medical therapy, leading to adrenalectomy. Pathology confirmed primary pigmented nodular adrenocortical disease (PPNAD). Whole-exome sequencing identified a pathogenic PRKAR1A variant (p.Glu11Glyfs*119), establishing the diagnosis of Carney Complex. The patient recovered uneventfully from the surgeries and is currently asymptomatic under outpatient follow-up. Conclusions: This case underscores the aggressive, multicentric, and recurrent nature of cardiac myxomas in Carney Complex. Early recognition is critical in young patients with recurrent tumors involving different cardiac chambers. A comprehensive multidisciplinary approach—including cardiology, endocrinology, genetics, dermatology, multimodality imaging, and pathology—is essential for accurate diagnosis, therapeutic planning, longitudinal long-term surveillance and family screening. The need for multiple cardiac surgeries throughout life represents a major challenge in these patients, given the increasing morbimortality associated with repeated procedures. To date, no therapies have been approved to reduce myxoma recurrence, and interventional management remains the only effective treatment strategy, either through surgical resection or, in selected cases, heart transplantation.

Introduction: Anomalous coronary arteries are classically associated with exercise-related sudden cardiac death in young athletes. However, some individuals may remain asymptomatic for decades despite high-risk anatomical features, raising important challenges regarding late diagnosis and sports eligibility. Case Description: A 70-year-old endurance athlete with a history of 35 completed marathons and ultramarathon participation underwent cardiovascular evaluation after incidental identification of a coronary artery anomaly. The patient had remained asymptomatic throughout decades of high-intensity physical activity. Coronary computed tomography angiography demonstrated anomalous origin of the right coronary artery from the left coronary sinus, with acute takeoff angle, elliptical proximal vessel morphology suggestive of dynamic compression, and an interarterial course between the aorta and pulmonary artery, consistent with high-risk anatomy. Despite the anatomical findings, multimodality evaluation demonstrated preserved cardiovascular performance. Transthoracic echocardiography and cardiac magnetic resonance imaging showed preserved biventricular systolic function, without myocardial fibrosis or late gadolinium enhancement. Functional ischemic assessment was negative. Cardiopulmonary exercise testing revealed excellent functional capacity, with peak VO2 of 34 mL/kg/min (124% of predicted) and physiological hemodynamic response to exercise. Only isolated and rare supraventricular and ventricular ectopy were observed during exertion and recovery. Current European sports cardiology guidelines acknowledge the paucity of evidence regarding exercise recommendations for patients older than 40 years with anomalous coronary arteries. Although restriction to moderate-intensity exercise was considered due to the recognized high-risk anatomical findings, the patient's high functional capacity, lifelong athletic performance, absence of symptoms, and lack of demonstrable ischemia made this decision particularly challenging. Conclusions: This case highlights the complexity of sports eligibility assessment in older athletes with anomalous coronary arteries. The dissociation between high-risk anatomical features and decades of uneventful endurance exercise emphasizes the limitations of current evidence and reinforces the need for individualized evaluation and shared decision-making in sports cardiology.

EIGHT-SECOND SINUS PAUSE IN AN ELDERLY ULTRAMARATHON RUNNER: IS CARDIONEUROABLATION A THERAPEUTIC OPTION?

BARBARA CAPRIOLI PAGAN YEPES PEREIRA1; MARCELO CUNHA DE FREITAS COSTACURTA1; MATHEUS ABREU DE SOUSA SANTOS1; LAURA MARIA DE SORDI RIGAMONTI1; LUIS FELIPE CHAGA MARONEZI1; VÍTOR CERCAL DE OLIVEIRA1; JOÃO FELIPE OLIVEIRA SANTOS1; VILIAN VELOSO DE MOURA FÉ1; GUSTAVO BANDONI TRABULSI1; ELTON ANSELMO PURGATO JUNIOR1; PAULO ROGÉRIO SOARES1; TATIANA DE CARVALHO ANDREUCI TORRES LEAL1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introduction: Prolonged sinus pauses are primarily caused by degenerative fibrosis in elderly individuals. But, they may also be associated with vagal hyperactivity. Factors that suggest this etiology are younger ages, an appropriate response to atropine testing, adequate chronotropic response, and the absence of structural heart disease. Case Description: A 77-year-old ultramarathon runner with no prior comorbidities or medication use and a baseline heart rate (HR) of 40 bpm, came for evaluation with 1.090 ventricular pauses, the longest one lasting 8 seconds, found on a routine 24-hour Holter monitor. Diagnostic investigation excluded hypothyroidism and electrolyte disturbances. Atropine testing showed a peak HR of 90 bpm. The electrocardiogram confirmed sinus bradycardia, atrial premature beats, and ventricular pauses. Exercise stress testing revealed appropriate hypertensive and chronotropic responses, and the patient reached 15.9 METs and remained asymptomatic. Transthoracic echocardiography showed preserved biventricular function with no segmental wall motion abnormalities. Coronary CT angiography showed no obstructive lesions (Calcium Score = 0). Cardiac MRI showed preserved biventricular function and no evidence of myocardial fibrosis. Polysomnography revealed moderate obstructive sleep apnea. A concurrent Holter monitor recorded frequent sinus pauses alternating with atrial or junctional escape rhythms. Findings were suggestive of enhanced vagal tone, and considering the severity of the ventricular pauses and age, therapeutic intervention was discussed. The patient declined pacemaker implantation. Therefore, cardioneuroablation (CNA) was performed without complications. The HR before the procedure was 33 bpm, and after CNA, it increased to 42 bpm. An atropine test further increased the HR to 53 bpm. Conclusions: This case highlights an etiology of prolonged sinus pause that, while uncommon at this age, must be considered. It is also crucial to define the mechanisms causing sinus node dysfunction. Management strategies may include discontinuation of medications, permanent pacemaker implantation, or cardioneuroablation. Cardioneuroablation may be considered, particularly if vagal hyperactivity is the main concern and there is a contraindication to pacemaker implantation.

HEMODYNAMICALLY UNSTABLE VENTRICULAR TACHYCARDIA IN AN IRONMAN ATHLETE USING ANABOLIC STEROIDS AND LISDEXAMFETAMINE

ANTONIO CARLOS AVANZA NETO1; ANTONIO CARLOS ANTONIO AVANZA JÚNIOR1;

(1) UNIVERSIDADE VILA VELHA - VILA VELHA - ES - BRASIL;

Introduction: The use of anabolic steroids (AS) is common among high-performance athletes. The association with other performance-enhancing substances has become increasingly frequent, leading to a rise in cardiovascular abnormalities and greater predisposition to arrhythmias and sudden cardiac death (SCD). We report a case of hemodynamically unstable tachyarrhythmia in an AS user concomitantly using lisdexamfetamine. Case Description: A 27-year-old male high-performance athlete (Ironman competitor), on anabolic steroids (AS) for 24 months and lisdexamfetamine 70 mg once daily for the past 6 months, presented to the Emergency Department with palpitations and syncope following intense training. He was diagnosed with hemodynamically unstable ventricular tachycardia and promptly treated with electrical cardioversion at 100 J. Physical examination was unremarkable. Biochemical workup was normal after cardioversion, as was the post-cardioversion ECG, which was consistent with an athlete's ECG pattern (sinus bradycardia, early repolarization, left ventricular hypertrophy, incomplete right bundle branch block). The patient underwent echocardiography, cardiac magnetic resonance imaging (MRI), 24-hour Holter monitoring, cardiopulmonary exercise testing (CPET), and genetic testing. Cardiac MRI demonstrated only mild enlargement of the left ventricle and left atrium, with no late gadolinium enhancement and no signs of ischemia. Maximal CPET was unremarkable. Echocardiographic findings were consistent with cardiac MRI results, and 24-hour Holter monitoring was also normal. Genetic testing revealed no relevant pathogenic variants. Return to athletic activity was authorized 30 days after CPET completion and discontinuation of all substances. At 12-month follow-up, the patient remains asymptomatic. Conclusions: Prolonged AS use has been associated with dopamine store depletion, manifesting as reduced performance. Athletes may respond in three ways: 1) attributing decline to insufficient training, leading to overtraining; 2) increasing AS doses, heightening arrhythmic risk; or 3) seeking dopamine-replenishing agents — such as lisdexamfetamine — further increasing arrhythmic susceptibility. The third pathway is the most likely mechanism underlying the arrhythmia described in this case.

Introduction: Background: Supraphysiological testosterone therapy is increasingly prescribed off-label in postmenopausal women. Chronic exposure to male-range androgen concentrations may induce neuroendocrine adaptation. The cardiovascular consequences of relative androgen reduction in this context remain poorly described. Case Description: Case report: A 63-year-old woman presented with resting and exertional sinus tachycardia, orthostatic and heat-induced presyncope, progressive fatigue, subjective muscle weakness, insomnia, absent libido and nocturnal hot flushes. She had received combined oestrogen, progesterone and testosterone therapy for 14 years for aesthetic purposes. Serial measurements between 2015 and 2021 documented total testosterone persistently within the male reference range, with peak values of 519 ng/dL and 503 ng/dL. Approximately three years prior to presentation, testosterone dosage was reduced, coinciding with progressive onset of symptoms. At evaluation, total testosterone remained elevated for females (104 ng/dL; reference <63 ng/dL) and free testosterone 70.2 pg/mL (reference 2.4–37 pg/mL), though substantially lower than prior levels. Echocardiography was normal (LVEF 70%). Twenty-four-hour Holter monitoring demonstrated sinus tachycardia (69–160 bpm) with isolated ectopic beats and no complex arrhythmias. Exercise testing showed 7.22 METs without ischaemia. Thyroid and adrenal dysfunction were excluded. Background history included chronic hypotension (90/60 mmHg), recurrent syncope since adolescence, family history of dysautonomia, and prior iliac vein thrombosis treated with stenting. Concomitant medications were atomoxetine 10 mg daily and quetiapine 12.5 mg nightly. Conclusions: Excluding structural heart disease and endocrine causes, the clinical picture was interpreted as androgen withdrawal syndrome due to neuroadaptation following prolonged supraphysiological exposure. Maintaining male-range testosterone levels for over a decade meant subsequent reductions—even to levels above female physiological norms—functionally resembled androgen deficiency. Pre-existing constitutional dysautonomia and concomitant medications likely exacerbated the autonomic instability. Thus, a relative reduction in chronic testosterone exposure may be linked to persistent sinus tachycardia in postmenopausal women. Awareness of this presentation is crucial when evaluating unexplained autonomic symptoms in patients receiving long-term exogenous androgens.

MANAGEMENT OF CHRONIC TYPE B AORTIC DISSECTION WITH ANEURYSMAL DEGENERATION DURING PREGNANCY: A STAGED HYBRID STRATEGY

LETICIA DE FREITAS BARRADAS SIEBRA1; GIANLUCA GOMES SIEBRA1; LILLIAN KAROLINE DE OLIVEIRA ROCHA1; MARIA GABRIELA MEDEIROS CUNHA DE ARAUJO1; FABIO MASTROCOLA1; CARLA SUELY SOUZA DE PAULA1; MICHELY NOBREGA MONTEIRO1; DANIEL VINICIUS RODRIGUES PINTO1; ROSIANE VIANA ZUZA DINIZ1;

(1) UFRN - NATAL - RN - BRASIL;

Introduction: Aortic dissection (AD) during pregnancy is a rare but potentially fatal condition, driven by hemodynamic and hormonal changes that increase aortic wall vulnerability, particularly in patients with underlying aortopathies. While most cases involve the ascending aorta, type B dissection with aneurysmal degeneration in pregnancy and genetic syndromes poses significant diagnostic and therapeutic challenges, requiring individualized management to balance maternal and fetal risks. Case Description: An 18-year-old woman at 12 weeks of pregnancy, with a history of bicuspid aortic valve and prior ascending aortic replacement with a Dacron graft and aortic valve repair at another institution (limited available data), was admitted after detection of a new cardiac murmur and reduced lower limb pulses, despite being asymptomatic. She had no prior diagnosis or phenotypic features suggestive of Marfan syndrome. Aortic CT angiography revealed a chronic descending thoracic aortic dissection (Stanford type B) with aneurysmal degeneration, measuring 7.5 cm in diameter and extending approximately 16 cm distal to the left subclavian artery. Given the high maternal risk, a staged strategy was proposed. However, delays in obtaining a customized endovascular graft, requiring legal authorization, and patient preference led to continuation of pregnancy. As the patient remained stable, a multidisciplinary team (cardiology and obstetrics) opted for close monitoring, aiming for fetal maturity. Cesarean delivery was performed at 32 weeks without complications. This was followed by supra-aortic trunk revascularization (carotid-carotid and left carotid-subclavian bypass) and thoracic endovascular aortic repair (TEVAR) with a custom graft. Control arteriography showed complete exclusion of the dissection and aneurysm, without endoleaks, and uneventful recovery. Genetic testing, obtained postoperatively during outpatient follow-up, identified a pathogenic mutation in the FBN1 gene, confirming Marfan syndrome. Conclusions: Pregnancy-associated AD with underlying genetic aortopathy and aneurysmal degeneration carries high risk and often requires intervention. This case demonstrates that a staged hybrid approach, integrating delayed delivery and endovascular repair within a multidisciplinary framework, is feasible and effective, even in complex clinical and logistical scenarios, with favorable maternal and fetal outcomes.

METHYLDOPA-INDUCED ACUTE HEPATITIS: A DIAGNOSIS TO BE REMEMBERED

INDRED HELLEN DE RESENDE ANDRADE1; MONICA HERMONT FALEIROS1; PATRICIA SABINO VIEIRA DE SÁ1; RAFAELA DE SOUZA FURTADO CAMOPS1; PATRÍCIA TAVARES FELIPE MARCATTI1;

(1) REDE MATER DEI DE SAUDE - BELO HORIZONTE - MG - BRASIL;

Introduction: Introduction: Methyldopa is considered a safe medication for the treatment of hypertension during pregnancy. Hepatitis secondary to its use is rare; however, it is a serious adverse effect that may be fatal. It is believed that hepatitis occurs due to abnormal metabolism by cytochrome P450 associated with an immune reaction to the resulting metabolite. Liver injury usually begins between 1 and 20 weeks after medication initiation, although cases have been reported up to 2 months postpartum. Case Description: Case description: A 35-year-old pregnant woman with asthma, previous history of preeclampsia (PE), and preterm delivery at 33 weeks was undergoing regular prenatal care and was using acetylsalicylic acid and calcium supplementation during the current pregnancy. At 15 weeks of gestation, she was referred for cardio-obstetric evaluation due to elevated blood pressure. Hypertension was confirmed, and methyldopa therapy was initiated.At 17 weeks, she developed a respiratory infection and was treated with amoxicillin/clavulanate. At 19 weeks, routine laboratory tests revealed a significant increase in liver transaminases, leading to hospital admission for further investigation. Viral hepatitis serologies and abdominal ultrasonography were normal. Drug-induced hepatitis secondary to amoxicillin/clavulanate was initially suspected, and close monitoring with serial laboratory testing was chosen. After stabilization of transaminase levels and in the absence of signs of liver failure, the patient was discharged for outpatient follow-up. However, liver enzymes increased again, accompanied by elevated bilirubin levels and jaundice, leading to readmission at 24 weeks of gestation. Autoimmune investigation and portal vein thrombosis screening were both negative. After discussion with the gastroenterology team, methyldopa was discontinued as a therapeutic test and replaced with nifedipine. Liver enzymes and bilirubin levels progressively decreased and subsequently normalized, supporting the diagnosis of probable methyldopa-induced acute hepatitis. The patient had a favorable clinical course, but developed preeclampsia and underwent cesarean delivery at 37 weeks. Conclusions: Conclusion: Although rare, methyldopa-induced acute hepatitis is a diagnosis that should be considered in patients presenting with compatible clinical findings and laboratory abnormalities. The treatment of gestational hypertension remains challenging, and cardiology follow-up is essential to achieve better outcomes.

Table 1. Laboratory Evolution During Pregnancy

Testosterone-Associated Myocarditis in a Female Patient: An Unusual Clinical Presentation

RAYANNE KALINNE NEVES DANTAS1; MARIANA DOS SANTOS RIBEIRO1; LÚCIO ROBERTO CANÇADO CASTELLANO11; MARIA CLARA DE LUCENA FREIRE1; GUILHERME AUGUSTO TEODORO ATHAYDE2;

(1) UNIPE - JOÃO PESSOA - PB - Brasil; (2) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - Brasil;

Introduction: Myocarditis is an inflammatory disease of the myocardium with heterogeneous clinical presentation and multiple etiologies. Although infectious causes are the most common, drug-induced myocarditis remains underrecognized. Experimental and clinical data suggest that androgens may modulate immune response, promote myocardial inflammation, and contribute to adverse cardiovascular remodeling. However, its cardiovascular safety in women remains poorly defined, particularly in the context of off-label use. Case Description: A 24-year-old woman with endometriosis had been using exogenous testosterone for four months when she presented with acute, non-radiating chest pain lasting approximately five days, with progressive worsening, without hemodynamic instability. Laboratory tests revealed elevated C-reactive protein (26 mg/L) and an initial high-sensitivity troponin level of 684 ng/L, with a progressive increase during hospitalization, peaking above 5000 ng/L. Electrocardiogram showed sinus rhythm, left axis deviation, and an early repolarization pattern. Transthoracic echocardiography demonstrated preserved left ventricular ejection fraction (72%). Pulmonary embolism was excluded by tomography pulmonary angiography, and noninvasive coronary evaluation showed no evidence of atherosclerotic disease. Cardiac magnetic resonance imaging revealed subepicardial late gadolinium enhancement in the inferolateral wall, along with mild pericardial thickening and a small pericardial effusion, consistent with non-ischemic myocarditis. Viral serologies and autoimmune workup were negative. Total testosterone levels were above 800 ng/dL. The patient showed clinical improvement with nonsteroidal anti-inflammatory therapy, with a progressive decline in troponin levels to 50 ng/L at discharge and normalization (<1.5 ng/L) at one-week follow-up. N-terminal pro–B-type natriuretic peptide levels decreased from 726 pg/mL during hospitalization to 85 pg/mL on follow-up. Conclusions: This case suggests a possible association between exogenous testosterone use and myocarditis in a female patient. After extensive etiological investigation with negative results for infectious, autoimmune, and ischemic causes, androgen use emerged as the most likely underlying factor. Given the increasing off-label use and the limited data regarding cardiovascular safety in this population, this case highlights the need for caution and further investigation into the effects of androgen therapy in women.

ASSOCIATION BETWEEN LEFT ATRIAL ENLARGEMENT AND ACUTE ISCHEMIC STROKE SEVERITY: EVIDENCE FROM A BRAZILIAN REFERRAL CENTER

NARA SAMARA SILVA FELIPE DOS SANTOS1; GABRIEL TELES DE OLIVEIRA PIÑEIRO1; GABRIEL SOUZA MEDRADO-NUNES1; VICTOR OGANDO SANTANA1; MARIVALDO YSLAN SILVEIRA LEAL1; LUIZ PAULO OLIVEIRA MARTINS1; GEANE VASCONCELLOS DE VASCONCELOS1; JOÃO VICTOR TEIXEIRA COSTA1; ANNA LARISSA CERQUEIRA MARTINS1; PEDRO ANTONIO PEREIRA DE JESUS1;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Stroke remains one of the leading causes of death and disability worldwide, with ischemic stroke accounting for most cases. Left atrial enlargement (LAE) has emerged as an important marker of cardiovascular remodeling and has been associated with increased risk of ischemic stroke, even in the absence of atrial fibrillation. However, evidence regarding the relationship between LAE and stroke severity as well as functional outcomes remains limited. Objetivos: To investigate the impact of left atrial enlargement (LAE) on acute ischemic stroke severity. Métodos: Prospective cohort study conducted with patients with ischemic stroke admitted to a semi-intensive stroke care unit in Bahia, Brazil, between November 2017 and November 2025. Stroke severity was assessed at admission using the National Institutes of Health Stroke Scale (NIHSS). Left atrial enlargement was defined by transthoracic echocardiography primarily as a left atrial diameter >38 mm in women and >40 mm in men. For a supplementary analysis, left atrial volume index > 34 ml/m² was considered. Multiple linear regression models were used to assess the association between LAE and stroke severity, adjusting for relevant confounders. Resultados e Conclusões: A total of 1,009 patients were included in the severity analysis, of whom 322 (31.9%) had left atrial enlargement. LAE was independently associated with higher admission NIHSS scores (B = 1.118; 95% CI 0.300–1.936; p = 0.007). In the supplementary analysis restricted to patients with available indexed left atrial volume data, findings were consistent, with indexed left atrial volume also associated with greater stroke severity (n = 281, B = 2.377; 95% CI 0.911–3.843; p = 0.002). These findings suggest that atrial structural remodeling may influence the acute clinical expression of ischemic stroke, even in the absence of AF. Given that left atrial diameter is a simple and widely available echocardiographic parameter, it may serve as a practical marker to help identify patients at risk of more severe stroke presentations.

CLINICAL PROFILE OF CHEST PAIN PRESENTATION IN PATIENTS WITH ACUTE CORONARY SYNDROME: COMPARISON BETWEEN OBSTRUCTIVE AND NON-OBSTRUCTIVE CORONARY ARTERY DISEASE IN A TERTIARY CENTER

PEDRO VOGEL ALMEIDA1; ANA BEATRIZ BOMFIM DE ALMEIDA1; CLARA TALITA SILVA LOBO1; MARCUS VINÍCIUS BARBOSA VALE1; LÍVIA RODRIGUES SAMPAIO CAVALCANTE1; RAFAEL FELIPE COELHO DE SIQUEIRA1; TAINA TEIXEIRA VIANA2; GUSTAVO PINHEIRO SANTANA1; FELIPE FREITAS COUTO2; RAISA MAINARTE FRANCO BARROS HAMILTON2; RODRIGO MOREL VIEIRA DE MELO2;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL; (2) IDOR - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Chest pain characteristics in acute coronary syndrome (ACS) may overlap between patients with obstructive and non-obstructive coronary artery disease (CAD). Although typical pain is classically associated with obstructive CAD, non-obstructive presentations may also involve anginal symptoms, making initial clinical differentiation difficult. Objetivos: To compare the clinical profile of chest pain at admission between patients with ACS and obstructive versus non-obstructive CAD in a tertiary center. Métodos: Prospective cohort study including patients hospitalized with ACS in a tertiary hospital between 02/09/2024 and 01/09/2026 who underwent coronary angiography. Patients with a final diagnosis other than ACS, including endocarditis, myocarditis, and pulmonary thromboembolism, were excluded. Obstructive CAD was defined as stenosis ≥50% in at least one major epicardial coronary artery. Non-obstructive CAD was defined as atherosclerosis <50% and absence of plaque instability on intravascular ultrasound, when available. Demographic and clinical data were collected during hospitalization. Categorical variables were expressed as absolute values and percentages, and continuous variables as mean ± standard deviation. The chi-square test and Student's t-test were used. Statistical significance was set at p<0.05. Resultados e Conclusões: A total of 311 patients were evaluated. Of these, 236 (75.9%) had obstructive CAD and 75 (24.1%) comprised the non-obstructive ACS group, including 17 with MINOCA, 6 with INOCA, and 52 with ANOCA. Female sex: 81 (34.3%) vs. 44 (58.7%); p<0.001. Mean age: 67.83 ± 10.75 vs. 66.84 ± 10.77 years; p=0.490. Chest pain at admission: 170 (72.0%) vs. 53 (70.7%); p=0.819. Pain-type distribution differed between groups: type A chest pain, 77 (32.6%) vs. 12 (16.0%); type B, 107 (45.3%) vs. 34 (45.3%); type C, 37 (15.7%) vs. 20 (26.7%); anginal equivalent, 14 (5.9%) vs. 5 (6.7%); and unspecified record, 1 (0.4%) vs. 4 (5.3%); p=0.001, respectively for the obstructive and non-obstructive groups. In patients with ACS, the presence of chest pain at admission was similar between those with obstructive and non-obstructive CAD. Although type A pain was more frequent in obstructive CAD, the overlap in symptom presentation reinforces that pain characteristics alone cannot safely distinguish obstructive from non-obstructive coronary disease.

COAGULOPATHY AND INFLAMMATORY PROFILE PREDICT INCIDENT ATRIAL FIBRILLATION IN HOSPITALIZED HEART FAILURE: A PHENOTYPIC AND PROGNOSTIC ANALYSIS

LUCAS ALENCAR QUEIROZ1; RAFAEL DE SOUZA NATIVIDADE LOPES2; ISABELA MARTINS VIANA3; VICTOR MATHEUS RICARDO TERRA4; MILTON CESAR VASCONCELOS MACHADO JUNIOR4; PAULA CORREA NOGUEIRA5;

(1) UNIVERSIDADE ESTADUAL DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) FUNDACAO HOSPITAL DE CLINICAS GASPAR VIANNA PA - BELÉM - PA - BRASIL; (3) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (4) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (5) HOSPITAL DA MULHER - SÃO PAULO - PA - BRASIL;

Introdução/Fundamentos: Atrial fibrillation (AF) frequently complicates heart failure (HF), but the laboratory signature and prognostic relevance of AF newly detected during acute hospital presentation remain poorly characterized. Objetivos: To identify the phenotype and prognostic impact of incident AF in patients with HF admitted via the emergency department (ED). Métodos: Retrospective cohort from a publicly available text-enriched ED database. HF was defined by ICD-10 I50.x; incident AF as AF detected after admission and absent on the initial ECG, ascertained via validated regular expressions over clinical text. Patients with current or prior atrial flutter (ICD I48.3, I48.4, I48.92 or text mention) were excluded. Laboratories were z-scored after multicollinearity control (variance inflation factor below 5). Logistic regression was adjusted for age, sex and chronic kidney disease (CKD). HF-specificity was tested through lab-by-HF interaction against a non-HF cardiac control cohort. Prognostic incremental value was assessed by delta-AUC and likelihood-ratio (LR) tests over a base demographic model. Outcomes: in-hospital, 30-day and 1-year mortality and 30-day readmission. Resultados e Conclusões: After flutter exclusion, 1,884 HF patients (incident AF rate 28.4%) were compared with 1,580 non-HF cardiac controls (14.5%; OR for HF 2.34, 95%CI 1.97-2.78). Adjusted lab predictors per 1 standard deviation included prothrombin time (OR 1.83, 1.62-2.06), MCHC (0.80, 0.72-0.89), red cell distribution width (1.24, 1.12-1.37), albumin (0.81, 0.73-0.90) and neutrophils (1.26, 1.12-1.43). Prothrombin time, INR, neutrophils, lymphocytes, creatine kinase and partial thromboplastin time showed significant HF-specific interaction (all p<0.01); albumin, MCHC and RDW behaved as global frailty markers. Incident AF was independently associated with in-hospital (OR 1.98, 1.10-3.58), 30-day (1.90, 1.26-2.88) and 1-year mortality (1.76, 1.39-2.22). Adding incident AF to the demographic model improved discrimination (delta-AUC +0.020 at 30 days, +0.017 at 1 year; LR p<0.01). Readmission at 30 days did not differ. In hospitalized HF patients, incident AF presents a HF-specific signature dominated by coagulopathy and inflammation and carries independent prognostic value beyond age, sex and CKD. AF emerging during acute presentation represents a distinct phenotype warranting dedicated risk stratification.

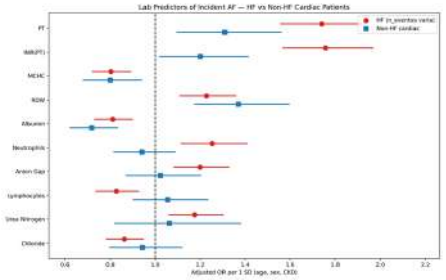

Figure 1. Forest plot of laboratory predictors of incident atrial fibrillation in heart failure (HF) versus non-HF cardiac controls. Adjusted odds ratios per 1 standard deviation. Coagulation markers (prothrombin time, INR, partial thromboplastin time), inflammatory cells (neutrophils, lymphocytes) and creatine kinase showed significant HF-specific interaction (all p<0.01); albumin, MCHC and red cell distribution width behaved as global frailty markers.

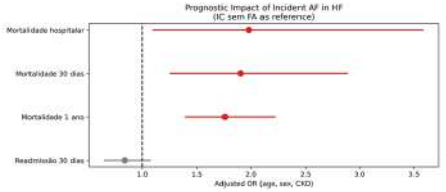

Figure 2. Independent prognostic value of incident atrial fibrillation in hospitalised heart failure patients. Adjusted odds ratios for in-hospital, 30-day and 1-year mortality, beyond age, sex and chronic kidney disease. Adding incident AF to the demographic model improved discrimination (delta-AUC +0.020 at 30 days, +0.017 at 1 year; LR p<0.01).

COLCHICINE IN THE POST–ACUTE MYOCARDIAL INFARCTION SETTING: IMPACT ON THE REDUCTION OF MAJOR CARDIOVASCULAR EVENTS - A SYSTEMATIC REVIEW OF RANDOMIZED CLINICAL TRIALS

PEDRO AUGUSTO PIMENTA DE ALMEIDA1; LUÍS FELIPE DE LIMA REZENDE1; ERICO RIBEIRO NETTO1; DAVI SILVEIRA MARTINS1;

(1) UFJF - JUIZ DE FORA - MG - BRASIL;

Introdução/Fundamentos: Acute myocardial infarction (AMI) is characterized by myocyte necrosis resulting from reduced coronary arterial blood flow, leading to often irreversible injury and, in severe cases, death. In this context, as it represents the leading cause of death in Brazil, the implementation of effective therapeutic strategies in the post-AMI period is essential to reduce morbidity and mortality in this population. Objetivos: To evaluate the efficacy and safety of colchicine in reducing adverse cardiovascular events in post-AMI patients. Métodos: A systematic review conducted in accordance with PRISMA guidelines. Searches were performed in PubMed, EMBASE, and Web of Science, including placebo-controlled randomized clinical trials published between 2021 and 2026. The following MeSH/DeCS terms were used: (colchicine) AND (myocardial infarction) AND (clinical trial). Original studies assessing outcomes of colchicine administration in post-AMI patients were included. After screening, a total of 8 studies were deemed eligible for review. A qualitative synthesis of findings was performed without meta-analysis due to methodological heterogeneity among the included studies. Resultados e Conclusões: The included studies showed predominantly neutral results regarding the efficacy of colchicine in post-AMI patients. In a trial with 7,062 patients, the composite endpoint occurred in 9.1% of the colchicine group versus 9.3% in the placebo group (HR 0.99; 95% CI 0.85–1.16; p=0.93), with no reduction in major cardiovascular events. Consistently, no significant differences were observed in infarct size (26.0 g vs. 28.4 g; p=0.87), ejection fraction, ventricular remodeling, or CRP levels. Some findings suggest potential benefits, such as a trend toward reduced atrial fibrillation and decreased biomarkers (MMP-9, NOX2, and TGF-β) in subgroups without revascularization (p<0.05). On the other hand, there was a higher incidence of gastrointestinal adverse effects (up to 34.4% vs. 10.1%) and an early increase in left ventricular thrombus (22.2% vs. 7.4%; p=0.01). It is concluded that colchicine did not demonstrate consistent clinical benefit in improving adverse cardiovascular outcomes in post-AMI patients.

COMPARATIVE EFFECTIVENESS AND SAFETY OF RIVAROXABAN VERSUS APIXABAN IN VENOUS THROMBOEMBOLISM: A SYSTEMATIC REVIEW AND META-ANALYSIS OF 248,579 PATIENTS

MARIA ANTONIA OLIVEIRA MACHADO PEREIRA1; JULIA ARÊA LEÃO AYRES DE SOUSA2; MATHEUS PRADO DOS SANTOS3; LUIZ RICARDO DE SOUSA FERNANDES2; DÁRIO CORREIA NEGREIROS2; GELSON DINGANA MBOLOQUELE4; LETÍCIA BEATRIZ COUTINHO ALVES2; LUIS FELIPE VIEIRA NUNES PORTO2; DIEGO CHEMELLO5;

(1) UNIVERSIDADE ESTADUAL DO PIAUÍ - TERESINA - PI - BRASIL; (2) UNIVERSIDADE FEDERAL DO PIAUI - PIAUÍ - PI - BRASIL; (3) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (4) UNIVERSIDADE JEAN PIAGET DE ANGOLA - ANGOLA; (5) UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL - PORTO ALEGRE - RS - BRASIL;

Introdução/Fundamentos: Direct oral anticoagulants, particularly Rivaroxaban and Apixaban, are widely used for the treatment and secondary prevention of Venous Thromboembolism (VTE). However, direct comparative evidence regarding their effectiveness and safety remains limited. Objetivos: This study aims to evaluate the comparative effectiveness and safety of rivaroxaban versus apixaban in patients with VTE. Métodos: PubMed, Embase, and Web of Science were systematically searched from inception to March 2026. We included randomized controlled trials (RCTs) and cohort studies comparing apixaban and rivaroxaban in patients with VTE. The primary outcomes were VTE recurrency and major bleeding, defined according to the criteria of the International Society on Thrombosis and Haemostasis (ISTH). Secondary outcomes included intracranial (ICB) and gastrointestinal (GIB) bleeding, and all cause mortality. Risk ratios (RRs) with 95% confidence intervals (CIs) were pooled using a random-effects model. Statistical heterogeneity was assessed using the I^2 statistic, and publication bias was evaluated with funnel plots and Egger's test when applicable. Resultados e Conclusões: Twelve studies including 248,579 patients were analyzed (144,405 in the apixaban group and 104,174 in the rivaroxaban group). Apixaban was associated with an overall significantly lower risk of major bleeding (RR: 0.77; 95% CI 0.72–0.81) and VTE recurrence (RR: 0.91; 95% CI 0.85–0.95) compared with rivaroxaban. However, no significant differences were observed for either outcome at 3 months or 5 years, indicating that these differences were not sustained over time. There was no significant difference in the risk of ICB (RR: 0.99; 95% CI: 0.74–1.31), GIB (RR 0.82; 95% CI 0.63-1.06), and all-cause mortality (RR 0.96; 95% CI 0.85-1.08) between groups. Apixaban may provide a more favorable overall balance between efficacy and safety than rivaroxaban in patients with VTE, although this advantage appears less evident at very early and long-term follow-up. Further large-scale prospective studies are needed to confirm the durability of these findings.

COMPARISON OF THE GRACE SCORE IN PATIENTS WITH ACUTE CORONARY SYNDROME: OBSTRUCTIVE VERSUS NON-OBSTRUCTIVE CORONARY ARTERY DISEASE

PEDRO VOGEL ALMEIDA1; LIVIA RODRIGUES SAMPAIO CAVALCANTE1; ANA BEATRIZ BOMFIM DE ALMEIDA1; CLARA TALITA SILVA LOBO1; MARCUS VINÍCIUS BARBOSA VALE1; RAFAEL FELIPE COELHO DE SIQUEIRA1; FELIPE FREITAS COUTO2; GUSTAVO PINHEIRO SANTANA2; RAISA MAINARTE FRANCO BARROS HAMILTON2; RODRIGO MOREL VIEIRA DE MELO2;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL; (2) IDOR - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: The GRACE score is widely used for prognostic stratification in patients with acute coronary syndrome (ACS). However, its application in patients with ACS without obstructive coronary artery disease (CAD) on catheterization remains less well defined, with limited evidence in this population. Objetivos: To compare GRACE score values between patients hospitalized with ACS and obstructive versus non-obstructive CAD in a tertiary center and to describe the demographic profile of the groups. Métodos: Prospective cohort study including patients hospitalized with ACS in a tertiary hospital between 02/09/2024 and 01/09/2026 who underwent coronary angiography. Patients with a final diagnosis other than ACS, including endocarditis, myocarditis, and pulmonary thromboembolism, were excluded. Demographic, clinical, and laboratory data were collected during hospitalization. Obstructive CAD was defined as stenosis ≥50% in at least one major epicardial coronary artery. Non-obstructive CAD was defined as atherosclerosis <50% and absence of plaque instability on intravascular ultrasound, when available. Categorical variables were expressed as absolute values and percentages, and continuous variables as mean ± standard deviation. The chi-square test and Student's t-test were used. Statistical significance was set at p<0.05. Resultados e Conclusões: During the study period, 2,108 patients were evaluated, of whom 313 had ACS and underwent coronary angiography. After exclusions, 311 patients comprised the final cohort. Of these, 236 (75.9%) had obstructive CAD and 75 (24.1%) comprised the non-obstructive ACS group. Female sex: 81 (34.3%) vs. 44 (58.7%); p<0.001. Mean age: 67.83 ± 10.75 vs. 66.84 ± 10.77 years; p=0.490. GRACE score did not differ between groups: 99.25 ± 28.90 vs. 92.59 ± 25.79; p=0.087. In patients with ACS undergoing coronary angiography, GRACE score values were similar between those with obstructive and non-obstructive CAD. In this cohort, non-obstructive ACS accounted for 24.1% of the sample, reinforcing the need for complementary methods beyond the clinical score for anatomical and functional evaluation, as well as for improved risk stratification and treatment personalization.

COMPARISON OF THE HEART SCORE IN PATIENTS WITH ACUTE CORONARY SYNDROME: OBSTRUCTIVE VERSUS NON-OBSTRUCTIVE CORONARY ARTERY DISEASE

PEDRO VOGEL ALMEIDA1; LÍVIA RODRIGUES SAMPAIO CAVALCANTE1; CLARA TALITA SILVA LOBO1; MARCUS VINÍCIUS BARBOSA VALE1; ANA BEATRIZ BOMFIM DE ALMEIDA1; TAINÁ TEIXEIRA VIANA2; RAISA MAINARTE FRANCO BARROS HAMILTON2; GUSTAVO PINHEIRO SANTANA2; RAFAEL FELIPE COELHO DE SIQUEIRA1; FELIPE FREITAS COUTO2; RODRIGO MOREL VIEIRA DE MELO2;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL; (2) IDOR - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: The HEART score is widely used for risk stratification in patients with chest pain and suspected acute coronary syndrome (ACS). However, its application in patients with ACS without obstructive coronary artery disease (CAD) on catheterization remains less well defined regarding its ability to differentiate distinct anatomical phenotypes. Objetivos: To compare HEART score values between patients hospitalized with ACS and obstructive versus non-obstructive CAD in a tertiary center and to describe the demographic profile of the groups. Métodos: Prospective cohort study including patients hospitalized with ACS in a tertiary hospital between 02/09/2024 and 01/09/2026 who underwent coronary angiography. Patients with a final diagnosis other than ACS, including endocarditis, myocarditis, and pulmonary thromboembolism, were excluded. Demographic, clinical, and laboratory data were collected during hospitalization. Obstructive CAD was defined as stenosis ≥50% in at least one major epicardial coronary artery. Non-obstructive CAD was defined as atherosclerosis <50% and absence of plaque instability on intravascular ultrasound. Categorical variables were expressed as absolute values and percentages, and continuous variables as mean ± standard deviation. The chi-square test and Student's t-test were used. Statistical significance was set at p<0.05. Resultados e Conclusões: A total of 311 patients comprised the final cohort. Of these, 236 (75.9%) had obstructive CAD and 75 (24.1%) comprised the non-obstructive ACS group. Female sex was more frequent in the non-obstructive than in the obstructive CAD group: 44 (58.7%) vs. 81 (34.3%); p<0.001. Mean age was 67.83 ± 10.75 years in the obstructive CAD group and 66.84 ± 10.77 years in the non-obstructive ACS group; p=0.490. HEART score was 5.12 ± 1.24 in the obstructive CAD group and 4.78 ± 1.09 in the non-obstructive ACS group; p=0.094. In patients with ACS undergoing coronary angiography, HEART score values were similar between those with obstructive and non-obstructive CAD. In this cohort, initial assessment using the HEART score did not differentiate the anatomical CAD phenotypes, supporting the need for complementary approaches for better anatomical characterization.

COST, LENGTH OF STAY, AND IN-HOSPITAL MORTALITY FROM ACUTE MYOCARDIAL INFARCTION ACROSS BRAZILIAN REGIONS: AN ECOLOGICAL ANALYSIS OF SIH/SUS DATA (2020–2024)

LUIZ EDUARDO COSTA DOS SANTOS1; LUIS HENRIQUE COSTA MONTEIRO1; ENRIQUE ARIEL OLIVEIRA BATISTA1; GUSTAVO DE MELO BAPTISTÃO1; VITOR GABRIEL QUARESMA DE SOUZA1; VITOR BARBOSA DIAS1; MATHEUS VINÍCIUS DA SILVA SANTOS BARBOSA1;

(1) UNIVERSIDADE FEDERAL DO AMAPÁ - MACAPÁ - AP - BRASIL;

Introdução/Fundamentos: Acute myocardial infarction (AMI) is one of the leading causes of in-hospital mortality in Brazil, representing 5,95% of the total deaths in the period. Regional disparities in healthcare access, density of specialized centers, and transportation infrastructure may directly influence clinical outcomes and care costs. The analysis of hospital indicators by region is a relevant tool for identifying inefficiencies and guiding cardiovascular health policies. Objetivos: To investigate whether Brazilian regions with higher mean cost per AMI hospitalization paradoxically present longer hospital stays and higher in-hospital mortality, testing the hypothesis that elevated costs reflect structural deficiencies rather than greater care resoluteness. Métodos: Cross-sectional, ecological, retrospective, and analytical study based on secondary data from the SIH/SUS, obtained through DATASUS, evaluating AMI hospitalizations by Brazilian region, mean hospital procedure cost per admission, mean length of stay (total inpatient days/number of admissions), and in-hospital mortality rate from 2020 to 2024. Resultados e Conclusões: The North region recorded the highest mean cost per AMI hospitalization (BRL 1,587.75) and the longest mean length of stay (8.14 days), while the South region presented the lowest values for both indicators (BRL 913.61 and 5.39 days, respectively). A direct and consistent association between cost and length of stay was observed across all regions. Regarding in-hospital mortality, the Northeast recorded the highest rate (10.20%), followed by the North (8.97%), Southeast (8.74%), South (8.20%), and Center-West (7.34%). The association between prolonged stays and higher costs suggests that longer hospitalizations in the North do not reflect greater care resoluteness, but rather late presentation with more severe clinical conditions, a hypothesis consistent with the region's geographical barriers, low density of hemodynamic services, and logistical challenges. Limitations include the ecological design, which precludes individual-level causal inference, and the inherent constraints of secondary administrative data. These findings reinforce the need for regionalized AMI care policies, prioritizing timely reperfusion access in the North and Northeast regions.

Data source: DATASUS / SIH-SUS · Period: 2020-2024 · Classification: Original Research

Region	Mean hospitalization cost (BRL)	Mean length of stay (days)	In-hospital mortality rate (%)
North	1,587.75	8.14	8.97
Southeast	1,407.53	7.03	8.74
Northeast	1,160.74	7.64	10.20
Central-West	1,096.56	6.17	7.34
South	913.61	5.39	8.20

DETERMINANTS OF DELAYED DOOR-TO-ECG TIME IN STEMI: A MULTICENTER STUDY

MANOELA MASSA MOURA1; LUCAS GABRIEL CASTRO CARVALHO1; GABRIEL CARVALHO FIUSA2; RODRIGO GOES GALVÃO3; NATAN TEIXEIRA DA SILVA3; VINICIUS CARVALHO FIUSA1; LALESCA MEDEIROS1; ANA CLARA PIEROTE VASCONCELOS1; PEDRO CÉSAR REZENDE SEGURADO1; ERYCLAUDIA CHRYSTIAN JORQUEIRA4; ANTONIO FAGUNDES4;

(1) UNIVERSIDADE DE BRASILIA - BRASÍLIA - DF - BRASIL; (2) UNIVERSIDADE CATOLICA DE BRASILIA - BRASÍLIA - DF - BRASIL; (3) ESCOLA SUPERIOR DE CIENCIAS DA SAUDE - BRASÍLIA - DF - BRASIL; (4) INSTITUTO D'OR DE PESQUISA E ENSINO - BRASILIA - DF - BRASIL;

Introdução/Fundamentos: Timely electrocardiogram (ECG) acquisition, ideally within 10 minutes of first medical contact, is essential for the early diagnosis and management of ST-segment elevation myocardial infarction (STEMI). However, delays in door-to-ECG time remain frequent and may reflect both patient-related factors and variability in initial clinical recognition. Objetivos: To identify clinical factors independently associated with delayed door-to-ECG time in patients with STEMI. Métodos: A multicenter study was conducted using a retrospective national registry with data from 14 Brazilian states between January 2020 and June 2024 from the largest private hospital network in the country. Multivariable logistic regression models were used to identify the factors independently associated with delayed door-to-ECG time (>10 min and >30 min) in the population with acute myocardial infarction with ST elevation. The data were analyzed using RStudio. Resultados e Conclusões: A total of 7,171 patients were included. In multivariable analysis, diabetes mellitus was independently associated with delayed ECG acquisition (>10 min) (aOR 1.66, 95% CI 1.09–2.51; p=0.017), while the AB phenotype (typical chest pain and highly probable coronary chest pain) was associated with a lower probability of delay (aOR 0.23, 95% CI 0.14–0.39; p<0.001). Age, sex, hypertension, smoking, and obesity were not independently associated with the outcome after adjustment for the other covariates. For more pronounced delays (>30 min), the AB phenotype remained the only significant factor (aOR 0.09, 95% CI 0.04–0.20; p<0.001). These findings suggest that diabetes may contribute to delayed recognition, potentially reflecting atypical presentations or lower initial clinical suspicion. In contrast, the association between the AB phenotype and shorter door-to-ECG time likely reflects differences in clinical presentation or triage prioritization. Targeted strategies focusing on high-risk groups, particularly those at risk for atypical presentation, may improve timely ECG acquisition and optimize STEMI care.

DETERMINANTS OF STROKE SEVERITY AND MORTALITY IN THE POST-COVID-19 ERA: A COHORT STUDY IN A REFERRAL UNIT

RAFAEL BATISTA FELIX1; ANA BEATRIZ SILVA PEREIRA1; MARCELO DE GÓIS FURTADO1; LUANA DIB FERNANDES PONTES1; HYGOR KAWAN LEANDRO FERREIRA1; EMERSON PEREIRA DOS SANTOS1; JOÃO AUGUSTO SOUZA LOPES DE CARVALHO1; BEATRIZ MARIA DE SÁ ROCHA1; JESIMIEL DOS SANTOS VITALINO1; RAYSSA SAMARA OLIVEIRA DA FONSECA1; LÍVIA CAROLINA SOUZA DANTAS1;

(1) UNIVERSIDADE FEDERAL DE ALAGOAS - MACEIÓ - AL - BRASIL;

Introdução/Fundamentos: Stroke is the leading cause of disability and death in Brazil. Acute complications can lead to respiratory failure and reduced level of consciousness, requiring invasive mechanical ventilation (IMV), a factor that drastically increases mortality. In the post-pandemic era, it is crucial to understand whether COVID-19 history and vaccination status have altered classic predictors of severity and the need for IMV. Objetivos: To evaluate clinical determinants and the influence of COVID-19 history and vaccination status on neurological severity, the need for invasive mechanical ventilation, and hospital mortality in stroke patients in the post-pandemic era. Métodos: This is a retrospective and ecological cohort study conducted in a regional hub in Northeastern Brazil. A random sample of 259 medical records of stroke patients (2021-2023) was analyzed. Clinical data, severity (NIHSS), functionality (mRS), and COVID-19/vaccination history were collected. Primary outcomes were death and invasive mechanical ventilation (IMV). Statistical analysis included multiple logistic and linear regression, as well as Joinpoint regression for temporal trends. A significance level of p < 0.05 and a 95% CI were adopted. The study was approved by the UFAL Ethics Committee (Opinion No. 81607524.0.0000.5013). Resultados e Conclusões: The sample (mean age 66.7 years; 50.6% women) showed a high prevalence of comorbidities (84.6%). Ischemic stroke predominated (59.1%), and 58.7% of patients presented with severe or very severe status (NIHSS > 10) upon admission. Although 68.7% reported prior COVID-19 infection and 85.7% were vaccinated, these factors were not associated with severity or death. The need for IMV (29.3%) was the strongest predictor of mortality (OR 24.43), followed by a diagnosis of hemorrhagic stroke (OR 3.58). Each additional point on the NIHSS increased the chance of IMV by 20%. Thrombolytic treatment (20.5% of cases) was associated with a 91% reduction in the risk of death. The NIHSS score and hemorrhagic stroke diagnosis are established as the main determinants of IMV and mortality, whereas COVID-19 history and vaccination status did not impact clinical outcomes. Optimizing early risk stratification and ensuring access to reperfusion therapy remain critical pillars for neurological survival in the post-pandemic era.

EARLY BLOOD PRESSURE VARIABILITY AS A PREDICTOR OF MORTALITY AND CARDIOVASCULAR COMPLICATIONS IN SEPSIS:A SYSTEMATIC REVIEW AND META-ANALYSIS

YASMINE TACHET1; OSAMA ELBAHY2;

(1) FACULTY OF MEDICINE MOULOUD MAMMERI TIZI OUZOU - ALGERIA; (2) PORTSAID UNIVERSITY, MEDECINE - EGYPT;

Introdução/Fundamentos: Sepsis remains a major cause of mortality worldwide.Although hemodynamic management primarily targets mean arterial pressure (MAP),blood pressure variability (BPV) may better reflect early cardiovascular instability and autonomic dysregulation studies suggest that increased early BPV may predict adverse outcomes in sepsis,yet evidence has not been systematically synthesised Objetivos: To systematically evaluate the association between early blood pressure variability and mortality and cardiovascular adverse events in patients with sepsis and severe infections Métodos: A systematic review and meta-analysis were conducted according to PRISMA 2020 and registered on PROSPERO. PubMed, Scopus, Google Scholar, and SpringerLink were searched for studies published between 2015 and 2025.Adult studies reporting early BPV and clinical outcomes were included. Risk of bias was assessed using ROBINS-I and RoB 2 Resultados e Conclusões: Seventeen studies including over 100,000 patients were analyzed. Increased systolic BP variability was associated with higher 28–30-day mortality (OR 1.18, 95% CI 1.03–1.36; I^2 = 0%; n = 1,407), while MAP variability showed a stronger association with in-hospital mortality (OR 1.81, 95% CI 1.37–2.39; I^2 = 92%; n = 23,802). Overall, 14 of 17 studies demonstrated an independent association between elevated BPV and mortality, with diastolic variability frequently emerging as the strongest predictor. Absolute MAP demonstrated a U-shaped relationship with mortality, with increased risk at both low (<70 mmHg) and high values and an apparent optimal range between 73 and 80 mmHg Evidence linking BPV to specific cardiovascular complications remained limited but suggested associations with acute heart failure, arrhythmias, and cardiovascular stress. Patients with pre-existing hypertension appeared more vulnerable to adverse outcomes in the presence of elevated BPV. Intensive MAP strategies in elderly patients were also associated with increased ischemic and arrhythmic events Several studies used invasive arterial monitoring, providing high-resolution assessment of short-term BPV while contributing to methodological heterogeneity Early BPV is consistently associated with increased short-term mortality in sepsis and may represent a clinically relevant marker of cardiovascular stress and hemodynamic instability, warranting further prospective validation Overall, early BPV emerges as a simple, real-time, low-cost and clinically meaningful predictor that could enhance early risk stratification in sepsis

21838

HEART RATE CONTROL WITH ESMOLOL IN SEPTIC SHOCK: IMPACT ON CARDIOVASCULAR OUTCOMES — A SYSTEMATIC REVIEW

MARIANA BARROS MELO1; NATHALIA ARCOVERDE MUSY1; YANA PEIXOTO AGUIAR1; LETICIA MARIA OLIVEIRA CORREIA1; CAROLINA RIBEIRO ROLA1; LARA CARVALHO VASCONCELOS DE OLIVEIRA1; YASMIN MARTINS DE OLIVEIRA AMARAL1; ANA BEATRIZ SOUSA COSTA1; JANINE NOVAIS MIRANDA1; MARIA CECILIA ARAÚJO DE NEGREIROS MELO1; ANA CATARINA GURGEL SILVA FERNANDES1; GABRIEL PINHEIRO FURTADO1;

(1) UNICHRISTUS - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Septic shock is a severe clinical condition characterized by hemodynamic instability and high mortality, frequently associated with adrenergic hyperactivity and persistent tachycardia. In order to reduce myocardial oxygen consumption and optimize cardiovascular performance in these patients, different chronotropic control strategies have been investigated, particularly the use of Esmolol. Objetivos: This systematic review aims to evaluate data presented in clinical studies regarding the impact of heart rate control with esmolol on cardiovascular outcomes in patients with septic shock. Métodos: This systematic review evaluated the effects of heart rate control with esmolol in patients with septic shock. Searches were conducted in the PubMed/MEDLINE and BVS/LILACS databases between January 2020 and May 2026 using MeSH and DeCS descriptors related to septic shock, esmolol, beta-blockers, heart rate control, mortality, hemodynamics, and cardiovascular outcomes, combined with Boolean operators (AND/OR). Original studies involving adult patients with septic shock treated with esmolol and assessing cardiovascular or hemodynamic outcomes were included, while reviews, editorials, duplicates, and studies not meeting the eligibility criteria were excluded. Study selection followed PRISMA 2020 recommendations and was independently performed by two reviewers using the Rayyan platform. Of the 90 studies identified, 15 were included in the final analysis. Resultados e Conclusões: Fifteen studies involving 13,313 patients with sepsis and/or septic shock were included. Esmolol use was associated with significant heart rate reduction, with higher control rates within 24 hours (100% vs. 58.3%; p = 0.037) and reductions from 116.8 to 90.6 bpm (p < 0.001), supported by meta-analysis (SMD −1.83; 95% CI −2.95 to −0.70; p = 0.001). Improvements in hemodynamics and tissue perfusion were observed, including increased stroke volume index, lower lactate levels, and improved $ScvO_2$, without major circulatory instability. Esmolol was also associated with reduced 28-day mortality (RR 0.68–0.71) and 90-day mortality (HR 0.84), as well as decreased inflammatory and myocardial injury biomarkers. Overall, esmolol demonstrated a favorable safety profile and may represent a promising adjunctive strategy in septic shock, although further studies are still needed

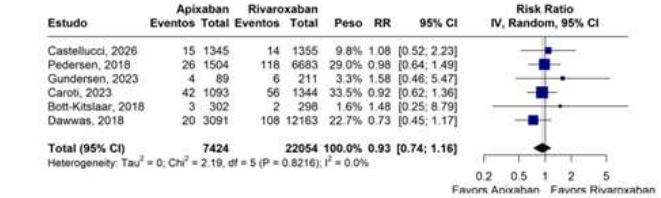
MAJOR BLEEDING AND RECURRENT VENOUS THROMBOEMBOLISM WITH APIXABAN VERSUS RIVAROXABAN: A SYSTEMATIC REVIEW AND META-ANALYSIS

MIGUEL CHAVES LENZI1; MILTON RANGEL DA SILVA NETO1; RAFAELA DUARTE VERGNA1; LUISA FURTADO DE CASTRO2; ANÍSIO UCHOA LEITE SANTANA3; RODOLFO ALVES LOPES4; MARCELA VASCONCELOS MONTENEGRO5; TIAGO JOSÉ NOGUES DE ALMEIDA2; GABRIEL ERZINGER6; ICARO HEICKMEN TAVEIRA EGÍDIO DE MELO2; LUCAS MENEZES2; ANDRÉ JORGE NOGUES DE ALMEIDA2;



(1) UNIVERSIDADE ESTADUAL DO RIO GRANDE DO NORTE - MOSSORÓ - RN - BRASIL; (2) UFRN - NATAL - RN - BRASIL; (3) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (4) MEMORIAL HEALTHCARE SYSTEM, HOLLYWOOD, FL, USA - UNITED STATES; (5) UPE - RECIFE - PE - BRASIL; (6) UNIVERSIDADE DA REGIAO DE JOINVILLE - JOINVILLE - SC - BRASIL;

Introdução/Fundamentos: Direct oral anticoagulants, including rivaroxaban and apixaban, are the most frequently prescribed treatments for acute venous thromboembolism. Despite their widespread use, head-to-head clinical trials directly comparing their safety and efficacy profiles have historically been lacking. This knowledge gap has led to uncertainty regarding the optimal choice between these agents in the acute setting. Objetivos: To compare the safety and efficacy of apixaban versus rivaroxaban in patients with acute venous thromboembolism, focusing on the risk of major bleeding and recurrent symptomatic VTE. Métodos: We conducted a systematic review and meta-analysis incorporating data from randomized controlled trials, such as the COBRRA trial, and real-world observational cohorts. The primary safety outcome was major bleeding, and the primary efficacy outcome was recurrent symptomatic VTE. Relative risks (RR) and 95% confidence intervals (CI) were pooled using a random-effects model. Resultados e Conclusões: Based on the pooled analysis, the risk of recurrent symptomatic VTE was comparable between apixaban and rivaroxaban (RR 0.93, 95% CI 0.74 to 1.16; I^2 = 0.0%). Regarding safety, there was a trend toward lower major bleeding with apixaban, although this did not reach statistical significance due to high heterogeneity (RR 0.62, 95% CI 0.27 to 1.42; I^2 = 81.6%). Notably, recent randomized evidence from the COBRRA trial demonstrated a significantly lower risk of major bleeding with apixaban. In conclusion, apixaban and rivaroxaban show comparable efficacy in preventing recurrent VTE, while apixaban may offer a more favorable safety profile. Further studies with standardized bleeding definitions are warranted.

MANAGEMENT OF ACUTE PULMONARY THROMBOEMBOLISM IN RISK C PATIENTS ACCORDING TO THE NEW RISK STRATIFICATION: A SYSTEMATIC REVIEW

RODRIGO CHAVES DA SILVA1; THIAGO CHAVES DA SILVA1; ISABELLE PINTO GONÇALVES BARROCA1; JULIANA DO VALLE EVANGELISTA1; VAGNER DE CAMPOS SILVA1;

(1) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL;

Introdução/Fundamentos: Acute Pulmonary Embolism (PE) encompasses a broad spectrum of clinical severity, a fact that emphasizes the need for risk-informed therapy. However, according to the 2019 European Respiratory Society guideline classification, the management of PE has not been fully elucidated, particularly in intermediate-risk patients. Objetivos: Elucidate the correct clinical management of PE in risk C patients according to the new risk classification proposed by the AHA/ACC 2026. Métodos: Studies originally published in English and from 2016 onwards in the SciELO and PubMed databases were analyzed. Inclusion criteria were randomized controlled trials that examined the clinical management of PE in intermediate-risk or C-risk patients. Studies that were not related to the topic, with unclear or poorly described methods, were excluded. For the research, combinations of keywords related to Pulmonary Embolism, Intermediate risk, and Treatment obtained from MeSH were used. Two reviewers independently examined the records, and disagreements were resolved by a third reviewer. The PRISMA 2020 scale was used to systematize the reporting of this review. Resultados e Conclusões: A total of 15 studies were analyzed, and after applying the exclusion criteria, 8 articles remained for review (n=8). The analysis considered the outcome and the best administration conditions for each therapy according to the selected patients. In C2 patients, anticoagulant therapy as the basis of treatment has demonstrated benefit. Inhaled pulmonary vasodilators have likewise been beneficial in improving right ventricular afterload. Regarding catheter-directed thrombolysis (CDL), associated with anticoagulation, the results were inconclusive as to whether it provides benefits in patients in categories C2–C3 in preventing short-term clinical deterioration, reducing mortality, or improving functional capacity and quality of life. The choice of systemic thrombolysis instead of isolated anticoagulation is indicated from classification C3 onwards. The new classification proposed by AHA/ACC 2026 brings a new perspective to the management of PE cases, especially in level C patients. With this, the distribution of patients across the new classification parameters facilitates guidance in the management of PE. However, a scientific gap is still noted regarding the use of thrombolytics and the benefits of CDL in risk C patients.

17864

MAPSE AS A MARKER OF HEMODYNAMIC SUPPORT AND CLINICAL OUTCOMES IN PATIENTS ADMITTED TO THE INTENSIVE CARE UNIT

LUANA SILVA DAMASIO1; BRUNA MIRLEY CAVALCANTE BARRETO REINHEIMER1; FELIPE CERBARO VIANA1; MARIA EDUARDA ISALINO E SILVA1; GIULIA ANDRADE SHIKANAI1; FELIPPE LEOPOLDO DEXHEIMER NETO1;

(1) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL;

Introdução/Fundamentos: Left ventricular systolic dysfunction is frequent in critically ill patients and can contribute to hemodynamic instability and the need for pharmacological support. Mitral annular plane systolic excursion (MAPSE) is a simple echocardiographic parameter that reflects the longitudinal function of the left ventricle and can be obtained rapidly at the bedside, even in scenarios of limited echocardiographic assessment. Despite its potential usefulness in clinical practice, there are still few studies evaluating the association between MAPSE values and clinical outcomes in patients admitted to intensive care units. Objetivos: To evaluate the association between MAPSE and the need for hemodynamic support in critically ill patients. Métodos: This was a prospective, single-center cohort study conducted in intensive care units of a tertiary hospital. Adult patients undergoing conventional echocardiography were included. MAPSE was measured and used to estimate left ventricular ejection fraction (EF = 4.8 × MAPSE + 5.8). Outcomes were obtained from electronic medical records and included the use of vasoactive, inotropic, and vasodilating drugs, hospital and 30-day mortality, and length of stay in the ICU. Associations were analyzed using Pearson correlation and Mann-Whitney test ($p < 0.05$). Resultados e Conclusões: 167 patients admitted to the intensive care unit were included. No significant association was observed between MAPSE values or estimated ejection fraction and length of stay in the ICU. A negative correlation was observed between MAPSE parameters and mortality, indicating a trend towards higher mortality among patients with lower values of the parameter; this association was statistically significant for lateral MAPSE, mean MAPSE, and estimated ejection fraction ($p < 0.05$). Furthermore, MAPSE showed a significant correlation with dobutamine use, suggesting that lower values reflect systolic dysfunction and a greater need for inotropic support. Among vasodilators, reduced MAPSE and estimated ejection fraction values were also associated with nitroglycerin use. Therefore, reduced MAPSE values were associated with the need for hemodynamic support and worse clinical outcomes.These findings reinforce the potential of MAPSE as a simple and rapid tool for assessing ventricular function in critically ill patients.

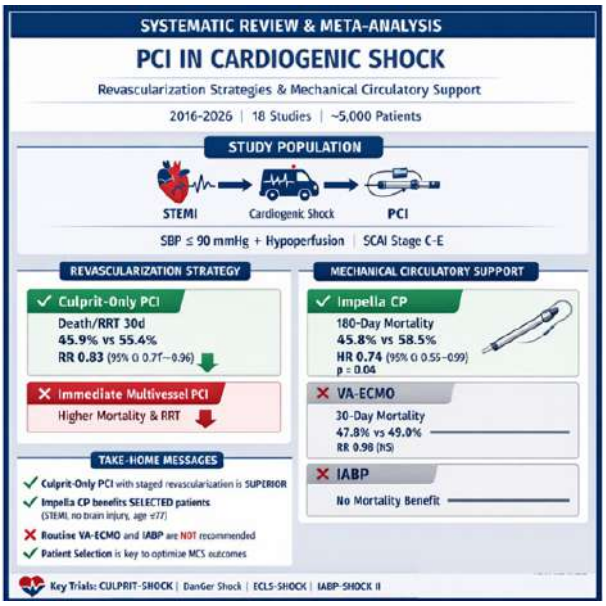
19070

NONINVASIVE VENTILATION IN ACUTE HEART FAILURE: IMPACT ON MORTALITY AND NEED FOR INTUBATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

RAFAEL ALVES DE OLIVEIRA1; LUCAS MARINHO REIS DA CUNHA SILVA1; BRUNO DE FREITAS SILVA1; THIAGO VITTOR SILVA FREITAS1; GABRIEL ALVES DE OLIVEIRA2; POLIANA MARCELINO JOIA1; GIOVANA CASAGRANDE DE ALENCAR1; TAYNARA TAVARES DOS SANTOS1; DANIELLY MARQUES ALVES3; MARIA GABRIELLA GENARO SEBASTIÃO1; TAÍS SANTANA GARGANTINI FERREIRA1; AMANDA OLIVA SPAZIANI1;

(1) UNIVERSIDADE BRASIL - FERNANDÓPOLIS - SP - BRASIL; (2) UNIVERSIDADE BRASIL - FERNANDÓLIS - SP - BRASIL; (3) FACERES - SÃO JOSÉ DO RIO PRETO - SP - BRASIL;

Introdução/Fundamentos: Acute heart failure is one of the main causes of hospital admission, often associated with respiratory distress and acute pulmonary edema. Noninvasive ventilation (NIV), including CPAP and BiPAP, has been used as an initial strategy to improve oxygenation and reduce the work of breathing. However, the impact of this intervention on clinically relevant outcomes still requires consolidation. Objetivos: To evaluate the impact of noninvasive ventilation on mortality and the need for orotracheal intubation in patients with acute heart failure. Métodos: A systematic review was conducted according to PRISMA guidelines, with searches in PubMed, Embase, and Cochrane Library up to January 2026. Randomized clinical trials comparing noninvasive ventilation with conventional oxygen therapy in patients with acute heart failure were included. The outcomes analyzed were in-hospital mortality and need for intubation. The meta-analysis was performed using a random-effects model, with calculation of relative risk (RR) and 95% confidence intervals. Heterogeneity was assessed using the I^2 index. Resultados e Conclusões: Nine studies were included, totaling 3,684 patients. Noninvasive ventilation was associated with a significant reduction in the need for intubation (RR = 0.58; 95% CI: 0.46–0.73; $p < 0.001$) and a trend toward reduction in in-hospital mortality (RR = 0.88; 95% CI: 0.76–1.01; $p = 0.07$). Heterogeneity was low ($I^2 = 27\%$). Noninvasive ventilation significantly reduces the need for intubation in patients with acute heart failure, with a trend toward mortality reduction. These findings reinforce its early use as an essential strategy in the management of these patients in emergency settings.



19459

PERCUTANEOUS CORONARY INTERVENTION IN CARDIOGENIC SHOCK FOLLOWING ACUTE MYOCARDIAL INFARCTION: SYSTEMATIC REVIEW AND META-ANALYSIS OF REVASCULARIZATION STRATEGIES AND MECHANICAL CIRCULATORY SUPPORT (2016-2026)

JADY BONARDI JOSE LIMA1; WAGNER ANTIDES RIBEIRO DE ALMEIDA PINA1; MARILIA DOS SANTOS ANDRADE1;

(1) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Cardiogenic shock complicates 5-10% of acute myocardial infarctions with in-hospital mortality of 40-50%. Controversies persist regarding optimal revascularization strategy (culprit-only versus multivessel) and the role of mechanical circulatory support (MCS). Recent clinical trials including CULPRIT-SHOCK, DanGer Shock, and ECLS-SHOCK have provided new evidence requiring systematic synthesis. Objetivos: To evaluate the efficacy and safety of different PCI strategies and MCS use in patients with cardiogenic shock secondary to STEMI, analyzing mortality and composite clinical outcomes. Métodos: Systematic review following PRISMA 2020 guidelines. Criteria: adults with cardiogenic shock (SBP ≤90mmHg + hypoperfusion or SCAI C-E) secondary to STEMI undergoing PCI. Included RCTs and multicenter prospective cohorts (≥100 patients) from January/2016 to April/2026. Databases: PubMed, Embase, Cochrane CENTRAL, Web of Science. Primary outcome: 30-day mortality. Random-effects meta-analysis using modified HKSJ method. Resultados e Conclusões: Eighteen studies were included (8 RCTs, 10 prospective cohorts). For revascularization strategy, culprit-only PCI reduced the composite outcome of death or renal replacement therapy at 30 days compared to immediate multivessel PCI (45.9% vs 55.4%; RR 0.83; 95%CI 0.71-0.96; p=0.01). For MCS, Impella CP reduced 180-day mortality (45.8% vs 58.5%; HR 0.74; 95%CI 0.55-0.99; p=0.04), but with increased bleeding and limb ischemia. VA-ECMO showed no benefit (47.8% vs 49.0%; RR 0.98; 95%CI 0.80-1.19). IABP did not reduce mortality at 30 days or 6 years. Individual patient data meta-analysis identified MCS benefit in STEMI patients without hypoxic brain injury risk (HR 0.77; 95%CI 0.61-0.97). Culprit-only PCI with staged revascularization is superior to immediate multivessel PCI. Impella CP benefits selected patients (STEMI, no brain injury, age 77 years), while routine VA-ECMO and IABP are not recommended. Appropriate patient selection is essential to optimize MCS outcomes.

21154

PREHOSPITAL NONINVASIVE VENTILATION FOR ACUTE HEART FAILURE IN ELDERLY PATIENTS: IMPACT ON IN-HOSPITAL MORTALITY AND INTUBATION RATES

LUISA PICCOLO DE LIMA1; ANA CLARA BRANDÃO CAETANO1; GIOVANA MARA FONSECA FRANÇA VALENTE1; MARIANA MONTEIRO GOMES1; STEFANNY SOARES CUNHA1; MARIANA ALMEIDA ARRUDA DE MIRANDA1; TÉRCIO CAMPOS LEÃO NETO1;

(1) AFYA FACULDADE DE CIENCIAS MEDICAS DE PALMAS - PALMAS - TO - BRASIL;

Introdução/Fundamentos: Acute heart failure (AHF) is a frequent cause of emergency care admissions, especially among elderly patients, and is associated with high morbidity and mortality. Rapid clinical deterioration makes early intervention essential, highlighting the prehospital setting as a critical window for initial management. Although noninvasive ventilation (NIV) is strongly recommended by the Brazilian Society of Cardiology (SBC) and the European Society of Cardiology (ESC) guidelines for the in-hospital management of acute heart failure, evidence regarding its use in the prehospital setting remains heterogeneous, particularly in elderly patients. Objetivos: To evaluate the impact of prehospital NIV in elderly patients with acute heart failure, focusing on in-hospital mortality and endotracheal intubation rates. Métodos: A systematic review was conducted in accordance with PRISMA guidelines, with searches performed in PubMed, Embase, and the Cochrane Library (2005–2025), using the descriptors “Noninvasive Ventilation,” “Acute Heart Failure,” “Cardiogenic Pulmonary Edema,” “Prehospital Care,” and “Emergency Medical Services.” A total of 198 studies were identified, of which 164 remained after duplicate removal; 52 were assessed in full text and 11 were included. The analyzed outcomes were in-hospital mortality and the need for endotracheal intubation. Resultados e Conclusões: The 11 included studies, comprising 3,067 predominantly elderly patients, demonstrated an association between prehospital NIV and reduced rates of endotracheal intubation and in-hospital mortality (OR <1; p <0.05). CPAP was the most commonly used modality, while some studies also evaluated BiPAP/bilevel PAP. Compared with conventional oxygen therapy, NIV was associated with lower intubation rates (8.9% vs. 25.3%; p=0.003), lower in-hospital mortality (5.4% vs. 23.2%; p<0.001), and lower odds of intubation (OR 0.31; 95% CI 0.19–0.51) and death (OR 0.41; 95% CI 0.19–0.87). Prehospital NIV, especially through CPAP, was associated with reduced intubation rates and early clinical improvement in patients with acute heart failure. However, study heterogeneity limits definitive conclusions, reinforcing the need for protocol standardization and further studies.

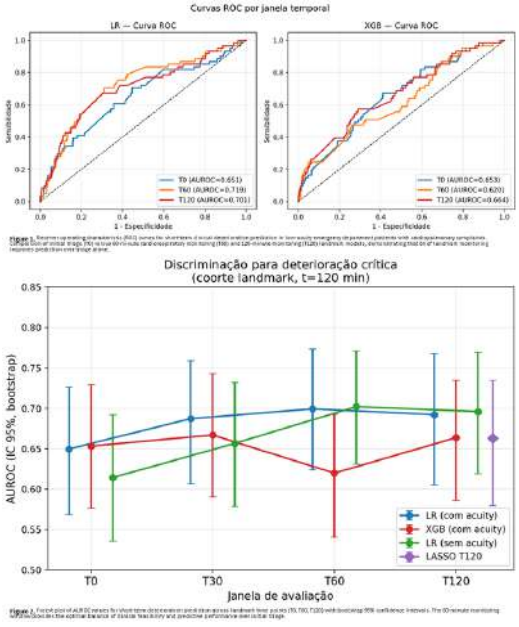
PROGNOSTIC PERFORMANCE OF THE OESIL AND EGSYS SCORES IN PATIENTS HOSPITALIZED FOR SYNCOPE: A RETROSPECTIVE COHORT STUDY

LÍVIA RODRIGUES SAMPAIO CAVALCANTE1; CLARA TALITA SILVA LOBO1; PEDRO VOGEL ALMEIDA1; ANA BEATRIZ BOMFIM DE ALMEIDA1; MARCUS VINICIUS BARBOSA VALE1; RAFAEL FELIPE COELHO SIQUEIRA1; RAISA MAINARTE FRANCO BARROS HAMILTON2; TAINA TEIXEIRA VIANA2; RODRIGO MOREL VIEIRA DE MELO1;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL; (2) HSR - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Syncope is a transient loss of consciousness resulting from cerebral hypoperfusion, with the main causes being vasovagal, cardiac, and orthostatic. It's a common condition in emergency departments and, although generally benign, may be associated with serious outcomes such as sudden death and the need for interventions. Clinical scores such as OESIL and EGSYS are widely used for risk stratification. However, uncertainties remain regarding the comparative accuracy of these instruments, particularly in predicting clinically relevant outcomes. Objetivos: To evaluate the prognostic performance of the OESIL and EGSYS clinical scores in patients hospitalized for syncope, comparing their discriminative ability to predict clinical severity, defined by length of hospital stay. Métodos: Is single-center retrospective observational study based on electronic health record data from patients presenting with syncope in the emergency department of a high-complexity hospital. A total of 728 patients were included between August 2023 and June 2025. The comparative prognostic performance of the EGSYS and OESIL scores in predicting severity—defined by length of hospital stay (>5 days vs. ≤5 days)—was assessed using ROC curve analysis. Resultados e Conclusões: Results: A total of 728 patients with syncope were analyzed; 622 (85.4%) had complete data for both the OESIL and EGSYS scores, while 106 (14.6%) had missing data in the medical records. The mean length of hospital stay was 2.68 days. In the analysis of prolonged hospitalization (>5 days), ROC curve analysis showed that the OESIL score had an area under the curve (AUC) of 0.611 (95% CI: 0.542–0.680; p=0.003), indicating modest but statistically significant discriminative performance for predicting prolonged hospitalization. The EGSYS score had an AUC of 0.558 (95% CI: 0.490–0.627; p=0.112), showing no statistical significance. For hospital stays ≤5 days, both scores demonstrated good performance on ROC analysis. The OESIL score had an AUC of 0.881 (95% CI: 0.831–0.931; p<0.001), while the EGSYS score had an AUC of 0.801 (95% CI: 0.721–0.881; p<0.001), indicating adequate discriminative ability. Conclusion: The OESIL score demonstrated better discriminative performance compared to the EGSYS score, particularly in predicting shorter hospitalizations. For prolonged hospital stays, OESIL showed modest predictive ability, whereas EGSYS did not reach statistical significance. These findings highlight differences in the applicability of these scores for risk stratification.



22095

SIXTY MINUTES OF CARDIORESPIRATORY MONITORING OUTPERFORMS INITIAL TRIAGE IN PREDICTING SHORT-TERM DETERIORATION IN LOW-ACUITY ED PATIENTS WITH CARDIOPULMONARY COMPLAINTS: A LANDMARK ANALYSIS

LUCAS ALENCAR QUEIROZ1; VICTOR MATHEUS RICARDO TERRA1; PAULA CORREA NOGUEIRA2;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) HOSPITAL DA MULHER - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Static initial triage may underestimate risk in low-acuity emergency department (ED) patients with cardiopulmonary complaints. Previously published dynamic prediction models are frequently confounded by immortal-time bias, which inflates apparent discrimination. Objetivos: To evaluate whether structured cardiorespiratory monitoring during the first 30, 60, and 120 minutes after ED arrival improves prediction of short-term critical deterioration over initial triage alone, using a landmark design that eliminates immortal-time bias. Métodos: Retrospective cohort using MIMIC-IV and the MIMICEL ED event log. Adults with cardiopulmonary chief complaints (chest pain, dyspnea, syncope, palpitations, dizziness, edema) were identified by NLP. A landmark cohort included only patients still in the ED at t=120 minutes. The primary outcome was a composite of ICU admission between 120 minutes and 12 hours, or in-hospital death. Logistic regression and XGBoost were trained on the same patients with progressive windows: T0 (triage), T30, T60, T120. AUROC with 95% CI (1,000 bootstrap replicates) was compared by DeLong's test. A parsimonious multivariable model identified independent predictors. Resultados e Conclusões: Of 2,832 eligible admissions, 184 were excluded by the landmark (final n=2,648); the composite outcome occurred in 339 (12.8%): 312 ICU admissions and 46 in-hospital deaths. Logistic regression AUROC rose from 0.650 (95% CI 0.569-0.726) at T0 to 0.699 (0.624-0.774) at T60 and plateaued at T120 (0.692). Only T60 outperformed T0 (Delta +0.068; DeLong p=0.009). In multivariable analysis (EPV 21.9), three independent predictors remained: ESI acuity (adjusted OR 0.73 per 1 SD; 95% CI 0.62-0.87; p<0.001), minimum systolic blood pressure (OR 0.77; 0.64-0.92; p=0.004), and maximum respiratory rate (OR 1.25; 1.03-1.51; p=0.025), all measured during the first 60 minutes. At 90% sensitivity, T60 yielded specificity 0.21 and NPV 0.94. Isotonic recalibration improved Brier from 0.219 to 0.094. Conclusions: sixty minutes of structured cardiorespiratory monitoring significantly improves deterioration prediction over triage alone, with no benefit from longer windows. Early hypotension and tachypnea were the dominant independent predictors, supporting a 60-minute reassessment paradigm.

21681

TIME TO DEFIBRILLATION AND SURVIVAL IN CARDIAC ARREST: A SYSTEMATIC REVIEW AND META-ANALYSIS

LUCAS MARINHO REIS DA CUNHA SILVA1; THIAGO VITTOR SILVA FREITAS1; TAYNARA TAVARES DOS SANTOS1; BRUNO DE FREITAS SILVA1; GIOVANA CASAGRANDE DE ALENCAR1; POLIANA MARCELINO JOIA1; RAFAEL ALVES DE OLIVEIRA1; AMANDA OLIVA SPAZIANI1;

(1) UNIVERSIDADE BRASIL - FERNANDÓPOLIS - SP - BRASIL;

Introdução/Fundamentos: Cardiac arrest is one of the leading causes of sudden death, with high mortality. Early defibrillation is one of the most determining factors for survival, especially in shockable rhythms. However, the magnitude of the impact of time to defibrillation on clinical outcomes still requires consolidation through systematic analysis. Objetivos: To evaluate the association between time to defibrillation and survival in patients with cardiac arrest. Métodos: A systematic review conducted in accordance with PRISMA guidelines, with a structured search in PubMed, Embase, and Cochrane Library databases up to January 2026. Prospective and observational studies evaluating time to defibrillation in patients with cardiac arrest were included. The primary outcome was in-hospital survival. The meta-analysis was performed using a random-effects model, with calculation of relative risk (RR) and 95% confidence interval (95% CI). Heterogeneity was assessed using the I^2 statistic. Resultados e Conclusões: A total of 12 studies were included, comprising 54,328 patients. Shorter times to defibrillation were associated with higher survival (RR=1.62; 95% CI: 1.41–1.86; p<0.001). A progressive reduction in survival was observed with each minute of delay. Heterogeneity was moderate (I^2=38%). Early defibrillation is strongly associated with increased survival in cardiac arrest, reinforcing the importance of rapid interventions and well-organized emergency response systems.

21839

UNCERTAINTY IN NEUROLOGICAL PROGNOSTICATION AFTER CARDIAC ARREST: ETHICAL IMPLICATIONS FOR LIFE-SUSTAINING TREATMENT DECISIONS

JULIANA ROCHA FERIANCI1; MARINA CALADO LIMA1; LUANA MARIA AGUIAR NOBRE CACAU1; MELINA VALÉRIA ASSUNÇÃO DE OLIVEIRA1; ISABELLE BORGES GURGEL1; JOANA BARRETO MORAES1; LETÍCIA ELTINK REIS1; JÚLIA FREITAS MAXSTER1; PEDRO MAN SUETO MELO DE SOUZA1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Neuroprognostication after cardiac arrest remains a major ethical challenge in intensive care medicine due to uncertainty regarding continuation or withdrawal of life-sustaining treatment in patients with severe neurological injury. Although guidelines recommend multimodal assessment 72 hours after return of spontaneous circulation, many patients still receive an indeterminate prognosis, complicating treatment decisions. In addition, differing expectations between healthcare teams and families may generate conflicts regarding care. Thus, post–cardiac arrest neuroprognostication involves not only technical limitations but also bioethical principles such as beneficence, non-maleficence, and autonomy. Objetivos: To evaluate how limitations in predicting neurological outcomes influence clinical and ethical decision-making in post–cardiac arrest patients. Métodos: A systematic literature review was conducted using the SciELO, PubMed, Cochrane Library, and VHL databases, including studies published up to the end of April 2026. Study selection was performed using the Rayyan platform, based on criteria defined by the PICO strategy. Studies published in Spanish, Portuguese, and English addressing the proposed topic were included. The study selection and eligibility process followed structured stages, including screening by titles, abstracts, and full-text reading. Resultados e Conclusões: The analyzed studies demonstrated persistent limitations in neuroprognostication after cardiac arrest despite multimodal assessment strategies. Bougouin et al. (2024) identified high specificity of ERC/ESICM recommendations for poor neurological outcome prediction; however, approximately 50% of patients remained in an indeterminate prognostic category. Sondag et al. (2017) showed that highly malignant EEG patterns were strongly associated with poor neurological outcomes, although sedatives, hypothermia, and metabolic disturbances may reduce predictive reliability. Wahlster et al. (2023) identified variability in early withdrawal of life-sustaining treatment among institutions, suggesting a possible self-fulfilling prophecy effect, while Rubenstein et al. (2023) observed treatment withdrawal even in patients without definitive predictors of irreversible neurological injury. Overall, prognostic uncertainty frequently generated ethical conflicts between healthcare teams and families, reinforcing the importance of cautious interpretation and shared decision-making in post–cardiac arrest care.

ACCURACY OF ELECTROCARDIOGRAPHIC CRITERIA FOR LEFT VENTRICULAR HYPERTROPHY AGAINST CARDIAC MAGNETIC RESONANCE AMONG AFRICAN-AMERICAN ADULTS: A JACKSON HEART STUDY ANALYSIS

LÍVIA MARIA DE PAULA CASTRO1; MATHEUS CLAPIS DE SOUZA GOUVEIA2; ERALDO RIBEIRO FERREIRA LEÃO DE MORAES3; JOSÉ NUNES DE ALENCAR4;

(1) FACULDADE DE MEDICINA DE MARILIA - MARÍLIA - SP - BRASIL; (2) FACULDADE ISRAELITA DE CIÊNCIAS DA SAÚDE ALBERT EINSTEIN - SÃO PAULO - SP - BRASIL; (3) INSTITUTO DE CARDIOLOGIA E RADIOLOGIA INTERVENCIONISTA DE RIO VERDE - RIO VERDE - GO - BRASIL; (4) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Electrocardiographic (ECG) criteria for left ventricular hypertrophy (LVH) are used as bedside surrogates of increases in left ventricular mass. However, they perform worse than commonly perceived by most clinicians when compared with cardiac magnetic resonance (CMR). We hypothesized that replacing dichotomous classification with a continuous spectrum-based approach could enhance their clinical utility. Objetivos: To evaluate the diagnostic accuracy of ECG-based LVH criteria using CMR as the reference standard in participants from the Jackson Heart Study (JHS). Métodos: We conducted a retrospective analysis of data from the JHS, a community-based cohort of African American participants of 21 to 94 years, recruited across the Jackson, Mississippi metropolitan area. The gold standard was CMR-LVH, which was defined using the Kawel-Boehm thresholds: left ventricular mass index indexed to body surface area greater than 83 g/m² in men and 65 g/m² in women. The index tests included most used ECG criteria (Cornell Voltage, Sokolow-Lyon, Peguero Lo-Presti, R wave in aVL) and the Multi-Ethnic Study of Atherosclerosis (MESA) LVH criteria that is defined as SV1 plus SV2 plus RV5. All ECG criteria were evaluated across a continuous spectrum increasing thresholds in 1mm increments evaluating sensitivity, specificity and likelihood ratios at each value. Resultados e Conclusões: A total of 945 participants were included, the prevalence of LVH, identified by the CMR, was 29%. Table 1 presented population baseline characteristics. Overall diagnostic performance of the evaluated ECG criteria remained limited, as illustrated in Figure 1. Among them, the Peguero–Lo Presti criterion demonstrated the highest area under the curve = 0.647, although its discriminative ability was still modest. MESA-LVH and Peguero Lo-Presti were the only criteria to demonstrate consistent diagnostic gradient behavior, exhibiting a steady rise in likelihood ratios as the index increased. In contrast, the remaining criteria showed abrupt and erratic increases, with isolated peaks at sparse thresholds, suggesting limited reliability of these estimates. In this African American cohort, ECG-based LVH criteria demonstrated a heterogeneous diagnostic accuracy when compared with CMR. These findings suggest that a spectrum-based interpretation may offer incremental value, but ECG criteria alone are insufficient for accurate LVH diagnosis

21521

ADJUNCTIVE LOW-VOLTAGE AREA ABLATION IN PERSISTENT ATRIAL FIBRILLATION: INCREMENTAL BENEFIT BEYOND PULMONARY VEIN ISOLATION? A SYSTEMATIC REVIEW

GABRIEL HENRIQUE SIMONI1; INGRID REIS MARCONI2; THAIZ NADINE LAVEZZO CARFI1; GUILHERME PYETRO MANINI DA SILVA1; ANA CLARA PIZARRO VARELLA1; EDVAN MANOEL DE AZEVEDO JÚNIOR1; CARLOS ALEXANDRE GOMES FARIAS3; JONATHAN RAMOS NUNES3; NATHALIE DE HOLANDA PANISSI4; THAUANE ÂNGELA SILVA CARDOSO4; PIETRA GRANCIERI PÓ4; ARTHUR VILAR DE OLIVEIRA MALHEIROS4;

(1) CENTRO UNIVERSITARIO DE VARZEA GRANDE - UNIVAG - CUIABÁ - MT - BRASIL; (2) UNIVERSIDADE DE CUIABA - UNIC - CUIABÁ - MT - BRASIL; (3) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (4) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Pulmonary vein isolation (PVI) is the cornerstone of catheter ablation for atrial fibrillation (AF), yet recurrence rates in persistent AF exceed 40–50% at one year. Left atrial low-voltage areas (LVAs) bipolar voltage <0.5 mV are electrophysiological surrogates of atrial fibrosis and have been proposed as adjunctive ablation targets to improve outcomes beyond PVI. Objetivos: To systematically evaluate the efficacy and safety of adjunctive LVA ablation combined with PVI compared to PVI alone in patients with persistent or paroxysmal AF. Métodos: Systematic review following PRISMA guidelines. Three prospective studies were included: SUPPRESS-AF (RCT; n=341; 12-month follow-up), SCAR-AF (RCT; n=211; 18 months), and VOLCANO Extended Follow-up (prospective cohort; n=402; median 25 months). LVA was consistently defined as bipolar voltage <0.5 mV. Due to clinically significant heterogeneity in AF type, mapping timing, ablation technique, and follow-up duration, formal statistical pooling was not performed; evidence was synthesized narratively with individual effect estimates and absolute event numbers. Resultados e Conclusões: Across 954 patients, adjunctive LVA ablation did not significantly reduce AF/AT recurrence in any included study: SUPPRESS-AF (61% vs 50%; HR 0.781, 95%CI 0.564–1.083; P=0.127), SCAR-AF (73.1% vs 75.7%; P=0.45), VOLCANO (57% vs 59%; P=0.83). Recurrence after multiple ablations was numerically lower with LVA ablation but non-significant across studies. Iatrogenic organized atrial tachycardia (AT) was significantly more frequent in the LVA ablation arm in two of three studies: SUPPRESS-AF (~23 vs ~15 patients; 36% vs 18%; P=0.029); VOLCANO (~12 vs ~6; 71% vs 32%; P<0.0001), including six exclusive cases of biatrial reentrant tachycardia. SCAR-AF showed no significant difference in AT incidence. Procedure-related serious adverse events were rare and comparable between groups in all studies. Adjunctive LVA ablation does not consistently improve AF/AT-free survival beyond PVI and significantly increases the risk of iatrogenic organized AT. LVA functions primarily as a marker of atrial cardiomyopathy rather than a universally effective ablation target. Patient selection refinement particularly in patients aged ≥75 years, LA diameter ≥45 mm, or LVA ≥20 cm² and standardized trial methodology are required before routine adjunctive LVA ablation can be recommended.

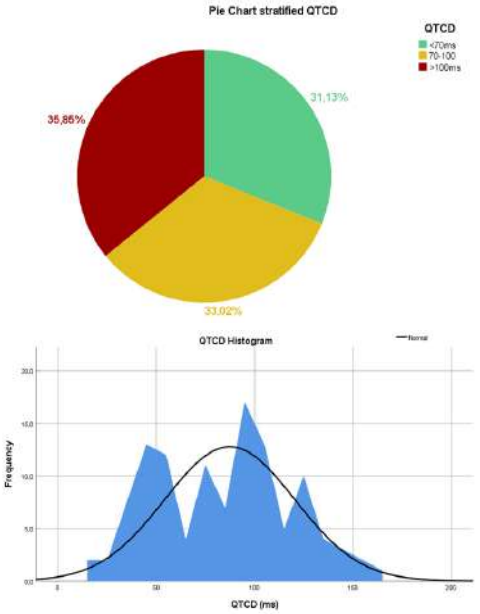
ARRHYTHMIA DETECTION BY 24-HOUR HOLTER MONITORING VERSUS 14-DAY CONTINUOUS ELECTROCARDIOGRAM PATCH: A SYSTEMATIC REVIEW AND META-ANALYSIS

JULIANA FERRAZ DE SOUSA1; FRANCINNY ALVES KELLY2; ARTUR DE OLIVEIRA MACENA LÔBO3; VICTORIA MORBACH SIEBEL4; LUIZA TREVISOL DAL PONTE5; CLARA ROCHA DANTAS6;

(1) UEMASUL - IMPERATRIZ - MA - BRASIL; (2) BETH ISRAEL DEACONESS CENTER - UNITED STATES; (3) UNIVERSIDADE FEDERAL DE PERNAMBUCO - RECIFE - PE - BRASIL; (4) UNIVERSIDADE FEEVALE - NOVO HAMBURGO - RS - BRASIL; (5) UNIVERSIDADE DE CAXIAS DO SUL - CAXIAS DO SUL - RS - BRASIL; (6) UNIVERSIDAD DE BUENOS AIRES - ARGENTINA;

Introdução/Fundamentos: Arrhythmia detection is directly dependent on monitoring duration. The 24-hour Holter, despite widespread use, captures a narrow temporal window, limiting sensitivity for paroxysmal or infrequent events. Continuous 14-day electrocardiogram (ECG) patches extend the recording period with improved adherence, yet their comparative diagnostic yield remains insufficiently quantified. Objetivos: To compare the diagnostic yield of 24-hour Holter monitoring versus 14-day continuous ECG patches for arrhythmia detection in adults. Métodos: This systematic review and meta-analysis was conducted following PRISMA guidelines. PubMed, Embase, and Cochrane were searched for studies comparing 24-hour Holter monitoring with 14-day continuous ECG patches for arrhythmia detection in adults (>18 years), including atrial fibrillation, supraventricular and ventricular tachycardia, atrioventricular block, and pauses. Outcomes were expressed as risk difference (RD) or risk ratio (RR) with 95% confidence intervals (CI). Heterogeneity was assessed using the I-squared statistic. Resultados e Conclusões: Five studies were included, totaling 1,255 patients. The 14-day ECG patch was significantly superior for detection of any arrhythmia (RD 36.1; 95% CI 21.7–50.5; p<0.001). This superiority was consistent for atrial fibrillation and flutter (RD 6.3; 95% CI 3.4–9.2; p=0.001), supraventricular tachycardia (RD 38.1; 95% CI 19.7–56.5; p<0.01), and ventricular tachycardia (RR 3.49; 95% CI 1.88–6.47; p=0.01). The 14-day continuous ECG patch demonstrated significantly higher diagnostic yield than 24-hour Holter monitoring for atrial fibrillation, supraventricular tachycardia, and ventricular tachycardia. In clinical practice, adoption of prolonged monitoring may allow earlier detection of clinically relevant arrhythmias. However, substantial heterogeneity in overall arrhythmia detection suggests that diagnostic yield may vary according to patient profile, and further studies are needed to identify the subgroups that benefit most from this technology.



18171

ASSESSMENT OF CORRECTED QT INTERVAL (QTC) AND QTC DISPERSION (QTCD) IN PATIENTS WITH DUCHENNE MUSCULAR DYSTROPHY

GABRIEL RANGEL COSTA DA SILVA CARDOSO1; MARCOS MORAIS DE MEIS1; DAVI WHATELY AMAR1; YASMIN VITORIA VICTORINO1; SEBASTIANA BESSA PORTO1; CAROLINA FERREIRA CARDOSO1; VITORIA ALVES DE OLIVEIRA SANTOS1; RAFAEL DE LORENZO LIMA1; MARIA LUIZA REBULA ROCHA1; ANA PAULA CASSETTA DOS SANTOS NUCERA1;

(1) UNIRIO - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Early detection of cardiac abnormalities is vital for effective management of diseases such as Duchenne muscular dystrophy (DMD). In this context, established electrocardiographic findings, such as T-wave inversion and ST-segment changes, are associated with early cardiac involvement. Corrected QT interval (QTc) and QTc dispersion (QTcD) are indirect electrocardiographic measures of ventricular repolarization heterogeneity and have been positively associated with increased cardiovascular mortality in the general population. Objetivos: This study aims to assess the correlation between QTc and QTcD in patients with DMD, exploring their potential as early markers of cardiovascular involvement. Métodos: This retrospective cross-sectional study involved the review of electrocardiograms (ECGs) from patients with genetically confirmed DMD followed at the cardiology outpatient clinic of a university hospital. Patients with poor-quality ECGs or conditions that compromised analysis were excluded. The QT interval was defined as the distance from the onset of the Q wave to the point where the T wave returned to the baseline. QTc was calculated using the Bazett formula, based on the mean RR interval, and QTcD as the difference between the maximum and minimum QTc on a 12-lead ECG recorded at 25 mm/s. Excel and Software IBM SPSS were used for data analysis and statistical evaluation. Resultados e Conclusões: A total of 106 ECGs from male patients were analyzed, with a mean age of 12.17 ± 4.91 years. The ECGs were classified into 3 groups: 38 (36%) high-risk ECGs with values above 100 ms, 35 (33%) moderate-risk ECGs between 71 and 99 ms, and 33 (31%) low-risk ECGs between 10 and 70 ms. The mean QTcD was 86.54 ± 33.08 ms, and the mean QTc was 421.20 ± 33.62 ms. Despite discrepancies in the literature, values above 100 ms are associated with a higher risk of arrhythmias, while values between 71 and 100 ms are considered abnormal, but with a weaker association. In DMD, this finding may suggest progressive myocardial involvement related to fibrosis, electrical instability, and cardiac remodeling, increasing the risk of early arrhythmias.

ASSOCIATION BETWEEN DURATION OF SUBCLINICAL ATRIAL FIBRILLATION AND RISK OF THROMBOEMBOLIC EVENTS: A SYSTEMATIC REVIEW

GIOVANA SIEBRA DE OLIVEIRA1; GIOVANA PAZ LIMA1; JULIA SIEBRA DE OLIVEIRA1; CLARA SIMÕES NOBRE1; MARIA EDUARDA SANTOS DE OLIVEIRA1; CLARA CARVALHO DE MORAIS LEITE1; BEATRIZ BARSI CUNHA1; LETÍCIA LIMA FELIX MARINHO1; MARINA CALADO LIMA1; BÁRBARA MAIA FERNANDES LYRA1; ANE KAROLINE MEDINA NÉRI1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Subclinical atrial fibrillation (SCAF) is defined as episodes of atrial tachyarrhythmia detected exclusively through continuous intracardiac monitoring using pacemakers, implantable cardioverter-defibrillators, and cardiac resynchronization devices, in the absence of clinical symptoms. In this context, the widespread adoption of cardiac monitoring devices has substantially contributed to early detection and the prevention of adverse events, since the first manifestation of SCAF can be a thromboembolic event. Given this scenario, there is a gap in risk stratification and clinical guidance, as there is no defined threshold for the duration of SCAF (burden) in predicting thromboembolic risk. Objetivos: The aim of this study is to assess whether the SCAF burden detected by implantable cardiac devices influences the thromboembolic risk in asymptomatic patients. Métodos: This systematic review was made according to PRISMA guidelines. This review evaluated the association between device-detected atrial high rate episodes (AHRE), focusing on its burden, and the risk of thromboembolic events, especially stroke and systemic embolism. A comprehensive literature search included studies published up to March 2026, performed across the Embase, PubMed and Cochrane Library databases. The study selection was undertaken independently by two reviewers, with any discrepancies resolved through a third reviewer. Resultados e Conclusões: Overall, six studies were included on this review, comprising a total of 11.320 patients with AHRE. Most studies consisted of retrospective cohort analyses and prospective randomized multicenter trials.The definition of arrhythmia burden varies across studies, ranging from 5 minutes to 24 hours. Regarding the risk of a thromboembolic event, results were heterogeneous and focused especially on stroke. Some studies reported that patients with episodes lasting at least 5-6 minutes were associated with higher risk of stroke. However other analyses found no significant association for episodes with less than 24 hours.In general, SCAF appears more as a marker of thromboembolic risk rather than a causal factor. These findings suggest that AHRE burden plays an important role in stratification, however current evidence remains insufficient to define exact values at which patients would benefit from therapy to prevent a stroke or a systemic embolism.

18294

ASSOCIATION BETWEEN GENETIC PROFILE AND CLINICAL FINDINGS IN PATIENTS WITH HYPERTROPHIC CARDIOMYOPATHY AT A TERTIARY CARDIOLOGY OUTPATIENT CLINIC IN SOUTHERN BRAZIL

JULIA CRESTANA RANGEL1; MAICO FURLANETTO2; JACQUELINE VAZ ALENCAR2; LUCAS TIBURSKI SOOMER2; BRUNA EIBEL2; ROBERTO TOFANI SANT'ANNA2; JULIANA TESSA2;

(1) PUCRS - PORTO ALEGRE - RS - BRASIL; (2) INSTITUTO DE CARDIOLOGIA / FUNDAÇÃO UNIVERSITARIA DE CARDIOLOGIA - PORTO ALEGRE - RS - BRASIL;

Introdução/Fundamentos: The genetic basis of hypertrophic cardiomyopathy (HCM) is poorly known in our setting, especially regarding its relationship with clinical presentation and the risk of sudden cardiac death. Objetivos: To evaluate the genetic profile of patients with HCM in southern Brazil and its association with clinical-morphological characteristics and indication for implantable cardioverter-defibrillator (ICD). Métodos: Cross-sectional study in a population aged ≥18 years with a diagnosis of HCM, followed at a tertiary hospital and submitted to genetic testing with a 19-gene panel. Resultados e Conclusões: A total of 157 patients were included, with a mean age of 53 years, of whom 61.1% were female. The predominant anatomical pattern was septal (79.6%), and the obstructive form was present in 39.5% of cases. Implantable cardioverter-defibrillator (ICD) was identified in 35% of patients. Genetic testing was abnormal in 71.3%, identifying 136 variants, of which 50.7% were pathogenic and 49.3% were of uncertain significance. The most frequently involved genes were MYH7 (46.4%), MYBPC3 (28%), and FLNC (11.1%). Patients with pathogenic variants were significantly younger (47.3 vs. 61.1 years; p<0.001) and showed a higher prevalence of septal hypertrophy. A significant association was observed between genetic test results and the presence of ICD (p<0.001), especially when considering the criterion of positive family history of sudden cardiac death (p=0.002). These findings demonstrate that, in a population from southern Brazil with hypertrophic cardiomyopathy, there was a predominance of variants in the MYH7 gene. Pathogenic variants were associated with earlier presentation, septal hypertrophy pattern, and greater indication for ICD. These findings provide novel data and reinforce the need for further research to refine disease management.

BRAIN INJURY AND CARDIOVASCULAR RISK: DOSE–RESPONSE ASSOCIATION AND THE ROLE OF AUTONOMIC DYSFUNCTION – A SYSTEMATIC REVIEW OF OBSERVATIONAL STUDIES

BEATRIZ DE LIMA VITORIO FERREIRA1; FLAVIA BEATRIZ DO CARMO MOREIRA2; EVELIN GABRIELLY DE VARGAS2; MARCOS AURELIO FONSECA MEDEIROS1; GIOVANNA VILA REAL MARQUES BARRA DE GOUVEIA TREVISAN2; MARIA EUGÊNIA RODRIGUES PAIVA2; CAROLAINE BRENDA RIDOLFI2; SABRINA CARDOSO DA COSTA2; MARIANA VIDAL MIYAZATO2; ANNE KAROLLYNE ALVARES SANTOS2;

(1) UNIFACISA - CAMPINA GRANDE - PB - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Patients with acute brain injury, including stroke and traumatic brain injury (TBI), have an increased risk of cardiovascular (CV) events even without prior heart disease. The brain–heart axis involves autonomic dysfunction characterized by sympathetic overactivity and reduced vagal modulation. However, the association between injury severity and subsequent CV risk has not been systematically synthesized. Objetivos: To evaluate the association between brain injury severity in stroke and TBI and adverse cardiovascular outcomes, and the potential role of autonomic dysfunction. Métodos: PRISMA-based review. PubMed was searched from 2011–2026. Cohort studies and meta-analyses including patients with stroke or TBI were eligible if they reported follow-up ≥1 year, adjusted risk estimates (HR, OR, RR), and cardiovascular outcomes including MACE, stroke, coronary artery disease, hypertension or cardiac mortality. Injury severity was assessed using NIHSS or TBI classification (mild, moderate–severe, penetrating). Data on heart rate variability, baroreflex sensitivity, and troponin were extracted. Only studies with adjusted analyses were included. Resultados e Conclusões: Eight studies involving >5.6 million participants were included. In TBI, a dose–response association was observed for composite CVD: mild (HR 1.62; 95% CI 1.58–1.66), moderate–severe (HR 2.63; 2.51–2.76), and penetrating injury (HR 4.60; 4.26–4.96). Stroke risk also increased progressively (HR 2.53, 5.32, and 12.15). A meta-analysis showed increased CVD risk (OR 1.78; 95% CI 1.39–2.29) and cardiac mortality (RR 3.07; 2.17–3.98). In stroke, elevated rates of major CV events and troponin elevation (30–60%) were reported. Neurological severity correlated with autonomic dysfunction (ρ 0.29–0.47). Right insular lesions were associated with higher mortality (HR 2.11) and new-onset atrial fibrillation (39%). Reduced heart rate variability and impaired baroreflex sensitivity were consistently observed. Beta-blocker use in TBI was associated with lower in-hospital mortality (OR 0.39; 0.30–0.51). There is a consistent dose–response association between brain injury severity and cardiovascular risk, possibly mediated by autonomic dysfunction. Patients with more severe injury and insular involvement represent a high-risk group. Findings regarding beta-blockers should be interpreted cautiously given the observational nature of the data. Limitations include study heterogeneity and lack of causal inference.

CONDUCTION SYSTEM PACING VERSUS BIVENTRICULAR PACING FOR CARDIAC RESYNCHRONIZATION IN HEART FAILURE WITH REDUCED EJECTION FRACTION: AN UPDATED SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

ARTHUR RONCARATI1; MARIA EDUARDA MARTINS FERNANDES2; EMMANUEL OBERDA NOMINATO1; CAIO LOUREIRO GIL1; ULISSES GRANERO FIEL1; LUISA ARAUJO SILVA2; THIAGO MACEDO RIBEIRO1; ANDRÉ COSTA1; ESTEBAN AREVALO3; JOSÉ CARLOS DA COSTA ZANON1;

(1) UNIVERSIDADE FEDERAL DE OURO PRETO - OURO PRETO - MG - BRASIL; (2) FACULDADE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) LOMA LINDA UNIVERSITY HEALTH - LOMA LINDA/CA - UNITED STATES;

Introdução/Fundamentos: Cardiac resynchronization therapy (CRT) is an established treatment for heart failure with reduced ejection fraction (HFrEF) and ventricular dyssynchrony. However, up to one-third of patients receiving conventional biventricular pacing (BiVP) fail to respond. Conduction system pacing (CSP), encompassing His bundle pacing (HBP) and left bundle branch area pacing (LBAP), directly engages the native His-Purkinje system, offering more physiologic resynchronization. Objetivos: To evaluate the efficacy and safety of CSP versus BiVP in patients with HFrEF. Métodos: PubMed, Embase, and Cochrane Library were searched from inception to April 2026. Eligible studies were RCTs comparing CSP (HBP or LBAP) versus BiVP in adults with HFrEF. Primary outcomes were changes in LVEF and NYHA functional class. Secondary outcomes were mortality, heart failure hospitalization, QRS duration (ms), pacing threshold, and procedural time (min). Continuous outcomes were analyzed as mean differences (MDs) and dichotomous outcomes as risk ratios (RRs), all with 95% confidence intervals (CIs). Heterogeneity was quantified by I². Prespecified subgroup analyses were performed by CSP modality (HBP vs. LBAP) and follow-up duration (≤12 vs. ≥12 months). The study was prospectively registered in PROSPERO. Resultados e Conclusões: We included eleven RCTs involving 1,003 patients. Baseline mean LVEF was 28.4% and mean NYHA functional class 2.5. CSP did not significantly improve LVEF compared to BiVP (MD +2.01%; 95% CI −0.80 to 4.82). CSP was associated with greater NYHA reduction (MD −0.18; 95% CI −0.36 to −0.01). Mortality and heart failure hospitalization were similar between groups; however, with follow-up ≥12 months, CSP was associated with significantly fewer heart failure hospitalizations (RR 0.37; 95% CI 0.15 to 0.91). CSP achieved greater QRS narrowing than BiVP (MD −9.68 ms; 95% CI −18.37 to −1.00). Regarding pacing threshold, LBAP demonstrated lower values than BiVP (MD −0.35 V; 95% CI −0.61 to −0.09), whereas HBP exhibited higher thresholds compared to BiVP. HBP required significantly longer procedural time than BiVP (MD +34.06 min; 95% CI 9.20 to 58.92), while LBAP was comparable. These findings suggest that CSP is associated with clinical and electrical benefits over BiVP, with LBAP emerging as the preferred modality given its superior QRS narrowing, lower pacing thresholds, and no added procedural burden, unlike HBP, which required significantly longer procedures. Confirmation in larger randomized trials is warranted.

Figure 1: Subgroup analysis of QRS duration reduction by CSP modality

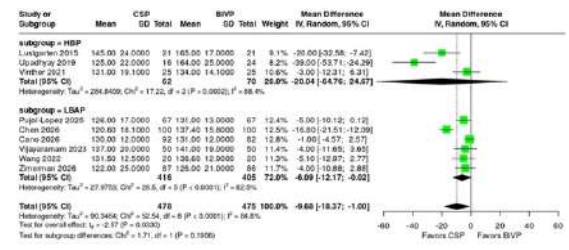

Figure 2 — Overall pooled analysis

Outcome	Studies (n)	Participants (n)	Favors	Effect estimate [95% CI]	I²	P-value
Primary outcomes						
LVEF (%)	9	944	NS	MD +2.01 [−0.80, 4.82]	80.2%	0.14

CONGENITAL COMPLETE HEART BLOCK: THE ROLE OF EXERCISE STRESS TESTING IN PACEMAKER INDICATION.

JAMILE TEREZA TEIXEIRA OLIVEIRA1; BEATRIZ MOREIRA AYUB FERREIRA SOARES2; NEMER LUÍS PICHARA2; LEONARDO FILIPE BENEDETI MARINUCCI2; BÁRBARA ORDONES BATISTA DE OLIVEIRA COSTA2; WILLIAM AZEM CHALELA2;

(1) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Congenital complete heart block (CCHB) is a rare condition, with estimated incidence: 1:15,000–20,000 live births, usually associated with maternal antibodies (anti-Ro/SSA). Although pacemaker implantation (MP) is well established in symptomatic patients, management of asymptomatic individuals remains challenging. Exercise stress testing is used for risk stratification in these patients, although its clinical utility is not well established. Objetivos: To evaluate the association between heart rate (HR) response and functional capacity during exercise stress testing and the need for pacemaker implantation in patients with CCHB. Métodos: Observational, retrospective study with analysis of medical records of patients with congenital complete heart block (CCHB) followed at a cardiology referral center. Individuals <50 years old who underwent exercise stress testing between 2015 and 2025, without prior pacemaker implantation (MP), were included. Patients were divided into two groups according to MP implantation: MP+ (with implantation) and MP- (without implantation). Clinical, echocardiographic, and exercise stress test variables were evaluated, including resting HR, peak HR, and HR response to exercise defined by achieving HR >100 bpm or doubling baseline HR, as well as achieving ≥10 METs. The outcome was the need for MP implantation within 12 months. Statistical analysis was performed using Fisher's exact test for categorical variables and unpaired Student's t-test for numerical variables (p<0.05). Resultados e Conclusões: A total of 35 patients were evaluated, with 17 in the MP+ group and 18 in the MP- group. No significant differences were observed between groups regarding age and echocardiographic parameters, including atrial volumes, ventricular volumes, and ejection fraction. The MP+ group showed, compared to the MP- group, lower resting HR (45.94±1.37 vs 53.78±1.96 bpm; p=0.0028), lower peak HR (94.41±5.27 vs 118.7±2.34 bpm; p=0.0001), and lower functional capacity (10.42±0.37 vs 12.27±0.35 METs; p=0.001). In categorical analysis, achieving HR >100 bpm was more frequent in the MP- group (18 vs 9; p=0.001), as well as doubling baseline HR (16 vs 8; p=0.0116) and achieving ≥10 METs (18 vs 12; p=0.0191). Heart rate response during exercise stress testing was associated with pacemaker implantation in CCHB. Lower peak HR, reduced functional capacity, and lower HR increment suggested a potential role for exercise testing in risk stratification.

EFFICACY AND SAFE OF CARDIAC RESYNCHRONIZATION THERAPY IN CHAGAS CARDIOMYOPATHY: A SYSTEMATIC REVIEW

FERNANDA SANTOS DA ANUNCIAÇÃO1; GIOVANNA OLIVEIRA STOPA1; PEDRO HENRIQUE SANTANA DE ALMEIDA1; GIULIA MACEDO SANTOS QUEIROZ1; ANNE KAROLINNE GOMES DAS MERCÊS1; VINÍCIUS OLIVEIRA MENDES1; PEDRO FAGUNDES TAVARES1; CARLOS RICARDO OLIVEIRA CARNEIRO1; CAIO CEZAR FERREIRA FRAGA1; MILENA GONZALES CORTES LAMARCA1; MANOEL LOUZADO BARRETO NETO1; JOSÉ BESSA JUNIOR1;

(1) UNIVERSIDADE ESTADUAL DE FEIRA DE SANTANA - FEIRA DE SANTANA - BA - BRASIL;

Introdução/Fundamentos: Chagas cardiomyopathy is a major cause of heart failure in Latin America. The effectiveness of cardiac resynchronization therapy (CRT) in this population remains uncertain. Objetivos: To systematically review the available evidence on the clinical outcomes of CRT in patients with Chagas cardiomyopathy. Métodos: Systematic review conducted according to PRISMA guidelines. Randomized and observational studies including patients with CRT and Chagas disease reporting clinical outcomes were included. A comprehensive search was performed in PubMed, Embase, Cochrane, and LILACS from inception to December 2025, without language or date restrictions. Study selection, data extraction, and quality assessment were conducted independently by two reviewers. Outcomes of interest included mortality (overall, cardiac, and non-cardiac), left ventricular function, and procedural complications. Methodological quality was assessed using the Risk of Bias in Non-randomized Studies of Interventions tool. Resultados e Conclusões: From 221 identified studies, 4 retrospective cohorts were included, comprising 250 patients with Chagas cardiomyopathy undergoing CRT. The mean age was 59 ± 12 years, 60% were male, and 87% were in NYHA class III/IV. Baseline characteristics included mean LVEF of 27% ± 7%, QRS duration of 154 ± 32 ms, atrial fibrillation in 28%, and ICD in 39%. Most patients were on guideline-directed medical therapy. Across studies, CRT was associated with improvement in functional status, with a consistent reduction in advanced NYHA classes. Echocardiographic outcomes were heterogeneous: some studies demonstrated significant improvement in LVEF and ventricular remodeling, while others showed no significant changes. Despite symptomatic and, in some cases, functional improvement, mortality remained high, predominantly due to cardiac causes, especially progressive heart failure. Non-cardiac deaths were less frequent. Cardiac resynchronization therapy is associated with improvement in functional status and, in some cases, ventricular function in patients with Chagas cardiomyopathy. However, the heterogeneity of echocardiographic responses and persistently high mortality—mainly driven by progressive heart failure—suggest a limited impact on long-term prognosis. These findings highlight the need for better patient selection and tailored therapeutic strategies in this high-risk population.

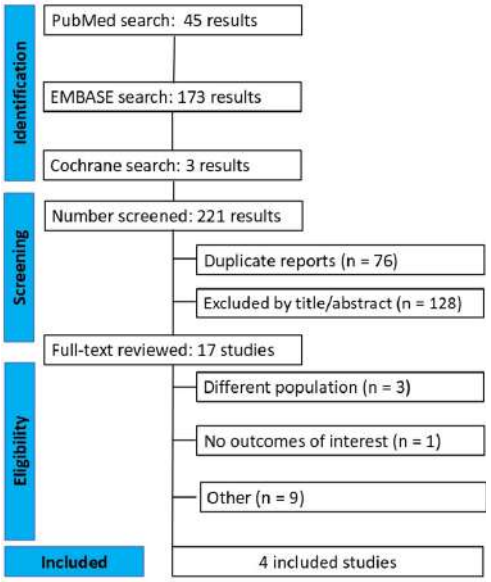

Figure 1. PRISMA flow diagram of study screening and selection

EFFICACY AND SAFETY BETWEEN LEFT ATRIAL APPENDAGE CLOSURE AND ORAL ANTICOAGULATION FOR ATRIAL FIBRILLATION: A COMBINED FREQUENTIST AND BAYESIAN NETWORK META-ANALYSIS

JOÃO VICTOR OLIVEIRA ESTRELA1; JOÃO VICTOR DE OLIVEIRA RAMOS1; MARCELO DANTAS TAVARES DE MELO1;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL;

Introdução/Fundamentos: Atrial fibrillation (AF) is associated with an increased risk of stroke, death and other complications. Many therapeutic approaches have emerged, focusing on new procedures and anticoagulants for the management of this condition. Objetivos: To evaluate the comparative effectiveness of left atrial appendage closure (LAAC), new oral anticoagulation (NOAC) and other therapies for AF. Métodos: A systematic review and network meta-analysis was conducted following PRISMA guidelines. PubMed, Cochrane Library and Embase were searched for randomized controlled trials (RCTs) involving AF patients that underwent LAAC or NOAC therapies. The main outcomes of interest compromised all bleeding events (ABE), all-cause mortality (ACM), stroke, and death from cardiovascular causes (DCC). A combined frequentist and bayesian approach was employed to estimate odds ratios (OR) and 95% confidence/credible intervals (CI). Surface under the cumulative ranking curve (SUCRA) values were estimated and used to determine the probability a treatment is among the most effective for each endpoint of interest. Resultados e Conclusões: A total of 8 RCTs involving 8,532 patients were included, assessing distinct interventions: LAAC, NOAC, aspirin, best medical therapy (physician-directed) and vitamin K antagonists. The connected network comprised 21 possible pairwise comparisons, with 6 direct comparisons available. No studies presented zero-event arms, ensuring robust statistical estimation. In the network meta-analysis, LAAC demonstrated a statistically superior safety profile regarding bleeding and mortality. For ABE, LAAC significantly outperformed NOAC (OR 1.84; 95% CI 1.51–2.25) and vitamin K antagonists (OR 2.20; 95% CI 1.45–3.33). Bayesian SUCRA rankings placed Aspirin and LAAC as the safest interventions for bleeding. Regarding ACM, LAAC showed a protective trend compared to NOAC without statistical significance (OR 1.09; 95% CI 0.77–1.55) and vitamin K antagonists (OR 1.40; 95% CI 0.89–2.18). For stroke incidence, NOAC (OR 0.68; 95% CI 0.46–1.00) showed a trend toward higher efficacy, although not reaching statistical significance compared to LAAC alone. For DCC, best medical therapy and LAAC achieved the highest SUCRA positions. LAAC was associated with a reduction in bleeding events and proved to be comparable or superior to anticoagulation for the assessed efficacy outcomes, except for stroke, for which NOACs have stood out as the best treatment for its prevention.

Introdução/Fundamentos: Catheter ablation is widely used to treat cardiac arrhythmias. However, accessing the arrhythmia substrate and creating reliable lesions can be challenging in patients with congenital heart disease (CHD). Objetivos: This study evaluated the feasibility, efficacy, and safety of catheter ablation in CHD patients. Métodos: Consecutive patients with CHD who underwent catheter ablation for arrhythmia were retrospectively included. Clinical, procedural, and follow-up data were collected. Patients were classified as having mild, moderate, or severe CHD based on disease complexity. Ablation efficacy was assessed over 12 months using device interrogation, ECG, or Holter monitoring. Acute success was defined as arrhythmia termination and non-inducibility at procedure completion, while long-term success was defined as freedom from clinical arrhythmia during follow-up. Resultados e Conclusões: The study included 224 patients (121 males) with a median age of 39 years (IQR, 29.1–51.5). CHD type and prior corrective procedures are shown in Figure 1. Atrial flutter was ablated in 98 procedures (43.8%), atrial tachycardia in 72 (32.1%), atrial fibrillation (AF) in 20 (8.9%), ventricular ectopy in 18 (8.0%), ventricular tachycardia (VT) in 10 (4.5%), and both AVNRT and accessory pathways in 15 procedures each (6.7%). AV junction ablation for permanent AF was performed in 2 patients (0.9%). Median procedural time was 110.0 minutes (IQR, 70.0–155.0) and was longer in patients with severe CHD (p < 0.001). The median radiation dose was 1.9 mGy·m² (IQR, 1.0–4.4). Acute arrhythmia termination was achieved in 96.0% of procedures. Procedure-related complications occurred in 11 cases (4.9%; Table 2), including one pharyngeal bleeding and one hematemesis, all managed conservatively without sequelae. Arrhythmia recurrence occurred in 47 patients (21.0%), most frequently in those with VT (40.0%) and AF (35.0%). Catheter ablation is a feasible and effective treatment for cardiac arrhythmias in patients with CHD, achieving a high 1-year success rate and a low recurrence rate. The overall safety profile is favorable, with complications being rare and manageable. These findings support the use of catheter ablation across a wide spectrum of arrhythmias and CHD severity.

Introdução/Fundamentos: Cardiac resynchronization therapy with defibrillator (CRT-D) is an established treatment for patients with heart failure and electrical dyssynchrony. However, conventional three-lead systems carry a known risk of increased procedural complexity and device-related complications. By using a floating atrial dipole to eliminate the need for an atrial lead, the CRT-DX system offers a compelling alternative. Nevertheless, systematic data comparing its safety and efficacy directly to conventional CRT-D remains scarce. Objetivos: We aimed to compare the efficacy and safety of the CRT-DX system versus conventional CRT-D in patients lacking an indication for permanent atrial pacing. Métodos: We conducted a systematic review and meta-analysis of prospective and retrospective studies following Cochrane guidelines. A systematic search was performed in PubMed, Embase, and Cochrane databases to identify studies comparing CRT-DX versus conventional CRT-D in patients without an indication for permanent atrial pacing. Risk ratios (RR) were pooled using random-effects models for short-term outcomes (12-16 months), comparing CRT-DX with conventional CRT-D for all-cause mortality, heart failure hospitalization, and major lead-related complications. Resultados e Conclusões: A total of 1 randomized and 2 non-randomized studies were included, comprising 1,075 patients. Our meta-analysis demonstrated no significant difference between CRT-DX and conventional CRT-D in all-cause mortality (risk ratio [RR] 0.82; 95% confidence interval [CI] 0.40–1.65; p=0.57; I²=4.2%) or heart failure hospitalization (RR 0.92; 95% CI 0.51–1.65; p=0.78; I²=0.0%). However, CRT-DX was associated with a significant reduction in major lead-related complications (RR 0.65; 95% CI 0.42–0.99; p=0.04; I²=0.0%). Despite the absence of differences in clinical outcomes, the direction of effect consistently favored CRT-DX across most endpoints. These findings suggest that CRT-DX provides comparable efficacy to conventional CRT-D, with a lower burden of major lead-related complications, supporting its use as a less complex and potentially safer alternative in patients without an indication for permanent atrial pacing.

EFFICACY AND SAFETY OF DIRECT ORAL ANTICOAGULANTS IN DEVICE-DETECTED SUBCLINICAL ATRIAL FIBRILLATION: A SYSTEMATIC REVIEW

DIEGO EVANGELISTA LABRUNA RODRIGUES1; BRUNA VICTORIA PIRES MACHADO1; GABRIELA MARIA VICENTE DE MELO1; CLARA BERGUETTE CHAVES1; LAURA CECHETTI GALLI BORGES1; LUCAS LEONARDO ALVES CARDOSO1; EDUARDA FRANCESCHET1; FELIPE DA SILVA PAULITSCH1;

(1) UNIVERSIDADE FEDERAL DO RIO GRANDE - RIO GRANDE - RS - BRASIL;

Introdução/Fundamentos: Atrial fibrillation is the most common sustained cardiac arrhythmia and is strongly associated with an increased risk of stroke and systemic embolism. The widespread use of implantable cardiac devices such as pacemakers and ICD has enabled detection of brief, asymptomatic episodes, termed device-detected subclinical atrial fibrillation. Although associated with increased thromboembolic risk, its absolute risk is lower than that of clinically overt atrial fibrillation, creating uncertainty regarding the net clinical benefit of anticoagulation, particularly given the bleeding risk associated with direct oral anticoagulants (DOACs). Objetivos: This study aims to evaluate the efficacy and safety of DOACs in patients with device-detected subclinical atrial fibrillation and to identify subgroups with the greatest net clinical benefit. Métodos: A systematic review was conducted in accordance with PRISMA guidelines. PubMed and Embase were searched in March 2026 using predefined descriptors and Boolean operators. Randomized controlled trials and cohort studies published within the last 10 years were included. Study selection was independently performed by three reviewers. Data were extracted in a standardized manner and synthesized qualitatively. Resultados e Conclusões: Eight studies were included. DOAC therapy, particularly apixaban, reduced stroke and systemic embolism by approximately 30–60%, depending on baseline risk. However, anticoagulation increased the risk of major bleeding (HR ≈1.8), with most events being gastrointestinal and rarely fatal. The net clinical benefit was strongly risk-dependent. Patients with CHA_2DS_2-VASc >4 demonstrated a favorable balance, with substantial absolute risk reduction and a number needed to treat of approximately 25 over 3.5 years. In contrast, patients with lower risk scores (CHA_2DS_2-VASc <4) derived limited benefit and experienced a relatively higher bleeding burden. Greater benefit was observed in individuals with prior stroke or transient ischemic attack, while atrial fibrillation burden did not consistently modify treatment effect. Based on these results we can conclude that DOACs reduce thromboembolic risk in device-detected subclinical atrial fibrillation but increase bleeding risk. Net clinical benefit is primarily observed in high-risk patients, supporting a personalized, risk-based approach to anticoagulation. Further studies are relevant to refine risk stratification and optimize patient selection

EFFICACY OF BETA-BLOCKER DISCONTINUATION AFTER MYOCARDIAL INFARCTION WITH PRESERVED EJECTION FRACTION: A SYSTEMATIC REVIEW OF RANDOMIZED CONTROLLED TRIALS

FERNANDA NEVES VILHENA MATOS1; CLARISSE DAS NEVES FONTES2; LUCAS EDUARDO CAVALCANTE NOGUEIRA1; RENAN VICTOR DOS SANTOS BRITO1; MADSON IGOR VINHAS ARAÚJO1; EDUARDO DOS SANTOS TENÓRIO2; JOSE ENRIQUE VASCONCELOS DA SILVA1; JOAO LUCAS SANTOS SANTANA1; GABRIEL LEAL MORAES1; DENISE SENA MAUÉS1; IGOR RIAN VIEIRA MENDONÇA1; LEILA MAUÉS OLIVEIRA HANNA1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: The use of beta-blockers after myocardial infarction (MI) is well established in clinical practice, particularly in patients with left ventricular dysfunction. However, in individuals with preserved left ventricular ejection fraction (LVEF), current recommendations are based on evidence derived from studies conducted prior to the widespread adoption of contemporary strategies, such as early coronary reperfusion and optimized pharmacological therapies. In this context, the true magnitude of benefit from prolonged use of this therapy remains uncertain. Objetivos: To critically evaluate the available evidence regarding the efficacy of beta-blocker discontinuation in post-MI patients with LVEF ≥40% without heart failure (HF). Métodos: This is a systematic review conducted in accordance with PRISMA recommendations. Randomized controlled trials (RCTs) comparing discontinuation versus continuation of beta-blocker therapy in post-MI patients with LVEF ≥40% without HF were included. The search was performed in PubMed, Cochrane, and BVS databases using controlled descriptors and free-text terms related to “Beta-blockers” and “Myocardial Infarction,” combined with Boolean operators. Study selection was carried out by two independent reviewers. Risk of bias was assessed using the RoB 2 tool. Studies with higher risk of bias were not automatically excluded but were considered in the interpretation of findings. Primary outcomes included all-cause mortality, recurrent MI, and stroke. Cardiovascular hospitalization was evaluated as a secondary outcome. Resultados e Conclusões: A total of 1,660 studies were identified, of which five eligible randomized clinical trials were included (n = 25,270). Significant heterogeneity was observed among the selected studies regarding the timing of intervention initiation and treatment duration. In trials assessing discontinuation strategies, results were inconsistent, precluding a robust determination of equivalence or non-inferiority, partly due to variability in confidence intervals and reported non-inferiority margins. In superiority analyses, continuation of therapy demonstrated statistically significant benefit in only one study (95% CI, 0.75–0.98; p = 0.03), while the others showed no significant differences between strategies. Therefore, current evidence remains inconclusive regarding the efficacy of discontinuation, highlighting the need for further trials with robust methodological design and well-defined outcomes to better inform evidence-based clinical practice.

EFFICACY OF EARLY VERSUS DELAYED INITIATION OF DIRECT ORAL ANTICOAGULANTS AFTER ISCHEMIC STROKE IN ATRIAL FIBRILLATION: A SYSTEMATIC REVIEW

FERNANDA NEVES VILHENA MATOS1; GLÓRIA ALBUQUERQUE FRANCO1; CLAUDIA LORENA XAVIER DA SILVA2; JULIANA OLIVEIRA DE ALMEIDA1; ALANNE RYLLARI DA SILVA DOS SANTOS1; GABRIELA PIXUNA DIAS1; ANA CAROLINA RODRIGUES NASCIMENTO3; MARIA GIOVANNA CRUZ TOCANTINS1; ANTONIO MARIA ZACARIAS ARAÚJO MONTEIRO4;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL; (3) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (4) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Atrial fibrillation is one of the main cardioembolic causes, being responsible for increasing the risk of ischemic stroke, an important determinant of morbidity and mortality, characterized by high early recurrence and its influence on the occurrence of other vascular events. The use of anticoagulants after an acute stroke is recommended in clinical practice; however, there is controversy among guidelines regarding the optimal timing (≤4 days and ≥7 days), mainly due to the increased risk of intracranial hemorrhage. Objetivos: To evaluate the efficacy of early versus delayed initiation of direct oral anticoagulants after acute ischemic stroke associated with atrial fibrillation. Métodos: A systematic review was conducted in accordance with PRISMA guidelines and the Cochrane Handbook. Randomized controlled trials comparing early and delayed initiation of oral anticoagulants in patients with acute stroke associated with atrial fibrillation, published within the last 10 years and written in Portuguese or English were included. Studies with high risk of bias, unrelated topics, post hoc analyses, and derivative studies were excluded. The search was performed in PubMed, Cochrane, and BVS databases. Risk of bias was assessed using the RoB 2 tool. The descriptors “Ischemic Stroke,” “Anticoagulation,” and “Atrial Fibrillation,” along with their synonyms, were used. Primary outcomes included recurrence of ischemic stroke, intracranial hemorrhage, and mortality; secondary outcomes included other ischemic or hemorrhagic events. Resultados e Conclusões: A total of 3,821 studies were identified, of which four randomized controlled trials (n = 6,722) were included. Only one trial showed risk reduction with early initiation, suggesting a 41% probability that 3–4 days represents the optimal timing for initiation among four groups. On this group, no ischemic events and one hemorrhagic event were observed within 30 days. The remaining studies demonstrated non-inferiority of delayed initiation for the analyzed outcomes (95% CI, −5.31% to 1.74%; p = 0.004 and 95% CI, −1.1% to +1.2%; p = 0.0003), although they suggested a potential benefit of early initiation in prevention, without statistical significance, with lower recurrence of ischemic stroke and mortality. Therefore, this review suggest that there is no consistent evidence of superiority of early initiation compared with delayed oral anticoagulation, highlighting the need for further studies with appropriate methodological design and well-defined outcomes.

EFFICACY OF PULSED FIELD ABLATION VERSUS CRYOBALLOON IN PAROXYSMAL ATRIAL FIBRILLATION: NETWORK META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

ARTHUR SANCHES SALES1; ISABELA ISABELA CAMPOS MOTA1; GEORGE DE SARGES AZEVEDO2; DANIEL MESSIAS VASCONCELLOS1; HEITOR CORREA MODESTO1; HENRIQUE KLOSOUSKI SANTOS DROSDOSKI1; GABRIEL ABUCATER WAL MENIN1; KAUÊ AVELAR PRICKEN CARDOSO1; NICOLAS ROSSY PENA1; VICENZO LORENZONI VALE1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: The current standard approach for paroxysmal atrial fibrillation (PAF) is the isolation of the pulmonary veins through catheter ablation. Thermal energy sources such as radiofrequency (RF) and cryoballoon (CRYO) are traditionally used in this manner. A novel energy delivery method, namely pulsed field ablation (PFA), has emerged as a potential alternative. Objetivos: To compare the efficacy of PFA and CRYO in patients with PAF. Métodos: A systematic review was conducted according to the PRISMA 2020 guidelines. PubMed, Embase, Cochrane Library and Web of Science databases were searched for randomized controlled trials (RCTs) that compared PFA, CRYO, and/or RF. The primary endpoint was treatment failure (recurrence of atrial fibrillation after 3 months in a follow-up of 12 months), expressed as odds ratio (OR) and 95% confidence intervals (95% CI), with RF as reference group. A random-effects network meta-analysis was performed in R software (version 4.5.2). Heterogeneity was assessed using I^2 statistic, with $I^2 > 50\%$ considered substantial. Treatment ranking was performed using P-scores. Global consistency test was assessed using Q decomposition. Risk of bias was evaluated with the RoB 2.0 tool. Resultados e Conclusões: A total of 6 RCTs and 2437 patients were included for the final analysis, comprising 8 pairwise comparisons. At 1-year follow-up, no statistically significant differences were observed in atrial fibrillation recurrence across interventions. Compared with RF, PFA showed a non-significant trend toward lower recurrence rate (OR = 0.855; 95% CI: 0.644 - 1.134; p = 0.813), while CRYO demonstrated similar outcomes (OR = 1.024; 95% CI: 0.84 - 1.25; p = 0.277). Indirect comparisons between PFA and CRYO also resulted in no statistical significance (OR 0.86; 95% CI: 0.64 - 1.13). Ranking analysis based on P-scores suggested PFA as the most favorable treatment (0.876), followed by RF (0.366) and CRYO (0.257). Heterogeneity was low ($I^2 = 0\%$) and no global (p = 0.71), within-design (p = 0.87) and between-design (p = 0.44) inconsistency was found. The findings indicate consistent yet non-significant differences across treatments, with a tendency favoring PFA in reducing atrial fibrillation recurrence in patients with PAF. This reinforces the need for more robust and long-term clinical trials to generate stronger evidence for clinical practice.

Introdução/Fundamentos: Background: Postoperative atrial fibrillation (PAOF) is a prevalent cardiac arrhythmia following heart surgeries, resulting in increased complications and prolonged hospital stays. Aldosterone antagonists (AA) demonstrate potential in managing PAF, but their effectiveness in significantly reducing the condition remains unclear in the existing literature. Objetivos: Purpose: We conducted a meta-analysis to evaluate the efficacy of the AA in reducing the risk of PAOF in patients undergoing cardiac surgery. Métodos: Methods: PubMed, Embase, and Cochrane database were analyzed. Outcome analyzed was PAOF. A random effects model was used to calculate the risk ratios (RRs) with 95% confidence intervals. Statistical analysis was performed using the R program (version 4.3.2). Heterogeneity was assessed with I2 statistics. Resultados e Conclusões: Results: We included 756 patients from 3 studies. Of those, 2 were derived from RCTs. Spironolactone was administered to 338 patients out of the 409 patients who received AA. The cardiac surgeries were: valvular surgery and coronary artery bypass graft (CABG). The remaining 71 patients received eplerenone as an intervention. The use of AA was associated with a significant reduction in the risk of PAOF compared to non-use (RR 0.73; 95% CI 0.58-0.92; P = 0.007; I2 = 47%). Conclusion: In this meta-analysis, AAs were associated with a lower risk of PAOF in patients undergoing cardiac surgery.

ELECTROCARDIOGRAPHIC ALTERATIONS INDUCED BY MANGANESE EXPOSURE IN COLOSSOMA MACROPOMUM

NAOTO NAOTO HAYASAKI1; LUIZ ANTONIO WANZELER DA SILVA1; ANEZITO DE LUCAS LOPES CORREA1; ANA CLARISSE FERREIRA RODRIGUES1; RAUL SILVA AVELLAR1; ALICE QUEIROZ SAMPAIO1; ABRAÃO ESTEVAM LOPES1; LEONARDO ARAÚJO CAMELO1; AXELL TIMOTHEO LIMA ACIOLI LINS1; LUCIANA EIRÓ QUIRINO1; RAYANE CAROLINE DOS SANTOS PEREIRA1; MOISÉS HAMOY1;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Manganese is an essential metal whose function is primarily associated with its role as an enzymatic cofactor, being important in the activation of mitochondrial metabolism. Its absorption occurs mainly through enterocytes in the form of the divalent ion (Mn^{2+}). However, the excessive release of this element into the environment poses risks to human health, whose mechanisms are not yet fully understood. Among its toxic effects, the increased efflux of Mn^{2+} in cardiac mitochondria stands out, as these organelles possess a slow and energy-dependent transport system. This process impairs the extrusion of the metal into the extracellular environment, leading to the depletion of cellular energy reserves. Objetivos: evaluate manganese-induced cardiotoxicity through the analysis of electrocardiographic biomarkers, investigating its influence on cardiac homeostasis. Métodos: A total of 45 Colossoma macropomum were used and maintained under controlled conditions, with water quality monitoring and adherence to ethical principles. The fish were divided into five groups, including one control group and four groups exposed to manganese (4 mg/mL) for different periods (24, 48, 72, and 96 h). Electrocardiograms were performed with digital signal recording and analyzed using specific software. Finally, statistical analyses were conducted using ANOVA followed by Tukey's test, considering $p < 0.05$. Resultados e Conclusões: A significant reduction in heart rate was observed in the groups exposed for 72 h (74.67 ± 2.44 bpm) and 96 h (67.33 ± 3.74 bpm) compared to the control group. The RR interval increased during the same exposure periods (72 h: 805.4 ± 30.64 ms; 96 h: 893.4 ± 51.85 ms), indicating bradycardia. The PQ interval was also prolonged at 72 h (98.67 ± 5.47 ms) and 96 h (101.3 ± 9.16 ms), suggesting impairment of atrioventricular conduction. No significant changes were observed in QRS complex duration ($p = 0.344$). The ST interval showed a progressive increase, with higher values at 72 h (310.9 ± 18.00 ms) and 96 h (303.7 ± 15.44 ms), indicating alterations in ventricular repolarization. These findings suggest that manganese exposure promotes progressive cardiotoxicity, possibly associated with reduced cardiac electrical activity and blockade of L-type calcium channels. Despite the maintenance of sinus rhythm, the prolongation of the PQ interval and ST segment demonstrates impairment of cardiac electrical conduction and repolarization.

Introdução/Fundamentos: Electrocardiographic (ECG) patterns in athletes vary according to ethnicity, and distinguishing physiological adaptations from pathological findings is essential for cardiovascular screening and sudden cardiac death (SCD) prevention. However, data from ethnically diverse athletic populations in Brazil remain limited, especially in sports other than soccer. Objetivos: To compare the ECG findings in competitive athletes with different self-reported racial groups participating in multiple sports. Métodos: This is a cross-sectional study including competitive athletes with different auto-declared races, aged ≥12 years, from multiple sports institutions in Brazil. Participants self-reported race. Indigenous were excluded from this analysis due to the small sample size (n <10). Demographic data, sport modality and weekly training hours were obtained through a standardized questionnaire. Resting 12-lead ECG was performed in supine position and analyzed by a sports cardiologist following standardized criteria. Resultados e Conclusões: A total of 1095 athletes were included (median age 20 [interquartile range 16-28]), 65.1% men). Of these, 206 (18.8%) were black, 411 (37.5%) mixed-race, 467 (42.6%) white and 11 (1%) asian. Weekly training time differed significantly between groups ($p = 0.001$), with black and white athletes training more (median 15 hours/week) than mixed-race (13 hours/week) and Asian athletes (13.5 hours/week). ECG abnormalities associated with increased risk of sudden cardiac death did not differ significantly across racial groups. Physiological ECG patterns predominated in all groups. Sinus bradycardia was significantly more prevalent in black and white populations combined (9.5%) than in the others (4.3%; p=0.001). The black athlete repolarization variant was found to be more prevalent in black population (2.9%), but it was also seen in the other groups (mixed-race: 0.7%; white 0.4%; asian 0%; p=0.023). The most prevalent ECG alteration across all athletes was sinus arrhythmia (18.7%), with no statistically significant difference between groups. Early repolarization pattern also did not differ. These findings are consistent with benign, exercise-induced physiological adaptations, and the observed variations across ethnic groups align well with existing literature. Furthermore, the presence of ECG patterns of black athletes in all ethnic groups highlights the importance of interpretation criteria that take into account the admixture characteristic of the Brazilian population.

ELECTROCARDIOGRAPHIC, CARDIORESPIRATORY, AND MYORELAXANT EFFECTS OF CAMPHOR IN NILE TILAPIA (OREOCHROMIS NILOTICUS): EXPERIMENTAL EVALUATION OF CARDIOTOXICITY

LUIZ ANTONIO WANZELER DA SILVA1; ANEZITO DE LUCAS LOPES CORREA1; RAUL SILVA DE AVELLAR1; NAOTO DA CUNHA HAYASAKI1; EWERTHON LEON LOPES RIBEIRO1; LEONARDO ARAUJO CAMELO1; LUCAS DA SILVA GATO1; ALEXANDRE GUILHERME DA SILVA DIAS1; RAYANE CAROLINE DOS SANTOS PEREIRA1; AXELL TIMOTHEO LIMA ACIOLI LINS1; LUCIANA EIRO-QUIRINO1; MOISES HAMOY1;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Aquaculture uses anesthetics to reduce stress in fish, but synthetic agents can cause adverse effects and environmental impacts. Camphor (CPR), of plant origin, is an aromatic compound naturally present in the essential oil of Cinnamomum camphora and other plants, with widespread use in traditional medicine. CPR presents anesthetic potential through action on the central nervous system and has reported toxicity, including cardiotoxicity. Its effects on Oreochromis niloticus (Nile tilapia) remain poorly understood, warranting further investigation. Objetivos: To evaluate the safety and efficacy of camphor as an anesthetic in Oreochromis niloticus, analyzing behavioral, electromyographic (EMG), electrocardiographic (ECG), and respiratory responses, as well as its effects on muscular, cardiac, and ventilatory functions. Métodos: Ninety-nine juvenile tilapia acclimated under controlled conditions were exposed by immersion to camphor at 150, 200, 250, and 300 mg/L for 5 minutes. Evaluated parameters included: loss and recovery of postural reflex, muscular activity (EMG), cardiac parameters (ECG: heart rate, intervals, and amplitudes), and opercular beat frequency. Data were analyzed by ANOVA with Tukey's post-hoc test. Resultados e Conclusões: CPR induced postural reflex loss in all groups, with reduced latency time as concentration increased (150–300 mg/L) and longer recovery at higher doses. EMG showed decreased muscular activity during exposure, with irregular tracings and gradual post-exposure recovery. ECG analysis revealed dose-dependent bradycardia, with prolonged RR, PQ, QRS, and QT intervals, most pronounced at 250–300 mg/L, and reduced T-wave amplitude at the highest concentrations, suggesting impaired ventricular repolarization and arrhythmia risk. During recovery, groups at 150–250 mg/L showed increased heart rate, while 300 mg/L maintained reduced values. Respiratory activity decreased during exposure, with slower recovery at the highest dose. These findings indicate an anesthetic effect in Oreochromis niloticus associated with dose-dependent cardiorespiratory alterations and potential cardiotoxicity. Partial reversibility at intermediate doses suggests a limited safety margin, reinforcing the need for a defined therapeutic window and further physiological investigation in tilapia.

EXTREME THERMAL EVENTS AND ADVERSE CARDIOVASCULAR OUTCOMES: A SYSTEMATIC REVIEW ON THE RELATIONSHIP BETWEEN HEAT AND ARRHYTHMIAS

GUSTAVO VILARINHO IZIDORO1; ALEX RIBEIRO ROMERO1; LUCAS SQUINELO RODRIGUES1; DARIO IKEDA CASTRILLON FERNANDEZ1; JOÃO OLIVEIRA DE LIMA NETO1; FABRICIUS MIGUEL STORCK1; BRUNO SOUZA BAMBIRRA1; ABNER MARCIANO DOS SANTOS1; GABRIELLA JÚLIA HERANE SHAUREN1; GEOVANNA BRUNA HERANE SCHAUREN2;

(1) UFMT - CUIABÁ - MT - BRASIL; (2) CENTRO UNIVERSITARIO DE VARZEA GRANDE - UNIVAG - CUIABÁ - MT - BRASIL;

Introdução/Fundamentos: Climate change has increased the frequency of extreme thermal events worldwide. Intense heat triggers responses like profuse sweating and sympathetic hyperactivation, leading to dehydration, electrolyte imbalance, and hemodynamic instability. These are known triggers for cardiac arrhythmias in vulnerable populations. Updating clinical evidence on thermal stress and cardiac electrical stability is essential. Objetivos: To evaluate the association between extreme heat exposure and the risk of cardiac arrhythmias and out-of-hospital cardiac arrest (OHCA) in adults. Métodos: Systematic review conducted according to PRISMA guidelines. PubMed, Embase, Cochrane, Scopus, and LILACS were searched for observational studies assessing extreme heat exposure (e.g., heatwaves, high temperature percentiles, or WBGT >30°C) and cardiovascular outcomes. Study selection and data extraction were performed independently by two reviewers using Rayyan. Risk of bias was assessed using the Newcastle-Ottawa Scale, with most studies classified as low to moderate risk. Resultados e Conclusões: Of 169 records, 36 studies were included, comprising over 100 million individuals and 14 million cardiovascular events. Extreme heat exposure was consistently associated with increased risk of arrhythmias and OHCA, particularly in large population-based studies with low risk of bias. Time-series analyses showed acute effects, with higher risk between lag 0–4 days. Significant increases in atrial fibrillation-related emergency visits were observed during peak heat periods, with relative rises exceeding 200% in localized analyses. Large registries from Japan, China, and Europe demonstrated higher rates of OHCA and sudden cardiac death. Older adults (≥65 years) and individuals with cardiovascular disease were disproportionately affected. Extreme heat exposure is associated with increased risk of cardiac arrhythmias and OHCA, particularly in vulnerable populations. Findings are primarily supported by high-quality studies, reinforcing the need to integrate environmental risk into cardiovascular care and preventive strategies during heatwaves.

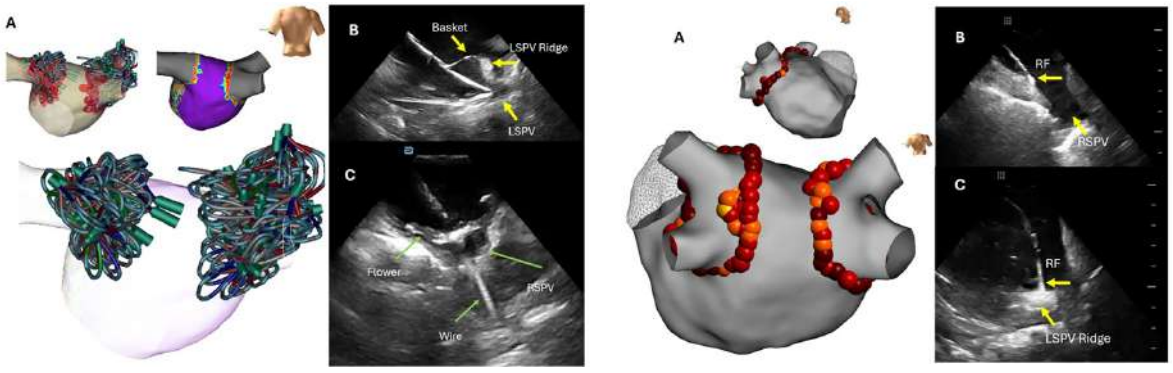
Continuous variables presented as mean (SD); categorical variables as n (%). BMI, body mass index; BP, blood pressure; CVD, cardiovascular disease; ECG, electrocardiogram; eGFR, estimated glomerular filtration rate; LA, left atrial; LAE, left atrial enlargement; LV, left ventricular; LVEF, LV ejection fraction; LVH, LV hypertrophy; ms, milliseconds

Introdução/Fundamentos: Electrocardiographic (ECG) criteria for left atrial enlargement (LAE) are often used as clinical surrogates for structural and hemodynamic left atrial (LA) overload. Their diagnostic performance compared to echocardiography remains suboptimal, and African American populations are consistently underrepresented in relevant diagnostic accuracy studies. Objetivos: To assess the diagnostic accuracy of P-wave duration across a continuous threshold spectrum for the detection of echocardiographic LAE in a large African American cohort. Métodos: We performed a retrospective analysis of the Jackson Heart Study, a community-based cohort of African American adults (aged 21–94 years). P-wave duration was evaluated as the index test across continuous thresholds using receiver operating characteristic (ROC) curve analysis and area under the curve (AUC) with 95% confidence intervals (95% CI). The reference standard was echocardiographic LAE defined by American Society of Echocardiography (ASE) sex-specific LA diameter thresholds (>40 mm in men; >38 mm in women). Diagnostic performance at the conventional ≥120 ms threshold was reported with sensitivity (Sn), specificity (Sp), positive and negative likelihood ratios (LR+ and LR−) with 95% CI. Exclusion criteria included unreadable and/or missing ECG, pacemaker rhythm, non-sinus rhythm, missing P-wave axis and/or duration, prevalent heart failure and lack of echocardiographic LA 2D diameter measure. Resultados e Conclusões: A total of 3,476 participants were included, of whom 607 (17.5%) met ASE diameter criteria for LAE. Baseline characteristics are summarized in Table 1. Overall discriminatory performance was poor (AUC 0.599; 95% CI 0.575–0.623), as shown in Figure 1. At the ≥120 ms threshold, Sn was 57.5% (95% CI 53.5–61.5%), Sp was 56.9% (95% CI 55.1–58.7%), LR+ was 1.34 (95% CI 1.23–1.45), and LR− was 0.75 (95% CI 0.68–0.82), reflecting limited capacity to rule in or rule out LAE. In this large African American cohort, P-wave duration demonstrated poor diagnostic accuracy for echocardiographically defined LAE. These findings highlight the inadequacy of this ECG criterion as a surrogate marker across a historically underrepresented population.



19615

FLUOROLESS HIGH-DENSITY PULSED FIELD VERSUS RADIOFREQUENCY ABLATION FOR ATRIAL FIBRILLATION GUIDED BY LEFT-ATRIAL INTRACARDIAC ECHOCARDIOGRAPHY: THE HALO PROTOCOL

GUILHERME PONTES SAAD1; JESSICA ARAUJO F FERNANDES1; GUSTAVO VIGNOLI DOS SANTOS1; LUIZ ANTONIO INACIO OLIVEIRA JR1; CHARLES SLATER1; EDUARDO BENCHIMOL SAAD1;

(1) HOSPITAL SAMARITANO - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Pulsed field ablation (PFA) is a tissue-selective alternative energy source to radiofrequency ablation (RFA) for atrial fibrillation (AF) with favorable safety and efficiency; however, outcomes are highly dependent on technique, lesion density, and tissue-contact assessment. Objetivos: To compare outcomes of AF ablation using PFA versus RFA when performed in an identical, fluoroless workflow incorporating electroanatomic mapping (EAM) and intracardiac echocardiography (ICE) using the HALO (High-density Antral Left-atrial ICE-guided Overlapping) protocol. Métodos: We retrospectively analyzed 192 consecutive patients undergoing AF ablation with EAM-guided 4-mm lesion tags (50%–75% overlap) and LA ICE for contact assessment. PFA (n=62) employed high-density overlapping lesions extending beyond ostial PV isolation, while RFA (n=130) combined ICE tissue enhancement with contact-force guidance. Lesion delivery was guided by spatial density and contact quality. Resultados e Conclusões: Mean follow-up was 10.6 ± 4.3 months. Arrhythmia recurrence was lower with PFA (4.8%) than RFA (13.1%; p=0.082). In paroxysmal AF, recurrence was significantly lower with PFA (2.1%) versus RFA (16.7%; p=0.011). In persistent AF, recurrence rates were similar (p=0.569) despite a 3.5-fold higher proportion of redo procedures in the RFA group (p=0.001) and more frequent posterior wall (PW) isolation in the PFA group (46.8% vs 20.8%). Procedure duration was significantly shorter with PFA. No major complications occurred. In a standardized fluoroless HALO workflow, PFA achieved superior short-term rhythm control in paroxysmal AF and significantly shorter procedure times. In persistent AF, outcomes were comparable with RFA. Lesion strategy and quality are critical determinants of ablation success beyond energy source selection alone.

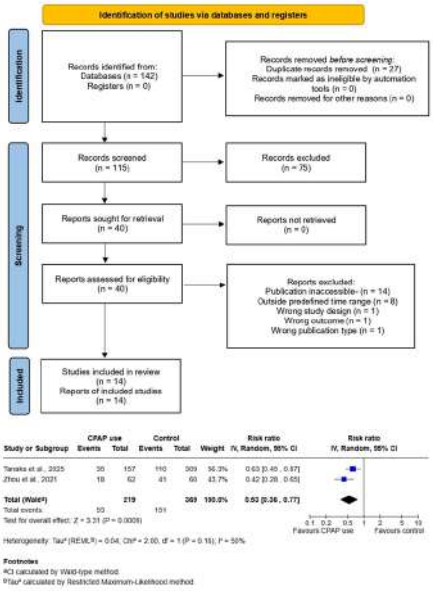
IMPACT OF GLP-1 AGONISTS ON ATRIAL FIBRILLATION REDUCTION IN OBESE PATIENTS WITHOUT DIABETES: A SYSTEMATIC REVIEW OF RANDOMIZED CLINICAL TRIALS.

ENRICO MAGELA BATALHA FALCAO1; LUIGI MAGELA BATALHA FALCAO2; SOPHIA GOUVEIA DAMASCENO1; EDUARDO COIMBRA COELHO DE ASSIS1; MARILIA MAGALHAES BATALHA MATEUS3; EZIO DO AMARAL RODRIGUES1; RONALDO VIEIRA DE OLIVEIRA FILHO1; JOAO PEDRO ARAUJO LIMA1; VINICIUS GABRIEL LOURINHO PINTO1; ANTONIO JOSE SOUZA NASCIMENTO1; THIERYS MAGALHAES BATALHA MATEUS2; THALES MAGALHAES BATALHA MATEUS2;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (3) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Obesity is an important risk factor for atrial fibrillation (AF), being associated with cardiac remodeling, systemic inflammation, and worse cardiovascular prognosis. Recently, glucagon-like peptide-1 (GLP-1) receptor agonists, especially Semaglutide, have demonstrated relevant cardiovascular and metabolic benefits in obese patients, suggesting a potential role in reducing AF occurrence and progression. Objetivos: To evaluate the impact of GLP-1 agonists on atrial fibrillation reduction and related cardiovascular outcomes in obese patients without diabetes through a systematic review of randomized clinical trials. Métodos: This systematic review was conducted according to PRISMA recommendations. Searches were performed in the PubMed, SciELO, and EMBASE databases using the terms “GLP-1 receptor agonist”, “atrial fibrillation”, “obesity”, and “semaglutide”, combined with the Boolean operators AND and OR, applying filters for randomized clinical trials published between 2020 and 2026. Studies involving obese patients without diabetes treated with GLP-1 agonists compared with placebo were included, evaluating atrial fibrillation and cardiovascular outcomes. Review articles, editorials, observational studies, and duplicate studies were excluded. Study selection and data extraction were independently conducted by two reviewers. Risk of bias was assessed using the Cochrane RoB 2 tool. Resultados e Conclusões: The search strategy identified 43 studies, of which 8 randomized clinical trials met the eligibility criteria, totaling more than 10,000 participants. The studies demonstrated consistent benefits of GLP-1 agonists on parameters associated with atrial fibrillation and cardiac remodeling. In the STEP-HFpEF program, semaglutide promoted a significant reduction in left atrial remodeling compared with placebo (estimated mean difference -6.13 mL; 95% CI -9.85 to -2.41; p=0.0013), in addition to functional improvement and reduction of inflammatory markers. Patients with a history of AF showed greater improvement in heart failure-related symptoms (interaction p=0.001). Risk of bias assessment demonstrated low risk across most evaluated domains. Therefore, GLP-1 agonists demonstrated favorable effects on cardiac remodeling and AF-related outcomes in obese patients without diabetes, suggesting potential cardiovascular benefit in this population.



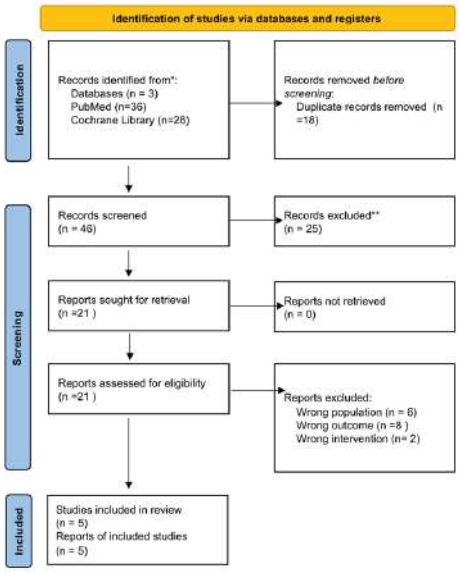
17180

IMPACT OF OBSTRUCTIVE SLEEP APNEA SYNDROME AND CPAP USE ON ATRIAL FIBRILLATION RECURRENCE

GIUSEPPE SPIROTTO STEIN DE OLIVEIRA MESQUITA1; YASMIM CARETA SANTOS2; REBECA DE PAULA BELMONT3; VINICIUS DE SOUZA PINTO3; ALICY HELLEN SOARES ALVES4; HIGO KIPPERT MOTINHO3; LOISE BASTOS ARAÚJO3; ANA PAULA GUEDES DE SOUZA3; LUIZ FABIANO AZEVEDO DE FREITAS4; PAMELA LETÍCIA CARVALHO MARTINS3; AMÁLLI OLIVEIRA FONTINELE1; VINICIUS TADEU RAMOS DA SILVA GRILLO3;

(1) UNIVERSIDADE FEDERAL DE RONDÔNIA - PORTO VELHO - RO - BRASIL; (2) CENTRO UNIVERSITÁRIO APARÍCIO CARVALHO - FIMCA - PORTO VELHO - RO - BRASIL; (3) AFYA CENTRO UNIVERSITÁRIO SÃO LUCAS - PORTO VELHO - RO - BRASIL; (4) FACULDADE METROPOLITANA - PORTO VELHO - RO - BRASIL;

Introdução/Fundamentos: Atrial fibrillation (AF) is the most prevalent sustained arrhythmia and is associated with high morbidity and mortality. Obstructive sleep apnea syndrome (OSAS) is a common comorbidity in these patients and contributes to pathophysiological changes that favor arrhythmia recurrence. Treatment with continuous positive airway pressure (CPAP) has been proposed as a strategy to reduce this risk, although the evidence remains heterogeneous. Objetivos: To analyze the relationship between OSAS and AF recurrence, as well as to evaluate the impact of CPAP use on reducing this clinical outcome. Métodos: This is a systematic review with meta-analysis conducted in accordance with PRISMA recommendations. The search was performed in PubMed, Embase, Cochrane, Web of Science, and LILACS, including studies published between 2016 and 2026. Studies involving adult patients with AF and OSAS were included, comparing CPAP use with no treatment. The primary outcome was clinical recurrence of AF. The effect measure adopted was relative risk, using a random-effects model. Resultados e Conclusões: Fourteen studies were included in the qualitative analysis, of which two were eligible for quantitative synthesis. In the meta-analysis, CPAP use was associated with a significant reduction in atrial fibrillation recurrence, with a relative risk (RR) of 0.53 (95% CI: 0.36–0.77), indicating an approximate 47% reduction in recurrence risk. A total of 53 events were observed among 219 patients in the CPAP group, compared to 151 events among 369 patients in the control group. Heterogeneity was moderate (I^2 = 50%), suggesting variability among studies, possibly related to methodological and clinical differences. The overall effect was statistically significant (p = 0.0009), reinforcing the robustness of the findings. Taken together, these results indicate that treatment of OSAS with CPAP may substantially reduce atrial fibrillation recurrence, particularly in post-intervention settings, although the limited number of studies included in the quantitative analysis underscores the need for further research to consolidate the evidence.



19047

IMPACT OF STRUCTURED PHYSICAL EXERCISE ON RECURRENCE AND BURDEN OF ATRIAL FIBRILLATION: A SYSTEMATIC REVIEW OF CLINICAL RANDOMIZED TRIALS

HENRIQUE CESAR OLIVEIRA ANTUNES1; ALANNE RYLLARI DA SILVA2; IAGO BARROS BRONI2; SAMUEL GODINHO VIEIRA2; MYLENA GEMAQUE VIEIRA2; LAURA FREITAS RODRIGUES1; ANA CAROLINA RODRIGUES3; MARIA GIOVANNA DA CRUZ TOCANTINS2; MARCIO BARROS ROCHA FILHO1; RANIEL GUERRA GARCIA1; VYTOR ANTONIO BARROSO LIMA1; ANTONIO MARIA ZACARIAS ARAÚJO MONTEIRO1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (3) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Atrial fibrillation is the most prevalent sustained arrhythmia, associated with increased morbidity and mortality, recurrent hospitalizations, and reduced quality of life. Despite advances in pharmacological and interventional treatment, non-pharmacological strategies have been gaining relevance, particularly structured physical exercise. Evidence suggests that this intervention may influence pathophysiological mechanisms such as atrial remodeling, autonomic dysfunction, and inflammation. However, its effects on the recurrence and burden of atrial fibrillation remain inconsistent in the literature. Objetivos: To evaluate the impact of structured physical exercise on the recurrence and burden of atrial fibrillation, as well as its effects on secondary outcomes, including functional capacity and cardiovascular-related hospitalizations. Métodos: A systematic review was conducted in accordance with PRISMA 2020 guidelines. Searches were performed in the PubMed and Cochrane Library databases. Randomized controlled trials evaluating the impact of structured physical exercise interventions with outcomes related to atrial fibrillation recurrence and burden, arrhythmias, or functional capacity, in comparison with pharmacological treatment and absence of treatment, were included. Studies that did not address the research question, incomplete articles, or those without original data were excluded. Study selection was performed independently by three reviewers. Risk of bias was assessed using the RoB 2 tool. Due to heterogeneity, data synthesis was conducted qualitatively. Resultados e Conclusões: Of 64 studies identified in the databases, 5 were included in the final review. The studies demonstrated that structured physical exercise improves functional capacity and cardiovascular parameters in patients with atrial fibrillation. A trend toward reduction in arrhythmia recurrence and burden was observed, with significant results in some studies (HR=0.50; 95% CI 0.33–0.78; p<0.05) and reduction in episodes and symptoms. However, others did not demonstrate significance (RR=0.83; 95% CI 0.33–2.10; p>0.05), highlighting heterogeneity. Thus, the overall body of evidence suggests a trend toward a beneficial effect of exercise in the control of atrial fibrillation; however, further multicenter randomized clinical trials are needed to consolidate this association and define the optimal exercise protocol.

INTOXICATION BY HIGH-DOSE HYDROXYCHLOROQUINE INDUCES CHANGES IN CARDIAC FUNCTION IN WISTAR RATS

ABRAÃO ESTEVAM LOPES ESTEVAM ESTEVAM LOPES1; FABIANO WELTER DA SILVA WELTER WELTER DA SILVA2; LUIZ ANTONIO WANZELER DA SILVA ANTONIO ANTONIO WANZELER DA SILVA2; ALICE QUEIROZ SAMPAIO QUEIROZ QUEIROZ SAMPAIO2; PEDRO DE ALMEIDA DA SILVEIRA DE ALMEIDA DE ALMEIDA DA SILVEIRA2; FELIPE GABRIEL LEAL VIANA GABRIEL GABRIEL LEAL VIANA2; ANABELA FRAZÃO BARBOSA GOMES FRAZÃO FRAZÃO BARBOSA GOMES2; SOFIA SILVA PASSOS SILVA SILVA PASSOS2; JULIA SCHNEIDER SANTIAGO SCHNEIDER SCHNEIDER SANTIAGO2; AXELL TIMOTHEO LIMA ACIOLI LINS TIMOTHEO TIMOTHEO LIMA ACIOLI LINS2; LUCIANA EIRÓ-QUIRINO EIRÓ EIRÓ-QUIRINO2; MOISES HAMOY HAMOY HAMOY2;

(1) UNIVERSIDADE FEDERAL DO PARA / FAMED - BELÉM - PA - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Interest in Hydroxycloriquine (HCQ)'s potential antiviral effects increased during research on SARS-CoV-2 throughout the year 2020, It was key towards the control of an epidemic caused by another type of covid virus in Egypt thus increasing such interest during the SARS-CoV-2 pandemic, but several studies have later shown that HCQ is ineffective against SARS-CoV-2. Consequently, research has shifted focus to investigate the potential effects of high-dose HCQ on organ systems due to the widespread misuse of HCQ by the population. In this context, the present study aims to evaluate the effects of high doses of hydroxychloroquine on the homeostasis of cardiac activity (ECG) in Wistar rats. Objetivos: Analyze the effects of potential intoxication by HCQ on the cardiac system by prolonged use or overdose on rats. Métodos: 53 Wistar rats were obtained from the Central Animal Facility of the Federal University of Pará. For the execution of this study, the following chemical substances were used: Ketamine Hydrochloride, Xylazine Hydrochloride, Lidocaine Hydrochloride, and Hydroxychloroquine. Electrodes were placed in the thoracic region for Electrocardiographic (ECG) recording, using lead D2. Electrocardiographic activity was recorded using lead DII. The reference electrode was placed under the right armpit (0.5 cm), and the recording electrode was fixed in the tenth intercostal space, 3.5 cm below the left armpit, in accordance with the recording vector. Each recording lasted for 3 minutes, and the analyzed data included: heart rate (BPM), amplitude (mV), R-R interval (ms), P-Q interval (ms), QRS duration (ms), and QT interval (ms). Resultados e Conclusões: Rats who'm were administred Hydroxycloriquine orally every 12 hours for a period of 96 hours had significant marked decrease in cardiac activity during 72 hours and 96 hours treatments, reflected in reduced heart rates and alterations in R-R and Q-T intervals, suggesting potential impacts on cardiac electrical activity. In this study, high doses (350 mg/kg PO) administered every 12 hours for 24, 48, 72, and 96 hours demonstrated that toxicity became more pronounced with increased duration of exposure. These results emphasize the necessity for thorough evaluation of cardiac function during HCQ treatment, particularly given that its use is linked to adverse cardiac reactions at therapeutic doses, thus ensuring safety and efficacy in treating medical conditions.

20166

INTRACARDIAC VERSUS TRANSESOPHAGEAL ECHOCARDIOGRAPHY IN PATIENTS UNDERGOING ATRIAL FIBRILLATION ABLATION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF CLINICAL OUTCOMES

KAUANN GARCIA RIDOLPHI1; JOÃO PEDRO CAMPOS LIMA1; KAUE ABREU CHAGAS1; DIOGO AYD BITTENCOURT2; LUCIANA ANDRADE AGOSTINHO1;

(1) CENTRO UNIVERSITÁRIO AFYA ITAPERUNA - ITAPERUNA - RJ - BRASIL; (2) INSTITUTO DE EDUCACAO MEDICA (IDOMED) - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Transesophageal echocardiography (TEE) is the gold standard to exclude left atrial and left atrial appendage (LAA) thrombus before atrial fibrillation (AF) ablation. Intracardiac echocardiography (ICE) has emerged as an alternative. ICE may have similar safety and additional procedural benefits. Objetivos: This meta-analysis aimed to compare clinical outcomes of ICE and TEE for patients undergoing AF ablation. Métodos: PubMed, Cochrane Library, and Embase databases were systematically searched for randomized and non-randomized trials comparing ICE and TEE in adult patients with AF undergoing ablation. The primary outcome was periprocedural thromboembolic events. Secondary outcomes were major bleeding, death, and procedure time. A random-effects model was used to calculate the odds ratios (ORs) and mean differences (MDs), with 95% confidence intervals (CIs). Resultados e Conclusões: Of 540 potential articles, five studies comprising 4,458 participants were included, of whom 2,423 were assigned to the ICE group. Paroxysmal AF was present in 53.1% of patients. CHA_2DS_2-VASc score ranged from 1.36 to 4.33 across the studies. Compared with TEE, ICE resulted in no difference in periprocedural thromboembolic events (OR 0.76; 95% CI 0.26, 2.25; p=0.62) and death (OR 1.41; 95% CI 0.17, 11.48; p=0.75). However, patients undergoing ICE had a 41% lower chance of major bleeding (OR 0.70; 95% CI 0.35, 1.42; p=0.33) and a trend toward shorter procedure time (MD -9.96 min; 95% CI -23.97, 4.06; p=0.16). In patients with AF undergoing ablation, ICE was associated with similar rates of periprocedural thromboembolic events and mortality compared to TEE, while demonstrating a trend toward reduced major bleeding and shorter procedure times. These findings suggest that ICE may be considered as an alternative to TEE for pre-ablation evaluation.

KARDIAMOBILE VS 12-LEAD ECG IN OLDER ADULTS: DATA FROM A BRAZILIAN LONGITUDINAL COGNITIVE ASSESSMENT COHORT

PEDRO VITOR ARAUJO VALADARES1; LEONARDO RYUITI KIMOTO1; JOÃO VITOR DA SILVA VIANA1; ANA CAROLINA OLIVEIRA SINZATO1; GIOVANNA CORREIA PEREIRA MORO1; THAISE VALLESCA QUEIROZ1; GABRIELA TOMÉ OLIVEIRA ENGELMANN1; BERNARDO DE MATTOS VIANA1; MARIA APARECIDA CAMARGOS BICALHO1; JOICE COUTINHO DE ALVARENGA1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: The 12-lead Electrocardiogram (ECG) is a valuable tool for cardiac evaluation. However, cost and need for trained professionals to perform the exam limit its availability for home monitoring. On the other hand, older adults might require close ECG monitoring, especially those exposed to polypharmacy because of the increased risk of cardiac side effects, while reduced mobility is common among this population. In this context mobile devices may represent a useful alternative, enabling the monitoring of essential ECG parameters without the need of dislocating to a healthcare facility. Objetivos: The aim of this study is to compare standard ECG with the Kardia Mobile (KM) by measuring heart rate, QRS duration, QTc, and PR interval in a Brazilian cognitive assessment cohort. The objective is to evaluate whether KM could be used to monitor such parameters with enough reliability to guide clinical decisions. Métodos: The baseline 12-lead ECG and KM were performed by medical students under supervision at a clinical research setting in the southeast region of Brazil. Measurements of heart rate, QT interval, PR interval and QRS interval in both devices were then analysed through a Spearman rho correlation to evaluate correlation, and through the Bland-Altman method to evaluate agreement between measurements. Resultados e Conclusões: 111 patients were included (mean age 76,82 (st. deviation 7.148), 73.87% female). The Spearman rho found a strong correlation between both devices in QRS interval (ρ= 0.631; p<0.001), a very strong correlation for Heart Rate (ρ = 0,878; p<0,001), QT interval (ρ = 0.814; p<0.001) and PR interval (ρ = 0.794; p<0.001). Bland–Altman analysis demonstrated a mean difference of −0.396 ms for QRS duration, with 95% limits of agreement ranging from −25.33 to +24.54 ms. For QTc, the mean difference was 3.568 ms (95% limits of agreement: −27.03 to +34.17 ms). Heart rate showed a mean difference of −2.640 bpm (95% limits of agreement: −12.23 to +6.95 bpm), while the PR interval demonstrated a mean difference of 6.757 ms (95% limits of agreement: −23.74 to +37.25 ms). These findings suggest that the KM demonstrates relatively small mean differences compared with the standard 12-lead ECG, indicating overall good agreement in this sample. However, the relatively wide limits of agreement may still be clinically relevant, particularly for parameters such as QTc and PR interval, potentially leading to missed or inaccurate identification of prolonged QT intervals or conduction abnormalities.

Standard QTc – Kardia QTc

Bias & Limits	Point Value
Mean difference + 1.96 SD	34.17
Mean difference	3.568
Mean difference - 1.96 SD	-27.03

Standard QRS – Kardia QRS

Bias & Limits	Point Value
Mean difference + 1.96 SD	24.54
Mean difference	-0.396
Mean difference - 1.96 SD	-25.33

Standard Heart rate – Kardia Heart rate

Bias & Limits	Point Value
Mean difference + 1.96 SD	6.947
Mean difference	-2.640
Mean difference - 1.96 SD	-12.23

Standard PRi – Kardia PRi

Bias & Limits	Point Value
Mean difference + 1.96 SD	37.25
Mean difference	6.757
Mean difference - 1.96 SD	-23.74

LATE OUTCOME OF EPICARDIAL CATHETER ABLATION FOR VENTRICULAR TACHYCARDIA IN CHRONIC CHAGAS CARDIOMYOPATHY

MARIA CLARA VIEIRA PIRES1; MARCELA CASÉ PASSOS MAGALHÃES1; HOMERO FALCÃO DE CARVALHO BISNETO1; JUSSARA DE OLIVEIRA PINHEIRO DUARTE2; ALEX TEIXEIRA GUABIRU2; FILIPE FERREIRA MARQUES2; ADIMEIA SOUZA SANTOS2; LUIZ PEREIRA DE MAGALHÃES2;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL; (2) HOSPITAL UNIVERSITARIO PROFESSOR EDGARD SANTOS DA FACULDADE DE MEDICINA DA UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Epicardial ablation has become established as a technique for treating ventricular tachycardia (VT) in chronic chagas cardiomyopathy (CCC) patients, especially due to the peculiar location of the scar, frequently transmural, which can make the endocardial approach insufficient. Objetivos: To analyze the clinical profile and late outcomes of patients with VT and CCC who underwent catheter ablation using epicardial technique in a public university hospital. Métodos: A descriptive, observational, retrospective study, involving consecutive patients with CCC and recurrent sustained VT, refractory to amiodarone, who underwent catheter ablation between 2022 and 2026. Ablation technique applied was subxiphoid with a Tuohy needle, using radioscopy and/or electroanatomical mapping (EAM). Application site was determined by the presence of ventricular potentials during induced VT, or by determination of functional channels in sinus rhythm. Success criteria were the non-reinduction of clinical VT, or the elimination of reentry circuits. Resultados e Conclusões: 9 patients were analyzed, 7 (77.8%) were male, the mean age was 59.3±11.2 years. 8 (88.9%) had an implantable cardioverter-defibrillator (ICD) and 1 (11.1%) had a resynchronizer and ICD (CRT-D). Mean left ventricular (LV) ejection fraction was 32.7%±11.5% on echocardiography. Electrical storm was the indication for ablation in 8 patients (88.9%), 2 of whom had previously undergone stellate ganglion block, and 5 left thoracoscopic sympathectomy. Subxiphoid exclusively epicardial approach occurred in 6 patients (66.7%) and associated with endocardial in 3 (33.3%). EAM was used in 8 (88.9%), addressing the basal lateral (5), apical lateral (4) and basal inferior (3) LV regions. At the end of the ablation, 5 underwent ventricular stimulation without reinduction of VT. There was a complication in 1 patient due to right ventricular injury, without cardiac tamponade. And recurrence of VT in 5 (55.6%), after 9.1±12.9 months (n=4). None underwent reablation; 1 had successful heart transplantation. There were 2 deaths (22%) due to heart failure after 1 and 30 months of ablation. Most patients with CCC and ICD who underwent catheter ablation of VT had electrical storm and significant LV dysfunction. Epicardial technique was used in all patients without major complications, proving to be safe and effective in this setting, in experienced, high complexity service.

POOR R-WAVE PROGRESSION AND LONG-TERM OUTCOMES IN THE MULTI-ETHNIC STUDY OF ATHEROSCLEROSIS

JOSÉ NUNES DE ALENCAR1; JOÃO VITOR GARDELLI TRINDADE2; CLAUDIONOR ANTÔNIO DOS SANTOS FILHO3; SANDRO PINELLI FELICIONI1; MARIANA FUZY NOGUEIRA DE MARCHI1;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (2) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL; (3) UNIVERSIDADE POTIGUAR (UNP) - NATAL - RN - BRASIL;

Introdução/Fundamentos: Poor R-wave progression (PRWP) has been taught as a marker of anterior myocardial injury since the 1970s, but its temporal stability, substrate, and prognostic value in patients free of coronary artery disease (CAD) are uncertain. Objetivos: We assessed whether PRWP reflects a stable cardiac trait or a transient thoracic-geometric pattern, and whether it predicts cardiovascular events in a CAD-free population. Métodos: We studied 6,323 participants from MESA free of clinical cardiovascular disease, with standardized 12-lead ECGs at baseline and after a median of 10 years. PRWP was defined as R-wave amplitude ≤3 mm in V3 with RV3 > RV2. We evaluated 10-year test–retest stability (Cohen's κ), pulmonary/thoracic correlates, mechanistic substrate via cardiac magnetic resonance and biomarkers, and long-term outcomes (all-cause death, cardiovascular death, MACE) over median 14 years using Cox and Fine–Gray models. Resultados e Conclusões: PRWP prevalence was 3.2% at baseline and 6.2% at 10 years. Binary reproducibility was limited (κ = 0.344) despite good continuous R-V3 reliability (ICC = 0.73); only 52% of baseline PRWP persisted. Emphysema (OR 4.48; 95% CI 2.30–8.22) and current smoking (OR 1.77; 1.14–2.73) were the strongest predictors. PRWP showed no association with RV volumes, ejection fraction, or NT-proBNP. After adjustment for smoking and emphysema, PRWP was not associated with all-cause mortality (HR 1.19; 0.90–1.58), cardiovascular death (HR 1.02; 0.67–1.57), or MACE (HR 0.89; 0.54–1.47). Isolated PRWP in a CAD-free cohort is a poorly reproducible ECG pattern linked to pulmonary exposure and thoracic habitus, without independent cardiovascular prognostic value. Isolated PRWP should not prompt cardiac workup in the absence of other clinical evidence.

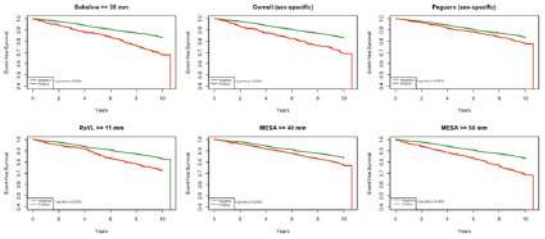
PROGNOSTIC VALUE OF ELECTROCARDIOGRAPHIC LEFT VENTRICULAR HYPERTROPHY CRITERIA IN THE JACKSON HEART STUDY



LÍVIA MARIA DE PAULA CASTRO1; MATHEUS CLAPIS DE SOUZA GOUVEIA2; ERALDO RIBEIRO FERREIRA LEÃO DE MORAES3; JOSÉ NUNES DE ALENCAR4;

(1) FACULDADE DE MEDICINA DE MARILIA - MARÍLIA - SP - BRASIL; (2) FACULDADE ISRAELITA DE CIÊNCIAS DA SAÚDE ALBERT EINSTEIN - SÃO PAULO - SP - BRASIL; (3) INSTITUTO DE CARDIOLOGIA E RADIOLOGIA INTERVENCIONISTA DE RIO VERDE - RIO VERDE - SP - BRASIL; (4) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Electrocardiographic criteria for left ventricular hypertrophy (LVH) demonstrate limited accuracy for detecting LVH when benchmarked against cardiac magnetic resonance (CMR). Despite diagnostic limitations, evidence from some cohorts suggests that these criteria could still carry prognostic significance for adverse outcomes, raising the question of whether they retain prognostic relevance even when failing to detect LVH. Objetivos: Assess the impact of the presence of electrocardiographic (ECG) LVH criteria in the mortality and major cardiovascular events (MACE) in participants from the Jackson Heart Study (JHS). Métodos: We retrospectively analyzed data from JHS, a community-based prospective cohort of African Americans aged 21-94 years from the Jackson Metropolitan Area. LVH was defined by echocardiogram as left ventricular mass indexed to height$^{2.7}$of ≥49 g/m$^{2.7}$ for men and ≥45 g/m$^{2.7}$ for women. 12-lead ECGs were analyzed for the presence of MESA (SV1 plus SV2 plus RV5), Cornell Voltage, Sokolow-Lyon, Peguero Lo-Presti, R wave in aVL criteria in different thresholds. Each criterion was evaluated as a binary variable. Co-primary outcomes were all-cause mortality and MACE, a composite outcome was also ascertained over the full follow-up period. Associations were examined using adjusted Cox proportional hazards regression models for LVH in ECO with 95% confidence interval (CI). Resultados e Conclusões: Among 1,923 participants followed for a median of 10 years, 536 outcomes were recorded. The population characteristics are shown in Table 1. In both Cox analyses, Cornell voltage and Peguero sex-specific were strong predictors of MACE, with a significant hazard ratio (HR) of 1.54 (CI 1.12–2.13) and 1.36 (CI 1.07–1.72) at traditional thresholds. MESA-LVH was the only criterion independently associated with all three endpoints across different cutoffs. At 40 mm it significantly predicted death but not MACE, although, at 50 mm, MACE prediction was statistically significant - HR of 1.42 (CI 1.03–1.94). Peguero also reached significance in composite endpoint. RaVL and Sokolow–Lyon did not demonstrate significant associations with any outcome. Kaplan Meier curves (Image 1) illustrate a higher cumulative event incidence among participants meeting ECG-LVH criteria. In this African American cohort, ECG-based LVH provided independent prognostic information for cardiovascular events and mortality, reinforcing their prognostic utility despite limited diagnostic accuracy for LVH.

Table 1. Baseline characteristics by echocardiographic LVH status

Characteristic	Echo-LVH(n = 224)	Echo-LVH− (n = 1,699)	p-value
Age (years)	59.0 ± 11.2	55.7 ± 12.4	<0.001

PULSED FIELD ABLATION VERSUS CONVENTIONAL THERMAL ABLATION FOR PERSISTENT ATRIAL FIBRILLATION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF EFFICACY AND SAFETY

FILIPE BELCHIOR BESSA ZANOVELLO1; GUSTAVO ANDRE PEDRAL DINIZ LEITE1; TAINA DE OLIVEIRA ENDO MARQUES2; BRUNO RAMOS NASCIMENTO3;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL; (3) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: Persistent Atrial Fibrillation (AF) often requires extensive substrate modification beyond pulmonary vein isolation to achieve durable rhythm control. Conventional thermal ablation modalities, such as radiofrequency and cryoballoon energy, are limited by the risk of non-selective collateral damage to adjacent structures. Pulsed field ablation (PFA) is a non-thermal technology that utilizes high-intensity electrical fields to induce irreversible electroporation with high myocardial tissue-selectivity. However, the evidence regarding its clinical benefits and safety for persistent AF remains uncertain. Objetivos: This meta-analysis aims to evaluate the clinical outcomes and safety of PFA versus conventional thermal ablation modalities in patients with persistent AF. Métodos: The search was conducted in PubMed, Embase and Cochrane databases, through March 2026, according to PRISMA guidelines. Studies comparing clinical outcomes and complications of PFA (intervention) with radiofrequency and/or cryoballon ablation (control) for the treatment of patients with persistent AF (minimum follow-up of 6 months) were included. The primary outcome was AF recurrence and secondary outcomes included major adverse events and vascular complications. Two independent reviewers extracted data and assessed the risk of bias using the Cochrane Risk of Bias tool (RoB 2). Risk Ratios and Odds Ratios with 95% Confidence Intervals were calculated using a random-effects model. Resultados e Conclusões: Ten studies comprising 2,216 patients were included. In the pooled analysis, PFA was associated with a statistically significant reduction in atrial fibrillation recurrence compared with conventional thermal ablation (RR 0.81; 95% CI: 0.69–0.96; I² = 8.1%). Regarding safety outcomes, PFA demonstrated a comparable incidence of any major adverse events across 1,592 patients when compared to thermal modalities (OR 0.81; 95% CI: 0.39–1.69; I² = 0.0%). Similarly, there was no significant difference in the risk of vascular complications between the groups (OR 1.22; 95% CI: 0.40–3.68; I² = 0.0%). This meta-analysis demonstrates that PFA significantly reduces the risk of AF recurrence compared to thermal modalities while maintaining an equivalent safety profile. Clinically, the relative risk reduction translates into a meaningful improvement in single-procedure efficacy. The consistency of effect across studies reinforces the robustness of this finding, supporting PFA as an effective and safe ablation alternative for persistent AF.

PULSED FIELD ABLATION VS CONVENTIONAL THERMAL ABLATION FOR PAROXYSMAL ATRIAL FIBRILLATION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

ANA LUISA COSTA ALENCAR1; GUILHERME DINIZ FERREIRA2; ISABEL FERREIRA AGRA3; MATHEUS DA SILVA FERREIRA4; LUÍS FELIPE CARVALHO PEREIRA1; ISAURA ELAINE GONÇALVES MOREIRA ROCHA1;

(1) UNIVERSIDADE FEDERAL DO CARIRI - BARBALHA - CE - BRASIL; (2) FACULDADE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) FAMENE - JOÃO PESSOA - PB - BRASIL; (4) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Atrial Fibrillation is the most common sustained cardiac arrhythmia, conferring substantial risk of stroke, heart failure, and cardiovascular mortality. In patients with paroxysmal atrial fibrillation (PAF), catheter-based therapeutic approaches are increasingly preferred, particularly conventional thermal ablation (CTA) and, more recently, pulsed field ablation (PFA). However, consolidated data from randomized controlled trials comparing both modalities remain scarce. Objetivos: To compare the efficacy and safety between CTA and PFA in the treatment of PAF. Métodos: A systematic search of PubMed, Embase, and Scopus was conducted following the PRISMA guidelines to identify randomized controlled trials (RCTs) comparing efficacy and safety of PFA vs CTA in patients with PAF. Statistical analysis was performed using R 4.5.3 software with random-effects models. Risk of bias was assessed using the Cochrane RoB 2 tool. Resultados e Conclusões: Four RCTs were identified, including 1,393 patients (mean age 62.5 years, 35.9% female) of whom 697 (50%) underwent PFA, with a median follow-up of 1 year. PFA demonstrated significantly shorter procedure duration (MD -22.32 min, 95% CI -33.35; -11.28, p<0.001) and left atrial dwell time (MD -25.73 min, 95% CI -34.85; -16.61, p<0.001), with no significant difference in fluoroscopy time (MD 7.34 min, 95% CI -0.10; 14.79, p=0.053). After the 60-day blanking period, there were no differences in efficacy endpoints, such as atrial fibrillation recurrence (RR 1.00, 95% CI 0.56-1.78, p=0.990), any atrial arrhythmia recurrence (RR 0.92, 95% CI 0.74-1.13, p=0.411), or resumption of antiarrhythmic drugs (RR 0.87, 95% CI 0.64-1.17, p=0.347), and PFA was associated with higher need for repeat ablation (RR 1.65, 95% CI 1.02-2.69, p=0.043). No significant differences were observed in safety outcomes between PFA and CTA regarding overall complications (RR 0.63, 95% CI 0.26-1.53, p=0.303), stroke or transient ischemic attack (OR 1.21, 95% CI 0.29-4.94, p=0.758), and all-cause death (RR 2.99, 95% CI 0.31-28.54, p=0.342). In conclusion, PFA demonstrated greater procedural efficiency compared to CTA, with shorter procedure durations. Both interventions showed comparable arrhythmia recurrence and safety outcomes, though PFA required more repeat ablations. Although PFA is a viable option for the treatment of PAF, large-scale randomized controlled trials with longer follow-up periods are necessary to accurately define its long-term role.

RELATIONSHIP BETWEEN CORRECTED QT INTERVAL DISPERSION AND LEFT VENTRICULAR EJECTION FRACTION IN PATIENTS WITH DUCHENNE MUSCULAR DYSTROPHY

GABRIEL RANGEL COSTA DA SILVA CARDOSO1; MARCOS MORAIS DE MEIS1; DAVI WHATELY AMAR1; YASMIN VITORIA VICTORINO1; SEBASTIANA BESSA PORTO1; CAROLINA FERREIRA CARDOSO1; VITORIA ALVES DE OLIVEIRA SANTOS1; MARIA LUIZA REBULA ROCHA1; RAFAEL DE LORENZO LIMA1; ANA PAULA CASSETTA DOS SANTOS NUCERA1;

(1) UNIRIO - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Cardiomyopathy and arrhythmias, are important determinants of morbidity and mortality in patients with Duchenne muscular dystrophy (DMD). The assessment of electrocardiographic variables and their associations with ventricular function is a low-cost strategy that is valuable for the early identification of myocardial involvement and cardiovascular risk stratification. Corrected QT interval dispersion (QTcD) is an indirect measure of ventricular repolarization heterogeneity and has been associated with increased cardiovascular mortality in the general population. Objetivos: To evaluate the association between QTcD and age with myocardial function, estimated by left ventricular ejection fraction (LVEF), in patients with DMD. Métodos: Retrospective cross-sectional study based on the review of transthoracic echocardiograms (TTEs) and electrocardiograms (ECGs) of patients with genetically confirmed DMD followed at the cardiology outpatient clinic of a university hospital. Patients with poor-quality ECGs or conditions that prevented adequate measurement of QTcD were excluded. Statistical analyses were performed in Excel and Software IBM SPSS using simple linear regression, analyzing ECG and TTE data from the same patients, obtained within an interval of less than 1 year. QTcD was defined as the difference between the longest and shortest corrected QT interval on a 12-lead ECG, with manual measurement and Bazett correction. LVEF was estimated using the Teichholz method. Resultados e Conclusões: Thirty-two DMD patients were analyzed, with a mean age of 11.56 years ± 4.19, mean QTcD of 96.49 ± 39.95 and mean LVEF 59.34% ± 11.76. There was an inverse and moderate association between QTcD and LVEF (R=0.47; R^2=0.228; p<0.01), with a correlation coefficient (β=-0.14) showing a 0.14% reduction in LVEF for each increase of 1 unit in QTcD (95% CI -0.23 to -0.04). Age was inversely associated with LVEF (R=0.55; R^2=0.309; p<0.01), with a correlation coefficient (β = -1.54) with a 1.55% reduction in ventricular function per year (95%CI −2.41 to −0.68), indicating a relevant impact of age progression on ventricular function. The inverse association between QTcD and Age with LVEF suggests that the greater heterogeneity of ventricular repolarization is related to aging and worse ventricular systolic function in patients with DMD. These findings reinforce the potential of ECG and TTE, widely available and low-cost tests, as complementary tools for cardiovascular risk stratification in this population.

RETROGRADE CATHETER-GUIDED DEEP SEPTAL PACING IN DILATED CARDIOMYOPATHY: FOCUS ON CHAGASIC ETIOLOGY IN NORTHEAST BRAZIL

ALFREDO AURELIO MARINHO ROSA FILHO1; MARIA CLARA DE SOUZA XAVIER2; LUCAS BRANDAO CAVALCANTE3; PEDRO VINICIUS SANTOS DE MEDEIROS4; ADRIANO DE HOLANDA PEDROSA2; ALFREDO AURELIO MARINHO ROSA5; JORGE FRANCISCO DA SILVA FILHO6; EDVALDO FERREIRA XAVIER JUNIOR6;

(1) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (2) CENTRO UNIVERSITARIO CESMAC - MACEIO - SP - BRASIL; (3) CENTRO UNIVERSITARIO DE MACEIO - UNIMA / AFYA - MACEIO - AL - BRASIL; (4) UNCISAL - MACEIO - AL - BRASIL; (5) SANTA CASA DE MISERICORDIA DE MACEIO - MACEIÓ - AL - BRASIL; (6) SANTA CASA DE MISERICORDIA DE MACEIO - MACEIÓ - SP - BRASIL;

Introduction: Conventional right ventricular (RV) apical pacing induces ventricular dyssynchrony, exacerbating heart failure in patients with dilated cardiomyopathy (DCM). Physiological pacing techniques are essential to mitigate these deleterious effects and promote reverse remodeling. Objetivos: Objective: To evaluate the feasibility and initial outcomes of an innovative deep septal ventricular lead implantation technique, guided by left septal electroanatomical mapping via retrograde aortic catheter, in patients with DCM and ventricular dyssynchrony, focusing on Chagasic etiology. Métodos: Material and Methods: Between January and August 2025, ten consecutive DCM patients (mean age 61±7 years, 60% male, mean LVEF 30±5%) with LBBB and CRT indication underwent deep septal lead implantation. The procedure involved three left subclavian vein punctures for atrial, left ventricular (via coronary sinus), and deep septal RV lead implantation, guided by a retrograde electroanatomical mapping catheter in the left postero-septal region via the right femoral artery. Success was defined by a paced QRS duration ≤120 ms with modified LBBB morphology, and adequate sensing/pacing thresholds. Echocardiographic and clinical (NYHA) evaluations were performed pre-op and at 7 months. Resultados e Conclusões: Results: Deep septal implantation was successful in 8 (80%) patients. Mean native QRS was 178±18 ms (max 196 ms). Post-implantation, paced QRS significantly reduced to 96±8 ms ($p<0.001$), with 80% achieving QRS ≤120 ms. DCM etiologies: Chagasic (50%, n=5), ischemic (40%, n=4), and one dilated hypertrophic (10%, n=1). No major complications. At 7 months, 70% showed improved ejection fraction (mean LVEF 30% to 57%, $p<0.001$) and functional class (NYHA IV to II in 60%). Conclusion: Retrograde catheter-guided deep septal pacing in DCM patients with dyssynchrony—including the endemic Chagasic population of Northeast Brazil—is a promising and safe alternative to conventional pacing. Initial results suggest relevant clinical, electrocardiographic, and echocardiographic benefits, paving the way for larger studies to validate its long-term efficacy and CRT role.

SURGICAL SITE INFECTION IN PATIENTS UNDERGOING IMPLANTABLE CARDIAC ELECTRONIC DEVICE PROCEDURES

EVELYN GENIELLY CAMILO BEZERRA1; DIEGO PEREIRA GREGÓRIO DE ANDRADE2; JOSÉ KLEBERTH TENÓRIO FILHO2; LAIO CAJU WANDERLEY2; JOSÉ DA SILVA LEITÃO NETO2; JESUS ANTONIO GUTIERRE SAURITH2; LEANDRO CASTELO ALVES2; FLÁVIO JOSÉ ALENCAR DE MELO3; JULIANO HENRIQUE SAMPAIO SIMÃO2; JOSÉ WANDERLEY NETO2; PETER CONDE VIDAL JÚNIOR2;

(1) CENTRO UNIVERSITARIO DE MACEIO - UNIMA / AFYA - MACEIO - AL - BRASIL; (2) HOSPITAL DO CORACAO ALAGOANO PROF. ADIB JATENE - MACEIO - AL - BRASIL; (3) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL;

Introdução/Fundamentos: Surgical Site Infection (SSI) related to Implantable Cardiac Electronic Devices (CIEDs) is one of the major postoperative complications, leading to prolonged hospitalization, increased morbidity and mortality, and even right-sided infective endocarditis. Furthermore, previous studies have demonstrated that pacemaker procedures are associated with lower complication rates when compared with Implantable Cardioverter-Defibrillators (ICDs) and Cardiac Resynchronization Therapy (CRT). Objetivos: To analyze the incidence of SSI in patients undergoing CIED procedures at a public hospital in Alagoas, Brazil, between January 2022 and November 2025. Métodos: This was a retrospective observational comparative study conducted through the review of a database from a public hospital in Alagoas. Patients older than 18 years who underwent CIED implantation procedures, lead replacement, or generator replacement between January 2022 and November 2025 were included. SSI diagnosis was established according to the 2025 ANVISA criteria for Healthcare-Associated Infections, including local clinical signs, fever, and microbiological isolation. Temporary pacemaker procedures were excluded. The identified infection rates were subsequently compared with data from international studies published within the last five years. Resultados e Conclusões: During the study period, 609 CIED-related procedures were performed, including 554 permanent pacemakers, 49 Implantable Cardioverter-Defibrillators (ICDs), 78 generator replacements, and 20 lead replacement procedures. All patients received prophylactic Cefazolin 2 g 30–60 minutes before incision. Interrupted sutures were systematically performed in skin and subcutaneous tissue. Follow-up occurred at 30 days and every 6 months thereafter, enabling identification of late infections. Only two isolated SSI cases were identified, one in September 2022 and another in May 2023, resulting in an overall SSI incidence of 0.33%. No additional infection cases or deaths related to SSI were observed during subsequent years. Despite the increasing number of procedures over the years, SSI rates remained below 1%, consistent with and even lower than recent international reports ranging from 1–2%. These findings suggest that preventive strategies, including appropriate antibiotic prophylaxis, interrupted suturing, glycemic control, and shorter operative times, may contribute to reducing SSI rates in CIED procedures.

SYNERGISTIC ELECTROPHYSIOLOGICAL AND CARDIORESPIRATORY DEPRESSION INDUCED BY ALCOHOL AND FLUNITRAZEPAM IN WISTAR RATS

SOFIA SILVA PASSOS1; ABRAÃO ESTEVAM LOPES1; ALICE QUEIROZ SAMPAIO1; LUANA PAULA CARDOSO GUIMARÃES1; PEDRO DE ALMEIDA SILVEIRA1; FABIANO WELTER DA SILVA1; HEITOR QUARESMA SILVA1; ALEXANDRE GUILHERME DA SILVA DIAS1; RAYANE CAROLINE DOS SANTOS PEREIRA1; AXELL TIMOTHEO LIMA ACIOLI LINS1; LUCIANA EIRÓ QUIRINO1; MOISÉS HAMOY1;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Alcohol is a widely consumed substance, while benzodiazepines, such as flunitrazepam, are frequently prescribed for sleep disorders and anxiety. The coadministration of these substances constitutes a public health concern due to the potential for synergistic depressant effects on the central nervous system, with possible cardiovascular and respiratory alterations. However, the integrated electrophysiological effects of this combination have not yet been fully elucidated. Objetivos: To investigate the effects of coadministration of alcohol and increasing doses of flunitrazepam on electrocorticographic, respiratory, and electrocardiographic parameters. Métodos: An experimental study with 72 Wistar rats divided into eight groups: control, alcohol (20%), flunitrazepam (0.1, 0.2, 0.3 mg/kg), and alcohol–flunitrazepam combinations at the same doses (CEUA protocol No. 6233270619). Electrocorticographic recordings, respiratory rate, and electrocardiographic parameters, including heart rate and P–Q, R–R, QRS, and Q–T intervals, were analyzed. Statistical analysis was performed using ANOVA followed by Tukey's test ($p < 0.05$). Resultados e Conclusões: The combination of alcohol and flunitrazepam led to a reduction in low-frequency brain oscillations (alpha and theta), intensification of central depressant effects, and a progressive, dose-dependent decrease in respiratory rate. In the cardiovascular system, heart rate decreased from 325.0 ± 11.7 bpm in the control group to 247.6 ± 6.3 bpm in the group receiving the highest dose of alcohol–flunitrazepam (0.3 mg/kg) ($p < 0.05$), indicating marked bradycardia and depression of autonomic control. In addition, Q–T interval prolongation was observed at higher doses, from 82.11 ± 5.061 ms (control) to 98.22 ± 5.783 ms (combination with 0.2 mg/kg) and 106.3 ± 4.873 ms (combination with 0.3 mg/kg), indicating a higher risk of electrical instability. Regarding the duration of the QRS complex, there were no significant changes, while a slight increase in P–Q and R–R intervals was observed, suggesting relative preservation of intraventricular conduction. These findings demonstrate a synergistic depressant effect, with impact on cerebral, respiratory, and cardiac activity. The study contributes to understanding the mechanisms involved in the combined toxicity of these substances, with implications for clinical practice in cardiovascular emergencies.

Graphics demonstrating the mean values of the cardiac activity records for the tested groups evaluating the following cardiac morphographic parameters: Heart rate (bpm) (A); QRS amplitude (mV) (B); R-R interval (ms) (C); P-Q interval (ms) (D); QRS complexduration (ms) (E); Q-T interval (ms) (F). After ANOVA and Tukey's test, (*) P<0.01; (**) P<0.001; (***) P<0.0001

TIMING OF ORAL ANTICOAGULATION DISCONTINUATION AFTER ATRIAL FIBRILLATION ABLATION: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

ARTHUR BEZERRA CAVALCANTI PETRUCCI1; JOÃO VICTOR DE OLIVEIRA RAMOS1; LUIS GUILHERME FRAZÃO DE AMORIM1; MARIA EDUARDA MARINHO SILVA1; DAVI ALBUQUERQUE MADRUGA1; LUCAS FREIRE MONTEIRO1; GABRIEL PELEGRINETI TARGUETA2; KAROLINA GUEDES1; MARCELO DANTAS TAVARES DE MELO1; GUILHERME AUGUSTO TEODORO ATHAYDE1;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (2) HOSPITAL UNIVERSITÁRIO LAURO WANDERLEY - JOÃO PESSOA - PB - BRASIL;

Introdução/Fundamentos: Whether oral anticoagulation (OAC) should be continued after atrial fibrillation ablation remains uncertain, as does the optimal timing for discontinuation. No prior network meta-analysis has directly compared continuation with specific post-ablation discontinuation timings. Objetivos: To compare the safety and efficacy of OAC continuation versus discontinuation after atrial fibrillation ablation and to evaluate the effect of discontinuation timing on clinical outcomes. Métodos: This systematic review and meta-analysis was conducted in accordance with PRISMA guidelines. PubMed, Embase, and Cochrane Library were systematically searched for randomized trials and propensity score–matched cohorts comparing OAC continuation with discontinuation after atrial fibrillation ablation. The primary outcome was thromboembolic events, and the secondary outcome was major bleeding. Direct comparisons were pooled using random-effects models, and a frequentist network meta-analysis compared different discontinuation timings. Analyses were performed using R software version 4.6.0. Resultados e Conclusões: Six studies were included, comprising a total of 116,530 patients, of whom 58,341 (50.1%) discontinued OAC. In the direct meta-analysis, discontinuation was not associated with a significant difference in thromboembolic events versus continuation (RR 1.13; 95% CI 0.99–1.28; p = 0.054; I^2 = 14.3%; Figure 1) but was associated with lower major bleeding (RR 0.49; 95% CI 0.28–0.87; I^2 = 14.3%). In the network meta-analysis, thromboembolic risk did not differ across strategies. Compared with continuation, discontinuation at 3 months (RR 0.29; 95% CI 0.11–0.79), 6 months (RR 0.69; 95% CI 0.60–0.79), and ≥12 months (RR 0.33; 95% CI 0.11–0.97) was associated with lower major bleeding, without significant differences among discontinuation timings (Figure 2). After atrial fibrillation ablation, OAC discontinuation was associated with lower major bleeding and no statistically significant increase in thromboembolic events, with comparable outcomes across discontinuation timing strategies.

WEARABLE AND PORTABLE CARDIAC MONITORING FOR EXERCISE-RELATED ARRHYTHMIAS IN ATHLETES: A SYSTEMATIC REVIEW

GABRIEL SANTARÉM JORGE PINTO DOS REIS1; URIEL SALZER BESTENE2; RENATA DA LUZ GOMES1; LUCAS JOSÉ COSTA SOUZA2; ÁLVARO ALBERTO DE OLIVEIRA TAVARES2; AGATHA KELLY BARBOSA TURAN3; ROGER VIANA HÜHN2; ALEXANDRE AFONSO FERREIRA REBELO2; GIOVANNA BARCELOS FONTENELE PEREIRA1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (3) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Monitoring physiological parameters in athletes aids in early identification of cardiovascular risk. Wearable devices enable continuous, non-invasive biometric data collection, while portable cardiac monitors allow electrophysiological recording outside clinical settings. Diagnostic accuracy in athletes is challenged by physiological adaptations of the “athlete’s heart” and by motion artifacts. Systematic reviews evaluating wearables have focused predominantly on general or elderly populations; athletes remain largely underrepresented, and available evidence is limited to small observational studies with heterogeneous methodologies. Objetivos: To evaluate the diagnostic accuracy and clinical utility of wearable and portable cardiac monitoring devices for arrhythmia detection in athletes, comparing them to gold-standard methods, and to identify technical and physiological limitations in high-intensity sports settings. Métodos: Systematic review following PRISMA 2020, registered in PROSPERO. PubMed/MEDLINE, Cochrane Library, LILACS/BVS, SPORTDiscus, and IEEE Xplore were searched for studies published in the last 10 years. Eligible studies included original human studies involving elite, competitive, or endurance athletes evaluated with wearable or portable cardiac monitoring devices for arrhythmia detection. Records were independently screened by two reviewers using Rayyan, with disagreements resolved by consensus. Risk of bias was assessed using ROBIS. Resultados e Conclusões: ECG-based wearables demonstrated high agreement with conventional electrocardiography (Pearson r=0.98–1.0). In marathon runners, abnormal ECG findings were observed in 16.8%, including 9.3% with non-sustained ventricular tachycardia. In contrast, non-ECG devices showed significant limitations: 45% of detected abnormal events were artifacts, and 15% of true arrhythmias were missed. Motion artifacts, sweating, and electrode displacement were the main sources of signal distortion. ECG-based technologies represent the most reliable option for rhythm assessment in athletes; however, their role remains complementary to standard diagnostic tools. Standardized validation protocols and studies specifically designed for athletic populations are warranted.

Introdução/Fundamentos: Undiagnosed atrial fibrillation (AF) is a significant contributor to preventable stroke in older adults with cardiovascular risk factors. Although wearable electrocardiographic (ECG) monitors offer a scalable screening approach, the effectiveness of routine AF screening with wearables remains uncertain. Objetivos: We aimed to evaluate whether routine screening with wearable ECG devices increases the detection of new-onset AF compared to usual care in older adults at risk. Métodos: We conducted a meta-analysis of randomized controlled trials (RCTs) comparing wearable ECG screening versus usual care in older adults without known AF but with cardiovascular risk factors.Searches were performed in PubMed, Embase, and Cochrane CENTRAL through April 2026. Odds ratios (ORs) with 95% confidence intervals (CIs) were pooled using a random-effects model. Heterogeneity was assessed using the I² statistic. R software was used for statistical analysis Resultados e Conclusões: Eight RCTs comprising 78,378 participants (mean age 74.3 years; 47.7% men) were included. Routine screening with wearable ECGs significantly increased the detection of new-onset AF compared to usual care (OR 1.87; 95% CI 1.40-2.51; p < 0.0001). Subgroup analyses showed this effect was consistent at 3 months (OR 3.42; 95% CI 2.36-4.97; p < 0.0001), at 4 months (OR 3.00; 95% CI 2.35-3.82; p < 0.0001), and at 24 months (OR 1.70; 95% CI 1.47-1.97; p < 0.0001). Additionally, wearable-based screening was associated with significantly higher rates of oral anticoagulant initiation (OR 2.29; 95% CI 1.39–3.78; p = 0.0012). Routine screening with wearable ECG devices significantly increases the detection of atrial fibrillation and initiation of anticoagulation therapy in older adults at cardiovascular risk. These findings support the use of wearable AF screening as an effective preventive strategy in this population.

ACUTE CARDIOVASCULAR TOXICITY FOLLOWING CAR-T CELL THERAPY IN PEDIATRIC PATIENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

GEOVANA DIAS SANTOS QUEIROZ1; PEDRO CESAR REZENDE SEGURADO1; LUÍS FILIPE REZENDE TOMÉ1; LUCAS RODRIGUES VAZ DE MELLO1; JOÃO NUNES DE MATOS NETO1;

(1) UNIVERSIDADE DE BRASILIA - BRASÍLIA - DF - BRASIL;

Introdução/Fundamentos: Chimeric antigen receptor T-cell therapy has revolutionized the treatment of refractory pediatric hematologic malignancies. However, cytokine release syndrome, its primary complication, can critically compromise myocardial function. Specific cardiovascular data in children remain scarce. Objetivos: To estimate the pooled incidence of acute cardiovascular toxicity in pediatric patients undergoing cellular immunotherapy via a systematic review and meta-analysis. Métodos: A search was conducted across the PubMed, Embase, Cochrane, LILACS, and Web of Science databases from 2018 to 2026 using the MeSH terms ''Chimeric Antigen Receptor'', ''Cardiotoxicity'', ''Heart Failure'', and ''Pediatrics''. Double-blind screening followed the PRISMA 2020 guidelines. Primary studies with quantitative cardiovascular data post-cellular infusion were included, excluding case reports, narrative reviews, and mixed samples. The risk of bias was assessed using the Joanna Briggs Institute (JBI) tools. For the meta-analysis, the DerSimonian-Laird random-effects model with logit transformation and a 95% confidence interval calculated by the Wilson score was adopted. Heterogeneity was evaluated using Cochran's Q test, the I² index, and the τ² variance. Resultados e Conclusões: Six studies with low to moderate risk of bias, comprising 527 pediatric patients, were included. Incidence of cytokine release syndrome was 72.8% (k=5, N=429, 95% CI 65.2–79.3%, I²=61.3%). Vasoactive support reached 22.6% (k=2, N=145, 95% CI 15.4–31.9%, I²=26.1%). Systolic dysfunction incidence was 11.5% (k=4, N=314, 95% CI 6.9–18.5%, I²=58.5%). Arrhythmias occurred in 9.5% (k=1, N=74, 95% CI 4.6–18.5%), 86% associated with cytokine release syndrome. Pericardial effusion occurred in 19.1% (k=1, N=115). Dysfunction was predominantly transient (resolution: 4 weeks–6 months). Global Longitudinal Strain reduction preceded ejection fraction decline by ≥1 week. Blast burden >25% (OR 15.5, p<0.001) and grade ≥3 cytokine release syndrome were the main predictors. Acute cardiotoxicity affects approximately 1 in every 9 children with systolic dysfunction and 1 in every 4 children with hemodynamic compromise, but is mostly reversible. The pediatric profile is distinguished by pericardial effusion and the predictive value of Global Longitudinal Strain. Standardized multicenter registries are needed.

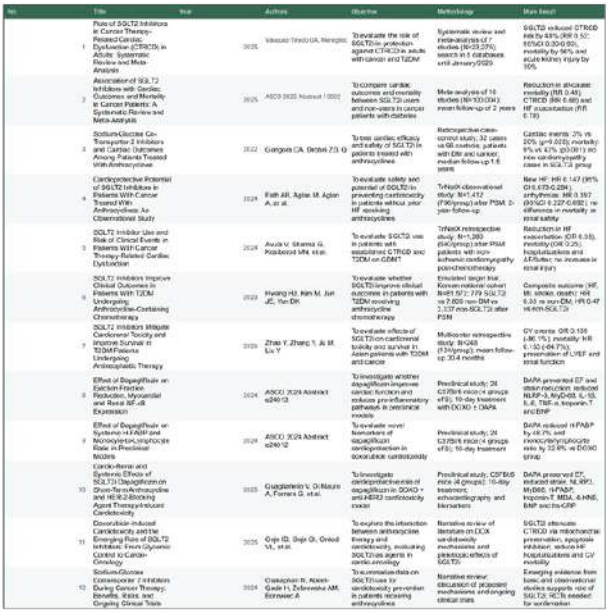
BIOMARKER-GUIDED VERSUS UNIVERSAL PRIMARY PREVENTION FOR ANTHRACYCLINE-INDUCED CARDIOTOXICITY: A SYSTEMATIC REVIEW OF RANDOMIZED TRIALS

PAULO EDUARDO GUARESQUI1; JULIA ACSA RODRIGUES DE ALMEIDA1; MONICA GUARESQUI1; ANA CAROLINA DE LIMA FERREIRA1; PEDRO HENRIQUE LOURENÇO DE SOUZA1; LUISA PERONI NEVES BARCELLOS1; HENRIQUE AUGUSTO GUARESQUI1; NÍCOLAS DE OLIVEIRA FRACAROLI1; MILENA REISEN NETTO1; ROBERTO RAMOS BARBOSA2;

(1) ESCOLA SUPERIOR DE CIENCIAS DA SANTA CASA DE MISERICORDIA DE VITORIA - VITÓRIA - ES - BRASIL; (2) HOSPITAL SANTA CASA DE MISERICORDIA DE VITORIA - VITÓRIA - ES - BRASIL;

Introdução/Fundamentos: Anthracyclines remain essential for treating breast cancer and lymphoma but are associated with a significant risk of cancer therapy-related cardiac dysfunction (CTRCD). Neurohormonal blockers such as ACE inhibitors (ACEi), ARBs, or beta-blockers (BB) are proposed for pharmacological prophylaxis; however, the optimal initiation strategy—universal versus biomarker-guided—remains clinically debated. Objetivos: To evaluate and compare the efficacy of biomarker-guided and universal prevention strategies in preventing CTRCD among adults receiving anthracycline-based chemotherapy. Métodos: A systematic review of randomized clinical trials (RCTs) published between 2021 and 2026 was conducted following PRISMA guidelines. Eligible studies included adults with breast cancer or lymphoma and preserved baseline left ventricular ejection fraction (LVEF). The primary outcome was CTRCD (LVEF reduction >10% or <50%); secondary outcomes included changes in global longitudinal strain (GLS) and cardiac biomarkers. Risk of bias was assessed using the Cochrane RoB 2 tool. Resultados e Conclusões: Trials demonstrated heterogeneous effects across strategies. In the Cardiac CARE trial, a biomarker-guided approach using troponin I to initiate candesartan and carvedilol did not significantly improve 6-month LVEF compared with standard care (mean difference -0.37%, p=0.82). Conversely, the SARAH trial showed that sacubitril/valsartan significantly reduced subclinical dysfunction (GLS decline >15%: 7% vs. 25%, p=0.015). Regarding universal prophylaxis, the PROACT trial found no significant reduction in myocardial injury with enalapril in high-dose anthracycline regimens. However, pooled evidence from randomized trials suggests that prophylactic ACEi are associated with a significantly smaller LVEF reduction (MD -5%, p<0.010), particularly in patients receiving concomitant trastuzumab (MD -3%, p<0.010). Overall, universal prevention provides modest but clinically relevant preservation of LVEF, especially in high-risk regimens. While biomarker-guided strategies effectively mitigate early subclinical myocardial injury (GLS), their impact on preventing overt cardiotoxicity requires further large-scale validation.



17763

CARDIOPROTECTIVE ROLE OF SGLT2 INHIBITORS IN CANCER PATIENTS RECEIVING ANTHRACYCLINES: A PRISMA SYSTEMATIC REVIEW

VINÍCIUS NASCIMENTO CAVALCANTE DA SILVA1; JULIANA FILGUEIRAS MEDEIROS1;

(1) UNIVERSIDADE SÃO JUDAS TADEU - CUBATÃO - SP - BRASIL;

Introdução/Fundamentos: Anthracyclines are essential in the treatment of hematologic malignancies and solid tumors, but their dose-dependent cardiotoxicity remains a major limitation. Cancer therapy–related cardiac dysfunction (CTRCD) affects 9–26% of exposed patients and is associated with increased morbidity and mortality. Sodium-glucose cotransporter-2 inhibitors (SGLT2i), recognized for their cardiovascular and renal benefits, have emerged as promising cardioprotective agents in cardio-oncology. Objetivos: To systematically evaluate the efficacy and safety of SGLT2 inhibitors in preventing and managing anthracycline-induced cardiotoxicity. Métodos: A PRISMA-guided systematic review was conducted including studies published between 2022–2026. Searches were performed in PubMed, Cochrane Library, Embase, Scopus, Web of Science, and major conference proceedings (ASCO/ESC), using the terms “SGLT2 Inhibitors” AND “Anthracycline” AND “Cardiotoxicity”. Twelve studies met inclusion criteria: 2 meta-analyses (n=123,279), 5 large observational cohorts, 3 mechanistic preclinical studies, and 2 narrative reviews. Due to dataset overlap and the absence of patient-level data, no formal meta-analysis was performed. Instead, a structured quantitative synthesis was undertaken, prioritizing meta-analytic populations for shared outcomes and individual cohorts for complementary endpoints. Effect estimates were derived using sample size–informed approximations. Resultados e Conclusões: All included studies showed a consistent direction of benefit, with improvement in at least one cardiorenal outcome. Quantitative synthesis found that SGLT2 inhibitors were associated with an approximately 35% reduction in CTRCD risk and a 50–55% reduction in all-cause mortality. Individual cohorts indicated an approximate 55% reduction in incident or worsening heart failure, representing the most pronounced clinical benefit. Renal outcomes were similarly favorable, with an estimated 55–65% reduction in adverse renal events and preservation of kidney function. Mechanistic studies were concordant, demonstrating attenuation of oxidative stress, suppression of inflammatory pathways (including NLRP3 inflammasome and NF-κB signaling), reduction of pro-inflammatory cytokines, and preservation of mitochondrial function. Safety outcomes were neutral overall, with no increase in severe adverse events and only a modest rise in genital infections. These findings support a clinically meaningful cardioprotective and renoprotective role of SGLT2 inhibitors in cardio-oncology.

No.	Title	Year	Authors	Objective	Methodology	Main Result
1	Role of SGLT2 Inhibitors in Cancer Therapy-Related Cardiac Dysfunction (CTRCD): in Adults: Systematic Review and Meta-Analysis	2025	Vilasco-Tinoco GA, Mengden	To evaluate the role of SGLT2i in protection against CTRCD in adults with cancer and T2DM	Systematic review and meta-analysis of 7 studies (N=23,276); search in 5 databases until January 2025	SGLT2i reduced CTRCD risk by 48% (RR 0.52; 95%CI 0.30-0.90), mortality by 56% and acute kidney injury by 16%
2	Association of SGLT2 Inhibitors with Cardiac Outcomes and Mortality in Cancer Patients: A Systematic Review and Meta-Analysis	2025	ASCO 2025 Abstract 10002	To compare cardiac outcomes and mortality between SGLT2i users and non-users in cancer patients with diabetes	Meta-analysis of 16 studies (N=100,004); mean follow-up of 2 years	Reduction in all-cause mortality (RR 0.48), CTRCD (RR 0.68) and HF hospitalization (RR 0.78)
3	Sodium-Glucose Co-Transporter 2 Inhibitors and Cardiac Outcomes Among Patients Treated With Anthracyclines	2022	Gongora CA, Drobni ZD, G	To test cardiac efficacy and safety of SGLT2i in patients treated with anthracyclines	Retrospective case-control study; 32 cases vs 66 controls; patients with DM and cancer; median follow-up 1.6 years	Cardiac events: 3% vs 20% (p=0.025); mortality: 9% vs 47% (p<0.01); no new cardiomyopathy cases in SGLT2i group
4	Cardioprotective Potential of SGLT2 Inhibitors in Patients With Cancer Treated With Anthracyclines: An Observational Study	2024	Fath AR, Aglan M, Aglan A, et al.	To evaluate safety and potential of SGLT2i in preventing cardiotoxicity in patients without prior HF receiving anthracyclines	TriNetX observational study; N=1,412 (706/group) after PSM; 2-year follow-up	New HF: HR 0.147 (95% CI 0.073-0.294); arrhythmias: HR 0.357 (95%CI 0.227-0.692); no differences in mortality or renal safety
5	SGLT2 Inhibitor Use and Risk of Clinical Events in Patients With Cancer Therapy-Related Cardiac Dysfunction	2024	Avula V, Sharma G, Pasbaksh MH, et al.	To evaluate SGLT2i use in patients with established CTRCD and T2DM on GDMT	TriNetX retrospective study; N=1,280 (640/group) after PSM; patients with non-ischemic cardiomyopathy post-chemotherapy	Reduction in HF exacerbation (OR 0.55), mortality (OR 0.25); hospitalizations and ER/Ambul. no increase in renal injury
6	SGLT2 Inhibitors Improve Clinical Outcomes in Patients With T2DM Undergoing Anthracycline-Containing Chemotherapy	2023	Hwang HJ, Kim M, Jun JE, Yun DK	To evaluate whether SGLT2i improve clinical outcomes in patients with T2DM receiving anthracycline chemotherapy	Emulated target trial; Korean national cohort; N=61,972; 779 SGLT2i vs 7,809 non-DM vs 2,337 non-SGLT2i after PSM	Composite outcome (HF, MI, stroke, death): HR 0.33 vs non-DM; HR 0.47 vs non-SGLT2i
7	SGLT2 Inhibitors Mitigate Cardiorenal Toxicity and Improve Survival in T2DM Patients Undergoing Antineoplastic Therapy	2025	Zhao Y, Zhang T, Ji M, Liu Y	To evaluate effects of SGLT2i on cardiorenal toxicity and survival in Asian patients with T2DM and cancer	Multicenter retrospective study; N=248 (134/group); mean follow-up: 20.4 months	CV events: OR 0.138 (-86.1%); mortality: HR 0.132 (-86.7%); preservation of LVEF and renal function
8	Effect of Dapagliflozin on Calcium-Handling Protection, Myocardial and Renal NF-κB Expression	2024	ASCO 2026 Abstract e24012	To investigate whether dapagliflozin improves cardiac function and reduces pro-inflammatory pathways in preclinical models	Preclinical study; 24 C57BL/6 mice (4 groups of 6); 10-day treatment with DOXO ± DAPA	DAPA preserved EF and strain; reduced NLRP-3, MyD-88, IL-1β, IL-6, TNF-α, troponin-T and BNP
9	Effect of Dapagliflozin on Systemic miRNA and Monocyte-Lymphocyte Ratio in Preclinical Models	2024	ASCO 2026 Abstract e24012	To evaluate novel biomarkers of dapagliflozin cardioprotection in doxorubicin cardiotoxicity	Preclinical study; 24 C57BL/6 mice (4 groups of 6); 10-day treatment	DAPA reduced miPAB-P by 48.7% and monocyte/lymphocyte ratio by 32.8% vs DOXO (p<0.05)
10	Cardio-Renal and Systemic Effects of SGLT2i Dapagliflozin on Short-Term Anthracycline and HER2-Blocking Agent Therapy-Induced Cardiotoxicity	2025	Guglielmini V, Di Mauro A, Ferrara G, et al.	To investigate cardioprotective role of dapagliflozin in DOXO + anti-HER2 cardiotoxicity model	Preclinical study; C57BL/6 mice (4 groups); 10-day treatment; echocardiography and biomarkers	DAPA preserved EF, reduced strain, NLRP3, MyD88, NFkBP, troponin-T, MDA, 4-HNE, BNP and hs-CRP
11	Doxorubicin-Induced Cardiotoxicity and the Emerging Role of SGLT2 Inhibitors: From Glycemic Control to Cardio-Oncology	2025	Goja ID, Goja G, Ondeck VL, et al.	To explore the interaction between anthracycline therapy and cardiotoxicity, evaluating SGLT2i as agents in cardio-oncology	Narrative review of literature on DOX cardiotoxicity mechanisms and pleiotropic effects of SGLT2i	SGLT2 attenuate CTRCD via mitochondrial preservation, apoptosis inhibition, reduce HF hospitalizations and CV mortality
12	Sodium-Glucose Cotransporter 2 Inhibitors During Cancer Therapy: Benefits, Risks, and Ongoing Clinical Trials	2024	Ganapathi R, Abdel-Qadir H, Zelkovska AM, Bonneau A	To summarize data on SGLT2i use to ameliorate cardiotoxicity prevention in patients receiving anthracyclines	Narrative review; discussion of proposed mechanisms and ongoing clinical trials	Emerging evidence from basic and observational studies supports role of SGLT2i; RCTs needed for confirmation

CARDIOVASCULAR RISK RECLASSIFICATION IN PATIENTS WITH MULTIPLE MYELOMA: COMPARISON BETWEEN THE PREVENT SCORE AND A NOVEL PREDICTIVE MODEL

ANA BEATRIZ BOMFIM DE ALMEIDA1; JENNIFER DO CARMO SOUZA PINHEIRO1; MARIA EDUARDA FREITAS CARVALHO1; GIOVANA ABREU GUSMÃO DE OLIVEIRA1; JÚLIA ALMEIDA SOUSA PASSOS1; EDVAN DE QUEIROZ CRUSOE1;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Patients with multiple myeloma (MM) are at increased cardiovascular risk, particularly due to treatment-related cardiotoxicity. Although the PREVENT score is widely used to estimate cardiovascular risk in the general population, data regarding its ability to identify risk in MM patients remain limited. Given the growing survival of onco-hematologic patients and the increasing impact of cardiovascular complications on prognosis and quality of life, accurate cardiovascular risk stratification has become increasingly relevant in contemporary clinical practice. Objetivos: This study aimed to compare cardiovascular risk estimates obtained with the PREVENT score and a novel predictive model in patients with MM. Métodos: This retrospective observational study included 12 patients diagnosed with MM treated at a tertiary referral hospital in Bahia, Brazil. Cardiovascular risk was initially estimated using the PREVENT score and subsequently reassessed with a novel predictive model. Descriptive analyses and assessment of normality using the Shapiro-Wilk test were performed. As the data showed a non-parametric distribution, paired comparisons between models were conducted using the Wilcoxon signed-rank test, with $p < 0.05$ considered statistically significant. Resultados e Conclusões: A total of 12 patients were evaluated. An overall increase in estimated cardiovascular risk was observed after application of the novel model, with a mean score of 19.23 (± 23.74) for baseline PREVENT versus 30.78 (± 22.72) for the new score. Risk values ranged from 9.64 to 46.24 with baseline PREVENT and from 11.62 to 46.31 with the novel model, indicating a trend toward reclassification into higher-risk categories. An individual increase in estimated cardiovascular risk was observed in 83.3% of patients (n = 10). Shapiro-Wilk analysis confirmed non-parametric distribution ($p < 0.001$). Paired comparison demonstrated a trend toward higher cardiovascular risk estimates with the novel model, although without statistical significance ($z = -1.883$; $p = 0.064$). Patients with MM showed higher cardiovascular risk estimates with the novel predictive model compared with the PREVENT score, with individual risk increases observed in 83.3% of the sample. These findings suggest that the PREVENT score may underestimate treatment-related cardiovascular risk in this population and highlight the need for more specific cardiovascular risk stratification tools for onco-hematologic patients. Larger studies are needed to validate these findings.

CARDIOVASCULAR SAFETY AND TOLERABILITY OF TRASTUZUMAB DERUXTECAN IN HER2-POSITIVE BREAST CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

STELLANNY CILENE RODRIGUES CASTRO1; ADRIELLE BARBOSA MARTINS1; LUÍS HENRIQUE CIRQUEIRA DA SILVA1; DILMA DO SOCORRO MORAES DE SOUZA2;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (2) FUNDACAO HOSPITAL DE CLINICAS GASPAR VIANNA PA - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Breast cancer (BC) remains one of the most prevalent malignancies among women, with the HER2-positive (HER2+) subtype requiring specific targeted therapies. Trastuzumab deruxtecan has emerged as a highly effective treatment for this population, significantly improving oncological outcomes. However, emerging clinical reports have raised concerns regarding its cardiovascular safety profile. Given the potential for treatment-induced cardiotoxicity, a comprehensive evaluation of its adverse effects on cardiac function and overall therapy tolerability is clinically imperative. Objetivos: To evaluate the cardiovascular safety and clinical tolerability of trastuzumab deruxtecan in patients with HER2-positive breast cancer, specifically focusing on the reduction of left ventricular ejection fraction (LVEF) and treatment discontinuation rates associated with adverse events. Métodos: A systematic review was conducted across Embase, PubMed, and Cochrane databases, adhering to PRISMA guidelines. We included randomized controlled trials (RCTs) comparing trastuzumab deruxtecan against standard-of-care treatments for HER2+ BC. Safety outcomes analyzed included LVEF reduction and therapy discontinuation due to adverse events. Effect sizes were expressed as Risk Ratios (RR) with 95% Confidence Intervals (CI), utilizing a random-effects model. Heterogeneity was assessed using the I^2 statistic. Resultados e Conclusões: Three randomized controlled trials were included, totaling 1,656 patients (928 in the trastuzumab deruxtecan group and 728 in the control group). Meta-analysis revealed a significantly higher incidence of LVEF reduction in the intervention group (RR: 5.73; 95% CI: 1.51-21.78; I2 = 33%). Additionally, a twofold increase in treatment discontinuation due to adverse events was observed (RR: 2.11; 95% CI: 1.54-2.89; I2 = 0%). While the efficacy of trastuzumab deruxtecan is well-documented, these results highlight a critical impact on treatment tolerability and cardiac safety. In conclusion, the use of this therapy is associated with a marked increase in cardiovascular adverse events. These findings underscore the necessity for rigorous cardiological monitoring and the implementation of standardized surveillance protocols during treatment to mitigate cardiotoxicity risks in clinical practice.

CLINICAL PHENOTYPE OF WOMEN WITH BREAST CANCER UNDERGOING CHEMOTHERAPY: ANALYSIS OF THE PREVALENCE OF SYMPTOMS SUGGESTIVE OF HEART FAILURE IN A REFERRAL HOSPITAL

DAYANNA GONÇALVES CAETANO1; MARIANA SOUZA TAVARES1; MANNUELLY FERNANDA PAULINO DE FIGUEIREDO1; MAYARA DOS SANTOS CAMÊLO MOREIRA1; BEATRIZ AMORIM ATTANÁZIO1; PEDRO HENRIQUE MARQUES DA NÓBREGA1; BIANCA SOUSA ALVES1; MATHEUS HENRIQUE OLIVEIRA DA NÓBREGA1; ANA SILVIA SUASSUNA CARNEIRO LÚCIO1; FABIANA MEDEIROS DE BRITO1; ANA BEATRIZ LUCENA MARCOLINO1; ALINNE BESERRA DE LUCENA1;

(1) AFYA - FACULDADE DE CIENCIAS MEDICAS DA PARAIBA - CABEDELO - PB - BRASIL;

Introdução/Fundamentos: Breast cancer is the leading cause of morbidity and mortality among women in Brazil, representing a major public health concern. In this context, complications associated with chemotherapy, particularly those related to cardiovascular health, significantly contribute to increased mortality rates in this population. Therefore, clinical monitoring and early detection of signs and symptoms may serve as essential tools for timely intervention and reduction of treatment-related complications. Objetivos: To evaluate the prevalence of symptoms suggestive of heart failure (HF) and their association with cardiovascular risk factors in women with breast cancer. Métodos: This is a cross-sectional, analytical, and descriptive study conducted with 39 women diagnosed with breast cancer and followed at a referral hospital in Paraíba, Brazil. Sociodemographic data, cardiovascular risk factors, and self-reported symptoms suggestive of HF (dyspnea, orthopnea, fatigue, and lower limb edema) were assessed through questionnaires, medical records, and interviews. A “clinical congestion phenotype” was defined as the presence of at least one congestive symptom. Descriptive and exploratory analyses were performed using SPSS. The study was approved by the Research Ethics Committee (CAAE: 92273025.4.0000.5178), and all participants provided informed consent. Resultados e Conclusões: A total of 39 women with breast cancer were evaluated, with a mean age of 52.6 years and a mean body mass index (BMI) of 29.3 kg/m². A high prevalence of cardiovascular risk factors was observed, including hypertension (41.0%; n = 16), dyslipidemia (40.0%; n = 12), and obesity (42.4%; n = 14). Smoking and alcohol consumption were reported by 30.8% of participants (n = 12), while 51.3% were physically inactive (n = 20). Regarding symptoms suggestive of heart failure, a high frequency of dyspnea (30.8%; n = 11), orthopnea (69.4%; n = 25), and lower limb edema (44.4%; n = 16) was observed, whereas fatigue was reported by 66.7% of patients (n = 26). Most participants presented at least one symptom, characterizing a clinical congestion phenotype. The high prevalence of symptoms suggestive of heart failure, combined with a substantial burden of cardiovascular risk factors, may indicate the presence of an underdiagnosed clinical congestion phenotype in women with breast cancer. These findings highlight the need for structured cardiovascular screening strategies within the context of cardio-oncology care.

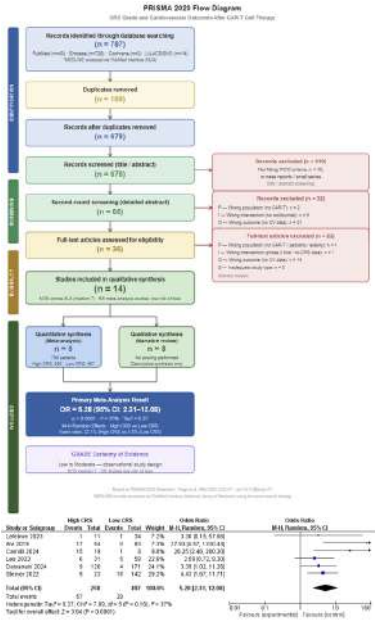
CORTICOSTEROID DOSE AND TIMING IN IMMUNE CHECKPOINT INHIBITOR–ASSOCIATED MYOCARDITIS: A SYSTEMATIC REVIEW WITH STRUCTURED QUALITATIVE SYNTHESIS AND EXPLORATORY META-ANALYSIS

MARINA ISADORA DE ANDRADE LEMOS1; AMANDA ROCHA MORAES RIBEIRO1; RAFAEL NUNES DAHER1; BEATRIZ PIRES MENEGHETTI1; BRUNO CARAMELLI1;

(1) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Immune checkpoint inhibitor–associated myocarditis (ICI-M) has a case fatality rate of up to 50%. Corticosteroids are first-line therapy, yet optimal dose and timing remain undefined. Objetivos: To evaluate whether corticosteroid dose and timing are associated with major adverse cardiovascular events (MACE) and mortality in ICI-M patients, and to quantify this association when possible. Métodos: Systematic search in PubMed (n=110), Embase (n=581), and Cochrane (n=5). After duplicate removal (n=10) and two-stage screening, 7 studies were included. Risk of bias was assessed with the Newcastle–Ottawa Scale (NOS); evidence certainty with GRADE. An exploratory Generic Inverse Variance (GIV) meta-analysis pooled adjusted hazard ratios from comparable studies. Resultados e Conclusões: Seven predominantly retrospective studies (n≈735) were included. Three of four studies with dose data consistently favored high-dose corticosteroids: MACE rates were 22.0% vs. 61.9% (high vs. low dose; HR 0.27, 95%CI 0.09–0.84, p=0.024). Two studies reported timing data: in Zhang 2020 (n=126), MACE was 7.0% with corticosteroid initiation ≤24h vs. 85.1% when initiated >72h from admission (HR 0.03, 95%CI 0.004–0.23, p=0.001); Xie 2022 (n=46) confirmed the timing effect on overall survival (log-rank p=0.038). The exploratory GIV meta-analysis (n=236; 2 studies) yielded a pooled HR of 3.80 (95%CI 1.67–8.65, p=0.001) for low vs. high dose, with no heterogeneity (I^2=0%). GRADE certainty was Low for all comparisons. Together, available observational evidence consistently associates high-dose corticosteroids and early initiation (≤24h) with reduced MACE and mortality in ICI-M.



16837

CRS GRADE AS AN INDEPENDENT PREDICTOR OF CARDIOVASCULAR OUTCOMES AFTER CAR-T CELL THERAPY AND SUPPORTING EARLY TOCILIZUMAB AS A CARDIOPROTECTIVE STRATEGY: A SYSTEMATIC REVIEW AND META-ANALYSIS

AMANDA ROCHA MORAES RIBEIRO1; MARINA ISADORA DE ANDRADE LEMOS1; RAFAEL NUNES DAHER1; BRUNO CARAMELLI2;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: CAR-T cell therapy induces cytokine release syndrome (CRS), an IL-6-driven inflammatory response associated with myocardial injury and endothelial dysfunction. Tocilizumab is standard-of-care for CRS grade ≥2; however, the impact of CRS severity on cardiovascular outcomes and the cardioprotective role of tocilizumab timing remain incompletely explored Objetivos: To evaluate the association between CRS grade and cardiovascular adverse events in CAR-T recipients and to explore tocilizumab timing as a hypothesis-generating secondary endpoint Métodos: Systematic search across PubMed (n=43), Embase (n=728), Cochrane CENTRAL (n=2), and LILACS/BVS (n=14) totaling 787 records; 109 duplicates removed. After two-stage screening, 14 studies were included. Cardiovascular toxicity was defined as any clinically relevant adverse event, from strict MACE to broader composites (arrhythmia, HF decompensation, LVEF decline). High-grade CRS: grade ≥2; low-grade: grade 0–1 (Lee 2014/ASTCT 2019). Random-effects Mantel-Haenszel meta-analysis was performed on extractable comparative data; methodological quality by NOS; certainty of evidence per GRADE. Resultados e Conclusões: Of 14 included studies, 6 contributed to meta-analysis (n=755; high-grade CRS: n=258; low-grade: n=497). NOS scores: 6–8 (median 7); 5/6 studies with low risk of bias. High-grade CRS was associated with over 5 fold higher odds of cardiovascular toxicity (OR 5.28; 95% CI 2.31–12.08; p<0.0001; I^2=37%), with absolute event rates of 22.1% vs. 5.8%. Despite more frequent tocilizumab use in high-grade CRS, event rates remained markedly elevated, consistent with confounding by indication and suggesting that IL-6 blockade after CRS escalation may be insufficient to fully prevent myocardial injury, suggesting that earlier IL-6 blockade, before CRS escalation, may be needed. Troponin elevation emerged as a key early biomarker across qualitative synthesis. GRADE certainty was low-to-moderate, reflecting observational design. These findings support prospective trials evaluating earlier tocilizumab initiation as a cardioprotective strategy in high-risk CAR-T recipients.

ECHOCARDIOGRAPHIC ASSESSMENT OF CHEMOTHERAPY-INDUCED LEFT VENTRICULAR DIASTOLIC DYSFUNCTION - BEYOND EJECTION FRACTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

MARCEL FELIPE ALVES1; ANA PAULA DELUCA1; ISABELA LAMIN KLEGIN1; CAROLINE OLIVEIRA FISCHER-BACCA1;

(1) UNIDAVI - CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL;

Introdução/Fundamentos: With newer cancer therapies and improved survival, the incidence of cancer-therapy induced cardiotoxicity (CTRCD) is increasing. Systolic dysfunction is more frequently assessed than diastolic dysfunction, and while it is widely recognised that left ventricular (LV) systolic heart failure assessment is key in chemotherapic-treated patients, less is known about the relevance of LV diastolic functional impairment. Objetivos: We aimed to conduct a systematic review and meta-analysis evaluating diastolic parameters in CTRCD patients. Métodos: PubMed, Embase, and Cochrane databases were systematically searched for studies evaluating LV diastolic parameters before and after cancer treatment. The protocol was prospectively registered in PROSPERO (CRD420261288754). Analyses were conducted using R software. Pooled mean differences (MDs) were calculated using a random-effects model. Sensitivity analyses with correlation coefficients (r) of 0.3, 0.5, and 0.7 showed consistent results; therefore, r = 0.5 was adopted for the primary analysis. Heterogeneity was assessed using the I^2 statistic, and subgroup analyses were performed to explore possible sources. Resultados e Conclusões: A total of 41 studies including 2.923 patients were analyzed, of whom 85.5% were women and 70.8% were diagnosed with breast cancer, with a mean age of 50.49 ± 11.02 years. After chemotherapy, changes in diastolic parameters were significantly observed, including a decrease in E/A ratio (MD = -0.09 [95% CI: -0.13, -0.05]; p < 0.0001, e' mean velocity (MD = -0.84 cm/s [95% CI: -1.28, -0.39]; p < 0.0001, along with an increase in deceleration time (MD = 5.24 [95% CI: 0.75, 9.72]; p < 0.0001 and E/e' ratio (MD = 0.41 [95% CI: 0.04, 0.78]; p < 0.0001. Conclusion: Echocardiographic findings suggest early alterations in diastolic function after chemotherapy exposure. Further longitudinal studies are needed to confirm these findings and clarify their potential role as early markers of CTRCD.

19507

EFFECTS OF SACUBITRIL/VALSARTAN IN THE PREVENTION OF ANTHRACYCLINE CARDIOTOXICITY: A SYSTEMATIC REVIEW

RAFAEL CARRARO DE REZENDE1; JOÃO PAULO CALEGARO SALVARANI1; PEDRO ARTHUR PAZDZIORNY PADILHA1; MARSELHA MARQUES BARRAL MONTESSI1;

(1) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL;

Introdução/Fundamentos: Anthracyclines are among the most widely used chemotherapeutic agents; however, they are associated with undesirable cardiotoxic effects, notably a reduction in left ventricular ejection fraction (LVEF) and heart failure (HF) onset. In a recent meta-analysis, sacubitril/valsartan (SV) was able to improve functional capacity in patients with cancer therapy-induced HF. Hence, new clinical trials were conducted to assess whether this drug could also prevent cardiotoxicity in patients undergoing anthracycline therapy (AT). Objetivos: To verify the effectiveness of SV in preventing cardiotoxicity in patients undergoing AT. Métodos: Randomized controlled clinical trials published in the last five years, in English, encompassing cancer patients who initiated AT, with no prior heart failure or cardiac dysfunction -- i.e., baseline LVEF ≥ 50%, assessed by cardiac magnetic resonance imaging (CMR) or echocardiography, or normal left ventricular global longitudinal strain (LVGLS), as well as no prior or current HF standard pharmacological treatment --, were included in the review. Studies not meeting these criteria were excluded. The outcomes analyzed were a decrease in LVEF ≥ 5%, assessed by CMR or echocardiography, and a decrease in LVGLS ≥ 15%. Initial research was conducted in MEDLINE using the entry terms "sacubitril/valsartan", "cardiotoxicity", and "anthracycline". The PRISMA 2020 checklist was used to systematize the review. Resultados e Conclusões: Three studies were included, comprising 352 patients, of whom 328 (93.2%) were women with breast cancer, and 151 (42.9%) were assigned to receive SV. The SARAH trial showed that a reduction in LVGLS ≥ 15% occurred in 7.1% of patients assigned to SV and in 25% of patients assigned to placebo (OR 0.23; 0.07–0.75, p = 0.015). A significant difference in LVEF decrease between the groups was observed when assessed by CMR (p = 0.011), but not by echocardiography. In the PRADA II trial, decrease in LVEF ≥ 5% assessed by CMR was not attenuated by SV when compared to placebo, but worsening in LVGLS was prevented by it (MD −0.9; −1.5 to −0.2). In another trial, 26.3% of patients in the control group showed a decline in LVGLS ≥ 15%, which did not occur in any patient in the SV group (p = 0.006). Therefore, in patients undergoing AT, SV attenuated the decrease in LVGLS, but such effect was not observed with respect to LVEF. More clinical trials are needed to confirm the potential cardioprotective effect of SV in these patients.

EFFICACY OF SACUBITRIL-VALSARTAN ON CHEMOTHERAPY-INDUCED CARDIOTOXICITY IN ONCOLOGY PATIENTS: A SYSTEMATIC REVIEW AND BAYESIAN META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

SOPHIA GOUVEIA DAMASCENO1; LEANDRO CORREIA CASTANHO2; MIGUEL OLIVEIRA ENTRINGE2; MARIA LUIZA BENTIVI MACHADO2; MARINA VINAGRE PIRES2; FLÁVIA SOEIRO SALGADO2; EDSON GABRIEL SANTOS NASCIMENTO2; LETHYCIA SANTANA DE ARAÚJO CASTRO1; ISABELA DE CASTRO FROTA LIMA2; GIORDANA TEIXEIRA DA SILVA PROFETI3; GIOVANNA BARCELOS FONTENELE PEREIRA3;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (3) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Chemotherapy-induced cardiotoxicity represents a significant complication in the management of oncology patients, potentially leading to subclinical ventricular dysfunction and heart failure. In this context, sacubitril–valsartan, an angiotensin receptor–neprilysin inhibitor (ARNI), has emerged as a promising cardioprotective strategy, particularly for preserving myocardial function assessed by sensitive parameters such as Global Longitudinal Strain (GLS). Objetivos: To evaluate the efficacy of sacubitril–valsartan versus control in reducing cardiotoxic outcomes in cancer patients undergoing chemotherapy. Métodos: A systematic review was conducted in accordance with the PRISMA 2020 checklist. PubMed, Cochrane Library, Embase, and Web of Science databases were searched to identify full-text randomized controlled trials (RCTs) comparing sacubitril–valsartan versus control (placebo, standard care, or no treatment) in cancer patients receiving chemotherapy. The primary outcome was the change in baseline Global Longitudinal Strain. Statistical analysis was performed using R software (version 4.4.3), applying a Bayesian random-effects meta-analysis model to estimate mean difference (MD), with 95% credible intervals (CrI) and posterior probability of benefit (MD < 0), using weakly informative priors. Risk of bias was assessed using the RoB 2.0 tool. Resultados e Conclusões: Four RCTs were included, comprising 405 patients treated with sacubitril–valsartan and 231 controls. The ARNI significantly improved GLS, with a pooled MD of −0.94 (95% CrI: −1.61 to −0.26). The posterior probability of benefit (MD < 0) was 99.6%, indicating high confidence in the positive clinical effect of ARNI on myocardial strain. Between-study heterogeneity was negligible (I^2 = 0%; Tau^2 = 0; p = 0.88), suggesting a consistent effect across studies. Overall risk of bias was rated as low (n=2) to moderate (n=2). Sacubitril–valsartan demonstrated a significant benefit in preserving GLS in patients undergoing chemotherapy, with a high probability of positive effect and low heterogeneity across studies. These findings support its potential as a cardioprotective strategy in this setting, although additional RCTs are needed to further establish its clinical application.

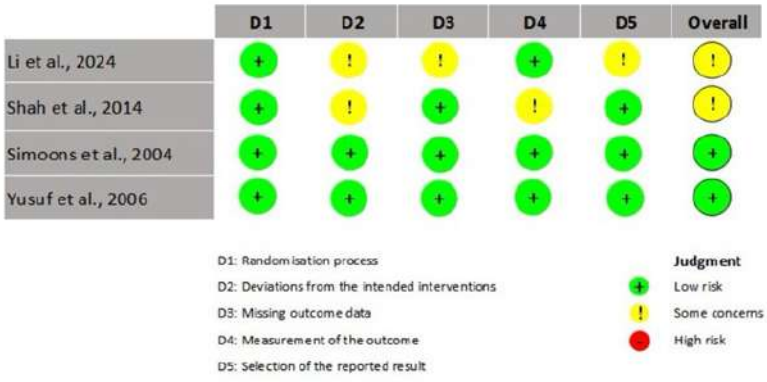
FRAILTY IN OLDER PATIENTS WITH HEMATOLOGIC MALIGNANCIES: PREVALENCE AND ITS ASSOCIATION WITH SYSTEMIC ARTERIAL HYPERTENSION

ANA FLÁVIA FURTADO TELES1; NIELE SILVA DE MORAES1; LUIZA DA PAZ DE SOUZA1; CAUÃ LEAL DO ESPÍRITO SANTO1; KAROLINA DO ESPÍRITO SANTO PINGARILHO1; GRETA EVELIN DA SILVA MOTA1; VITÓRIA CAMPOS CORDEIRO1; THIAGO XAVIER CARNEIRO1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: The convergence of population aging, hematologic malignancies, and cardiovascular comorbidities represents one of the most challenging paradigms in contemporary medicine. Within this context, frailty has emerged not merely as a static marker of vulnerability, but as a dynamic determinant of clinical risk, with direct implications for treatment tolerance and outcomes. In cardio-onco-hematology, systemic arterial hypertension deserves particular attention due to its high prevalence and potential contribution to reduced functional reserve in older adults undergoing cancer care. Objetivos: To assess the prevalence of frailty in older adults with hematologic malignancies and to explore the association between systemic arterial hypertension and frailty in this population. Métodos: This was a single-center, cross-sectional, exploratory descriptive study conducted during routine outpatient care at a referral onco-hematology center in Belém, Pará, Brazil. Older adults with hematologic malignancies were evaluated using the FRAIL Scale and the Fried frailty phenotype. Clinical and treatment-related data were obtained from medical records. Frailty prevalence was compared between hypertensive and non-hypertensive patients using Fisher's exact test, with a significance level of 5%. Resultados e Conclusões: A total of 53 older patients with hematologic malignancies were included. Median age was 69 years (range 60–85), and 56.6% were male. The prevalence of systemic arterial hypertension was 62.9% (n=34). The most frequent hematologic diagnoses were lymphoma (32.1%), multiple myeloma (30.2%), and chronic lymphocytic leukemia (26.4%), followed by myelodysplastic syndrome (5.7%) and chronic leukemia (5.7%). Frailty prevalence was 30.2% according to the FRAIL Scale and 49.1% according to the Fried phenotype. Among hypertensive patients, frailty prevalence was 32.4% by FRAIL Scale and 47.1% by Fried criteria, compared with 26.3% and 47.4%, respectively, among non-hypertensive patients. No statistically significant association was observed between hypertension and frailty, either by FRAIL Scale (p=0.76) or Fried phenotype (p=1). Older adults with hematologic malignancies showed a high prevalence of frailty, especially by the Fried phenotype. Systemic arterial hypertension was not associated with increased frailty in this cohort. Findings are limited by small sample size but highlight the importance of routine frailty assessment.

18783



FROM CLINICAL TO SUBCLINICAL DYSFUNCTION: THE EVOLUTION OF TROPONIN-GUIDED CARDIOPROTECTION IN ANTHRACYCLINE TOXICITY

VITÓRIA CAMPOS CORDEIRO1; RODOLFO AUGUSTO DE ALMEIDA JÚNIOR1; ELIEL PEREIRA FAUSTINO NETO1; SOFIA DE ALVARENGA TEIXEIRA1; LUANA KAORI SAKAGUCHI SAKAMOTO1; LEONARDO GOUVÊA DE OLIVEIRA1; ANA FLÁVIA FURTADO TELES1; LUANA NÓBREGA DOS SANTOS1; RENATO GARCIA LISBOA BORGES1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Anthracyclines are fundamental in oncological treatment, but the risk of cardiotoxicity limits patient prognosis. Historically, troponin monitoring enabled prevention strategies focused on preserving the left ventricular ejection fraction (LVEF) during high-toxicity regimens. With the evolution toward contemporary reduced doses, the diagnostic focus has shifted to detecting subclinical myocardial damage, requiring a reevaluation of neurohormonal therapies against novel imaging modalities and high-sensitivity biomarkers. Objetivos: Analyze the historical evolution and efficacy of troponin-guided prophylactic cardioprotection strategies in preventing ventricular dysfunction (clinical and subclinical) in patients treated with anthracyclines. Métodos: A systematic review of randomized controlled trials (RCTs) was conducted according to the PRISMA protocol. The PICO strategy included patients using anthracyclines with troponin elevation undergoing preventive neurohormonal blockade versus control/placebo. Risk of bias was assessed using the Cochrane RoB 2 tool. Qualitative synthesis evaluated outcomes of clinical dysfunction (LVEF drop) and subclinical dysfunction (GLS drop >15%). Due to high clinical and methodological heterogeneity, a meta-analysis was not performed. Resultados e Conclusões: Three RCTs (n=403) were analyzed. The Cardinale study (2006; n=114) showed a high risk of bias (open-label) and demonstrated that enalapril prevented an LVEF drop >10% (0% vs. 43%; ARR=43%; p<0.001). In contemporary settings, the Cardiac CARE trial (2023; n=175) also presented high risk of bias (PROBE design, 31% discontinuation) and found no significant LVEF benefit (mean difference -0.37%; p=0.82). The SARAH trial (2025; n=114), with low risk of bias (double-blind), showed that sacubitril-valsartan significantly reduced GLS decline >15% (7.1% vs. 25%; OR 0.23; 95% CI 0.07–0.75; ARR=18%; p=0.015). Evidence demonstrates that cardioprotective efficacy has evolved alongside diagnostic refinement. While classical ACE inhibitor therapies in open-label studies prevented clinical dysfunction in high-toxicity settings, the methodological rigor of the SARAH trial proves that ARNI is effective in preserving subclinical function (GLS). This consolidates the need for early intervention and sensitive monitoring in contemporary cardio-oncology.

Figure 2. Assessment of the risk of bias in the included studies RoB 2.0.

GLOBAL LONGITUDINAL STRAIN VERSUS LEFT VENTRICULAR EJECTION FRACTION FOR EARLY DETECTION OF IMMUNE CHECKPOINT INHIBITOR-INDUCED CARDIOTOXICITY: A SYSTEMATIC REVIEW

ANNA THEREZA ROCHA PEREIRA1; LAURA SUAVEK GRANEMANN2; LAUREN ZIMMER MARTINS3; RENATA DE SOUSA VINHAL4; GUSTAVO FRANKENSTEIN MARTINS5; JOSÉ CARLOS BRUNETTI FILHO6; GEAN GIMENES MOURA6; REBECA SOARES ALMEIDA7; MATHEUS FEITOSA DE AZEVEDO8; VINÍCIUS AUGUSTUS BARUSSO BELEZE9;

(1) PONTIFÍCIA UNIVERSIDADE CATÓLICA DO PARANÁ - LONDRINA - PR - BRASIL; (2) UNIVERSIDADE POSITIVO - CURITIBA - PR - BRASIL; (3) UNIVERSIDADE DO PLANALTO CATARINENSE - LAGES - SC - BRASIL; (4) CENTRO UNIVERSITÁRIO TOCANTINENSE PRESIDENTE ANTÔNIO CARLOS-UNITPAC - ARAGUAÍNA - TO - BRASIL; (5) CENTRO UNIVERSITARIO SAO CAMILO - GUARULHOS - SP - BRASIL; (6) MULTIVIX - CACHOEIRO DE ITAPEMIRIM - ES - BRASIL; (7) UNIVERSIDADE FEDERAL DO OESTE DA BAHIA (UFOB) - BARREIRAS - BA - BRASIL; (8) UNIVERSIDADE ESTADUAL PAULISTA JÚLIO DE MESQUITA FILHO (UNESP) - BOTUCATU - SP - BRASIL; (9) UNIVERSIDADE ESTADUAL DE LONDRINA (UEL) - LONDRINA - PR - BRASIL;

Introdução/Fundamentos: Immune checkpoint inhibitors (ICIs) are used to treat a variety of cancers, however cardiotoxicity, defined by a relative Global Longitudinal Strain (GLS) reduction of of ≥15% or asymptomatic decrease in Left ventricle Ejection Fraction (LVEF) of ≥10% to <55%, may occur during the treatment. In the spectrum of cardiovascular events that can happen, myocarditis is the most common. Using imaging methods to evaluate cardiotoxicity is essential for early assessment of dysfunction before significant reduction of the ejection fraction or major clinical events. To detect abnormalities in echocardiography, advanced options like GLS or conventional LVEF can be used. Objetivos: The objective of this study is to compare the temporal sensitivity of GLS and LVEF for the early detection of subclinical ICI-induced cardiotoxicity. Métodos: This is a systematic review conducted in accordance with PRISMA guidelines using PubMed and Embase. Studies (2021–2026) evaluating GLS and/or LVEF for early detection of cardiotoxicity in adult cancer patients treated with immune checkpoint inhibitors were included. The primary outcome was early detection of cardiotoxicity before LVEF reduction or major clinical events. Screening and data extraction were performed by three independent reviewers. Of 356 records, 36 studies were included. Resultados e Conclusões: GLS detects ICI-induced cardiotoxicity significantly earlier than LVEF. A relative GLS reduction of ≥15% occurred at a median of 14 days, whereas LVEF decline was a late finding, manifested at a median of 109 days. Notably, LVEF remained preserved during the subclinical phase (e.g., 66 ± 6% vs. 65 ± 5%, p=0.493). Conversely, GLS shows significant early reductions (e.g., -12.8 ± 3.2% vs. -16.6 ± 1.9%, p=0.028) despite normal LVEF, successfully identifying subclinical dysfunction. A strong negative correlation exists between GLS and LVEF (r = -0.64; p<0.002). Furthermore, GLS deterioration is an independent predictor for Major Adverse Cardiovascular Events (MACE). While biomarkers predict adverse outcomes, they frequently present asymptomatic elevations that cause diagnostic ambiguity. Consequently, GLS is demonstrably superior to LVEF for the early detection of subclinical myocardial injury. Integrating GLS with clinical screening and biomarkers maximizes diagnostic accuracy and risk stratification by combining biochemical alerts with mechanical sensitivity. Ultimately, this approach guides timely cardioprotective interventions long before LVEF declines.

17680

HIGH-SENSITIVITY TROPONIN I AS A PREDICTOR OF EARLY SUBCLINICAL MYOCARDIAL INJURY IN BREAST CANCER PATIENTS: A PROSPECTIVE STUDY

KARLA VASCONCELOS1; NAIRA SANTOS D'AGOSTINI2; LETÍCIA BATISTA AZEVEDO2; JONATHAN GRASSI2; MARINA MARINA CARLETTO3; KAROLINI ZUQUI NUNES2; LUÍS CARLOS LOPES-JÚNIOR2;

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (2) UNIVERSIDADE FEDERAL DO ESPIRITO SANTO - VITÓRIA - ES - BRASIL; (3) FUNDACAO TECNICO EDUCACIONAL SOUZA MARQUES - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Cardiotoxicity is a critical factor limiting the prognosis of breast cancer patients. While risk stratification typically relies on oncological staging and the type of chemotherapy, these conventional parameters often fail to identify subclinical myocardial injury in its earliest, most reversible stages. High-sensitivity cardiac Troponin I (hs-TnI) has emerged as a potential biomarker for detecting microscopic cardiac damage before the onset of functional changes. Objetivos: To investigate the longitudinal dynamics of hs-TnI during chemotherapy and evaluate whether conventional oncological risk factors (tumor stage and cardiotoxicity profile of the regimen) are associated with biomarker elevation. Métodos: We conducted a prospective cohort study of 48 women with histopathologically confirmed breast cancer (ICD-10 C50, stages I–III). Patients underwent serial biomarker assessment: at baseline (QT1) and after six chemotherapy cycles (QT6). Staging was categorized into early vs. locally advanced, and chemotherapy regimens were stratified by cardiotoxic potential (High-risk: anthracyclines/monoclonal antibodies vs. Lower-risk: taxanes/platinum). Statistical analysis employed the Wilcoxon signed-rank test for longitudinal changes and Fisher's exact/Mann-Whitney U tests for group comparisons (α=5%). Resultados e Conclusões: A significant longitudinal increase in hs-TnI levels was observed from QT1 to QT6 ($p < 0.001$). By the end of treatment (QT6), 12.5% (5/40) of the evaluable patients reached hs-TnI levels above the assay-specific threshold for myocardial injury. Crucially, this elevation was not associated with baseline tumor stage ($p = 0.845$) or the cardiotoxicity classification of the chemotherapy regimen ($p = 0.113$). No other clinical or sociodemographic variables analyzed in the baseline demonstrated a significant association with the development of subclinical injury. Conclusion: Chemotherapy induces significant subclinical myocardial injury that is independent of traditional oncological risk factors and drug classifications. These results suggest that current stratification models may underrepresent the risk of cardiac damage in certain patients. Our findings reinforce the need for universal, biomarker-based monitoring strategies in cardio-oncology to ensure early detection and personalized cardioprotective interventions.

Table 1: Clinical Profile and Distribution of Risk Factors (N=48)

Variable	Statistics (N=48)
Age (years), Mean ± SD	53.4 ± 11.6
Staging, n (%)	
Early Stages (I and II)	27 (56.25%)
Locally Advanced (Stage III)	21 (43.75%)
Cardiotoxicity Risk Profile, n (%)	
High Risk	41 (85.42%)
Low Risk	7 (14.58%)

Table 2: hs-TnI Evolution and Association Analysis (QT1 vs. QT6)

Biomarker Analysis	Pre-Chemo (QT1)	Post-6 Cycles (QT6)	p-value
hs-TnI Elevation, n (%)	0 (0%)	5 (12.5%)	< 0.001*
Associations with hs-TnI at QT6		**p-value**	
Tumor Stage (Early vs. Advanced)		0.845	
Cardiotoxicity Profile (High vs. Low)		0.113	

*Significant longitudinal change ($p < 0.05$). All data extracted from the study cohort and analyzed via R software.

IMPACT OF TIME TO TOCILIZUMAB ADMINISTRATION ON CARDIOVASCULAR EVENTS ASSOCIATED WITH CYTOKINE RELEASE SYNDROME IN CAR-T CELL THERAPY: A SYSTEMATIC REVIEW

LUCAS MARINHO REIS DA CUNHA SILVA1; BRUNO DE FREITAS SILVA1; THIAGO VITTOR SILVA FREITAS1; RAFAEL ALVES DE OLIVEIRA1; RODRIGO BOTTURA NUEVO VIVEIROS DE ARAUJO1; LEONARDO COCHARRO PRETO1; LUCAS RODRIGUES SANTA RITA1; JADSON FERREIRA DA SILVEIRA1; VALÉRIA SILVEIRA DIAS1; EDGAR DE PAULA LADEIA FILHO1; DEISE JANIELLY PEREIRA MELO ARAÚJO1; RAFAEL ALVES PINA1;

(1) UNIVERSIDADE BRASIL - FERNANDOPOLIS - SP - BRASIL;

Introdução/Fundamentos: CAR-T cell therapy is associated with cytokine release syndrome (CRS), the primary mediator of cardiotoxicity, manifested as tachycardia, left ventricular dysfunction, arrhythmias, heart failure, and cardiovascular death. Tocilizumab, an IL-6 receptor antagonist approved for the management of severe CRS, has been investigated as a modulator of cardiovascular risk in this context. Objetivos: To systematically evaluate the relationship between time to tocilizumab administration following CRS onset and the occurrence of major adverse cardiovascular events (MACE) in patients undergoing CAR-T cell therapy. Métodos: An electronic search was conducted in the PubMed and Cochrane databases using Boolean operators (AND, OR, NOT) and the following descriptors: (CAR-T cells), (cytokine release syndrome), (cardiotoxicity), and (tocilizumab), encompassing publications from 2016 to 2026. Of the 243 records identified, duplicates, reviews, case reports, theses, and studies published in languages other than English were excluded. Following double-blind screening by title and abstract, succeeded by full-text review, 6 studies were prioritized for directly addressing predictive mechanisms and prevention strategies. Data were systematically extracted according to the PRISMA protocol and meticulously tabulated, categorizing: study design, protocols, patient populations, adverse events, and predictive factors. Resultados e Conclusões: CRS occurred in 59–93% of patients, with troponin elevation in 54% of tested cases and reduction in left ventricular ejection fraction (LVEF) in 28%. MACE were observed in 12–21% of patients, exclusively among those with grade ≥2 CRS. The risk of cardiovascular events increased 1.7-fold for every 12-hour delay in tocilizumab administration following CRS onset. Early administration protocols (grade 1 CRS persisting for >24 hours) were associated with 12-month MACE rates of 10%, compared with higher rates observed in late-intervention protocols. In 95% of cases involving MACE, prior troponin elevation was documented. Time to tocilizumab administration is a modifiable factor associated with cardiovascular risk in CAR-T cell therapy. Troponin is regarded as a sentinel biomarker for the early identification of high-risk patients. Institutional protocols for cardiac monitoring and early tocilizumab intervention are essential in contemporary cardio-oncology practice.

PERFORMANCE OF THE HFA-ICOS RISK SCORE FOR PREDICTING ANTHRACYCLINE-RELATED CARDIOTOXICITY IN A BRAZILIAN COHORT OF BREAST CANCER PATIENTS

SOFIA FRANKL1; GIULIA EIMI RAMOS ARIMA1; LUCAS FERNANDO URATANI1; RAPHAEL HENRIQUE DÉA CIRINO1;

(1) UNIVERSIDADE FEDERAL DO PARANÁ - CURITIBA - PR - BRASIL;

Introdução/Fundamentos: Anthracyclines are essential in breast cancer treatment but carry a risk of cardiotoxicity, leading to cardiac dysfunction and increased mortality. Early risk stratification is vital to minimize cardiovascular complications while optimizing cancer care. The HFA-ICOS risk score, proposed by the European Society of Cardiology (ESC), stratifies patients for cardiotoxicity risk, but its performance in non-European populations remains underexplored. Differences in cardiovascular risk profiles and healthcare infrastructure may influence its predictive accuracy, necessitating further validation in distinct populations. Objetivos: To evaluate the applicability, calibration, and accuracy of the HFA-ICOS risk score for predicting cardiotoxicity in a Brazilian cohort of breast cancer patients. The study also aims to compare cardiotoxicity incidence across risk groups and assess the association between clinical and oncological variables and cardiotoxicity risk. Métodos: This retrospective cohort study included 211 patients treated with anthracyclines from 2018 to 2023. Data were extracted from medical records. Patients were categorized into risk groups (low, moderate, high, very high) using the HFA-ICOS score. Cardiotoxicity was defined per ESC criteria, including symptomatic heart failure and asymptomatic ventricular dysfunction, assessed by left ventricular ejection fraction, global longitudinal strain, and cardiac biomarkers. Continuous variables were analyzed using ANOVA or Kruskal-Wallis tests, and categorical variables were compared using Fisher's exact test. Resultados e Conclusões: Out of 211 patients, 46.9% were low risk, 45.0% moderate, 7.1% high, and 0.9% very high risk. The overall cardiotoxicity rate was 8.5%, increasing across risk groups: 5.1% in low risk, 9.5% in moderate, and 23.5% in high/very high. The HFA-ICOS score showed good calibration (Hosmer-Lemeshow p = 0.7662) but limited discriminatory accuracy (AUC 0.6373, 95% CI 0.510–0.770). Cardiovascular factors, such as age, hypertension, and diabetes, were significantly associated with higher risk, while oncological variables showed no significant association. These findings highlight that while the HFA-ICOS score is useful for population-level risk estimation, its ability to predict individual cardiotoxicity risk in a Brazilian cohort is limited. The results underscore the need for region-specific predictive models to improve risk stratification and guide clinical decision-making in patients undergoing anthracycline therapy.

QTC PROLONGATION AND ELECTROCARDIOGRAPHIC CHANGES DURING CHEMOTHERAPY IN BREAST CANCER PATIENTS

NAIRA SANTOS D'AGOSTINI1; LETÍCIA BATISTA AZEVEDO1; KARLA VASCONCELOS2; JONATHAN GRASSI1; MARINA MARINA CARLETTO3; KAROLINI ZUQUI NUNES1; LUÍS CARLOS LOPES-JÚNIOR1;

(1) UNIVERSIDADE FEDERAL DO ESPIRITO SANTO - VITÓRIA - ES - BRASIL; (2) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (3) FUNDACAO TECNICO EDUCACIONAL SOUZA MARQUES - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Cardiotoxicity remains a leading cause of morbidity and mortality among women with breast cancer. Early electrophysiological changes often precede cardiac structural damage and are frequently missed by conventional imaging. The corrected QT interval (QTc) is a sensitive marker of electrical instability and increased risk of ventricular arrhythmias; however, prospective data on its dynamics during treatment are still limited. Objetivos: To evaluate and compare electrocardiographic changes, focusing on QTc prolongation, in women with breast cancer before (QT1) and after six chemotherapy cycles (QT6). Métodos: A prospective observational study was conducted with 48 women (≥18 years, stages I–III) at a High Complexity Oncology Center in Brazil. We excluded patients with pre-existing structural heart disease, uncontrolled arrhythmias, incomplete data, or palliative care. Chemotherapy regimens were stratified by cardiotoxic potential: (1) High (anthracyclines and/or monoclonal antibodies) and (2) Lower (taxanes and/or platinum-based, without anthracyclines/antibodies). 12-lead ECGs were performed at QT1 and QT6, analyzing rhythm, heart rate, QRS duration, and QTc (Bazett's formula). Statistical analysis was performed using R software (Shapiro-Wilk, Spearman correlation, and Stuart-Maxwell tests for paired comparisons), adopting a significance level of 5%. Resultados e Conclusões: Mean age was 53.4 ± 11.6 years, and 85.4% of patients were exposed to highly cardiotoxic regimens. A significant increase was observed in the proportion of patients with prolonged QTc, rising from 8.33% at QT1 to 25.0% at QT6 (p=0.039). A trend towards increased irregular heart rhythms was noted (2.08% vs. 12.50%; p=0.082), although not statistically significant. Notably, no association was observed between QTc prolongation and the cardiotoxicity class of the regimens (QT1: p=0.999; QT6: p=0.655), suggesting a generalized electrical effect. QRS duration, ST-segment changes, and T-wave inversion remained stable (p>0.05). Conclusions: Chemotherapy was associated with a significant increase in QTc prolongation, indicating subclinical electrical instability regardless of the traditional cardiotoxicity classification of the drugs. This reinforces the need for systematic ECG monitoring during treatment for early identification of arrhythmic risk and preventive cardio-oncology strategies.

Table 1: Clinical Characteristics and Chemotherapy Risk Stratification (N=48)

Variable	Statistics
Age (years), Mean ± SD	53.4 ± 11.6
Diagnosis, n (%)	
Breast Cancer (ICD-10 C50)	48 (100%)
Clinical Staging, n (%)	
Early Stages (I and II)	27 (56.25%)
Locally Advanced (Stage III)	21 (43.75%)
Chemotherapy Cardiotoxic Potential, n (%)	
High Cardiotoxicity (Anthracyclines/Antibodies)	41 (85.42%)
Lower Potential (Taxanes/Platinum)	7 (14.58%)

Table 2: Longitudinal ECG Evolution and Association Analysis (QT1 vs. QT6).

Electrocardiographic Variable	Pre-Chemo (QT1)	Post-6 Cycles (QT6)	p-value
Prolonged QTc Interval, n (%)	4 (8.33%)	12 (25.00%)	**0.039***
Irregular Heart Rhythm, n (%)	1 (2.08%)	6 (12.50%)	0.082
Wide QRS Complex (>120ms), n (%)	2 (4.17%)	3 (6.25%)	0.807
ST-Segment Changes, n (%)	3 (6.25%)	5 (10.42%)	0.655
T-Wave Inversion, n (%)	12 (25.00%)	11 (22.92%)	0.905
Association: QTc vs. Cardiotoxicity Class			
p-value (Fisher's Exact Test)	0.999	0.655	-

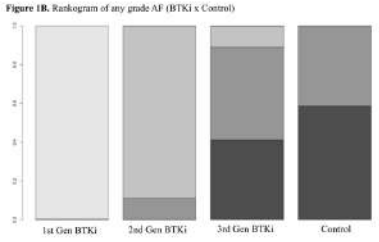
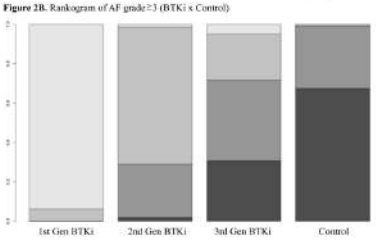
RISK OF ATRIAL FIBRILLATION IN PATIENTS TREATED WITH BRUTON'S TYROSINE KINASE INHIBITORS FOR ONCOHEMATOLOGICAL MALIGNANCIES: AN UPDATED SYSTEMATIC REVIEW AND BAYESIAN NETWORK META-ANALYSIS OF RANDOMIZED CLINICAL TRIALS



CAUÃ ARAUJO DE CARVALHO1; FELIPE GILDO VILELA MIRANDA SANTOS1; DAVI CHAVES ROCHA DE SOUZA1; JOÃO VITOR BENJAMIM PIRES1; JOÃO VICTOR TEIXEIRA COSTA1; PEDRO VITOR DE BRITO FERREIRA1; EDVAN DE QUEIROZ CRUSOE1;



(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Bruton tyrosine kinase inhibitors (BTKi) revolutionized the treatment of patients with B-cell malignancies. However, these drugs have also been associated with a cardiovascular burden, notably atrial fibrillation (AF). New generations of BTKi were developed and have been associated with lower cardiotoxicity. Due to the relationship between BTKi and AF, a thorough review of their associated risk with each generation of BTKi was performed to provide insight into the management of these patients. Objetivos: To compare the risk of AF between patients treated with different BTKi generations for oncohematological malignancies. Métodos: PRISMA guidelines for network meta-analyses were applied. MEDLINE/PubMed, Cochrane and Embase were systematically searched on April 1st, 2026. Randomized clinical trials reporting AF in patients with oncohematological malignancies enrolled for treatment with BTKi were included. Risk of bias was assessed with Cochrane RoB 2 tool and findings were summarized with GRADE assessment. Data were extracted for statistical analysis using Excel and Rayyan software. Heterogeneity (I2), relative risks (RR) with 95% credible intervals (CrI) and surface under the cumulative ranking curve (SUCRA) were calculated in RStudio software. The primary outcome was any grade AF and secondary outcome was AF grade>/=3 Resultados e Conclusões: The systematic search yielded 4.830 studies, of which 32 met the inclusion criteria and were analyzed, including N=14.279 patients. Primary outcome analysis (I2=6%) showed increased risk of any grade AF with 1st generation (ibrutinib) (RR 5.20; 95% CrI 3.83-7.70; SUCRA 0.00) and 2nd generation BTKi (acalabrutinib/zanubrutinib) (RR 2.16; 95% CrI 1.35-3.70; SUCRA 0.37), with no statistically significant risk increase with 3rd generation BTKi (pirtobrutinib) (RR 1.11; 95% CrI 0.43-3.26; SUCRA 0.76) when compared with control (SUCRA 0.86). Secondary outcome assessment (I2=12%) showed increased risk of grade3 AF with 1st generation (RR 4.51; 95% CrI 2.79-8.53; SUCRA 0.02) and 2nd generation (RR 2.16; 95% CrI 1.01-4.33; SUCRA 0.43) BTKi, with no statistically significant risk increase with 3rd generation BTKi (RR 1.42; 95% CrI 0.36-6.76; SUCRA 0.65) when compared with control (SUCRA 0.88). These findings suggest that pirtobrutinib prevails as the lowest AF-risk BTKi, although it remains largely unavailable to most centers. Patients being treated with 1st or 2nd generation BTKi may benefit from regular electrocardiographic screening with a cardio-oncology follow-up team.

SGLT2 INHIBITORS IN THE PREVENTION OF IMMUNE CHECKPOINT INHIBITOR-INDUCED CARDIOTOXICITY IN SOLID MALIGNANCIES: A SYSTEMATIC REVIEW AND META-ANALYSIS

LUÍS FILIPE REZENDE TOMÉ1; GEOVANA DIAS QUEIROZ1; LUCAS RODRIGUES MELLO1; PEDRO CÉSAR REZENDE SEGURADO1; JOÃO NUNES NETO1;

(1) UNIVERSIDADE DE BRASILIA - BRASÍLIA - DF - BRASIL;

Introdução/Fundamentos: Immune checkpoint inhibitor (ICI)-induced cardiotoxicity represents a serious complication, with mortality rates of up to 50% in cases of myocarditis. SGLT2 inhibitors (SGLT2i) possess anti-inflammatory and cardioprotective properties; however, their preventive role in this setting remains uncertain. Objetivos: To evaluate the efficacy of SGLT2i in the prevention of cardiotoxicity in patients with solid malignancies undergoing ICI therapy. Métodos: Systematic review and meta-analysis conducted in accordance with PRISMA 2020. Five databases were searched (PubMed, Embase, Cochrane, Scopus, Web of Science) through May 2026. Studies comparing SGLT2i versus standard of care in adults receiving ICIs (anti-PD-1/L1, anti-CTLA-4) were included. Risk of bias was assessed using ROBINS-I and certainty of evidence using the GRADE framework. Primary outcomes: MACE, cardiovascular mortality, and immune-related myocarditis. Secondary outcomes: HF hospitalization, atrial fibrillation (AF), and all-cause mortality. A random-effects model (DerSimonian-Laird) was applied; heterogeneity was assessed by I² and Cochran Q test. Resultados e Conclusões: Eight studies were included (N≈28,000), predominantly retrospective cohorts with propensity score matching (GRADE Low to Very Low). SGLT2i use was associated with a significant reduction in all-cause mortality [HR 0.55; 95%CI 0.45–0.67; p<0.001; I²=86%], with a marked decrease in heterogeneity in the sensitivity analysis restricted to ICI-specific studies [HR 0.65; 95%CI 0.58–0.72; I²=13%]. Significant reductions were also observed in HF hospitalizations [HR 0.60; 95%CI 0.40–0.91; p=0.016] and AF [OR 0.68; 95%CI 0.54–0.85; p<0.001], with moderate-to-high heterogeneity explored in subgroup analyses. The composite MACE endpoint did not reach statistical significance [HR 0.74; 95%CI 0.38–1.46; p=0.38], given the insufficient number of studies addressing this outcome. Immune-related myocarditis did not differ between groups (0 vs. 2 events, Perelman 2024; RR 1.001, Sabri 2025), with possible underreporting by electronic coding systems. SGLT2i were associated with significant reductions in mortality and cardiovascular complications in patients receiving ICIs. The consistency of the effect in ICI-specific studies supports the plausibility of benefit in this population. Randomized clinical trials are warranted to confirm these findings and establish the role of SGLT2i in cardioprotection in oncoimmunology.

STATINS FOR PREVENTION OF CARDIOTOXICITY IN PATIENTS UNDERGOING ANTHRACYCLINE-BASED CHEMOTHERAPY: AN UPDATED SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

LUCAS ALENCAR QUEIROZ1; MILTON CESAR VASCONCELOS MACHADO JUNIOR1; VICTOR MATHEUS RICARDO TERRA1; RAFAEL DE SOUZA NATIVIDADE LOPES2; ISABELA MARTINS VIANA3; PAULA CORREA NOGUEIRA4;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) FUNDACAO HOSPITAL DE CLINICAS GASPAR VIANNA PA - BELÉM - PA - BRASIL; (3) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (4) HOSPITAL DA MULHER - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Anthracyclines remain a cornerstone of oncology but cause cancer therapy-related cardiac dysfunction (CTRCD) in up to 21% of patients. Statins have pleiotropic antioxidant, anti-inflammatory and endothelial effects that may attenuate this damage, supporting a class IIa recommendation in current cardio-oncology guidelines for high-risk patients. Recent randomized controlled trials (RCTs) yielded conflicting results, leaving the role of statins uncertain. Objetivos: To update a previously published meta-analysis (search through October 2023) by incorporating RCTs published thereafter and estimate the pooled effect of statins on CTRCD and left ventricular function in patients on anthracycline-based chemotherapy. Métodos: PRISMA-compliant systematic review. PubMed, Embase, Cochrane CENTRAL, Web of Science and ClinicalTrials.gov were searched from inception to May 2026. RCTs comparing any statin versus placebo or no intervention in adults with planned anthracycline therapy were eligible. Two reviewers screened, extracted data and assessed risk of bias with RoB-2. Random-effects models pooled risk ratios (RR) for binary outcomes and mean differences (MD) for continuous outcomes, with 95% confidence intervals (CI). A pre-specified subgroup analysis was performed by cumulative anthracycline dose (≥250 mg/m²). Resultados e Conclusões: Eleven RCTs were included; 920 patients (49% on statin) contributed to the primary outcome. Compared with controls, statin therapy significantly reduced CTRCD (RR 0.46; 95% CI 0.32–0.68; I-squared=0%; k=8). The benefit was consistent across cumulative anthracycline dose strata (interaction p=0.34). Post-anthracycline left ventricular ejection fraction was significantly higher with statins (MD +1.45%; 95% CI 0.33–2.56; p=0.011; k=8), and post-anthracycline left ventricular end-systolic volume was lower (MD −4.31 mL; 95% CI −6.57 to −2.04; p<0.001; I-squared=0%; k=5). Statins also reduced left ventricular end-diastolic volume (MD −4.20 mL; p=0.04). No cases of myositis or rhabdomyolysis attributable to statins were reported. In this updated meta-analysis, statin therapy reduced anthracycline-induced CTRCD by approximately 54% and produced consistent benefits on early markers of left ventricular dysfunction, with no apparent safety signal. These findings reinforce the consideration of statins as a cardio-protection strategy in patients with planned anthracycline-based chemotherapy.

TEMPORAL PATTERNS OF EARLY MORTALITY PREDICTORS IN IMMUNE CHECKPOINT INHIBITOR-ASSOCIATED MYOCARDITIS: A SYSTEMATIC REVIEW

SOFIA MASSA VALLE1; MANOELA MASSA MOURA2; THAINA MACHADO MOTA1; SOFIA FRAGNAN SILVA1; VÍTOR PAIVA MARQUES DA SILVA1; RAFAEL MESQUITA BERNARDES1; ALEXANDRA OLIVEIRA DE MESQUITA3;

(1) UNICEUB - BRASÍLIA - DF - BRASIL; (2) UNIVERSIDADE DE BRASILIA - BRASÍLIA - DF - BRASIL; (3) HOSPITAL DE BASE DO DISTRITO FEDERAL - BRASÍLIA - DF - BRASIL;

Introdução/Fundamentos: Immune checkpoint inhibitor (ICI)-associated myocarditis is a rare but potentially fatal immune-related adverse event. Although early mortality is substantial, predictors of adverse outcomes and their temporal prognostic behavior remain poorly characterized. Objetivos: To identify predictors of early mortality and evaluate their time-dependent prognostic significance in ICI-associated myocarditis. Métodos: A systematic review was conducted in accordance with PRISMA 2020 guidelines. PubMed, Embase, and the Cochrane Library were searched from January 2020 to April 2026 using terms including “immune checkpoint inhibitor”, “myocarditis”, “cardiotoxicity”, “predictors”, and “mortality”, combined with Boolean operators (AND). Two independent reviewers screened titles, abstracts, and full texts, with disagreements resolved by consensus. Eligible studies included observational cohort studies evaluating adults (≥18 years) with confirmed or suspected immune checkpoint inhibitor-associated myocarditis reporting predictors of early mortality (≤60 days) or major adverse cardiovascular events. Data extraction included time of onset, biomarker profiles, ventricular function, overlap syndromes, and clinical outcomes. Five studies comprising 549 patients met inclusion criteria. Due to methodological heterogeneity, findings were synthesized qualitatively. Risk of bias was assessed using the Newcastle-Ottawa Scale. Resultados e Conclusões: Incidence estimates ranged from 0.1% to 1.0%, with myocarditis typically occurring within 4 weeks of ICI initiation. Across included studies, markedly elevated troponin levels, reduced left ventricular ejection fraction (<50%), and concomitant myositis were recurrently associated with fulminant presentation and increased early mortality. Included multicenter cohorts identified reduced LVEF, elevated CK-MB, alanine aminotransferase, and overlap myositis as independent predictors of cardiotoxicity-related death. Landmark analyses showed that prognostic effects were strongest within the first 60 days and attenuated thereafter among survivors. Severe myocarditis was associated with increased 1-year cardiovascular mortality in a multicenter cohort (HR 6.52; 95% CI 2.2–19.6). These findings highlight the first 60 days as a critical therapeutic window for early recognition, biomarker-guided risk stratification, and risk-adapted management.

TRANSCRIPTOMIC ANALYSIS OF HUMAN CARDIOMYOCYTES EXPOSED TO TYROSINE KINASE INHIBITORS REVEALS MOLECULAR SIGNATURES ASSOCIATED WITH CARDIOTOXICITY

LEANDRO CORREIA CASTANHO1; RAFAELA CARVALHAES MATIAS2; SOFIA DE MENEZES ALVES2; PRISCILA SABINO DOS SANTOS3; KEVENI HAGATA PINHO LEAL4; SOPHIA GOUVEIA DAMASCENO4; MARINA VINAGRE PIRES2; FLÁVIA SOEIRO SALGADO2; EDSON GABRIEL SANTOS NASCIMENTO2; GIORDANA TEIXEIRA DA SILVA PROFETI3; LETHYCIA SANTANA DE ARAÚJO CASTRO4; JORGE RODRIGUES DE SOUSA5;

(1) UNIVERSIDADE ESTADUAL DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (3) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (4) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (5) INSTITUTO EVANDRO CHAGAS (IEC) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Cardiotoxicity associated with targeted therapies represents a challenge in cardio-oncology. Treatment with tyrosine kinase inhibitors (TKIs) - widely used in oncology - may induce myocardial dysfunction through mechanisms still incompletely understood. Therefore, the characterization of transcriptomic signatures associated with TKI exposure may help identify biological pathways and potential early biomarkers of risk of cardiotoxicity. Objetivos: To identify transcriptomic alterations due to exposure of human cardiomyocytes to TKIs. Métodos: A transcriptomic analysis was performed using RNA sequencing data from the dataset GSE146096 from the Gene Expression Omnibus. The dataset included gene expression profiles of human cardiomyocytes exposed to a panel of TKIs and controls. The analysis was conducted in R 4.4.3., with differential gene expression estimated using negative binomial regression. P-values were adjusted using the Benjamini-Hochberg method (padj<0.1 as significant), and the magnitude of expression change was estimated by log2 fold change (log2FC). Differentially expressed genes were subjected to functional enrichment analysis using Gene Ontology and KEGG pathways. Resultados e Conclusões: The initial matrix contained 38,478 genes (109 samples). A total of 1,717 differentially expressed genes were identified, including 1,006 upregulated and 711 downregulated genes. Among the most significantly downregulated genes were ACTG1 (log2FC=−1.57; padj=5.84×10-29), TPM1 (log2FC=−1.70; padj=6.32×10-13), TAGLN (log2FC=−2.48; padj=5.52×10-13), and LMO7 (log2FC=−2.38; padj=4.00×10-13), associated with cytoskeletal organization and myocardial contractility, while NAMPT (log2FC=2.61; padj=2.03×10-13), a regulator of cellular stress response, showed increased expression. Functional enrichment analysis revealed overrepresentation of genes related to actin filament organization, endoplasmic reticulum stress response, and cell-substrate adhesion. KEGG analysis indicated enrichment in pathways involving the muscular cytoskeleton, protein processing, and hypertrophic cardiomyopathy. Exposure of human cardiomyocytes to TKIs is associated with significant transcriptomic alterations involving genes related to cytoskeletal structure and cellular stress response. These transcriptomic signatures may contribute to the identification of molecular biomarkers with potential diagnostic and prognostic value for cardiotoxicity associated with targeted cancer therapies.

TRANSCRIPTOMIC IDENTIFICATION OF PERIPHERAL BLOOD BIOMARKERS ASSOCIATED WITH ANTHRACYCLINE-RELATED CARDIOMYOPATHY

RAFAELA CARVALHAES MATIAS1; LEANDRO CORREIA CASTANHO1; JULIANE DI PAULA CRUZ CHAVES2; GIOVANA SEIXAS DE MELO1; MANUELA CARVALHAES MATIAS3; GIORDANA TEIXEIRA DA SILVA PROFETI4; FLAVIA SOEIRO SALGADO1; ISABELA DE CASTRO FROTA LIMA1; LETCHYCIA SANTANA DE ARAUJO CASTRO5; EDSON GABRIEL SANTOS NASCIMENTO1; EMANUELLE FONSECA CARVALHO DA SILVA4; GIOVANNA BARCELOS FONTENELE PEREIRA4;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL; (3) CENTRO UNIVERSITÁRIO DA AMAZÔNIA (UNIESAMAZ) - BELÉM - PA - BRASIL; (4) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (5) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Cardiomyopathy is characterized by structural changes in the myocardium, impairing cardiac function. Anthracyclines, widely used in chemotherapy, may induce cardiotoxicity by inhibiting topoisomerase IIβ in cardiomyocytes and triggering apoptotic pathways. In this context, peripheral blood transcriptomic biomarkers represent a promising non-invasive strategy. Objetivos: To identify transcriptomic biomarkers associated with anthracycline-induced cardiotoxicity. Métodos: This was a secondary bioinformatic analysis of RNA-seq data from the GSE218276 dataset, obtained from the Gene Expression Omnibus. The dataset included peripheral blood transcriptomic profiles from 104 childhood cancer survivors exposed to anthracyclines, including 40 with cardiomyopathy and 64 controls. Differential gene expression analysis was performed using DESeq2 in R 4.4.3, considering genes with adjusted p-value <0.05 and |log2 fold change| >1 as significant. Functional enrichment analyses were conducted using Gene Ontology and KEGG databases. LASSO regression and random forest were used to identify predictive genes; hub genes were the overlap between differentially expressed and machine learning-selected genes. Diagnostic performance was evaluated using ROC analysis. Resultados e Conclusões: The dataset included 58,101 genes across 104 samples. Differential expression analysis identified 187 significantly dysregulated genes between groups. Integration of differential expression and machine learning identified seven hub genes: HSPA8P1, TUBAP2, LOC644456, EEF1A1P14, KIF26A, TAF9BP2, and MTCO1P40. Enrichment analysis implicated mitochondrial metabolism, cellular stress response, and metabolic pathways in cardiac injury. A multigene logistic regression model based on these genes demonstrated moderate discriminative performance, with an area under the ROC curve (AUC) of 0.80 in the training dataset (72 samples) and 0.675 in the test dataset (32 samples). Overall, the study identified peripheral blood transcriptomic biomarkers potentially associated with anthracycline-related cardiomyopathy in childhood cancer survivors, suggesting involvement of genes and pathways related to mitochondrial function, cellular stress, and metabolic regulation. Despite its potential for risk stratification, the model showed moderate diagnostic performance, supporting validation in larger independent and broader cohorts before clinical application.

CHALLENGES IN THE CLASSIFICATION OF VARIANTS IN THE FBN1 GENE: A CRITICAL ANALYSIS OF CONFLICTING DATA IN CLINVAR

MURILO KOSINSKI1; FELÍCIO FREITAS NETTO1;

(1) UNIVERSIDADE ESTADUAL DE PONTA GROSSA - PONTA GROSSA - PR - BRASIL;

Introdução/Fundamentos: The clinical interpretation of genetic variants remains a major challenge in genomic medicine due to variability in classification criteria across laboratories. The FBN1 gene, which encodes fibrillin-1, is classically associated with Marfan syndrome, an autosomal dominant multisystem disorder. Despite the establishment of the ACMG/AMP guidelines 2015 and additional specifications proposed by the Clinical Genome Resource (ClinGen), approximately 7% of FBN1 variants recorded in ClinVar show conflicting classifications, which may compromise diagnostic reproducibility. Objetivos: To analyze FBN1 variants deposited in ClinVar that present conflicting molecular interpretations. Métodos: A cross-sectional, analytical, and exploratory study was conducted using 629 FBN1 variants with conflicting interpretations retrieved from ClinVar. Only submissions from specialized institutions were included. Variants were categorized as benign, variants of uncertain significance (VUS), or pathogenic according to ACMG/AMP criteria. Descriptive analyses were performed to evaluate the distribution of variants by molecular type and year of submission. An interlaboratory discordance matrix was constructed and visualized as a heatmap. All analyses were performed using R (2025) and Python (v3.11). Resultados e Conclusões: Missense variants predominated (70.1%), followed by synonymous (14.9%) and intronic variants (11%). A marked increase in missense variants was observed after 2015, accompanied by growth in pathogenic classifications, whereas VUS remained the most frequent category throughout the study period. Some variants retained conflicting interpretations for up to 16 years. The discordance matrix demonstrated high intragroup concordance (4,197 benign pairs, 2,751 VUS pairs, and 802 pathogenic pairs), alongside notable divergences between benign and VUS classifications (3,374 pairs) and between VUS and pathogenic classifications (537 pairs). Direct conflicts between benign and pathogenic classifications were rare (7 cases). A high prevalence of missense variants with uncertain interpretation was observed in FBN1, frequently remaining classified as VUS for extended periods. This pattern may affect genetic counseling and clinical decision-making. Harmonization of variant interpretation based on ACMG/AMP guidelines and ClinGen recommendations is essential to improve diagnostic reliability.

MUTATED GENES IDENTIFIED THROUGH GENETIC TESTING IN A BRAZILIAN COHORT WITH DILATED CARDIOMYOPATHY

LEONARDO CEDRO MACHADO1; EDUARDO KILIAN LUCENA1; EDIMAR ALCIDES BOCCHI1; FABIO FERNANDES1; EMANUELLE LEONILIA MARQUES1; SILAS RAMOS FURQUIM1; LUCAS VIEIRA LACERDA PIRES1; JOSÉ EDUARDO KRIEGER1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Dilated cardiomyopathy (DCM) is associated with clinically relevant variants (CRVs) in up to 40% of cases. Current guidelines recommend genetic evaluation and counseling for individuals with DCM, in addition to cascade screening of first-degree relatives, providing an opportunity for early diagnosis and treatment. Furthermore, genetic testing enables the timely identification of mutations in genes not directly related to DCM. Objetivos: The objective of this study was to determine the prevalence of each mutated gene identified in genetic tests of a Brazilian cohort of patients with DCM, including primary findings (CRVs or variants of uncertain significance - VUS related to DCM) and secondary findings (genes not related to DCM). Métodos: This is an observational, retrospective, cross-sectional, multicenter study, based on the analysis of results from genetic tests previously performed in DCM patients participating in MAPA Genoma Brasil project. Eligible participants were adults (≥18 years) with a left ventricular ejection fraction <50% and a diagnosis of DCM established after the age of 14. Genes identified by genetic sequencing were quantified and classified as primary findings (CRVs and VUS) or as secondary findings (genes included in ACMG SF v3.3 list). Resultados e Conclusões: Genetic test results from 788 DCM patients were evaluated, of whom 462 (58.6%) were male. 785 exomes and 3 genomes were analyzed. A total of 445 variants in DCM-related genes were identified in 392 (49.7%) individuals, including 178 CRVs in 172 (21.8%) patients and 267 VUS in 239 (30.3%) patients. Among the 445 variants identified (Figure 1A), the most prevalent genes involved were TTN (19.6%), FLNC (9.4%), and MYH7 (6.1%). Within the subgroup of CRVs (Figure 1B), TTN predominated significantly (40.4%), followed by FLNC (10.7%). Conversely, VUS (Figure 1C) were most frequently located in MYH7 (9.7%) and FLNC (8.6%). Furthermore, 55 secondary findings (Figure 2) were identified in 52 (6.6%) individuals, with the most prevalent genes involved being HFE and G6PD (12.7%, n=7 each), followed by PMS2 (9.1%, n=5), HBB (7.3%, n=4), and TTR (5.5%, n=3). These findings reinforce the genomic consistency of DCM between Brazilian and predominantly European cohorts, as the prevalence of mutated genes is in line with that reported in the ESC guidelines. Moreover, the results underscore the importance of secondary findings to timely diagnosis of comorbid genetic disorders and broader counseling for patients and their relatives.

ALDOSTERONE SYNTHASE INHIBITORS IN PATIENTS WITH RESISTANT HYPERTENSION: A SYSTEMATIC REVIEW OF RANDOMIZED CLINICAL TRIALS.

ISABELA CRISTINA SILVA DA SILVA1; DEBORAH VICTÓRIA DOS SANTOS GANZER1; JENIFER DE MOURA PEIXOTO1; LUÍDI LOBATO GONÇALVES1; VITOR MICKAEL SERRÃO GARCIA1; ARLEY NIKSON OLIVEIRA BARRETO1; LEONARDO AGUIAR DOS SANTOS1; FELIPE FERREIRA PINHEIRO2; NELSON VEIGA GONÇALVES1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE FEDERAL DO AMAPÁ (UNIFAP) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Resistant hypertension is associated with a 47% higher risk of cardiovascular events. Spironolactone, the drug of choice, is limited by hyperkalemia and reduced applicability in advanced kidney disease, while other treatments, such as renal denervation, alpha-blockers, and centrally acting agents, offer modest benefits or have notable side effects, highlighting aldosterone synthase inhibitors as a promising therapy. Objetivos: This review aims to evaluate the effect of aldosterone synthase inhibitors on blood pressure in patients with resistant hypertension. Métodos: A systematic search was conducted in PubMed, Embase, and The Cochrane Library databases, and the study included randomized clinical trials that had the following characteristics: a study population of patients with resistant hypertension; an intervention involving aldosterone synthase inhibitors; a comparison with placebo; and outcomes involving changes in systolic and diastolic blood pressure. Studies that did not provide a specific analysis for patients with resistant hypertension were excluded, including those that grouped individuals with uncontrolled and resistant hypertension without separately stratifying the results. Resultados e Conclusões: Four studies were included. LCI699 (osilodrostat), compared to placebo, did not result in statistically significant reductions in systolic and diastolic blood pressure in patients with resistant hypertension. Similarly, the 0.5 mg dose of Baxdrostat showed no significant effect in the trial conducted by Freeman et al. In contrast, at doses of 1 mg and 2 mg, baxdrostat produced clinically relevant and statistically significant reductions in blood pressure in all trials in which it was evaluated, with decreases in systolic blood pressure ranging from 8.1 mmHg to 11.0 mmHg and in diastolic blood pressure ranging from approximately 3.3 mmHg to 5.0 mmHg. Thus, aldosterone synthase inhibitors, particularly baxdrostat, represent a promising therapeutic strategy for the treatment of resistant hypertension. However, evidence remains limited, as only four randomized clinical trials have specifically evaluated this population, in addition to the short follow-up duration in most studies.

Table 1. Characteristics of Randomized Controlled Trials of Aldosterone Synthase Inhibitors in Resistant Hypertension

Study	Local	Study design	N (total)	Intervention (N)	Control (N)	Duration
Karns et al. (2013)	United States and Iceland	RCT, phase II	155	LCI699 in one of three regimens: 0.25 mg twice daily (n = 32); 1 mg once daily (n = 26); or 0.5 mg twice daily titrated to 1 mg twice daily after 4 weeks (n = 31)	Placebo (n = 33) or eplerenone 50 mg twice daily (n = 33)*	8 weeks
Freeman et al. (2023)	United States	RCT, phase II	275	Baxdrostat in one of three regimens: 0.5 mg once daily (n = 69); 1 mg once daily (n = 70); or 2 mg once daily (n = 67)	Placebo once daily (n = 69)	12 weeks
Flack et al. (2025)	North America, Europe and Oceania	RCT, phase III	794	Baxdrostat at either 1 mg (n = 264) or 2 mg (n = 266)	Placebo once daily (n = 264)	12 weeks
Azizi et al. (2026)	North America, South America, Europe, Asia, Oceania, and Africa	RCT, phase III	217	Baxdrostat 2 mg once daily (n = 108)	Placebo once daily (n = 109)	12 weeks

Notes: RCT: randomized controlled trial.
*In the study by Karns et al. (2013), eplerenone was used as an active control.

Table 2. Efficacy of Aldosterone Synthase Inhibitors on Blood Pressure in Resistant Hypertension: Placebo-Corrected Changes in SBP and DBP

Study	Drug / Dose	msSBP (Δ vs placebo, mmHg [95% CI])	msDBP (Δ vs placebo, mmHg [95% CI])	Significance
Karns et al. (2013)	LCI699 0.25 mg twice daily (n = 32)	−2.6	+0.3	NS
	LCI699 1 mg once daily (n = 26)	−4.3	−1.2	NS
	LCI699 0.5 mg twice daily titrated to 1 mg twice daily after 4 weeks (n = 31)	−3.7	−1.2	NS
Freeman et al. (2023)	Baxdrostat 0.5 mg once daily (n = 69)	NS	+0.6	NS
	Baxdrostat 1 mg once daily (n = 70)	−8.1 (−13.5 to −2.8)	−2.6	p=0.003
	Baxdrostat 2 mg once daily (n = 67)	−11.0 (−16.4 to −5.5)	−5.2 (−8.7 to −1.6)	p<0.001
Flack et al. (2025)	Baxdrostat 1 mg once daily (n = 264)	−9.1 (−12.6 to −5.7)	−3.3 (−5.2 to −1.4)	p<0.001
	Baxdrostat 2 mg once daily (n = 266)	−9.8 (−13.1 to −6.4)	−3.9 (−5.7 to −2.0)	p<0.001
Azizi et al. (2026)	Baxdrostat 2 mg once daily (n = 108)	−10.3 (−14.9 to −5.6)	−5.0 (−7.7 to −2.3)	p<0.001

Notes: Δ = placebo-corrected change; msSBP = mean seated systolic blood pressure; DBP = mean seated diastolic blood pressure; NS = not statistically significant.

ARTERIAL STIFFNESS AND DIASTOLIC RESERVE DURING EXERCISE IN RESISTANT HYPERTENSION

GUILHERME GUILHERME VALLE1; MARCO ROGERIO DUARTE JUNIOR2; JOÃO VICTOR SOUTELLO FERREIRA2; RAÍSSA MARQUES DOS SANTOS2; LARYSSA FERNANDES FIGUEIRA RIBEIRO2; DÉBHORA TRINDADE PEIXOTO MARIANO2; MARIA EDUARDA SOARES CALAZANS2; GABRIEL RANGEL COSTA DA SILVA CARDOSO2; WILSON BRAZ CORRÊA FILHO2; SEBASTIANA BESSA PORTO2; FABIO DE SOUZA2;

(1) UNIRIO - RIO DE JANEIRO - DF - BRASIL; (2) UNIRIO - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Resistant hypertension (RH) is associated with increased cardiovascular risk, including heart failure, stroke, and mortality. Chronic pressure overload promotes accelerated vascular aging, assessed by pulse wave velocity (PWV), an independent predictor of adverse outcomes. Resting echocardiography may underestimate early diastolic dysfunction, a key mechanism in the development of heart failure. Objetivos: To assess arterial stiffness by comparing vascular and chronological age, describe the prevalence of diastolic dysfunction using stress echocardiography in RH, and explore variables associated with exercise-induced diastolic abnormalities. Métodos: Single-center cross-sectional study including patients with RH on ≥3 antihypertensive agents, including a thiazide diuretic, with adherence confirmed by the Morisky questionnaire. PWV was measured using an oscillometric method and compared with age- and sex-adjusted reference values. Diastolic function was evaluated by transthoracic echocardiography at rest and during supine bicycle exercise (25 W/3 min). The E/e' ratio estimated filling pressures and associations with demographic variables. Continuous variables are presented as mean ± SD or median [IQR]. The study was approved by the local ethics committee. Resultados e Conclusões: Thirty-two patients were included, 66% women, using a median of 5 [4–6] antihypertensive drugs, with mean office blood pressure of 159/97 ± 38/19 mmHg. Median BMI was 31.6 kg/m² [28.3–34.4]. Median PWV was 8.2 m/s [7.4–9.3], higher than expected, with vascular age of 60 vs. 54 years. At rest, 39% had normal diastolic function, 52% abnormal patterns, and 9% overt dysfunction; median E/e' was 9.5 [7.9–11.4]. During stress (n=15), normal findings decreased to 20%, abnormal patterns increased to 60%, and diastolic dysfunction was present in 20%. E/e' increased to 11.5 at peak exercise, suggesting elevated filling pressures. BMI was associated with E/e' during exercise (rho = -0.552, p = 0.041).Patients with RH may exhibit features consistent with early vascular aging and a possible reduction in diastolic reserve during exercise. Stress echocardiography suggested elevations in filling pressures not evident at rest, supporting a potential complementary role in detecting subclinical dysfunction. Obesity was associated with exercise-induced diastolic disfunction. Further studies are warranted to clarify the clinical implications and potential role of these measures in risk stratification.

ASSOCIATION BETWEEN INTRACRANIAL COMPLIANCE DYNAMICS AND COGNITIVE PERFORMANCE: A MULTICENTER ANALYSIS

JULIA CAMILE DE OLIVEIRA1; ELIANE FÁTIMA MANFIO1; LAURA OTTA NUNES1; MIKAELLE COSTA CORREIA2; ADRIANA CAMARGO OLIVEIRA2; VIVIANE SANTOS MENDES CARNEIRO2; ANA LUIZA LIMA SOUSA2; GUSTAVO HENRIQUE FRIGIERI VILELA3; WEIMAR KUNZ SEBLBA BARROSO2; EDUARDO COSTA DUARTE BARBOSA1;

(1) UNIVERSIDADE FEEVALE - NOVO HAMBURGO - RS - BRASIL; (2) FACULDADE DE MEDICINA DA UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL; (3) BRAIN4CARE - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Reduced intracranial compliance (IC) is emerging as a potential biomarker for cognitive impairment of vascular origin. The Mini-Mental State Examination (MMSE) is widely used for screening functional deficits, but its correlation with non-invasive cerebral hemodynamics remains poorly explored. Objetivos: To evaluate the association between the P2/P1 ratio (one of the markers of IC) and cognitive performance as measured by the MMSE, analyzing the moderating influence of age, sex, and cardiometabolic comorbidities. Métodos: This was a multicenter, cross-sectional observational study, following the STROBE guidelines. The sample consisted of 268 individuals (69.7% women), aged 21 to 84 years, with a mean BMI of 32.48 kg/m2. Intracranial compliance was assessed non-invasively (Brain4care device) for 7 minutes in the supine position; the mean P2/P1 ratio was calculated from the 5 minutes of central stability. Multivariable regression models associated the MMSE score with the P2/P1 ratio, age, sex, and comorbidities (arterial hypertension, dyslipidemia, and type 2 diabetes). Resultados e Conclusões: In the overall sample, the P2/P1 ratio was not independently associated with MMSE (p=0.344), with cognitive performance being predominantly predicted by advanced age (p=0.001) and the presence of arterial hypertension (p=0.035). However, a significant interaction by sex was observed. In the male group, the P2/P1 ratio was the only independent predictor of worse MMSE performance (p=0.010), outweighing the impact of age and comorbidities. In females, cognitive decline was exclusively associated with aging (p=0.006), with no influence from the P2/P1 ratio (p=0.580). An increase in the P2/P1 ratio may be associated with cognitive decline in males, independently of traditional risk factors. Although the MMSE is effective in global screening, non-invasive cerebral dynamics monitoring proves to be a promising clinical tool and sensitive for early identification of cognitive vulnerability, especially in men with a cardiometabolic risk profile.

ASSOCIATION OF SYSTOLIC BLOOD PRESSURE STRATA AND TRAJECTORIES WITH ACUTE KIDNEY INJURY RISK IN HOSPITALIZED HEART FAILURE: A SYSTEMATIC REVIEW

SAMUEL DE ANDRADE COSTA1; ARTUR VICTOR CAVALCANTE MEDEIROS2; ALOÍSIO JOSÉ INOCÊNCIO NETO2; BRUNO PIMENTEL ROCHA2; ERIK GABRIEL OLIVEIRA ALMEIDA2; HENRIQUE JOSÉ FERNANDES DE SOUZA VIEIRA2; JOÃO VICTOR NUNES CADETE2; KAYO MAURICIO FERREIRA DE FRANÇA LISBOA DA TRINDADE2; LAVÍNIA BARBOSA FARIAS COSTA2; MARIA CLARA BARROS DE SOUSA ARAÚJO2; MARIA VITÓRIA NOBRE OLIVEIRA LISBOA DA TRINDADE2; ANTONIO EVERALDO VITORIANO DE ARAÚJO FILHO2;

(1) UNIVERSIDADE ESTADUAL DE CIÊNCIAS DA SAÚDE DE ALAGOAS - UNCISAL - MACEIO - AL - BRASIL; (2) CENTRO UNIVERSITARIO DE MACEIO - UNIMA / AFYA - MACEIO - AL - BRASIL;

Introdução/Fundamentos: Acute kidney injury (AKI) is a frequent complication in heart failure (HF), affecting up to 30% of hospitalized patients and significantly worsening prognosis and mortality. Blood pressure (BP) management is essential for renal perfusion; however, optimal BP targets remain controversial because of the opposing risks of hypoperfusion and venous congestion. Objetivos: To analyze the association between different strata of systolic blood pressure (SBP) and the risk of development or progression of AKI in adults hospitalized with HF. Métodos: Systematic review conducted according to PRISMA guidelines via PubMed, Embase, and Cochrane. Studies from the last 5 years were included, with no language restriction and available in free full text, that evaluated SBP and mean arterial pressure (MAP) trajectories as exposure in adults with HF and AKI defined by KDIGO criteria. Risk of bias was assessed using ROBINS-I and RoB-2 tools. Screening and selection were performed by two independent reviewers, with disagreements resolved by discussion. Resultados e Conclusões: Five studies were selected, totaling 25,893 unique patients estimated after adjustment for sample overlap. The data reveal a non-linear U-shaped association between SBP and AKI risk, with the lowest predicted risk (nadir) at approximately 120 mmHg. Compared with the lenient stratum (SBP ≥140 mmHg), the standard (110–139 mmHg; aOR 0.77; 95% CI 0.69–0.86) and strict (<110 mmHg; aOR 0.74; 95% CI 0.67–0.82) strata were associated with lower odds of overall AKI. However, trajectories of rapid MAP decline were correlated with an increased risk of AKI (HR 1.284; 95% CI 1.085–1.521) compared with stable trajectories. Stable moderate MAP levels (85–91 mmHg) demonstrated a protective effect (HR 0.846; 95% CI 0.745–0.960). Strict management (<110 mmHg) was also associated with higher 28-day mortality (HR 1.162; 95% CI 1.012–1.334). Conclusions: SBP levels around 120 mmHg are associated with greater renoprotection. Although low values may reduce AKI through relief of congestion, abrupt declines and persistent levels <110 mmHg increase the risk of progression to severe stages and death, requiring dynamic monitoring of hemodynamic stability. This review is limited by the predominance of retrospective single-center studies, the presence of potential unmeasured confounders, and evaluation based on achieved pressures rather than randomized therapeutic targets.

BEYOND BLOOD PRESSURE: CARDIOVASCULAR RISK FACTOR BURDEN AND CONTROL ACCORDING TO SEX IN A BRAZILIAN COHORT OF INDIVIDUALS WITH REFRACTORY HYPERTENSION

EIJI TAIRA1; THIAGO ARTIOLI2; MANUELA DRIGO DE ALMEIDA1; LUCAS YUJI YONEHARA1; TAREK CASTRO FAYYAT3; ANTONIO LAURINAVICIUS2; MÁRCIO GONÇALVES SOUSA2; FERNANDO YUE CESENA2;

(1) FACULDADE DE CIENCIAS MEDICAS DA SANTA CASA DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (3) UNIVERSIDADE POSITIVO - CURITIBA - PR - BRASIL;

Introdução/Fundamentos: Refractory hypertension (RefHTN) is an extreme phenotype of antihypertensive treatment failure associated with higher cardiovascular disease (CVD) risk. It is not well described to what extent risk factors other than hypertension (HTN) are controlled in patients with RefHTN, and whether there are sex differences in this aspect. Objetivos: We sought to evaluate the burden and control of CVD risk factors other than HTN by sex in patients with RefHTN. Métodos: This was a cross-sectional, single-center study conducted in a Brazilian cohort of patients attended by a public tertiary hypertension service between 2021 and 2025. We included participants with RefHTN, defined as office BP ≥140/90 mmHg and 24h ambulatory BP ≥130/80 mmHg despite the use of at least five classes of antihypertensive medications, in the absence of signs of poor treatment adherence. Patients with secondary hypertension were excluded. Cardiovascular risk factors assessed included LDL-c, HDL-c, non-HDL-c, triglycerides, diabetes mellitus (DM; uncontrolled DM defined as fasting glucose ≥130 mg/dL or HbA1c ≥7.0%), body mass index, and smoking status. LDL-c cutoff values and targets were defined according to current guideline recommendations. The 10-year atherosclerotic cardiovascular disease (ASCVD) risk was estimated using the PREVENT score, and patients were categorized according to the 2026 Dyslipidemia Guideline from the USA. Resultados e Conclusões: We analyzed 180 patients (76% female, 62.6 ± 11.4 years, mean office BP 167/93 mmHg, mean 24h ambulatory BP 149/90 mmHg). Median LDL-c was 88 (interquartile range: 69-106) mg/dL in individuals with ASCVD, 91 (75-125) mg/dL in those without ASCVD but with DM, and, in those with neither ASCVD nor DM, 120 (112-136) mg/dL, 142 (95-170) mg/dL, and 106 (96-129) mg/dL in high-, intermediate-, and borderline/low-risk patients, respectively (p=0.023, Kruskal–Wallis test). A low proportion of patients met recommended LDL-c targets, particularly among those with higher CVD risk (Tables 1 and 2). Table 2 shows a high burden of cardiometabolic risk factors and a low prevalence of current smoking in this population, without a significant difference between sexes. We observed a high prevalence of uncontrolled cardiovascular risk factors beyond HTN in both females and males with RfHTN that may potentiate the CVD risk. These findings highlight the urgent need for targeted strategies to improve risk factor control and reduce the burden of CVD.

Table 1. Prevalence of participants with LDL-c below selected cutoffs according to risk group

Condition	LDL-c cutoff (mg/dL)	Prevalence
ASCVD (n=53)	<55	3 (5.7%)
No ASCVD, with DM (n=59)	<70	8 (13.6%)
	<100	33 (55.9%)
No ASCVD, no DM		
High ASCVD risk (n=8)	<70	0
Intermediate ASCVD risk (n=8)	<100	3 (37.5%)
Low / Borderline ASCVD risk (n=15)	<100	5 (33.3%)
	<115	9 (60.0%)

Data expressed as number of observations (%).
The 10-year ASCVD risk was estimated using the PREVENT score for participants with available data within recommended ranges.
ASCVD: atherosclerotic cardiovascular disease; DM: diabetes mellitus, LDL-c: low-density lipoprotein cholesterol.

Table 2. Cardiovascular risk factor burden according to sex

Characteristic	Total (n=180)	Female (n=136)	Male (n=44)	p-value
LDL-c out of target*	120 (83.9%)	91 (83.5%)	29 (85.3%)	0.80
Non-HDL-c out of target**	71 (49.7%)	55 (50.5%)	16 (47.1%)	0.73
TG ≥150 mg/dL	76 (42.2%)	54 (39.7%)	22 (50.0%)	0.23
Low HDL-c***	103 (57.2%)	78 (57.4%)	25 (56.8%)	0.95
DM	93 (51.7%)	72 (52.9%)	21 (47.7%)	0.55
Uncontrolled DM	64 (68.8%)	48 (66.7%)	16 (76.2%)	0.41
BMI category				
Low / normal	21 (11.7%)	15 (11.1%)	6 (13.6%)	0.71
Overweight	59 (33.0%)	43 (31.9%)	16 (36.4%)	
Obesity	99 (55.3%)	77 (57.0%)	22 (50.0%)	
Current smoking	10 (5.6%)	9 (6.6%)	1 (2.3%)	0.46

Data expressed as number of observations (%).
* Target for participants with ASCVD: <55 mg/dL; target for participants without ASCVD and with DM: <70 mg/dL; targets for participants with neither ASCVD nor DM: <70 mg/dL (high risk), <100 mg/dL (intermediate risk), and <115 mg/dL (borderline/low risk).
** Non-HDL-c targets are 30 mg/dL above LDL-c targets.
*** <40 mg/dL in males and <50 mg/dL in females.
Statistical tests: chi-squared and Fisher's exact tests.
BMI: body mass index; DM: diabetes mellitus, HDL-c: high-density lipoprotein cholesterol; LDL-c: low-density lipoprotein cholesterol; TG: triglycerides

BEYOND MEAN BLOOD PRESSURE: ADVANCED ABPM METRICS FOR CARDIOVASCULAR RISK STRATIFICATION

GIULIA OLIVEIRA COSTA1; ANA CLARA MELO DA COSTA E SILVA1; AUGUSTO VICENTE FERREIRA DA SILVA1; ANA LUISA LIMA RODRIGUES DE OLIVEIRA ROCHA1; LETÍCIA SIMÕES BABICK1; GABRIEL GIOVANE NEVES REINBOLD1; JOÃO VICTOR PEREIRA DA COSTA1; GABRIEL ESQUIVEL MANGUEIRA1; BRENDA BASILIO BOAVENTURA1; EDUARDA VITÓRIA ARAÚJO EMÍDIO1; FERNANDA PRISCYLA SILVA SANT'ANA TRINDADE1; FERNANDO JOSÉ PEREZ DA SILVA GRAÇA1;

(1) UNIVERSIDADE FEDERAL DE RORAIMA - BOA VISTA - RR - BRASIL;

Introdução/Fundamentos: Conventional ambulatory blood pressure monitoring (ABPM) parameters, particularly mean systolic and diastolic values, may underestimate the cumulative hemodynamic burden associated with cardiovascular risk. Advanced ABPM-derived metrics — such as time-weighted average (TWA), area under the curve (AUC), hemodynamic stress time (HST), and blood pressure variability — have emerged as tools for refined risk assessment. Objetivos: To evaluate the association and predictive value of advanced ABPM parameters in cardiovascular risk stratification compared to conventional mean blood pressure measurements. Métodos: A systematic review was conducted according to PRISMA 2020 guidelines. Studies published between 2015 and 2025 were identified in PubMed/MEDLINE, SciELO, and LILACS. Inclusion criteria comprised adult populations undergoing ABPM with analysis of advanced parameters (TWA, AUC, HST, or variability indices) and reporting cardiovascular outcomes or target organ damage. Study selection was performed by five independent reviewers. Methodological quality was assessed using the Newcastle – Ottawa Scale. Due to heterogeneity, a qualitative synthesis was performed. A total of 25 studies were identified. Resultados e Conclusões: Of 25 identified studies, 6 met inclusion criteria, comprising 437 patients in ABPM-focused cohorts. Advanced ABPM parameters showed consistent associations with target organ damage, particularly left ventricular hypertrophy and increased carotid intima-media thickness. Systolic BP variability demonstrated stronger correlations with structural vascular changes compared to mean BP ($p < 0.05$). TWA improved detection of cumulative hemodynamic burden and dynamic BP fluctuations. Integrated variability indices enhanced risk discrimination, especially in high-risk populations. Conventional ABPM parameters tended to underestimate cardiovascular risk. Advanced ABPM-derived parameters improve cardiovascular risk stratification and are more closely associated with target organ damage than conventional mean BP. These findings support a paradigm shift toward dynamic hemodynamic assessment in hypertension management.

18806

BLOOD PRESSURE VARIABILITY AND RISK OF MAJOR CARDIOVASCULAR EVENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

LUCAS MARINHO REIS DA CUNHA SILVA1; GIOVANA CASAGRANDE DE ALENCAR ALENCAR1; BRUNO DE FREITAS SILVA1; THIAGO VITTOR SILVA FREITAS2; POLIANA MARCELINO JOIA2; RAFAEL ALVES DE OLIVEIRA2; TAYNARA TAVARES DOS SANTOS2; LEONARDO COCHARRO PRETO2; LUCAS RODRIGUES SANTA RITA3; MARIA GABRIELLA GENARO SEBASTIÃO2; VALÉRIA SILVEIRA DIAS2; AMANDA OLIVA SPAZIANI2;

(1) UNIVERSIDADE BRASIL - FERNANDÓPOLIS - SP - BRASIL; (2) UNIVERSIDADE BRASIL - FERNANDOPOLIS - SP - BRASIL; (3) UNIÃO DAS FACULDADES DOS GRANDES LAGOS - SÃO JOSÉ DO RIO PRETO - SP - BRASIL;

Introdução/Fundamentos: Blood pressure variability has emerged as an important independent prognostic marker beyond absolute blood pressure levels. Blood pressure fluctuations may reflect hemodynamic instability and increased vascular risk. However, the magnitude of its association with major cardiovascular events still requires consolidation through systematic analysis. Objetivos: To evaluate the association between blood pressure variability and the risk of major cardiovascular events in adults. Métodos: A systematic review was conducted in accordance with PRISMA guidelines, with a structured search in PubMed, Embase, and the Cochrane Library up to January 2026. Prospective studies assessing blood pressure variability using different methods (office measurements, ambulatory blood pressure monitoring, or home monitoring) and its relationship with cardiovascular events were included. The primary outcome was major adverse cardiovascular events (MACE). Meta-analysis was performed using a random-effects model, with calculation of relative risk (RR) and 95% confidence intervals (95% CI). Heterogeneity was assessed using the I^2 statistic. Resultados e Conclusões: Eleven studies were included, totaling 89,462 participants. Higher blood pressure variability was associated with a significant increase in the risk of major cardiovascular events (RR = 1.53; 95% CI: 1.36–1.72; $p < 0.001$). Heterogeneity was moderate ($I^2 = 34\%$). Blood pressure variability is associated with a relevant increase in cardiovascular risk, reinforcing its importance as an additional marker in risk stratification and clinical management.

ABELARDO SANTOS - BELÉM - PA - BRASIL; (6) FACULDADE DE MEDICINA DE SÃO JOSÉ DO RIO PRETO - SÃO JOSE DO RIO PRETO - SP - BRASIL; (7) UNIVERSIDADE ESTADUAL DE CAMPINAS - CAMPINAS - SP - BRASIL;

Introdução/Fundamentos: Upper-arm blood pressure (BP) measurement may be limited in hemodialysis (HD) patients because of local vascular restrictions, making calf BP a relevant alternative. Objetivos: To assess the relationship between standardized calf and arm BP measurements in HD patients and to derive calf BP thresholds corresponding to elevated arm BP levels. Métodos: This cross-sectional study included 277 patients receiving thrice-weekly HD for ≥3 months at four Brazilian outpatient centers between January and August 2025. BP was measured immediately before the midweek dialysis session using an automated oscillometric device (Omron HEM-7320) with appropriately sized cuffs. After a 5-min rest, participants remained seated with the back supported at 90° and legs fully extended and supported parallel to the floor, reflecting their usual posture during dialysis (Figure 1). Simultaneous measurements were obtained in the non-arteriovenous fistula arm (or right arm when no fistula was present) and the ipsilateral calf. Three readings were taken at 1-minute intervals, and the mean of the second and third was used for analysis. Associations between arm and calf BP were assessed by Pearson correlation and linear regression. Calf BP thresholds corresponding to elevated arm BP (≥140/90 and ≥130/80mmHg) were estimated from regression models. Diagnostic performance was evaluated by receiver operating characteristic curve analysis, and agreement by Bland-Altman analysis. The study was approved by the Ethics Committee. Resultados e Conclusões: Mean age was 55±14 years, 64% were male, median dialysis vintage was 759[286-1708] days, and 82% were receiving antihypertensive therapy. Mean arm and calf BP were 140±24/83±14 and 167±29/92±17mmHg, respectively, with correlations for systolic and diastolic BP of r=0.72 and r=0.74. Calf BP values of 167/98 and 158/89mmHg corresponded to arm BP thresholds of 140/90 and 130/80mmHg (Figure 2-A/B), yielding AUCs of 0.755 and 0.804, sensitivities of 82% and 88%, and specificities of 69% and 73%, respectively. Bland-Altman analysis showed higher calf than arm BP, with mean systolic and diastolic biases of 26.7 and 8.8mmHg and wide but expected limits of agreement (Figure 2-C/D). In conclusion, when upper-arm BP measurement is not feasible in HD patients, calf BP thresholds of approximately 165/100 and 160/90mmHg may help identify arm BP levels of 140/90 and 130/80mmHg, respectively, supporting more accurate BP assessment in this setting.

CARDIOMETABOLIC INDEX AND EARLY RENAL DYSFUNCTION IN YOUNG ADULTS: A POPULATION-BASED STUDY

JINGYING ELENA CHEN1; JOÃO PEDRO SOARES DA SILVEIRA1; MATHEUS HENRIQUE MARINHO MARQUES1; ISABEL RIPPEL HAMMES1; CAUÃ CORRÊA DA SILVA FERNANDO1; LUÍZA LIMA ILYDIO DOS SANTOS1; CATARINA SIEBERER1; JANAINA FRANCO DE ANDRADE1; AMANDA BARBUDA HASSAN1; MARIA VICTORIA FERES NASCIF1; INAH MARIA DRUMMOND PECLY1; ELIZABETH SILAID MUXFELDT1;

(1) INSTITUTO DE EDUCACAO MEDICA (IDOMED) - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Hypertension is the leading cause of mortality and disability-adjusted life years worldwide. Individuals with hypertension have a higher risk of metabolic syndrome and early target-organ damage. The cardiometabolic index (CMI) has emerged as a simple marker for screening diabetes mellitus, stroke, and renal dysfunction. However, its association with early cardiovascular and renal alterations in young adults remains unclear. Objetivos: To investigate the association between the cardiometabolic index (CMI) and renal function in young adults. Métodos: This study included 543 adults (60% female gender; mean age 37,9 ± 8,9 years old) aged 20–50 years from a population-based cohort in Rio de Janeiro, Brazil. Sociodemographic, anthropometric, and cardiovascular risk factor data were collected. All participants underwent laboratory testing to assess metabolic profile and renal function, office blood pressure measurement, and home blood pressure monitoring (HBPM; 7-day protocol). The cardiometabolic index (CMI) was calculated as (waist circumference/height) × (triglycerides/HDL-cholesterol) and categorized according to the median value (1.12). Resultados e Conclusões: Individuals with higher CMI were older (40.3 ± 8.3 vs. 35.6 ± 8.8 years, p<0.001), had higher obesity prevalence (40.2% vs. 14.9%, p<0.001), were more frequently smokers (15.2% vs. 9.2%, p=0.024), and exhibited a worse glycemic and lipid metabolic profile. Estimated glomerular filtration rate was lower in individuals with higher CMI (102 vs. 111 mL/min/1.73m², p=0.001), indicating an association with reduced renal function even in a relatively young population. Consistently, individuals with lower eGFR presented higher CMI values (p<0.001) and a worse metabolic profile, including higher prevalence of diabetes, glucose intolerance, and metabolic syndrome. No significant differences were observed in albuminuria, indicating that early renal alterations associated with CMI may occur independently of albuminuria. In conclusion, CMI was associated with lower eGFR in young adults, suggesting its potential role as a simple and cost-effective biomarker of early subclinical renal dysfunction and risk stratification.

Introdução/Fundamentos: Hypertension is the leading cause of mortality and disability-adjusted life years worldwide. Individuals with hypertension have a higher risk of metabolic syndrome. The cardiometabolic index (CMI) is an emerging metabolic marker for screening diabetes mellitus, stroke, and renal dysfunction. However, the association between CMI and hypertension in young adults remains unclear. Objetivos: To investigate the association between CMI and hypertension in young adults. Métodos: This study included 543 adults (60% female gender; mean age 37,9 ± 8,9 years old) aged 20–50 years from a population-based cohort in Rio de Janeiro, Brazil. Sociodemographic, anthropometric, and cardiovascular risk factor data were collected. All participants underwent laboratory testing to assess metabolic profile and renal function, office blood pressure measurement, and home blood pressure monitoring (HBPM; 7-day protocol). Participants were classified as normotensive (n=232), prehypertensive (n=215), or hypertensive (n=96). The cardiometabolic index (CMI) was calculated as (waist circumference/height) × (triglycerides/HDL-cholesterol) and categorized according to the median value (1.12). Resultados e Conclusões: Individuals with higher CMI were older (40 ± 8 vs. 35 ± 8 years, p<0.001), had higher obesity prevalence (40.4% vs. 14.8%, p<0.001), were more frequently smokers (15.1% vs. 9.2%, p=0.025), and exhibited a worse glycemic and lipid metabolic profile, as well as a lower ankle–brachial index. Blood pressure levels were higher both in office and HBPM measurements, and the prevalence of prehypertension (43.4% vs. 35.8%, p=0.043) and hypertension (21.3% vs. 14.0%, p=0.017) was significantly greater. A progressive increase in CMI was observed according to hypertension severity (normotension: 1.19 ± 0.81; prehypertension: 1.46 ± 0.88; hypertension: 1.74 ± 1.69), suggesting that CMI may serve as an early risk marker even in the prehypertensive stage. In conclusion, CMI showed a positive association with hypertension in young adults, indicating that it may represent a simple and cost-effective biomarker for early cardiovascular risk stratification.

CARDIOMETABOLIC INDEX IS ASSOCIATED WITH OBSTRUCTIVE SLEEP APNEA IN YOUNG ADULTS: A POPULATION-BASED STUDY

AMANDA MEDEIROS DE SÁ PORDEUS1; LUIZ OTÁVIO DE AZEREDO XAVIER COELHO1; AMANDA WOLKOFF LACHTER1; NYCKOLAS KENNEDY DA SILVA JERONIMO1; MARIANA ARAUJO DE NORONHA ROCHA1; JOANNA MARIA VALENTE ZABEU1; LUCCAS DA SILVA FLOR FERREIRA1; NINA ROCHA DE FARIA1; AGATHA XAVIER ARTEMENKO1; MARIA VITÓRIA PEIXOTO BARRETO LEAL1; ANA CRISTINA TENÓRIO DA COSTA FERNANDES1; ELIZABETH SILAID MUXFELT2;

(1) IDOMED/ESTACIO - RIO DE JANEIRO - RJ - BRASIL; (2) INSTITUTO DO CORACAO EDSON SAAD/UFRJ - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Obstructive sleep apnea (OSA) is strongly associated with cardiometabolic abnormalities. However, the role of composite indices integrating multiple metabolic parameters in OSA risk assessment remains poorly defined. Objetivos: To investigate the association between the cardiometabolic index (CMI) and OSA in a cohort of young adults. Métodos: This study included 85 adults (57.6% women; mean age 37.9 ± 8.9 years) aged 20–50 years from a population-based cohort in Rio de Janeiro, Brazil. Sociodemographic, anthropometric, and cardiovascular risk factor data were collected. All participants underwent laboratory evaluation of metabolic profile and renal function, office blood pressure measurement, and 7-day home blood pressure monitoring (HBPM). Domiciliary polysomnography (ApneaLink Air, ResMed) was performed in all individuals, and OSA was defined as an apnea–hypopnea index (AHI) >5 events/hour. The cardiometabolic index (CMI) was calculated as (waist circumference/height) × (triglycerides/HDL-cholesterol) and categorized according to the median value (1.25). Resultados e Conclusões: Individuals with OSA were more frequently male (60% vs. 33%, p=0.014), had a higher prevalence of central obesity (57% vs. 36%, p=0.04), and increased neck circumference (33% vs. 13%, p=0.025). They also showed a higher prevalence of hypertension (77% vs. 31%, p<0.001) and dyslipidemia (80% vs. 47%, p=0.003). CMI was significantly higher in patients with OSA (1.67 ± 0.61 vs. 1.17 ± 0.45, p<0.001). Moreover, individuals with higher CMI (above the median) exhibited a worse polysomnographic profile, with a higher prevalence of moderate-to-severe OSA (16.3% vs. 2.4%, p=0.031), higher AHI (4.8 vs. 2.0 events/hour, p=0.013), and greater oxygen desaturation indices. In conclusion, CMI is significantly associated with both the presence and severity of OSA in young adults. These findings suggest that CMI may serve as a simple, low-cost, and clinically useful biomarker for early identification and risk stratification of OSA in this population.

Introdução/Fundamentos: Arterial hypertension affects approximately 40% of adults worldwide and contributes substantially to cardiovascular mortality. Oxidative stress is central to hypertension pathophysiology, with reduced nitric oxide (NO) bioavailability and increased lipid peroxidation, reflected by malondialdehyde (MDA) levels. Objetivos: To quantitatively compare circulating NO and MDA levels between hypertensive and normotensive adults. Métodos: A systematic search of PubMed, Embase, and Cochrane Library identified randomized controlled trials and observational studies comparing circulating NO and MDA levels in hypertensive versus normotensive adults. The study was conducted in accordance with the PRISMA guidelines. Primary outcomes were serum and plasma NO and MDA levels. Subgroup analyses were performed by biological sample type and MDA assay method. Mean differences (MD) with 95% confidence intervals (CI) were pooled using a random-effects model. Resultados e Conclusões: Fourteen studies (3 randomized and 11 observational), comprising 1,029 participants, were included. For NO, the overall analysis (10 studies; 386 hypertensive and 272 normotensive participants) showed no significant difference between groups (MD -0.96, 95% CI -9.34 to 7.41; I²=99.7%). However, subgroup analysis by sample type revealed that serum NO levels were significantly lower in hypertensive individuals (MD -10.05, 95% CI -19.20 to -0.90), whereas plasma NO did not differ significantly (MD 4.93, 95% CI -5.59 to 15.45). Regarding MDA (9 studies; 376 hypertensive and 321 normotensive participants), hypertension was associated with higher overall levels (MD 1.56, 95% CI 0.51 to 2.61; I²=99.5%). Subgroup analysis confirmed this trend in both serum (MD 2.15, 95% CI 0.57 to 3.74) and plasma (MD 1.43, 95% CI 0.12 to 2.74). Additionally, the assay method influenced MDA estimates, with larger effects observed in TBARS and ELISA studies compared to HPLC analyses. Conclusions: Hypertension is associated with increased circulating MDA levels, supporting enhanced lipid peroxidation in this condition. Although NO levels were not significantly different overall, lower serum NO suggests impaired NO bioavailability in hypertensive adults. The marked heterogeneity indicates that sample type and assay methodology substantially affect biomarker estimates, underscoring the need for standardized measurement strategies in future studies.

CLINICAL AND CENTRAL HEMODYNAMIC PROFILES OF SPURIOUS AND SUSTAINED HYPERTENSION IN YOUNG ADULTS: A PHENOTYPE-BASED ANALYSIS

JOSE GUILHERME PINHATTI CARRASCO1; DANIEL COSTA GONÇALVES DO VALE1; IGOR HENRIQUE RIGOTTO ALTOÉ1; VICTORIA VIGNOTTI SABINO1; ISABELA PONTES SERRA1; PEDRO HENRIQUE GORRI CUSTÓDIO DE MELO BRITES1; PEDRO RIBEIRO BICUDO1; MARIA CLARA DE MATTOS MIRA1; LUIZ GUSTAVO VILHENA PEREIRA1; WENDELL ARTHUR LOPES1; GABRIELLI PALUDETTO DE VICENTE GASPAR1; ROGERIO TOSHIRO PASSOS OKAWA1;

(1) UNIVERSIDADE ESTADUAL DE MARINGA - MARINGÁ - PR - BRASIL;

Introdução/Fundamentos: Isolated systolic hypertension in young adults is a heterogeneous condition including true hypertension related to increased arterial stiffness and spurious systolic hypertension driven by peripheral pulse pressure amplification. Differentiating these phenotypes is essential due to distinct prognostic and therapeutic implications, yet remains underrecognized. Objetivos: To compare the clinical, metabolic, and central hemodynamic characteristics of young adults classified as normotensive, spurious systolic hypertensive, or sustained hypertensive. Métodos: This retrospective cross-sectional study included 363 individuals aged 18–40 years evaluated between 2018 and 2022. Clinical, metabolic, peripheral blood pressure, and central hemodynamic data were obtained from medical records. Participants were classified into normotensive, spurious systolic hypertensive, or sustained hypertensive groups based on peripheral and central blood pressure. Isolated systolic hypertension was defined as systolic blood pressure ≥140 mmHg and diastolic blood pressure <90 mmHg. Ambulatory blood pressure monitoring confirmed systolic hypertension and excluded white-coat effect. Central systolic blood pressure ≥120 mmHg defined elevated central pressure. Central hemodynamic parameters, including central blood pressure, pulse wave velocity, and augmentation index, were assessed using a validated noninvasive device (Complior system). Comparisons were performed using ANOVA and chi-square tests, with post hoc analyses when appropriate. A p-value <0.05 was considered significant. The study was approved by the Human Research Ethics Committee (number 5.779.058.). Resultados e Conclusões: Of 363 individuals, 199 were normotensive, 36 had spurious systolic hypertension, and 128 had sustained hypertension. Sustained hypertensive individuals showed higher body mass index, greater prevalence of dyslipidemia, and higher peripheral and central blood pressure. Pulse wave velocity and augmentation index were increased, indicating greater arterial stiffness. In contrast, spurious systolic hypertension showed elevated systolic blood pressure without differences in arterial stiffness, with preserved central hemodynamics. Sustained hypertension is associated with increased arterial stiffness and elevated central blood pressure. Spurious systolic hypertension reflects a functional phenotype driven by peripheral amplification, without structural vascular damage, supporting phenotype-based evaluation.

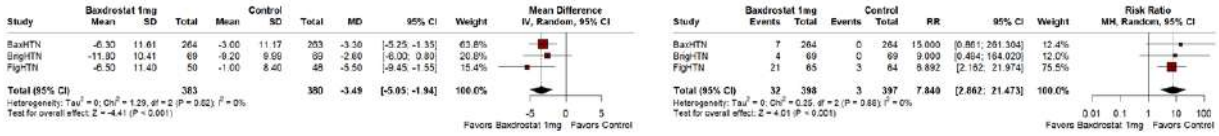
EFFECTS OF NEW INTENSIVE BLOOD PRESSURE TARGETS ON THE PROGRESSION OF CHRONIC KIDNEY DISEASE IN PATIENTS WITH PRE-EXISTING NEPHROPATHY: A SYSTEMATIC REVIEW

GIULIA OLIVEIRA RAMALHO1; DAVI DANTAS FREIRE1; EDER OLIVEIRA COSTA1; JULIA VASCONCELOS DA SILVEIRA1; RODRIGO GOUVEIA AZEVEDO BORGES1; RODRIGO ALVES DE SOUZA GALVÃO2;

(1) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL; (2) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Intensive blood pressure (BP) control reduces cardiovascular events, but its direct impact on pre-existing Chronic Kidney Disease (CKD) progression remains debated. Clinical observations of acute Glomerular Filtration Rate (GFR) declines following strict targets raise renal safety concerns, demanding an in-depth analysis of long-term risks and benefits. Objetivos: To evaluate the effect of intensive BP targets (systolic <120 mmHg) versus standard control on CKD progression risk, incidence of end-stage renal disease (ESRD), and GFR decline. Métodos: Following Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, a systematic review was conducted in PubMed and EMBASE (last 10 years). Inclusion criteria used the PICOT strategy, encompassing trials and observational studies comparing intensive versus standard BP targets on renal progression in adults with pre-existing CKD. Initially, 481 records were identified. Double-blind, independent screening was performed by two reviewers, with disagreements resolved by a third. After duplicate removal and screening, 23 full texts were reviewed. Nine were excluded, resulting in 14 studies. Methodological quality and risk of bias were assessed using appropriate tools. Resultados e Conclusões: Analysis of 14 studies shows that higher systolic BP (>120 mmHg) accelerates GFR decline and increases End-Stage Renal Disease (ESRD) risk. Intensive SBP targets (<120 mmHg), aligning with KDIGO 2021 guidelines, significantly reduce long-term progression to kidney failure across diverse cohorts. While intensive control frequently causes acute GFR declines (>15% to >30%), longitudinal biomarker analyses confirm this reflects a reversible hemodynamic response, not intrinsic tubular damage. Notably, this GFR drop occurs primarily during the active intervention, without sustained progressive risk post-trial. Benefits remain consistent regardless of baseline albuminuria, and intensive control attenuates the impact of baseline tubular dysfunction. In subgroups like IgA nephropathy, optimal targets lie between 110-119 mmHg due to a U-shaped risk curve. In conclusion, implementing strict SBP targets (<120 mmHg) in pre-existing CKD safely and effectively mitigates long-term ESRD risk. The initial GFR decline is an adaptive response. Continuous monitoring is essential to individualize treatment and prevent hypotension.



21262

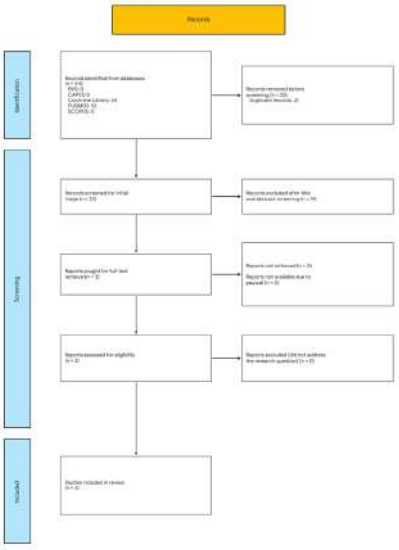
EFFICACY AND SAFETY OF BAXDROSTAT IN RESISTANT AND UNCONTROLLED HYPERTENSION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CLINICAL TRIALS

JULIANA FERRAZ DE SOUSA1; FRANCINNY ALVES KELLY2; LUIZA TREVISOL DAL PONTE3; ARTUR DE OLIVEIRA MACENA LÔBO4; CLARA ROCHA DANTAS5; SHARIE LOHANNA DE MORAES NASCIMENTO6;

(1) UEMASUL - IMPERATRIZ - MA - BRASIL; (2) BETH ISRAEL DEACONESS CENTER - UNITED STATES; (3) UNIVERSIDADE DE CAXIAS DO SUL - CAXIAS DO SUL - RS - BRASIL; (4) UNIVERSIDADE FEDERAL DE PERNAMBUCO - RECIFE - PE - BRASIL; (5) UNIVERSIDAD DE BUENOS AIRES - ARGENTINA; (6) UNIVERSIDADE FEDERAL DO AMAZONAS - MANAUS - AM - BRASIL;

Introdução/Fundamentos: Resistant hypertension poses a high cardiovascular risk, frequently driven by aldosterone dysregulation. Baxdrostat, a selective aldosterone synthase inhibitor, directly targets the pathophysiology of sodium-water retention and arterial stiffness. Objetivos: To evaluate the antihypertensive efficacy and safety profile of baxdrostat compared with placebo in patients with resistant or uncontrolled hypertension. Métodos: This systematic review and meta-analysis was conducted following PRISMA guidelines. PubMed, Embase, and Web of Science were searched for randomized controlled trials comparing baxdrostat (1–2 mg) versus placebo for at least 12 weeks in adults with resistant or uncontrolled hypertension. Pooled estimates were calculated using a random-effects model. Heterogeneity was assessed with the I-squared statistic. Effects were reported as mean difference (MD) for systolic (SBP) and diastolic blood pressure (DBP), and risk ratio (RR) for safety outcomes, both with 95% confidence intervals (CI). Resultados e Conclusões: Three randomized controlled trials were included, totaling 1,260 patients (863 baxdrostat; 397 placebo). The 1 mg dose reduced SBP by 8.33 mmHg (MD −8.33; 95% CI −10.67 to −5.99) and DBP by 3.49 mmHg (MD −3.49; 95% CI −5.05 to −1.94). The 2 mg dose yielded greater reductions in SBP (MD −9.89; 95% CI −12.21 to −7.56) and DBP (MD −4.11; 95% CI −5.57 to −2.65). Hyperkalemia incidence was higher with baxdrostat (RR 7.84 for 1 mg; RR 11.88 for 2 mg). Discontinuation due to adverse events was significantly increased only with the 2 mg dose (RR 2.31; 95% CI 1.19–4.48), with no significant difference for the 1 mg dose versus placebo. Baxdrostat produced consistent, dose-dependent blood pressure reductions in patients with resistant or uncontrolled hypertension. Although hyperkalemia risk was increased, particularly at higher doses, discontinuation rates were significantly elevated only with the 2 mg dose. These findings support baxdrostat as a potential therapeutic option for this difficult-to-treat population, pending further long-term safety dat

15963



EFFICACY AND SAFETY OF SACUBITRIL/VALSARTAN COMPARED TO CONVENTIONAL THERAPY IN THE MANAGEMENT OF SYSTEMIC ARTERIAL HYPERTENSION: A SYSTEMATIC REVIEW.

RANIEL GUERRA GARCIA1; ALAN CASSIUS SANCHES PANTOJA2; VITÓRIA CONDE MAIA2; GABRIEL ALENCAR ECKER3; PIETRA TABOSA PIETRA TABOSA CABRAL1; MARIA GIOVANNA DA CRUZ TOCANTINS2; ALANNE RYLLARI DA SILVA DOS SANTOS2; ANA CAROLINA RODRIGUES NASCIMENTO3; ANTONIO MARIA ZACARIAS ARAÚJO MONTEIRO1; THIAGO CÉSAR DA CUNHA FONTES3; GLEYDSON DE AZEVEDO ALMEIDA4; DANILLO MONTEIRO PORFÍRIO3;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (3) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (4) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Hypertension is a chronic condition that compromises the integrity of the cardiovascular system. Despite being established, traditional therapy presents limitations and side effects, highlighting the need for other pharmacological managements Objetivos: To evaluate the efficacy and safety of Sacubitril/Valsartan on the control of essential or resistant hypertension when compared to conventional therapy Métodos: Systematic review according to PRISMA guidelines. Research conducted in PubMed, BVS (VHL), Cochrane Library, SciELO, and EMBASE databases, including studies published between 2021 and 2026. DeCS/MeSH descriptors related to Sacubitril/Valsartan and Systemic Arterial Hypertension were used, combined by the Boolean operator “AND”. Identified studies were independently evaluated by two reviewers on the Rayyan platform. Randomized controlled trials (RCT) were included, featuring adult patients with essential or resistant hypertension as the population, regardless of treatment duration, with previous use of ACE inhibitors or ARBs. Studies that did not answer the research question or those involving specific populations with associated comorbidities, such as diabetes or chronic kidney disease, were excluded. The risk of bias was assessed using the RoB 2.0 tool Resultados e Conclusões: 22 studies were found, but only 3 RCTs were included, with a total sample of approximately 1,784 patients. Regarding essential hypertension, the ZHANG study demonstrated a greater reduction in SBP with sacubitril/valsartan (200mg) vs. olmesartan (20mg) ($p < 0.001$), and RAKUGI evidenced superiority in SBP/DBP ($p < 0.001$) vs. olmesartan, with a dose-dependent effect (200-400mg). Regarding resistant hypertension, BITAR reported blood pressure control (<140/90mmHg) of 94.9% vs. 69.2% in the standard therapy group (ACEi/ARB) ($p = 0.03$) and SBP reduction of -26.71 vs. -12.34 mmHg, with an advantage in pulse pressure in the intervention group ($p = 0.008$). Reported adverse events were: dizziness (21.3% vs. 16.4%), hypotension (17.9% vs. 10.3%; $p = 0.517$), and hyperkalemia (2.6% vs. 7.7%). The included studies suggest that Sacubitril/Valsartan presents benefits in the control of essential hypertension compared to conventional therapies. Furthermore, it indicates a reduction in systolic pressure and a similar safety profile, highlighting the potential of Sacubitril/Valsartan as an alternative to traditional pharmacological therapy

Introdução/Fundamentos: In hemodialysis (HD), blood pressure (BP) measured outside the dialysis unit predicts cardiovascular outcomes better than peridialytic BP. Home BP monitoring (HBPM) is a practical alternative to ambulatory BP monitoring, but the protocol that best reflects cardiac target-organ damage remains uncertain. Objetivos: To compare three HBPM protocols and their associations with echocardiographic markers of left ventricular (LV) remodeling in HD patients. Métodos: This cross-sectional study included 265 adults on thrice-weekly HD for ≥3 months at three Brazilian centers between August 2023 and January 2025. HBPM was performed with validated oscillometric devices (Omron HEM-7320), with three morning and three evening readings obtained after 3 minutes of rest for 6 days. HBPM was analyzed as three protocols: 6-day total (all days), 6-day off-dialysis (non-dialysis days), and 6-day on-dialysis (dialysis days). Echocardiograms performed within 12 months of HBPM were used to assess LV mass index (LVMI), relative wall thickness (RWT), LV hypertrophy (LVH), and LV concentricity. Associations between BP and LV remodeling were evaluated using multivariable linear and logistic regression. The study was approved by the Ethics Committee. Resultados e Conclusões: Mean age was 57±16 years, 69% were male, and median dialysis vintage was 922 [336-2110] days. Mean HBPM was 132±22/79±12mmHg for 6-day total, 132±23/78±13mmHg for off-HD, and 132±23/80±12mmHg for on-HD. LVH and LV concentricity were present in 47.8% and 37.8%, respectively. Patients with LVH had higher 6-day total HBPM than those without LVH (138±23/82±13 vs 126±20/76±11mmHg; both p<0.001), and similar differences were observed for LV concentricity (138±23/82±12 vs 128±21/77±12mmHg; p<0.001 and p=0.001). In multivariable linear models, systolic HBPM 6-day on-HD showed the strongest association with LVMI (β=0.234, p<0.001, R^2=0.092) and RWT (β=0.179, p=0.007, R^2=0.061). In logistic models, systolic HBPM 6-day total was most strongly associated with LVH (OR 1.026, 95% CI 1.012-1.039; p<0.001, pseudo-R^2=0.166), whereas diastolic HBPM 6-day on-HD was most strongly associated with LV concentricity (OR 1.045, 95% CI 1.018-1.074; p=0.001, pseudo-R^2=0.141). In conclusion, HBPM protocols that include dialysis-day readings showed the strongest associations with echocardiographic markers of LV remodeling, supporting their inclusion in BP assessment in HD patients.

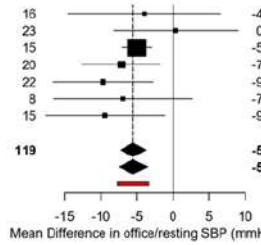
ISOMETRIC HANDGRIP TRAINING AND OFFICE/RESTING SYSTOLIC BLOOD PRESSURE IN ADULTS WITH ELEVATED BLOOD PRESSURE OR HYPERTENSION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED TRIALS



MIKAEL DA SILVA SILVEIRA1; FELIPE SALES DE ALENCAR1; GUSTAVO LEAL DAITX1; LEONARDO ALVES1;

(1) UNIVERSIDADE FEDERAL DO RIO GRANDE - RIO GRANDE - RS - BRASIL;

Introdução/Fundamentos: Hypertension remains one of the leading modifiable cardiovascular risk factors worldwide. According to the 2025 Brazilian Guidelines of Hypertension, non-pharmacological interventions are a cornerstone of both prevention and management of hypertension. Isometric handgrip training has emerged as a simple, low-cost, and feasible non-pharmacological strategy, although randomized evidence remains scattered. Objetivos: To quantify the effect of isometric handgrip training on office/resting systolic blood pressure in adults with elevated blood pressure or hypertension. Métodos: This systematic review and meta-analysis was conducted according to PRISMA guidelines. Randomized controlled trials were identified through systematic searches of PubMed, Scopus, and LILACS up to March 2026. Studies including adults with elevated blood pressure or hypertension undergoing isometric handgrip training versus control or usual care were eligible. Risk of bias was assessed using the Cochrane RoB 2 tool, evaluating bias arising from the randomization process, deviations from intended interventions, missing outcome data, measurement of the outcome, and selection of the reported result. The primary outcome was post-intervention office/resting systolic blood pressure. Pooled estimates were calculated as mean difference (MD) using a random-effects model (REML) with Hartung–Knapp adjustment. Heterogeneity was assessed using the I^2 statistic. All statistical analyses were performed using R version 4.5.3. Resultados e Conclusões: Results: Seven randomized controlled trials were included, totaling 249 participants. Risk of bias assessment showed that one trial was judged as low risk, five raised some concerns, and one was classified as high risk of bias. Isometric handgrip training was associated with a significant reduction in office/resting systolic blood pressure compared with control (MD −5.53 mmHg; 95% CI −7.48 to −3.58; p < 0.001), with no statistical heterogeneity (I^2 = 0%; τ^2 = 0; p = 0.571). Results were highly consistent across studies, and the prediction interval remained entirely below zero, supporting the robustness of the pooled effect. Conclusion: Isometric handgrip training was associated with a clinically meaningful reduction in office/resting systolic blood pressure in adults with elevated blood pressure or hypertension, supporting its role as a simple, accessible, and potentially useful adjunctive strategy in the non-pharmacological management of hypertension.

Forest plot - isometric handgrip training and systolic blood pressure

Study	IHG	Control	MD	95% CI	Weight (common)	Weight (random)
Fecchio 2023	15	16	-4.00	[-14.57; 6.57]	2.7%	2.7%

PREVALENCE OF PRIMARY ALDOSTERONISM IN SYSTEMATICALLY SCREENED HYPERTENSIVE PATIENTS AT FIRST CLINICAL EVALUATION

LUIZ GUSTAVO VILHENA PEREIRA1; BRUNA SAYURI MATSUMURA KANASHIRO1; MARIA CLARA DE MATTOS MIRA1; PEDRO RIBEIRO BICUDO1; DANIEL COSTA GONÇALVES DO VALE1; JOSE GUILHERME PINHATTI CARRASCO1; LUKA MATEUS METELSKI SANTOS1; ANA LUIZA COMIM HENRIQUE1; GUILHERME AUGUSTO GUIMARÃES RESENDE1; ANTONIO PAULO FELICE RODRIGUES LEITE1; ANA CAROLINA AMARAL CARNEIRO1; ROGERIO TOSHIRO PASSOS OKAWA1;

(1) UNIVERSIDADE ESTADUAL DE MARINGA - MARINGÁ - PR - BRASIL;

Introdução/Fundamentos: Primary aldosteronism is increasingly recognized as a frequent and underdiagnosed cause of hypertension, characterized by autonomous aldosterone secretion and increased cardiovascular risk beyond blood pressure levels. Contemporary data suggest a prevalence of 5–10% in general hypertensive populations and higher rates in selected groups. However, the impact of systematic screening at first clinical evaluation remains insufficiently explored. Objetivos: To determine the prevalence and clinical characteristics of primary aldosteronism in hypertensive patients undergoing systematic screening at their first outpatient evaluation. Métodos: This retrospective cross-sectional study included 745 consecutive patients evaluated at their first hypertension consultation between October 2024 and January 2026. All patients underwent screening with the aldosterone-to-renin ratio (ARR). A positive screening test was defined as ARR ≥30, in the presence of plasma aldosterone concentration ≥15 ng/dL and suppressed renin levels. Confirmatory testing was performed using a saline infusion test. Adrenal computed tomography was obtained in all confirmed cases. The study was approved by the Human Research Ethics Committee (number: 81761324.7.0000.0104). Resultados e Conclusões: Among 745 patients, 56 (7.5%) had a positive ARR. Primary aldosteronism was confirmed in 24 patients, corresponding to a prevalence of 3.2% in the overall cohort and 42.9% among those with positive screening. Among confirmed cases, mean age was 45 years, and most patients were male (66.7%). Resistant hypertension was present in 33.3% of cases. Hypokalemia was observed in 30% of patients, with a mean serum potassium level of 3.3 mmol/L among affected individuals. Adrenal imaging identified unilateral adenoma in 6 patients (25%) and bilateral disease in 18 (75%). The observed prevalence was lower than that reported in contemporary literature, which describes primary aldosteronism in approximately 5–10% of hypertensive populations and higher rates in selected cohorts. This difference may be explained by the inclusion of an unselected population at first clinical evaluation, the absence of enrichment for high-risk phenotypes, and the use of strict diagnostic criteria, which likely reduced false-positive results. Primary aldosteronism prevalence was lower than expected. However, high confirmation rates and heterogeneous presentation, without universal hypokalemia and with predominance of bilateral disease, support systematic screening and careful phenotyping.

SINGLE-PILL QUADRUPLE COMBINATION OF ANTIHYPERTENSIVE AGENTS VERSUS STANDARD THERAPY OR PLACEBO FOR BLOOD PRESSURE REDUCTION AND TARGET ACHIEVEMENT: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

LEONARDO GOUVÊA DE OLIVEIRA1; VITÓRIA CAMPOS CORDEIRO1; LUANA KAORI SAKAGUCHI SAKAMOTO1; LUANA CARDOSO TAVARES1; LUANA NOBREGA DOS SANTOS1; EVA LUDMILA DO SOCORRO DA CRUZ MARQUES1; LEONAN SILVA DA SILVA1; LUIZ ARTHUR DE OLIVEIRA NANTES1; VINICIUS SILVA LARA1; RENATO GARCIA LISBOA BORGES1; RITA DE CASSIA SILVA DE OLIVEIRA1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Arterial hypertension (AH) is a chronic, non-communicable disease characterized by persistent elevation of systolic blood pressure (SBP) and/or diastolic blood pressure (DBP). The combination of four low-dose antihypertensive drugs, in a single pill, may represent an innovative and potentially more effective therapeutic strategy in controlling blood pressure. Objetivos: To evaluate, through meta-analysis (MA), the efficacy of quadruple therapy in a single pill compared to standard therapy or placebo in adults with AH. Métodos: This MA followed the PRISMA 2020 guidelines and was registered in PROSPERO. The Cochrane Library, Embase, PubMed, Scopus, and Web of Science databases were searched to identify randomized controlled trials (RCTs) comparing quadruple single-pill therapy versus placebo or usual medication. Outcomes included reduction in office SBP and DBP, 24-hour ambulatory blood pressure, and achievement of target blood pressure. Analyses were performed using the R software (v4.4.1), using fixed or random effects models according to heterogeneity. The results were expressed as mean difference (MD) or relative risk (RR), with 95% confidence intervals (95% CI). Heterogeneity was assessed using Cochran's Q test and I², and risk of bias was assessed using the RoB 2.0 tool. Resultados e Conclusões: Six RCTs were included (932 patients). Quadruple therapy significantly reduced office SBP and DBP at weeks 4-6 (SBP: MD -10.37, 95% CI -15.98 to -4.77; DBP: MD -6.25, 95% CI -8.93 to -3.57; p<0.001; figure 1), with maintenance of effect until week 12 (SBP: MD -6.34, 95% CI -8.27 to -4.40; DBP: MD -6.41, 95% CI -9.12 to -3.69; p<0.001; figure 2). In 24-hour assessment, the intervention was superior to the control, with a sustained reduction. There was a significantly higher probability of achieving the target blood pressure in the intervention group (RR 1.85; 95% CI 1.24-2.77; p<0.05; figure 1). Heterogeneity ranged from low to high, and one of the studies was classified as having a high risk of bias. This MA showed that low-dose quadruple therapy demonstrated superiority in lowering blood pressure over standard therapy, promoting early and sustained blood pressure control. It also increased the likelihood of reaching target blood pressure, with the potential to reduce therapeutic complexity and clinical inertia. This may be a promising strategy for optimizing hypertension control. Further studies with long-term outcomes should be conducted to confirm these results.

TARGET ORGAN DAMAGE ACCORDING TO ASCVD RISK CATEGORIES IN A BRAZILIAN COHORT OF INDIVIDUALS WITH REFRACTORY HYPERTENSION

MANUELA DRIGO DE ALMEIDA1; THIAGO ARTIOLI2; EIJI TAIRA1; LUCAS YONEHARA YUJI1; TAREK CASTRO FAYYAT3; ANTONIO LAURINAVICIUS2; MÁRCIO GONÇALVES SOUZA2; FERNANDO YUE CESENA2;

(1) FACULDADE DE CIENCIAS MEDICAS DA SANTA CASA DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (3) UNIVERSIDADE POSITIVO - CURITIBA - PR - BRASIL;

Introdução/Fundamentos: Guidelines recommend atherosclerotic cardiovascular disease (ASCVD) risk stratification based on the identification of high-risk groups (e.g., individuals with ASCVD or diabetes mellitus [DM]) and risk estimation by scores. Hypertension (HT) associated left ventricular hypertrophy (LVH), chronic kidney disease (CKD), and albuminuria are independently related to ASCVD events, and refractory HT (RefHT) is a high-risk phenotype. It is not known how the presence of target organ damage aligns with traditional ASCVD risk stratification in patients with RefHT. Objetivos: To determine the prevalence of target organ damage (CKD, albuminuria, and LVH) according to ASCVD risk categories in patients with RefHT. Métodos: This was a single-center, cross-sectional study conducted in a tertiary hypertension outpatient clinic from the public Unified Health System in Brazil. We included patients who attended the service from 2021 to 2025 and met criteria for RefHT, meaning office BP ≥ 140/90 mmHg and 24-hour ambulatory BP ≥ 130/80 mmHg despite the use of at least five classes of antihypertensive medications, with no evidence of poor treatment adherence. Patients with secondary hypertension or Stage 5 CKD were excluded. Participants were categorized into risk groups according to the presence or absence of ASCVD and DM, and, for those with neither ASCVD nor DM, the 10-year ASCVD risk was estimated by the PREVENT score. CKD and albuminuria were defined according to KDIGO guideline criteria. LVH was defined as a left ventricular mass index >115 g/m² in men and >95 g/m² in women. Resultados e Conclusões: We analyzed 180 patients (76% female, 62.6 ± 11.4 years, mean office systolic BP 167 ± 23 mmHg, mean 24h systolic BP 149 ± 16 mmHg). Prevalence rates of Stages 3a, 3b, and 4 CKD were 28 (15.6%), 18 (10.0%), and 6 (3.3%), respectively. Frequencies of albuminuria categories A2 and A3 were 54 (30.9%) and 22 (12.6%), respectively. Prevalences of CKD and albuminuria increased across higher ASCVD risk categories, with the highest frequencies observed in patients with DM (Figure 1). In contrast, LVH prevalence did not differ significantly across ASCVD risk strata (Figure 2). In this sample of patients with RefHT, we found a graded association between traditional ASCVD risk categories and kidney disease, but not LVH. The prevalence of LVH was high even in the lowest-risk groups determined by the PREVENT score. These results highlight the limitations of risk scores in specific populations, such as those with RefHT.

THE CLINICAL IMPACT OF INTENSIVE VERSUS STANDARD BLOOD PRESSURE TARGETS IN ELDERLY HYPERTENSIVE PATIENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

MARIA CLARA DE MATTOS MIRA1; GUILHERME AUGUSTO GUIMARÃES RESENDE1; PEDRO HENRIQUE GORRI CUSTÓDIO DE MELO BRITES1; LUIS FELIPE GODIN DE MARIA1; JULIA FAVORO BRENNY2; JOÃO MARCELO LORGA CARNIELLI1; LUANA MANGANOTI NEGRO1; LUANA DO NASCIMENTO FAHUR1; MILENA BABUGIA PINTO1; VINÍCIUS FERNANDES MONTANHOLI1; CARLOS DENILSON SILVA SOARES1; ROGÉRIO TOSHIRO PASSOS OKAWA1;

(1) UNIVERSIDADE ESTADUAL DE MARINGA - MARINGÁ - PR - BRASIL; (2) UNIVERSIDADE ESTADUAL DE LONDRINA - LONDRINA - PR - BRASIL;

Introdução/Fundamentos: The optimal systolic blood pressure (SBP) target for elderly patients remains a subject of intense discussion, balancing cardiovascular protection against potential adverse events. While guidelines move toward tighter control, evidence regarding all-cause mortality and clinical consistency in the elderly requires updated synthesis. This study aimed to investigate the clinical impact of intensive (SBP <120 – 130 mmHg) versus standard (SBP <140 – 150 mmHg) strategies in this specific population. Objetivos: This study aimed to evaluate the clinical impact of intensive blood pressure targets (SBP <120 – 130 mmHg) compared to standard control (SBP <140 – 150 mmHg) in elderly hypertensive patients. The primary goal was to determine the effect of these strategies on all-cause mortality, major adverse cardiovascular events (MACE), and the incidence of stroke. Métodos: We performed a systematic review and meta-analysis of randomized controlled trials (RCTs) identified via PubMed, Embase, and Cochrane databases up to May 2026. From an initial pool of 136 articles, 61 remained after de-duplication. Following rigorous screening and quality assessment, 10 studies met the inclusion criteria. Primary outcomes were all-cause mortality, major adverse cardiovascular events (MACE), and stroke. Random-effects models (DerSimonian-Laird) were used, and sensitivity analyses were performed to address population overlap and outliers. Resultados e Conclusões: Results: A total of 10 RCTs comprising 72,433 patients were included. Intensive BP control was associated with a significant 16% reduction in all-cause mortality (RR 0.84; 95% CI 0.76–0.92; I 2 = 23.2%). For MACE, the intensive strategy showed a 25% risk reduction (RR 0.75; 95% CI 0.71–0.80) with exceptional consistency across trials (I2 = 0.0%). Stroke risk was also significantly reduced by 23% (RR 0.77; 95% CI 0.71– 0.83; I2 = 34.4%). Sensitivity analyses excluding small-scale outliers and redundant cohorts (overlapping populations) confirmed the robustness of these findings. Conclusion: The clinical impact of intensive blood pressure targets (SBP <130 mmHg) is superior to standard care in elderly hypertensive patients, providing significant protection not only against MACE and stroke but, crucially, reducing all-cause mortality. The high consistency of these results supports the implementation of more stringent BP targets in the elderly, provided that individual frailty and safety profiles are considered, aligning with the most recent international cardiology guidelines.

USE OF ELECTROCARDIOGRAPHY FOR LEFT VENTRICULAR HYPERTROPHY DIAGNOSIS: A COMPARATIVE ANALYSIS OF ECG CRITERIA

GUSTAVO GUSTAVO FUKUOKA1; BRUNA GUSTAVO OVIEDO DE OLIVEIRA1; GUSTAVO JOSÉ MODESTO2; MIGUEL ANTÔNIO MORETTI1; ADRIANO GUSTAVO MENEGHINI1; ANTÔNIO CARLOS PALANDRI CHAGAS1;

(1) CENTRO UNIVERSITÁRIO FMABC - SANTO ANDRÉ - SP - BRASIL; (2) CENTRO UNIVERSITÁRIO FMABC - AFGHANISTAN;

Introdução/Fundamentos: Left Ventricular Hypertrophy (LVH) is the most prevalent manifestation of target-organ damage in Systemic Arterial Hypertension (SAH) and a strong predictor of adverse outcomes, including heart failure, arrhythmias, and thromboembolic events. With nearly 38 million hypertensive individuals in Brazil, early and accurate detection of LVH is a major clinical priority. Although echocardiography is the gold standard for LVH diagnosis, its high cost and limited availability significantly restrict its use, particularly in resource-limited settings. Consequently, electrocardiography (ECG) remains the most accessible tool for large-scale screening. However, the diagnostic performance of ECG is highly variable, with most criteria demonstrating low sensitivity and no clear consensus on the optimal method. This limitation directly impacts clinical decision-making and risk stratification. In this context, identifying the most accurate ECG criterion is essential to improve early detection and optimize patient care Objetivos: To identify the most accurate electrocardiographic criterion for detecting LVH, using echocardiography as the reference standard. Métodos: Cross-sectional study based on retrospective analysis of medical records from a tertiary cardiology outpatient clinic. LVH was assessed using ECG criteria (Perugia, Cornell Voltage, Cornell Duration, and Sokolow-Lyon), selected for their widespread use and diagnostic performance. Echocardiography was used as the reference standard. ECG criteria were compared to assess diagnostic performance across subgroups by age, sex, and ethnicity (White, Black or Mixed [Pardo], Indigenous, and Asian).Inclusion criteria: patients aged 18–60 years. Exclusion criteria: valvular disease, chronic arterial disease, arrhythmias, and bundle branch blocks. Resultados e Conclusões: The sample was predominantly male (N=88) and White (N=48). Among men with LVH (N=35), Black, Mixed, or Indigenous individuals predominated (N=18), while women (N=73) were mainly White (N=38). Cornell Duration demonstrated the highest diagnostic accuracy, especially in women, whereas Sokolow-Lyon showed no sensitivity in females. Significant differences were observed in LVH prevalence between sexes (p=0.0042) and in Cornell Duration performance (p=0.0003), higher in women. Cornell Duration was the most accurate ECG criterion for LVH in both sexes, supporting its use as a reliable and accessible screening tool in resource-limited settings.

DIAGNOSTIC ACCURACY OF HANDHELD POINT-OF-CARE ULTRASOUND (POCUS) BY NON-EXPERTS FOR DETECTION OF RHEUMATIC CARDITIS IN ENDEMIC REGIONS: A SYSTEMATIC REVIEW

MARCOS REIS1; MARIA LAURA BARROSO2; MATHEUS VALLE1; CAIO COUGO1; MARIA FERNANDA SILVA1; JÚLIA GIL GIL2; BEATRIZ GONÇALVES1; PETERSON GONTIJO1;

(1) FACULDADE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: The 2015 revision of the AHA Jones criteria marked a paradigm shift by incorporating echocardiography-detected subclinical carditis as a new major diagnostic criterion for acute rheumatic fever (ARF). This update made echocardiographic assessment indispensable, however, standard transthoracic echocardiography (TTE) remains largely unfeasible in high-prevalence, resource-limited regions due to high costs and specialist scarcity. Meanwhile, handheld point-of-care ultrasound (POCUS) emerges as a transformative low-cost option, but its accuracy when operated by non-experts requires systematic validation. Objetivos: To systematically evaluate the diagnostic accuracy of cardiac POCUS performed by non-specialist clinicians for detecting clinical and subclinical rheumatic carditis (mitral/aortic regurgitation) in patients with suspected ARF or asymptomatic individuals in endemic regions, using standard TTE as the reference standard. Métodos: Following PRISMA guidelines, a systematic search was conducted across PubMed, SciELO, MEDLINE, and LILACS for studies published between January 2015 and December 2025, and blindly screened by two independent reviewers. Eligible studies met strict PICO criteria: populations in endemic areas undergoing ARF diagnosis or rheumatic heart disease (RHD) screening, assessed via handheld POCUS by non-experts (focusing strictly on Doppler-detected valvular regurgitation), compared to standard TTE performed by certified experts using WHF 2012/2023 or Jones 2015 criteria. Methodological quality and risk of bias were assessed using QUADAS-2. Resultados e Conclusões: Out of 170 records, 5 studies (n=9,200) were included. QUADAS-2 indicated high bias risk in 3 studies due to partial verification, but universally high applicability. For RHD screening (n=9,123), sensitivity ranged from 70.4% to 86.5% and specificity from 61.4% to 92.0%, with offsite expert review significantly improving specificity. In acute settings (n=77), POCUS achieved 88.0% sensitivity and specificity for subclinical carditis. Diagnostic heterogeneity was strongly linked to operator training intensity. In conclusion, while not replacing standard TTE, POCUS by non-specialists yields acceptable accuracy for initial screening. These findings suggest that task-shifting (delegating echocardiography to non-experts) is a viable strategy for endemic regions. However, its safe implementation requires rigorous standardized training (≥100 supervised exams) and remote expert review to mitigate false positives.

DISTRIBUTION OF GLOBAL LONGITUDINAL STRAIN AND ITS RELATIONSHIP WITH CARDIOVASCULAR RISK FACTORS IN PATIENTS UNDERGOING STRESS ECHOCARDIOGRAPHY

NICOLE CAROLINE ALCÂNTARA1; THIEGO BELLO RIBEIRETE1; ROBERTO DONIZETE NOBRE JUNIOR1; GABRIEL MOHR HENN1; ANA CRISTINA CAMAROZANO1;

(1) COMPLEXO HOSPITAL DE CLÍNICAS DA UNIVERSIDADE FEDERAL DO PARANÁ (CHC-UFPR) - CURITIBA - PR - BRASIL;

Introdução/Fundamentos: Global longitudinal strain (GLS) is a sensitive marker of subclinical systolic dysfunction, allowing for the identification of early changes in myocardial mechanics before a reduction in left ventricular ejection fraction. Changes in GLS have been associated with the presence of cardiovascular risk factors and may contribute to the early detection of subclinical myocardial dysfunction. Objetivos: To describe the global longitudinal strain profile in patients undergoing stress echocardiography and to explore its relationship with cardiovascular risk factors. Métodos: This observational, retrospective, and exploratory study was conducted at a tertiary care hospital in Paraná, Brazil. Clinical and echocardiographic data from patients undergoing stress echocardiography were analyzed, including GLS values at rest and during stress. GLS abnormalities were evaluated according to the presence of hypertension, dyslipidemia, type 2 diabetes mellitus, obesity, and smoking, as well as their relationship with myocardial contractile reserve assessed by ΔGLS. Resultados e Conclusões: A total of 69 patients were included, with a mean age of 70.26 ± 14.16 years, and 78.26% were female. Hypertension was present in 72.46% of the sample, dyslipidemia in 63.77%, and type 2 diabetes mellitus in 30.43%. Alterations in resting GLS were observed in 33.33% of patients, with 21.74% in the gray zone and 11.59% in the pathological zone. Among patients with one cardiovascular risk factor, 38.46% presented abnormal resting GLS. Reduced myocardial contractile reserve assessed by ΔGLS was observed in 57.14% of patients with two cardiovascular risk factors and in 46.15% of those with three or more risk factors. No significant association was found between overall cardiovascular risk burden and ΔGLS (p=0.223). However, in multivariate analysis, hypertension was the only factor independently associated with impaired myocardial contractile reserve assessed by ΔGLS (β=−2.12; p=0.030). A significant prevalence of GLS abnormalities was observed in patients undergoing stress echocardiography, including abnormalities at rest and reduced myocardial contractile reserve. Although the overall burden of risk factors was not significantly associated with ΔGLS, hypertension was independently associated with poorer myocardial contractile reserve. These findings reinforce the potential of GLS for the early identification of subclinical myocardial changes.

ECHOCARDIOGRAPHY IN ADVANCED HFREF ON DOBUTAMINE: VENTRICULAR REMODELING IN CHAGAS CARDIOMYOPATHY AND PARAMETERS ASSOCIATED WITH IN-HOSPITAL MORTALITY

IGOR ROCHA FREIRE1; GABRIEL YSHIDA ALVES BRANDÃO1; JOÃO GABRIEL PEIXOTO SANTANA1; RAFAEL CAMPOS OLIVEIRA1; AGUINALDO FREITAS JUNIOR1; SALVADOR RASSI1; DANIELA DO CARMO RASSI1;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL;

Introdução/Fundamentos: Advanced heart failure with reduced ejection fraction (HFrEF) is associated with high in-hospital mortality. Patients receiving dobutamine represent a high-risk group, often related to Chagasic cardiomyopathy, still prevalent in Brazil's Central-West region. In this setting, the discriminatory value of left ventricular ejection fraction (LVEF) may be limited due to the near-universal presence of severe systolic dysfunction, highlighting the importance of additional parameters such as right ventricular function and functional valvular regurgitation. Objetivos: To describe the echocardiographic profile of patients with HFrEF receiving dobutamine; compare parameters according to etiology; and identify variables associated with in-hospital mortality. Métodos: This was a retrospective, single-center observational study including 67 patients. The following variables were analyzed: LVEF, left ventricular diameters, left atrial volume, tricuspid annular plane systolic excursion (TAPSE), pulmonary artery systolic pressure (PASP), and severity of mitral and tricuspid regurgitation. Comparisons were performed using the Mann–Whitney U test and Fisher's exact test, and correlations using Spearman's coefficient, with a significance level of 5%. Resultados e Conclusões: Median LVEF was 26%, with 62.7% of patients <30%. Among 67 patients, 61.2% had Chagasic etiology. These patients showed greater ventricular remodeling: larger LV end-diastolic diameter (68 vs. 60 mm; p=0.001), lower LVEF (25% vs. 32%; p=0.023), and higher frequency of severe dilation (61% vs. 19%; p=0.028) (Figure 1). LVEF did not differ between death and discharge (24.5% vs. 27.0%; p=0.268). Right ventricular dysfunction (TAPSE <17 mm) was more frequent in deaths (80% vs. 48%; p=0.035). Higher grades of mitral (p=0.013) and tricuspid (p=0.017) regurgitation were associated with in-hospital mortality (Figure 2). In advanced HFrEF receiving dobutamine, LVEF has limited prognostic value, whereas right ventricular dysfunction and functional regurgitation are more strongly associated with in-hospital mortality. Chagasic etiology correlates with more pronounced ventricular remodeling, reinforcing the importance of etiological stratification.

IMPACT OF PRIMARY ALDOSTERONISM ON CARDIAC REMODELING: A SYSTEMATIC REVIEW AND META-ANALYSIS OF STRUCTURAL AND FUNCTIONAL DATA

JOÃO PEDRO BARATIERI PIRES1; ISRAEL FARIAS DA SILVA1; ISADORA MARTINELLI VIEIRA2; JOÃO VICTOR MACEDO TOSETTO1; KAYLE FERRAZ CAMPARA3; GIOVANA SCUSSEL1; ISADORA DOMINIAK DA SILVEIRA1; GIOVANNA CAROLINA GIROTTO2; BRUNO ZILLI PERONI4; VANDERLEI MAGALHÃES DA SILVEIRA3;

(1) UNIVERSIDADE DE PASSO FUNDO - UPF - PASSO FUNDO - RS - BRASIL; (2) ATITUS EDUCACAO - PASSO FUNDO - RS - BRASIL; (3) UNIVERSIDADE DE PASSO FUNDO - PASSO FUNDO - RS - BRASIL; (4) UNIVERSIDADE FEDERAL DA FRONTEIRA SUL - PASSO FUNDO - RS - BRASIL;

Introdução/Fundamentos: Primary aldosteronism (PA) confers a greater cardiovascular risk than essential hypertension (EH) due to the direct cardiotoxicity of aldosterone, which induces adverse myocardial remodeling in addition to pressure overload. This study systematizes echocardiographic evidence to quantify the magnitude of this structural and functional damage to the heart. Objetivos: To quantify the impact of PA on cardiac remodeling, evaluating differences in structural and functional echocardiographic parameters compared to patients with HE. Métodos: A systematic review and meta-analysis was conducted according to PRISMA guidelines. The PubMed, EMBASE, Scopus, and Web of Science databases were searched from their creation until 2025. Observational studies (cross-sectional, case-control, cohort) comparing echocardiographic parameters between adult patients with PA and controls with EH were included. The primary outcome was Left Ventricular Mass Index (LVMI). Secondary outcomes included the incidence of left ventricular hypertrophy (LVH) and GLS. Mean differences (MD) and odds ratios (OR) were calculated using random-effects models, and heterogeneity was assessed using Higgins' I^2. Resultados e Conclusões: After screening 2752 articles, 19 studies were selected for final analysis. It was found that patients with PA had significantly higher LVMI compared to controls with EH (MD: 15.58 g/m²; 95% CI: 12.36-18.80; p<0.001), however, there was heterogeneity (I^2=76%) reflecting methodological, population, and clinical variations in PA. In this context, the direction of the effect was consistent across studies; Subgroup analyses using indexing methods explored these sources of variability, supporting the robustness of the findings. Furthermore, the incidence of left ventricular hypertrophy was approximately 150% higher in the PA group (OR: 2.47; 95% CI: 1.93-3.18; p<0.001). GLS analysis demonstrated subclinical systolic dysfunction in the PA group, with significantly reduced absolute GLS values (MD: 2.98%; 95% CI: 2.65-3.32; p<0.001), indicating compromised longitudinal myocardial deformation. It is concluded that PA induces a more severe phenotype of structural and functional myocardial injury than HE. The increase in ventricular mass with worsening subclinical systolic function (GLS) supports the direct cardiotoxicity of aldosterone. These findings reinforce its myocardial impact and highlight the importance of early diagnosis and management to reduce cardiovascular risk.

LEFT VENTRICULAR DIASTOLIC DYSFUNCTION IN METABOLIC SYNDROME: A SYSTEMATIC REVIEW AND META-ANALYSIS

HENRIQUE VERAS ALVES NAZARIO1; EDUARDO SALOMÃO GONÇALVES ESCAÑO1; HENRIQUE LEITE DA SILVA CABRAL1; ANA LIBERALI SAWABINI CLARA1; ARTHUR DE OLIVEIRA MALHEIROS VILAR1; CARLOS GUN2;

(1) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL; (2) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Metabolic syndrome (MetS) is an increasingly prevalent cardiovascular risk condition associated with adverse cardiac remodeling. Left ventricular diastolic dysfunction (LVDD) represents a common subclinical manifestation and an independent predictor of heart failure with preserved ejection fraction (HFpEF). However, the magnitude of this association has not yet been fully established in the literature. Objetivos: To systematically evaluate the association between MetS and LVDD through a systematic review and meta-analysis, estimating the prevalence of LVDD and the difference in E/e' ratio between individuals with and without MetS. Métodos: A systematic review was conducted in accordance with PRISMA 2020 guidelines and submitted to PROSPERO (under review). PubMed/MEDLINE, Cochrane Library, Embase, and LILACS databases were searched (January 2000 to December 2025). Observational studies comparing echocardiographic diastolic parameters between adults with MetS (defined by NCEP-ATP III, IDF, or harmonized criteria) and controls were included. Outcomes were LVDD prevalence (odds ratio, OR) and E/e' ratio (mean difference, MD). A random-effects model using the DerSimonian-Laird method was applied. Heterogeneity was assessed using I^2 and Cochran's Q test, and publication bias was evaluated by funnel plot and Egger's test. Resultados e Conclusões: A total of 12 studies (n = 12,629) were included in the prevalence analysis and 8 studies in the E/e' analysis. MetS was associated with a higher prevalence of LVDD (OR = 2.49; 95% CI 2.18–2.85; p < 0.001; I^2 = 42.5%). The E/e' ratio was significantly higher in individuals with MetS (MD = 2.08; 95% CI 1.73–2.42; p < 0.001; I^2 = 52.8%). Sensitivity analyses (leave-one-out) confirmed the robustness of the findings, with no significant influence of individual studies on pooled estimates. Metabolic syndrome is associated with a significantly increased prevalence of left ventricular diastolic dysfunction and higher E/e' ratio. These findings highlight the relevance of diastolic impairment as an early manifestation of cardiovascular damage in MetS and suggest a potential role for echocardiographic assessment in risk stratification of these patients.

LEFT VENTRICULAR REMODELING IN PATIENTS WITH ACROMEGALY RECEIVING LONG-TERM CABERGOLINE THERAPY: A 10-YEAR LONGITUDINAL ECHOCARDIOGRAPHIC STUDY

MARIA FERNANDA DE SÁ BEZERRA1; ANNA JÚLIA ANDRINO SCHNEIDER1; MARÍLIA CAVALCANTI DA TRINDADE1; LUDMILLA ALINE GUIMARÃES MOREIRA FARIAS1; ANA GARDENIA LIBERATO PONTE FARIAS1; MARCIA MARIA CARNEIRO2; ERICK FRAGA REBOUÇAS1; ANA BEATRIZ OLIVEIRA DA FONSECA1; ANA ROSA PINTO QUIDUTE1; MANOEL RICARDO ALVES MARTINS1;

(1) UFC - FORTALEZA - CE - BRASIL; (2) HOSPITAL UNIVERSITARIO WALTER CANTIDIO - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Acromegaly is associated with structural and functional cardiac alterations, including ventricular remodeling, increased cardiac dimensions, and diastolic dysfunction, which together comprise the spectrum of acromegalic cardiomyopathy. Although cabergoline is widely used as an adjuvant therapy in the treatment of acromegaly, its long-term effects on cardiac function remain poorly characterized in longitudinal echocardiographic studies. Objetivos: To evaluate changes in cardiac dimensions and left ventricular systolic and diastolic function in patients with acromegaly undergoing long-term cabergoline therapy. Métodos: A historical prospective cohort study conducted at a university referral center. Twenty-one patients with acromegaly receiving cabergoline therapy were included and underwent two serial echocardiographic evaluations performed in 2013 and 2025, corresponding to approximately 10 years of follow-up. Structural and functional cardiac parameters were analyzed, including left ventricular end-diastolic diameter (LVEDD), left ventricular end-diastolic volume (LVEDV), left atrial (LA) volume, left ventricular ejection fraction (LVEF), and the presence of diastolic dysfunction. Resultados e Conclusões: No significant differences were observed in left atrial volume (30 ± 8 mL vs. 34 ± 7 mL; p = 0.068) or left ventricular end-diastolic diameter (49.2 ± 5.4 mm vs. 47.6 ± 5.6 mm; p = 0.085). A significant reduction in left ventricular end-diastolic volume was observed over the follow-up period (114 ± 32 mL vs. 86 ± 29 mL; p < 0.001), accompanied by an increase in left ventricular ejection fraction (64.7 ± 4.7% vs. 68.5 ± 6.4%; p = 0.026). The prevalence of diastolic dysfunction increased numerically from 25% to 55% of patients, although this change was not statistically significant (p = 0.221). In patients with acromegaly receiving long-term cabergoline therapy, a significant reduction in left ventricular end-diastolic volume along with an increase in ejection fraction was observed, suggesting favorable ventricular remodeling over follow-up. Global cardiac dimensions remained stable, and diastolic dysfunction showed a numerical increase without statistical significance. These findings indicate that prolonged cabergoline therapy is not associated with deterioration of cardiac function, with preservation of left ventricular systolic performance during long-term follow-up.

TABLE 1. Echocardiographic variables evolution between evaluations of 21 patients receiving cabergoline therapy

	First Evaluation 2013	Second Evaluation 2025	P value
LVEDD (mm)	49,2 ± 5,4	47,6 ± 5,6	0,085
LVEDV (mL)	114 ± 32	86 ± 29	**<0,001**
LA volume (mL/m²)	30 ± 8 (30)	34 ± 7 (32)	0,068
LVEF (%)	64,7 ± 4,7	68,5 ± 6,4	**0,026**

1 Mean ± sd, (median). **LVEDD** - Left Ventricular End-Diastolic Dimension, **LVEDL** - Left Ventricular End-Diastolic Volume, **LA** - Left Atrium, **LVEF** - Left Ventricular Ejection Fraction.

PROGNOSTIC VALUE OF LEFT VENTRICULAR MYOCARDIAL WORK INDICES IN SEVERE AORTIC STENOSIS UNDERGOING TRANSCATHETER AORTIC VALVE REPLACEMENT: A SYSTEMATIC REVIEW AND META-ANALYSIS

LEANDRO RAFAEL OLIVEIRA SILVA1; KAMILA LUANA SANTOS SILVA2; VICTOR LENO SILVA PAES1; ERIK WILLIAM FARIAS COELHO1; ZILDIVAN ROCHA NASCIMENTO ARAUJO1; ALEF HENRIQUE SPÍRITO SANTO LIMA1; KHAELSON ANDREY BARROSO MOURA1; MONIQUE GISELA OLIVEIRA SILVA1; REGIS BRUNI ANDRIOLO1; JOÃO HENRIQUE ANDRADE ALMEIDA1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Left ventricular myocardial work (LVMW) indices from noninvasive pressure-strain loop analysis provide afterload-corrected assessment of systolic function, overcoming limitations of ejection fraction (EF) and global longitudinal strain (GLS) in aortic stenosis. Individual studies suggest prognostic value in transcatheter aortic valve replacement (TAVR) patients, but no systematic synthesis exists. Objetivos: To evaluate the prognostic value of LVMW indices — global work index (GWI), constructive work (GCW), wasted work (GWW), and work efficiency (GWE) — for mortality in severe aortic stenosis patients undergoing TAVR. Métodos: A PRISMA-compliant systematic review was performed across PubMed, Embase, Cochrane CENTRAL, Scopus, and LILACS through April 2026. Cohort studies reporting hazard ratios (HR) for LVMW indices and clinical outcomes in TAVR patients (minimum 3-month follow-up) were included. Risk of bias was assessed using QUIPS. Adjusted HRs (with study-specific covariate sets) were harmonized to a common scale (per 100 mmHg% GWI increase) via dose-response conversion and pooled using DerSimonian-Laird random-effects inverse-variance meta-analysis; a Hartung-Knapp sensitivity adjustment was applied given small k. Resultados e Conclusões: Seven studies from six countries (1,196 unique patients across 7 cohort-analyses; follow-up 12–60 months) were included, with all-cause mortality (n=5), cardiovascular mortality (n=1), or composite endpoints (n=2). Pre-TAVR GWI independently predicted all-cause mortality in 6/7 studies with incremental value over EF and GLS; GWW showed no prognostic association. Pooled analysis of three studies with harmonizable pre-TAVR GWI (n=854; 297 deaths) demonstrated that each 100 mmHg% increase reduced mortality risk by 5.5% (HR 0.945; 95% CI 0.919–0.972; p<0.001; I²=12.5%); Hartung-Knapp adjustment yielded HR 0.945 (95% CI 0.887–1.006). Sensitivity analyses confirmed robustness of the point estimate (HR range 0.937–0.949). Two post-TAVR studies were not pooled due to heterogeneous endpoints and unverified HR scales. Proposed GWI cut-offs ranged 1234–2323 mmHg%. One study identified GWE as the strongest post-TAVR predictor, linked to ventricular dyssynchrony. Higher pre-TAVR GWI is consistently associated with lower all-cause mortality with low heterogeneity. LVMW provides incremental prognostic value beyond EF and GLS, potentially improving risk stratification and timing of intervention in TAVR candidates.

Legend: Forest plot of pre-TAVR global work index (GWI) and all-cause mortality. Squares represent study-level hazard ratios (HR) per 100 mmHg% increase in GWI, sized by inverse-variance weight; horizontal lines show 95% CI. The diamond indicates the pooled estimate from a DerSimonian-Laird random-effects model (HR 0.945; 95% CI 0.919–0.972; p < 0.001; I² = 12.5%). Values left of HR = 1.0 favor higher GWI.

Abbreviations: AV: aortic valve; CV: cardiovascular; FU: follow-up; GWI: global work index; HF: heart failure; LVEF: left ventricular ejection fraction; NR: not reported; RoB: risk of bias; TAVR: transcatheter aortic valve replacement. Data are presented as mean ± SD or median (IQR). Risk of bias was assessed using the QUIPS tool (Quality in Prognosis Studies) across 6 domains; each domain rated Low (L), Moderate (M), or High (H). The overall judgment reflects the predominant rating across domains.

* Pedersen 2024 reported LVEF and hemodynamic data classified by AR subtype and EF category; no single global value was available.

† Aemer 2024: MW was measured post-TAVR (within 2 weeks after the procedure), not at baseline.

‡ Composite endpoint: all-cause death, worsening of dyspnea (NYHA class ≥ 3), or rehospitalization for cardiovascular events at 1 year.

§ Wu 2023 and Wu 2024 represent partially overlapping pre- and post-TAVR analyses of the same Leiden cohort (2013–2020; ~854 unique patients). Wu 2023 contributed to the pre-TAVR meta-analysis; Wu 2024 was described narratively.

PROGNOSTIC VALUE OF MYOCARDIAL STRAIN AND CONVENTIONAL ECHOCARDIOGRAPHIC PARAMETERS IN CHRONIC CHAGAS CARDIOMYOPATHY: A SYSTEMATIC REVIEW AND META-ANALYSIS

FELIZARDO JOSÉ LEANDRO PEREIRA1; JOÃO GUILHERME GOMES PEDROSA1; KAROLINA AZEVEDO BRINGEL1; MARIA EDUARDA FRANCO LONDRES GOMES1; LETICIA FONSECA SILVA1; SADRAK LYON DANTAS PONTES1; JOSÉ RICARDO PIRES PEREIRA1; ANDRE TELIS DE VILELA ARAÚJO1;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL;

Introdução/Fundamentos: Chagas Disease remains a major cause of cardiomyopathy in endemic regions. Chagas Cardiomyopathy (CC) is associated with progressive myocardial damage and adverse outcomes. While left ventricular ejection fraction (LVEF) is widely used for risk stratification, myocardial strain imaging has emerged as a more sensitive tool for detecting subclinical dysfunction. Objetivos: To evaluate the prognostic value of myocardial strain parameters and compare their performance with conventional echocardiographic measures in patients with chronic CC. Métodos: A systematic review was conducted following PRISMA guidelines, we searched in PubMed, Embase, Web of Science, and Cochrane Library using descriptors and their variations for the terms: Chagas Cardiomyopathy; Echocardiography; Prognosis. Study selection was performed independently by two reviewers using the Rayyan platform. Studies that evaluated strain and conventional echocardiographic parameters were included. Hazard ratios (HRs) were standardized to ensure consistency in the direction of effect. Statistical analysis was performed at RStudio. A random-effects meta-analysis was conducted based on log(HR) and standard errors. Resultados e Conclusões: A total of 4 studies were included, with 704 participants. In univariate analyses, global longitudinal strain (GLS) (HR 1.25; 95% CI 1.21–1.30) and LVEF (HR 0.93; 95% CI 0.92–0.94; I² = 0%) showed strong and consistent associations with adverse outcomes. However, in multivariable analyses, GLS (HR 1.03; 95% CI 0.97–1.11; I² = 60.9%) and LVEF (HR 1.56; 95% CI 0.50–4.85; I² = 80.9%) were not significantly associated with outcomes. Circumferential strain remained significantly associated in both univariate (HR 1.26; 95% CI 1.20–1.31) and multivariable analyses (HR 1.10; 95% CI 1.04–1.16; I² = 47.8%). Radial strain showed a modest association in multivariable analysis (HR 0.98; 95% CI 0.96–1.00; I² = 34.1%), but not in univariate analysis. The E/e' ratio was significantly associated with outcomes (HR 1.12; 95% CI 1.05–1.19). Myocardial strain parameters provide incremental and complementary prognostic information in chronic CC. Circumferential strain demonstrated the most consistent and independent association with adverse outcomes, whereas global longitudinal strain and left ventricular ejection fraction primarily reflected overall disease severity without consistent independent prognostic value. These results support a multiparametric approach integrating myocardial deformation analysis to improve risk stratification.

SUBCLINICAL MYOCARDIAL DYSFUNCTION IN ADULT PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF GLOBAL LONGITUDINAL STRAIN PARAMETERS

VICTOR LENO SILVA PAES1; LEANDRO RAFAEL OLIVEIRA SILVA1; ZILDIVAN ROCHA NASCIMENTO ARAUJO1; ERIK WILLIAMS FARIAS COELHO1; ALEF HENRIQUE ESPIRITO SANTO LIMA1; KHAELSON ANDREY BARROSO MOURA1; KAMILA LUANA SANTOS SILVA2; REGIS BRUNI ANDRIOLO1; JOÃO HENRIQUE ANDRADE ALMEIDA1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Cardiovascular disease is a leading cause of mortality in Systemic Lupus Erythematosus (SLE). Myocardial involvement often progresses silently, driven by inflammation, autoantibodies, and secondary metabolic insults. Left Ventricular Ejection Fraction (LVEF) is notoriously insensitive to this early-stage damage, frequently leading to a false sense of security in SLE patients with “normal” conventional echocardiograms. Conversely, Global Longitudinal Strain (GLS) by 2D-speckle-tracking has emerged as a highly sensitive “biological sensor,” capable of detecting subclinical myocardial failure long before LVEF declines. Objetivos: To assess the magnitude of the difference in Global Longitudinal Strain (GLS) between patients with SLE and healthy controls in order to quantify subclinical systolic dysfunction and analyze its correlation with disease activity (SLEDAI). Métodos: A systematic review and meta-analysis were conducted in accordance with the PRISMA 2020 guidelines. A search of the PubMed/MEDLINE, Embase, and Cochrane databases identified the initial records. After rigorous selection and full-text review, 9 observational studies were included in the final analysis. The studies compared GLS in adult patients with SLE and preserved LVEF (≥50%) with healthy controls. Methodological quality was assessed using the Newcastle-Ottawa Scale (NOS), and data were synthesized using random-effects models. Resultados e Conclusões: A total of 9 studies comprising 634 SLE patients and 451 healthy controls were included. The population consisted predominantly of young females with preserved LVEF. Pooled analysis using a random-effects model demonstrated a significantly impaired GLS in SLE patients compared to controls (Mean Difference [MD]: 2.15%; 95% CI: 1.49 to 2.82; p < 0.0001). Significant heterogeneity was observed across studies (I^2 = 81.9%, p < 0.0001). Furthermore, qualitative synthesis indicated a consistent correlation between higher disease activity, measured by SLEDAI scores, and a greater magnitude of GLS impairment. This meta-analysis confirms the presence of subclinical systolic dysfunction in young women with SLE, a high-risk demographic group often overlooked by conventional echocardiography. The correlation between reduced GLS and elevated SLEDAI scores highlights the direct cardiotoxic impact of inflammatory flares. Ultimately, these findings support the routine integration of GLS into cardiovascular monitoring of SLE to enable early risk reclassification and cardioprotective interventions.

Table 1: Characteristics of the included studies

Legend: SLE: Systemic Lupus Erythematosus; **LVEF:** Left Ventricular Ejection Fraction; **GLS:** Global Longitudinal Strain; **SLEDAI:** Systemic Lupus Erythematosus Disease Activity Index; **NR:** Not Reported. Numeric data are presented as Mean ± Standard Deviation (SD). The quality score was assessed using the Newcastle-Ottawa Scale (NOS), where higher scores indicate a lower risk of bias.

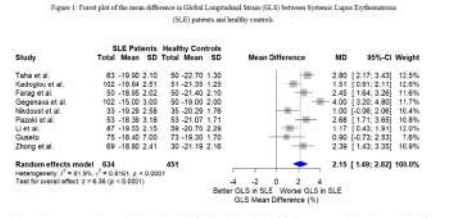

Figure 1. Forest plot of the mean difference in Global Longitudinal Strain (GLS) between Systemic Lupus Erythematosus (SLE) patients and healthy controls.

Legend: Squares represent the mean difference (MD) of GLS for each individual study, with the size proportional to the study's statistical weight. Horizontal lines indicate the 95% Confidence Intervals (95% CI). The blue diamond represents the pooled overall effect (MD = 2.15%, 95% CI: 1.49 to 2.82; p < 0.0001) using a random-effects model. Since normal GLS is a negative value, effect sizes to the right of the line of no effect (zero) indicate less negative values, thereby reflecting **worse subclinical myocardial function** in the SLE group compared to controls.

THREE-DIMENSIONAL SPECKLE TRACKING ECHOCARDIOGRAPHY IN MEASURING LEFT VENTRICULAR MYOCARDIAL FUNCTION IN ADULT DIABETIC PATIENTS WITH OR WITHOUT OTHER COMMORBIDITIES: A SYSTEMATIC REVIEW AND META-ANALYSIS

VERA LOUISE FREIRE DE ALBUQUERQUE FIGUEIREDO1; JOÃO VICTOR DE OLIVEIRA RAMOS1; LUIZ HENRIQUE CARTAXO FERNANDES1; JOÃO RICARDO CAVALCANTI DO NASCIMENTO1; FELIPE BEZERRA ANDRADE1; GABRIEL SOUZA DANTAS MENDES LEITE1; GIOVANNA DE SOUSA OLIVEIRA1; PABLO OLIVEIRA CORDEIRO1; MARCELO DANTAS TAVARES DE MELO1;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL;

Introdução/Fundamentos: Diabetes mellitus (DM) is associated with structural and functional myocardial alterations that may lead to diabetic cardiomyopathy and subclinical left ventricular (LV) dysfunction. Conventional echocardiographic parameters, particularly LV ejection fraction (LVEF), often remain preserved in early stages, limiting early detection.Three dimensional speckle-tracking echocardiography (3D-STE) enables comprehensive assessment of LV mechanics through multidirectional myocardial strain analysis. However, evidence regarding its diagnostic performance in diabetic populations remains heterogeneous. Objetivos: To evaluate the use of 3D-STE in assessing LV myocardial function in adults with DM and determine the impact of other commorbidities on these parameters. Métodos: A systematic review and meta-analysis was conducted following PRISMA guidelines. PubMed, Web of Science, and Embase were searched for observational studies evaluating 3D-STE in adults with DM. Primary outcomes included LVEF and myocardial strain parameters: global longitudinal strain (GLS), global circumferential strain (GCS), global radial strain (GRS), and global area strain (GAS). Pooled mean differences (MD) with 95% confidence intervals (CI) were calculated using random-effects models. Subgroup analyses evaluated glycemic control, obesity, and hypertension. Resultados e Conclusões: Twenty-eight studies including 1,182 diabetic patients and 1,269 healthy controls were analyzed. Compared with controls, diabetic patients showed significant impairment in all strain parameters: GLS (MD −2.73%; 95% CI −3.27 to −2.18; p<0.001), GCS (MD −1.65%; 95% CI −2.15 to −1.15; p<0.001), GAS (MD −2.61%; 95% CI −3.42 to −1.81; p<0.001), and GRS (MD −5.06%; 95% CI −6.59 to −3.52; p<0.001). Heterogeneity was moderate to high. In contrast, LVEF showed only a modest reduction (MD −1.04%; 95% CI −1.68 to −0.39; p=0.002; I^2=61.9%). Poor glycemic control (HbA1c ≥7%) was associated with greater impairment in GLS (MD −3.43%) and GAS (MD −5.07%). Obese diabetic patients (BMI ≥25 kg/m²) showed pronounced reductions in LVEF (MD −3.78%) and GLS (MD −4.64%), while hypertensive diabetics exhibited greater GLS impairment than normotensive patients (−2.83% vs −1.54%). Conclusion: 3D-STE consistently detects early subclinical LV dysfunction in adults with DM, evidenced by significant impairment across multiple strain parameters, while myocardial dysfunction is exacerbated by poor glycemic control, obesity, and hypertension.

A DECADE OF MYOCARDIAL PERFUSION SCINTIGRAPHY REVEALS PERSISTENT REGIONAL INEQUALITIES IN CARDIAC IMAGING ACROSS BRAZIL

JOÃO VITOR DOMINGOS ALVES1; ERICK FROTA GOMES FIGUEIREDO2; RICARDO FERREIRA GOMES3; SALWA MUHAMMAD MUSA HAMDAN3; RONILSON FERREIRA FREITAS3; ANTHONIA YASMYN BARAUNA MELO1; MARIA LINA BRITTO DE SOUZA1; SUELLEN LIMA DA COSTA1;

(1) AFYA MANACAPURU - MANACAPURU - AM - BRASIL; (2) UEA - MANAUS - AM - BRASIL; (3) UNIVERSIDADE FEDERAL DO AMAZONAS - MANAUS - AM - BRASIL;

Introdução/Fundamentos: Access to cardiovascular imaging remains uneven in middle-income countries. Myocardial perfusion scintigraphy (MPS) is a guideline-recommended test for Coronary Artery Disease, which represents a significant global public health problem. Early and accurate detection of myocardial ischemia is essential for proper risk assessment, therapeutic decision-making, and optimization of clinical outcomes; however, its distribution within public health systems is still poorly understood. Objetivos: To evaluate temporal trends, regional disparities, and costs of MPS in Brazil's Unified Health System from 2016 to 2025. Métodos: Time-series study using DATASUS outpatient data and IBGE population estimates. Outcomes included procedure volume and public expenditure for stress and rest MPS by region. Statistical analyses included Mann-Kendall trend test, ANOVA for regional comparisons, and compound annual growth rate. Rates were adjusted per capita. Resultados e Conclusões: Over the decade (2016-2025), national MPS volume showed an overall upward trend (stress exams: 124,760 to 151,031), despite a sharp COVID-19 disruption in 2020, followed by a robust recovery (CAGR +9.1%). Regional disparities, evaluated using population-adjusted rates, remained extreme. In 2025, the Southeast concentrated the highest volume (90,034 stress exams; 1.01/1,000 inhabitants), starkly contrasting with the South (0.76/1,000), Midwest (0.45/1,000), Northeast (0.43/1,000), and North (0.27/1,000) (p<0.001). Total investment exceeded R$ 521 million. Stress and rest volumes remained proportional (≈1:1). Limitations inherent to administrative databases, including underreporting, should be considered; however, the comprehensive decade-long national dataset and robust population-adjusted statistics strengthen these findings. In conclusion, despite general procedural growth, extreme geographic inequalities in MPS volumes persist, with the Southeast performing 3.7 times more per capita exams than the North. These findings highlight structural disparities that demand targeted health policy strategies.

Introdução/Fundamentos: Cardiac amyloidosis is a progressive and often underdiagnosed infiltrative cardiomyopathy, resulting from the extracellular deposition of protein fibrils in the myocardium. Clinical nonspecificity and overlap with other causes of left ventricular hypertrophy contribute to diagnostic delay and worse prognosis. Objetivos: To evaluate the main diagnostic methods used in the identification of cardiac amyloidosis, analyzing their accuracy, clinical applicability, and prognostic impact. Métodos: Systematic review conducted according to the PRISMA protocol, with searches in the PubMed and LILACS databases. A total of 50 studies published between 2021 and 2026 were identified, of which 15 met the eligibility criteria after methodological screening. Resultados e Conclusões: Myocardial scintigraphy by SPECT showed the best diagnostic performance among noninvasive imaging methods, with sensitivity of 98%, specificity of 92%, and AUC of 0.99, outperforming cardiac magnetic resonance imaging (84%, 87%, and 0.92) and PET (78%, 95%, and 0.95), consolidating itself as the main diagnostic tool for ATTR-CM. Computed tomography with myocardial extracellular volume fraction demonstrated sensitivity of 92.8%, specificity of 84.8%, and AUC of 0.94, proving to be a promising alternative, especially in patients with contraindications to magnetic resonance imaging. In the prognostic field, cardiac magnetic resonance imaging showed relevant stratification value, as higher extracellular volume values were associated with increased mortality (HR 2.90; 95% CI 1.68–5.01), reinforcing its utility beyond structural diagnosis. Artificial intelligence tools also demonstrated high diagnostic accuracy, with AUC up to 0.999, sensitivity of 98.9%, and specificity of 99.5%, highlighting their potential in optimizing early screening. Furthermore, patients diagnosed at early stages showed a 57% reduction in mortality when early disease-modifying therapy was initiated, reinforcing the direct prognostic impact of early recognition. Noninvasive diagnostic methods play a central role in the identification and prognostic stratification of cardiac amyloidosis. The integration of multimodal diagnostic strategies and early recognition of the disease favor greater diagnostic accuracy, better risk stratification, and higher therapeutic effectiveness, directly impacting clinical outcomes.

DIAGNOSTIC ACCURACY OF IMAGING MODALITIES FOR ATTR CARDIAC AMYLOIDOSIS DETECTION IN CANDIDATES FOR TRANSCATHETER AORTIC VALVE IMPLANTATION WITH SEVERE AORTIC STENOSIS: A SYSTEMATIC REVIEW

LUCAS MARINHO REIS DA CUNHA SILVA1; RAFAEL ALVES DE OLIVEIRA1; THIAGO VITTOR SILVA FREITAS1; BRUNO DE FREITAS SILVA1; RODRIGO BOTTURA NUEVO VIVEIROS DE ARAUJO1; LEONARDO COCHARRO PRETO1; LUCAS RODRIGUES SANTA RITA1; JADSON FERREIRA DA SILVEIRA1; VALÉRIA SILVEIRA DIAS1; EDGAR DE PAULA LADEIA FILHO1; DEISE JANIELLY PEREIRA MELO ARAÚJO1; RAFAEL ALVES PINA1;

(1) UNIVERSIDADE BRASIL - FERNANDOPOLIS - SP - BRASIL;

Introdução/Fundamentos: TTR cardiac amyloidosis (ATTR-CM) and severe aortic stenosis (AS) frequently coexist in elderly patients, with concomitant disease associated with one-year mortality exceeding 50% versus 20% in isolated AS. ATTR-CM remains underdiagnosed in TAVI candidates due to the lack of a standardized imaging-based screening strategy. Objetivos: To systematically review and compare the diagnostic accuracy of imaging modalities — echocardiography, CMR, CT, bone scintigraphy, and PET/MRI — for ATTR-CM detection in severe AS patients evaluated for TAVI. Métodos: Systematic review following PRISMA guidelines. Searches were performed in PubMed and EMBASE. Of 307 records identified, 178 were screened by title, 58 by abstract, and 31 by full text; 8 studies (n=1,603 patients) met eligibility criteria. Diagnostic accuracy metrics (sensitivity, specificity, AUC) were synthesized. Heterogeneity in reference standards (bone scintigraphy grade ≥2, endomyocardial biopsy, or ESC criteria) precluded formal statistical pooling. Resultados e Conclusões: The prevalence of ATTR-CM among TAVI candidates ranged from 3.5% to 22% across studies, highlighting relevant underdiagnosis in routine practice. Diagnostic performance varied substantially by modality. ^{18}F-fluoride PET/MRI achieved perfect discrimination in LGE regions (sensitivity and specificity 100%; AUC 1.00), though its widespread applicability remains limited. CT-derived ECV demonstrated excellent accuracy. CMR-ECV was significantly elevated in ATTR-CM patients; however, typical transmural LGE was absent in up to 64% of confirmed cases, underscoring its limited sensitivity as a standalone criterion. Echocardiographic indices demonstrated moderate accuracy with high negative predictive value (up to 96%), supporting their role as first-line screening tools. In conclusion, no single imaging modality combines optimal accuracy, availability, and feasibility for universal ATTR-CM screening in TAVI candidates. The evidence supports a stepwise strategy incorporating echocardiographic strain indices as initial screening for tracking ATTR.

FDG PET/CT VERSUS CARDIAC MAGNETIC RESONANCE IMAGING IN THE DIAGNOSIS OF CARDIAC SARCOIDOSIS WITHOUT PRIOR SYSTEMIC DIAGNOSIS: A SYSTEMATIC REVIEW

LUCAS MARINHO REIS DA CUNHA SILVA1; THIAGO VITTOR SILVA FREITAS1; RAFAEL ALVES DE OLIVEIRA1; BRUNO DE FREITAS SILVA1; RODRIGO BOTTURA NUEVO VIVEIROS DE ARAUJO1; RAFAEL ALVES PINA1; LEONARDO COCHARRO PRETO1; LUCAS RODRIGUES SANTA RITA2; JADSON FERREIRA DA SILVEIRA1; VALÉRIA SILVEIRA DIAS1; EDGAR DE PAULA LADEIA FILHO1; DEISE JANIELLY PEREIRA MELO ARAÚJO1;

(1) UNIVERSIDADE BRASIL - FERNANDOPOLIS - SP - BRASIL; (2) UNIÃO DAS FACULDADES DOS GRANDES LAGOS - SÃO JOSÉ DO RIO PRETO - SP - BRASIL;

Introdução/Fundamentos: Cardiac sarcoidosis (CS) is a significant cause of ventricular arrhythmia, advanced atrioventricular block, and sudden cardiac death. In patients without an established systemic diagnosis, the choice between fluorodeoxyglucose positron emission tomography/computed tomography (FDG PET/CT) and cardiac magnetic resonance imaging (CMR) as the initial diagnostic modality remains controversial, hindering early diagnosis and appropriate clinical management. Objetivos: To compare the diagnostic accuracy of FDG PET/CT and CMR in patients with suspected CS in the absence of a previously established systemic diagnosis. Métodos: A systematic electronic search was conducted in the PubMed and Cochrane databases. Original studies evaluating the diagnostic performance of FDG PET/CT and/or CMR in adults with suspected or confirmed CS were included, provided they reported accuracy measures and were published between 2016 and 2026. Of the 59 records identified, duplicates, review articles, case reports, theses, and studies published in languages other than English were excluded. Additional exclusion criteria comprised narrative reviews, therapeutic monitoring studies, and populations in which active systemic sarcoidosis with prior documentation was a mandatory inclusion criterion. Following double-blind title and abstract screening and full-text review, four studies were prioritized based on their direct focus on predictive mechanisms and prevention strategies. Data were systematically extracted according to the PRISMA protocol and methodically tabulated. Resultados e Conclusões: Four studies were included, encompassing a total of 176 patients. The findings demonstrated that CMR with late gadolinium enhancement (LGE) yielded superior standalone diagnostic accuracy (sensitivity 82%, specificity 78%, AUC 0.80) compared to standalone cardiac FDG PET/CT (sensitivity 60%, specificity 56%, AUC 0.58). The PET/CMR fusion approach maximized sensitivity (94%), albeit with a reduction in specificity (44%). Furthermore, significant evidence of diagnostic reclassification was observed in 22% of cases when CMR was added to standalone FDG PET/CT, reinforcing the complementary nature of both modalities. The available evidence suggests that CMR with LGE demonstrates superior standalone diagnostic accuracy for CS relative to FDG PET/CT, whereas the combination of both modalities maximizes sensitivity at the expense of specificity.

IMAGING-DEFINED CARDIOVASCULAR RISK IN ASYMPTOMATIC TYPE 2 DIABETES: A META-ANALYSIS COMPARING SPECT AND MYOCARDIAL STRAIN

RODRIGO DIÓGENES MARTINS1; MARINA ISADORA DE ANDRADE LEMOS1; CAROLINE MARTINS FAVERO1; VITOR LUÍS FERREIRA PAIVA1; ANISIO UCHOA LEITE SANTANA1; ANA CAROLINA DE JESUS SOARES FREIRE1; JOÃO VITOR BIANCALANA FERREIRA PERES CALIL1; LEONARDO DEXHEIMER DA SILVA1; BRUNO CARAMELLI2;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Adults with type 2 diabetes mellitus (T2DM) are at increased cardiovascular risk even without symptoms. Non-invasive cardiovascular imaging may improve risk stratification, but the prognostic value of myocardial perfusion imaging with single-photon emission computed tomography (SPECT) and strain-based echocardiography remains uncertain. Objetivos: To evaluate the prognostic value of abnormal non-invasive cardiovascular imaging findings and compare imaging modalities in asymptomatic adults with T2DM. Métodos: We conducted a systematic review and meta-analysis of longitudinal studies (prospective cohorts and randomized trial follow-up analyses) assessing the association between abnormal imaging findings and cardiovascular outcomes, including major adverse cardiovascular events (MACE) and myocardial infarction/acute coronary syndrome (MI/ACS). PubMed/MEDLINE, Embase, and Cochrane Library were searched from inception to January 4, 2026. Random-effects models pooled hazard ratios (HRs) with 95% confidence intervals (CIs). Subgroup analyses and meta-regression were performed by imaging modality, allowing indirect comparisons. Resultados e Conclusões: Twelve studies were included in the qualitative synthesis and nine in the meta-analysis, comprising 5,181 patients. Mean age was 60.6 years, 57.4% male, mean HbA1c 8.13%, and diabetes duration 10.8 years. Follow-up varied across studies. Abnormal imaging findings were associated with increased risk of MACE (HR 2.40, 95% CI 1.77–3.26; I^2 = 0%) and MI/ACS (HR 1.96, 95% CI 1.64–2.34; I^2 = 2.2%). SPECT showed consistent associations for MI/ACS (HR 2.24, 95% CI 1.76–2.87) and MACE (HR 2.48, 95% CI 1.52–4.05). Echocardiographic and strain parameters also showed relevant associations, particularly for MACE (HR 3.95 and 2.00), though based on fewer studies. Meta-regression showed no significant effect modification. In asymptomatic adults with T2DM, abnormal non-invasive cardiovascular imaging findings are associated with increased risk of adverse cardiovascular events. These associations were observed across different imaging approaches, supporting the concept of a shared high-risk phenotype rather than modality-specific effects. These findings support imaging-based risk stratification and highlight the need for prospective head-to-head studies to define the role of each modality.

MYOCARDIAL FLOW RESERVE IDENTIFIES LOWER-RISK PHENOTYPES ACROSS CORONARY CALCIUM BURDEN: A SYSTEMATIC REVIEW AND META-ANALYSIS

MARIA ANTÔNIA COSTA CRUZ AKABANE1; HANSA HARESH MULCHAND NAWANI2; MAHMOUD EINIEH3; MAHDI MOHAMMED4; LEE JOSEPH5; SIMONE CRISTINA SOARES BRANDAO5; MARCELO F DI CARLI5;

(1) UFJF - JUIZ DE FORA - MG - BRASIL; (2) UNIVERSIDAD LATINA DE PANAMÁ - PANAMA; (3) UNIVERSITY OF DEBRECEN, DEBRECEN, HUNGARY - HUNGARY; (4) UNIVERSITY COLLEGE DUBLIN - IRELAND; (5) BRIGHAM AND WOMEN'S HOSPITAL/HARVARD MEDICAL SCHOOL - UNITED STATES;

Introdução/Fundamentos: Introduction: Coronary artery calcium (CAC) reflects atherosclerotic burden but not functional significance. Myocardial flow reserve (MFR), derived from positron emission tomography (PET), integrates epicardial and microvascular function. Their combined prognostic value remains unclear. We evaluated the joint prognostic role of CAC and MFR and whether preserved MFR identifies lower-risk phenotypes across CAC strata. Objetivos: Objective: To evaluate the combined prognostic value of coronary artery calcium (CAC) and positron emission tomography (PET)–derived myocardial flow reserve (MFR), and to determine whether preserved MFR identifies lower-risk phenotypes across different CAC strata. Métodos: Methods: A systematic review and meta-analysis were conducted according to PRISMA and MOOSE guidelines. PubMed, Embase, and Cochrane databases were searched in March 2026 for observational studies reporting CAC categories and PET-derived MFR. Impaired MFR was defined as <2, and CAC as 0, 1–399, and ≥400. The primary outcome was major adverse cardiovascular events (MACE). Random-effects models estimated pooled risk ratios (RRs) and prevalence with 95% confidence intervals (CIs). Resultados e Conclusões: Results: Four studies (N = 10,971; mean age 65.2 ± 11.1 years; 53.9% female) were included. Overall, 49.5% had impaired MFR. Its prevalence increased with CAC (40% in CAC=0, 49% in CAC 1–399, 53% in CAC ≥400). Preserved MFR (≥2) was associated with a 66% lower risk of MACE (RR 0.34, 95% CI 0.26–0.44; p<0.001; I^2=47.3%). This association was consistent across CAC strata: CAC=0 (RR 0.27; I^2=0%), CAC 1–399 (RR 0.32; I^2=58%), and CAC ≥400 (RR 0.46; I^2=0%). Conclusion: Preserved MFR identifies a lower-risk phenotype across all CAC categories. Despite increasing impairment with higher CAC, MFR provides complementary prognostic information, supporting its integration with CAC for improved risk stratification.

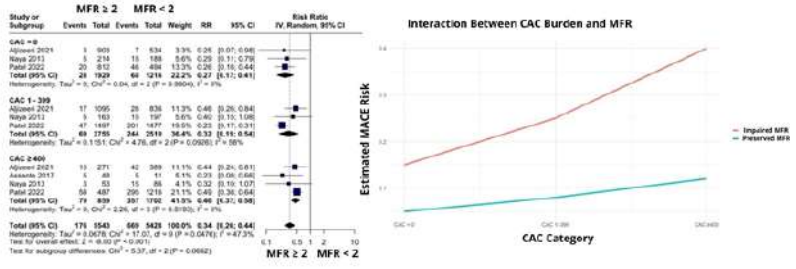

Figure. Association of myocardial flow reserve (MFR) and coronary artery calcium (CAC) with MACE. Preserved MFR (≥2) is associated with lower risk across all CAC strata, despite increasing risk with higher CAC burden.

TEMPORAL TRENDS IN MYOCARDIAL PERFUSION IMAGING: A LONGITUDINAL ANALYSIS OF ABNORMAL SPECT RESULTS

RAFAEL DE LORENZO LIMA1; RONALDO DE SOUZA LEÃO LIMA2; PAULA FAVIERI DE MELO SILVA3; ANDRÉ LUIZ BEZERRA4; ANDREA DE LORENZO3;

(1) UNIVERSIDADE FEDERAL DO ESTADO DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) DASA - RIO DE JANEIRO - RJ - BRASIL; (3) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL; (4) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Myocardial Perfusion Imaging (MPI) remains a cornerstone in the diagnostic workup of patients with suspected coronary artery disease (CAD). Over the past decade, there have been substantial shifts in cardiovascular care, characterized by more aggressive management of cardiac risk factors as well as evolving criteria for imaging referrals. Despite these advancements, gender-based disparities in the presentation, diagnosis, and outcomes of CAD continue to be a subject of intense clinical scrutiny. Objetivos: This study aimed to evaluate longitudinal trends in the prevalence of abnormal results in MPI and to identify potential disparities based on patient gender. Métodos: Institutional records of a network of Brazilian, private, Nuclear Cardiology laboratories, were analyzed to determine the diagnostic yield of MPI over a 15-year period (2009–2024). MPI studies were read by 2 experienced observers, and abnormal results were considered as the presence of either myocardial ischemia or infarction. A value of $p<0.05$ when comparing frequencies was considered statistically significant. Resultados e Conclusões: In the overall period, 96,009 studies were performed, among which 18.2% were abnormal. From 2009 to 2024, there was a reduction in the frequency of abnormal MPI studies, from 31.5% to 16.2% ($p<0.001$). In contrast to the general trend, the percentage of abnormal MPI results within the female subgroup increased, from 50.4% to a maximum of 56.4% in 2020 ($p<0.001$), stabilizing at 54% in the final 2 years of the analyzed period. In conclusion, in this cohort, along 15 years there was an overall decline in abnormal MPI results, which may suggest a shift towards the indication of the test for lower-risk individuals, or even improvements in primary cardiovascular prevention and earlier medical intervention in the general patient population. However, there was a paradoxical increase of the frequency of abnormal scans in women, which might reflect either an increase in the burden of CAD in women, driven by multiple (including sex-specific) biologic and social risk factors, or an increased awareness regarding the atypical presentation of CAD in women, leading to more appropriate patient selection for imaging. The rising trend among women highlights a significant shift in the diagnostic landscape, from a male to a female predominance.

ABDOMINAL AORTIC ANEURYSM BIOMECHANICAL EVALUATION: IN SILICO EVALUATION

LEONARDO CAMPOS JUNQUEIRA1; DANIEL CAMPOS SILVA1; MARCONE LIMA SOBREIRA1;

(1) UNIVERSIDADE ESTADUAL PAULISTA - BOTUCATU - SP - BRASIL;

Introdução/Fundamentos: Abdominal aortic Aneurysm (AAA) is defined as a local dilatation of the aorta with diameter exceeding 30 mm. This condition affects 35.12 million people between the ages of 30 and 79 worldwide and, although manly asymptomatic, the dilatation of the aortic wall weakness the vessel structure and eventually leads to its rupture. With the advance of technology, biomechanical analysis is being developed to better evaluate AAA behavior and rupture risk. Therefore, Peak wall stress (PWS), the highest tension exerted on the AAA wall, Peak wall rupture index (PWRI), the ratio between the local stress and the wall resistance, and Regional aortic weakness (RAW), an estimate of the local weakness of the aortic wall, are posted as promising index for better understanding the AAA. Objetivos: The aim of this study was to evaluate the biomechanical indexes behaviors in large AAA, utilizing finite element analysis (FEA) on computed generated 3D-model. Métodos: Computed tomography (CT) scan images were collected from patients with AAA larger than 55 mm in men and 50 mm in women. Patients with low-quality CT scans were excluded. For each image a 3D model of the aorta was produced, and FEA was used to divide the geometry into a mesh with several smaller elements, from which the pressure distribution was calculated. Based on these results, PWS, PWRI and RAW were obtained (Img.1). For data analysis, Kruskal-Wallis and Tau-Kendall test were used. Resultados e Conclusões: Five patients were evaluated, with a mean age of 71 years (61-78) and a mean BMI of 30.2 (25.3–38.7). The average maximum diameter was 75.18mm. Geometrical and biomechanical aspects are shown in Img 2. Between patients, the average of PWSmax was 1.859MPa and of PWSmean was 0.2814MPa. Although the average PWS for all patients remained within the tension values observed in stable and smaller aneurysms described in literature (below 0.45MPa), all patients presented maximum PWS values similar to those found in ruptured AAA (above 0.7MPa). This suggests that the point of highest tension is significantly more relevant for predicting aneurysmal rupture than just the average AAA wall tension. The same can be observed in RAW, which although meanRAW suggests low levels of wall weakness, the high maximum value of RAW indicates that there is structural heterogeneity with localized regions of lower resistance. And this heterogeneity may play an important role in initiating rupture. Thus, this suggests that AAA distorts aortic wall biomechanical properties region specific.

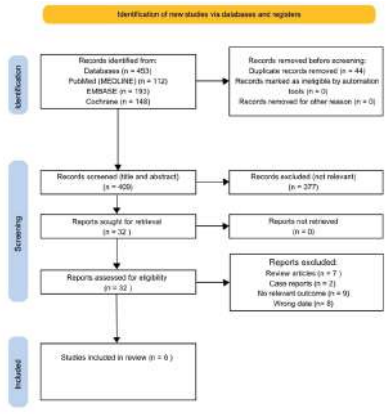
EFFECTS OF GLP-1 RECEPTOR AGONISTS ON CARDIAC REMODELING AND EPICARDIAL ADIPOSE TISSUE ASSESSED BY CARDIAC MAGNETIC RESONANCE: A SYSTEMATIC REVIEW

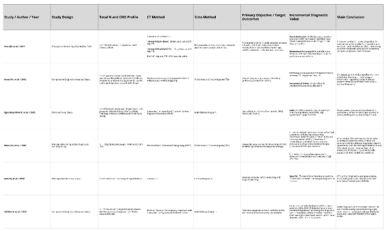
CARLA GROSSL1; GIOVANA FOGGIATTO PROCHNER1; GUSTAVO CESNIK MIRANDA1; ISABELA SAORI AGUIAR TESLUK1; LETICIA LAZZARINI BULLA1; LORRAYNE MARIA COBLINSKI HRYSAY1; VALÉRIA TRENTO1; VITÓRIA GABRIELLE VENTURA1; ALEXANDRA INGRID DOS SANTOS CZEPULA1;

(1) FACULDADES PEQUENO PRINCIPE - CURITIBA - PR - BRASIL;

Introdução/Fundamentos: Cardiometabolic diseases are key determinants of pathological cardiac remodeling and epicardial adipose tissue (EAT) expansion, both recognized as early markers of cardiovascular risk. GLP-1 receptor agonists (GLP-1RA) have emerged as a promising therapeutic class, with demonstrated reduction in major adverse cardiovascular events (MACE). In this context, cardiac magnetic resonance (CMR) represents the gold standard for the assessment of cardiac structure, function, and tissue characterization. Objetivos: To evaluate the effects of GLP-1 receptor agonists on cardiac remodeling and epicardial adipose tissue volume in patients with cardiometabolic diseases, as assessed by CMR. Métodos: This systematic review followed PRISMA guidelines. The PICO strategy included patients with cardiometabolic diseases; intervention with GLP-1RAs; comparison with placebo or standard care; and outcomes defined as CMR-derived parameters of cardiac remodeling and EAT. A search was performed in PubMed, BVS, Scopus, and Embase from database inception to 2026. Study selection was conducted independently by two reviewers, followed by standardized data extraction. The protocol was registered in PROSPERO. Risk of bias was assessed by Cochrane RoB 2 and ROBINS-I V2 tools. Resultados e Conclusões: A total of 157 records were identified, of which 13 were selected for full-text assessment. After exclusions, 9 studies were analyzed (6 evaluating liraglutide, 2 tirzepatide, and 1 exenatide). Populations predominantly comprised middle-aged women (mean age 52–62 years). CMR assessments focused on left ventricular (LV) mass/volumes (cine imaging) and ectopic fat quantification (planimetry, Dixon techniques, and proton magnetic resonance spectroscopy). Tirzepatide demonstrated more effects on cardiac remodeling, including reductions in LV mass. In contrast, liraglutide findings were heterogeneous: some studies reported reverse atrial remodeling and prevention of LV dilation, others showed no structural changes. Liraglutide and exenatide generally reduced EAT, although the magnitude and consistency of these effects varied across studies. Exenatide did not significantly impact cardiac remodeling. GLP-1-based therapies improve favorable cardiometabolic effects, reducing weight and ectopic fat, with more consistent improvements in cardiac remodeling observed with tirzepatide. The effects on epicardial adipose tissue remain heterogeneous. High-quality CMR trials are warranted to clarify mechanisms and long-term cardiovascular outcomes.



19076

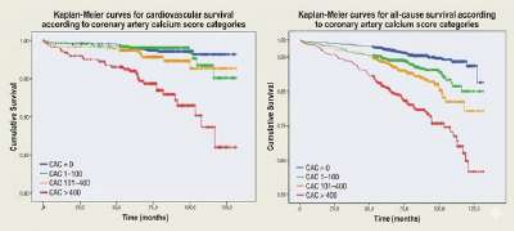


INCREMENTAL DIAGNOSTIC VALUE OF CARDIAC COMPUTED TOMOGRAPHY FOLLOWING INCONCLUSIVE ECHOCARDIOGRAPHY IN ADULT AND PEDIATRIC PATIENTS WITH CONGENITAL HEART DISEASE: A SYSTEMATIC REVIEW

GIULIA OLIVEIRA RAMALHO1; EDER OLIVEIRA COSTA1; JULIA BARBOSA SALES DE LIMA1; MARIANA LANDIM VIANA1; MARINA MARIA RODRIGUES AGUIAR1; THIAGO CERVEIRA DIÓGENES1; RODRIGO ALVES DE SOUZA GALVÃO2;

(1) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL; (2) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Congenital heart disease (CHD) often requires multimodality imaging. While Echocardiography is the first-line tool, limited acoustic windows or complex anatomy may yield inconclusive results. Cardiac computed tomography provides crucial incremental diagnostic value in these scenarios. Objetivos: The purpose of this study was to conduct a systematic review of the incremental diagnostic value of cardiac CT after inconclusive echocardiography in adult and pediatric CHD patients. Métodos: Following Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, we searched PubMed, Cochrane, and EMBASE databases up to March 2026 for studies evaluating the incremental diagnostic value of cardiac computed tomography following inconclusive echocardiography in adult and pediatric patients with congenital heart disease. Randomized clinical trials and observational studies published within the last 15 years were included. Two independent reviewers screened 453 records, with disagreements resolved by a third reviewer. The included studies demonstrated overall high methodological quality and were carefully assessed for potential bias. Resultados e Conclusões: Six studies (N=1,225) were analyzed. CT showed substantial incremental value mainly for extracardiac structures and complex cases. In pediatric CHD, CT identified 36 additional morphological lesions missed by echo. It demonstrated high sensitivity for systemic venous return and coronary anomalies, while echo was superior for intracardiac structures (valves) and infants (<1 year). In adults, CT clarified septal defect subtypes. For infective endocarditis, PET/CT increased definitive diagnosis from 39% to 88%, detecting elusive right-sided lesions. However, for broad clinical severity restratification in adults, CT reclassified only 1% of cases. In conclusion, while echocardiography remains the standard for intracardiac defects, cardiac CT offers crucial incremental diagnostic value for detailing extracardiac anatomy, coronaries, and right-sided lesions, serving as a vital complementary tool for presurgical planning in complex cases.



19059

PROGNOSTIC VALUE OF CORONARY ARTERY CALCIUM SCORE IN PREDICTING MORTALITY: A COHORT STUDY FROM SOUTHERN BRAZIL

PEDRO HENRIQUE BRAMBILA RODRIGUES BINOTTO1; FRANCO CAMARGO ZAPPAROLI1; MATHEUS FURTADO THA1; GUILHERME ALVES MARIATH COSTA1; LUCAS KAISER GOMES DA SILVA1; RODRIGO JULIO CERCI1; JOSE ROCHA FARIA NETO1; MARCIA LIMA DE OLIVEIRA MUGNAINI1; JOAO VICENTE VITOLA1;

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL;

Introdução/Fundamentos: The coronary artery calcium score (CAC) is a well-established marker of subclinical atherosclerosis and is widely used for cardiovascular risk re-stratification. However, its association with mortality, particularly across different stratification levels, requires further definition. Objetivos: To evaluate the association between different CAC values and all-cause and cardiovascular mortality, aiming to identify CAC ranges that act as independent risk predictors regardless of clinical comorbidities. Métodos: This retrospective observational study included 2,784 patients who underwent CAC evaluation at a diagnostic imaging center in Southern Brazil. Individuals were categorized into four groups: CAC 0, 1–100, 101–400, and >400. Clinical variables and cardiovascular risk factors (age, sex, hypertension, diabetes mellitus, dyslipidemia, smoking, and BMI) were collected. The outcomes analyzed were all-cause mortality and cardiovascular mortality. Statistical analysis included Chi-square and ANOVA for group comparisons, Kaplan-Meier curves with log-rank tests for survival analysis, and univariate/multivariate Cox regression to identify independent predictors. The mean follow-up period was 80.79 months. Resultados e Conclusões: All-cause mortality was 9.2% and cardiovascular mortality was 2.4%. A progressive increase in mortality was observed as CAC levels rose (p<0.001). Kaplan-Meier curves showed a significant reduction in survival across groups (log-rank p<0.001). In multivariate analysis, age and dyslipidemia were independent predictors of both general and cardiovascular mortality. CAC >400 remained independently associated with the outcomes: all-cause mortality (HR 1.59; 95%CI 1.08–2.33; p=0.019) and cardiovascular mortality (HR 2.21; 95%CI 1.09–4.49; p=0.028). Intermediate categories did not maintain significance after adjustment. CAC >400 was independently associated with all-cause and cardiovascular mortality, with a greater impact on the latter. The lack of association in intermediate categories reinforces a threshold effect, identifying high CAC as a high-risk marker and a valuable tool for prognostic re-stratification.

Variable	General Mortality HR (IC95%)	p	Cardiovascular Mortality HR (IC95%)	p
Age (years)	**1,09 (1,08–1,10)**	**<0,001**	**1,09 (1,06–1,12)**	**<0,001**
Male sex	**1,41 (1,08–1,83)**	**0,012**	1,69 (0,98–2,91)	0,060
Dyslipidemia	**1,58 (1,22–2,06)**	**0,001**	**2,23 (1,29–3,85)**	**0,004**
Hypertension	1,15 (0,87–1,51)	0,327	1,09 (0,63–1,89)	0,758
Diabetes	1,23 (0,93–1,63)	0,146	1,04 (0,59–1,86)	0,887
Tabagism	1,32 (0,98–1,77)	0,065	0,92 (0,49–1,72)	0,794

SUBCLINICAL LEFT VENTRICULAR DYSFUNCTION IN PATIENTS WITH BETA-THALASSEMIA MAJOR: A SYSTEMATIC REVIEW AND META-ANALYSIS

AUGUSTO MONTEIRO CASTRO XAVIER CARVALHO1; JUAN PERES OLIVEIRA2; ENRICO VESCOVI SALLES1; VICENTE CASTOR BRITO3; BARBARA REIS SILVA4; IGOR RAFAEL SANTANDER5; CAROLINE OLIVEIRA FISCHER-BACCA2;

(1) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (2) UNIDAVI - CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL; (3) UNIVERSIDADE FEDERAL DE CAMPINA GRANDE - UFCG - CAMPINA GRANDE - PB - BRASIL; (4) PONTIFICIA UNIVERSIDADE CATOLICA DE GOIAS - GOIÂNIA - GO - BRASIL; (5) CARDIO LOGICA PB - JOÃO PESSOA - PB - BRASIL;

Introdução/Fundamentos: Beta-thalassemia major (BTM) is associated with long-term cardiovascular morbidity, historically attributed to cardiac iron overload (CIO) from chronic transfusion therapy. Despite preserved left ventricular ejection fraction (LVEF) in most patients, speckle-tracking echocardiography suggests that myocardial dysfunction may already be present at a subclinical stage. The magnitude of this early dysfunction, and its relationship with iron burden assessed by T2* cardiac MRI, remains incompletely defined. Objetivos: To systematically review and meta-analyze subclinical left ventricular dysfunction in BTM compared with healthy controls, and to assess its relationship with cardiac iron overload. Métodos: PubMed, Embase, and Cochrane were searched for studies evaluating subclinical cardiac dysfunction in BTM patients with preserved LVEF versus healthy controls. Global longitudinal strain (GLS) was the primary outcome and LVEF the secondary outcome. For studies stratified by T2* CMR, subgroup data were extracted for CIO+ (T2* <20 ms) and CIO− (T2* ≥20 ms). Pooled mean differences (MD) were estimated with a random-effects model; heterogeneity was assessed using I². Analyses were performed in RStudio. Resultados e Conclusões: Eleven observational studies were included, comprising 484 BTM patients and 329 controls. GLS was significantly impaired in BTM patients versus controls (MD 1.88 [95% CI 0.96 to 2.79]; p < 0.001; I² = 86.7%). LVEF did not differ significantly (MD −1.17 [95% CI −2.54 to 0.21]; p = 0.097; I² = 77.1%). In the subgroup analysis of six studies stratified by T2*, GLS was significantly impaired in CIO+ patients versus controls (MD 1.95 [95% CI 0.89 to 3.02]; I² = 64.7%), with a similar directional impairment in CIO− patients that did not reach significance (MD 1.72 [95% CI −0.15 to 3.58]; I² = 89.2%). No significant difference was observed between CIO+ and CIO− subgroups (p = 0.83). Conclusions: Patients with beta-thalassemia major exhibit impaired left ventricular global longitudinal strain despite preserved ejection fraction, consistent with early subclinical myocardial dysfunction. The presence of reduced GLS even in patients without cardiac iron overload, and the absence of significant subgroup differences by T2* status, suggest that mechanisms beyond iron deposition contribute to early myocardial involvement, supporting strain imaging for early cardiovascular risk stratification in BTM.

T1 MAPPING OUTPERFORMS LGE AND T2 MAPPING IN ICI-ASSOCIATED MYOCARDITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

LUCAS RODRIGUES VAZ DE MELLO1; PEDRO CÉSAR REZENDE SEGURADO1; GEOVANA DIAS SANTOS QUEIROZ1; LUÍS FILIPE REZENDE TOMÉ1; MARIA ESTEFÂNIA BOSCO OTTO1; MARIANA UBALDO BARBOSA PAIVA1;

(1) UNIVERSIDADE DE BRASILIA - BRASÍLIA - DF - BRASIL;

Introdução/Fundamentos: Immune checkpoint inhibitor (ICI)-associated myocarditis has a high case fatality rate (25–50%). Although cardiovascular magnetic resonance (CMR) is the main non-invasive diagnostic tool, the real-world performance of late gadolinium enhancement (LGE) and parametric mapping remains uncertain, particularly after early corticosteroid use, which may limit the applicability of the Lake Louise criteria. Objetivos: Primary: to estimate pooled LGE prevalence and compare diagnostic stability of T1 and T2 mapping in ICI-associated myocarditis. Secondary: to assess the prognostic value of CMR parameters for major adverse cardiovascular events (MACE). Métodos: PRISMA systematic review (PubMed, Embase, Cochrane). Eligibility: adults with confirmed or suspected ICI-associated myocarditis, CMR performed, comparator by endomyocardial biopsy or validated clinical criteria (Bonaca/ESC). Study selection and data extraction were performed independently. Risk of bias was assessed using QUADAS-2. Prevalence meta-analysis using random-effects model (DerSimonian-Laird) with pre-specified sensitivity analysis. Resultados e Conclusões: Of 31 full-text articles assessed, 18 were included (n=870). Pooled LGE prevalence was 65.0% (95% CI 54.3–75.6; 8 studies, n=303; I²=73.2%). The study with the highest histological confirmation rate reported the lowest LGE prevalence (47.6%), arguing against methodological bias. Sensitivity analysis confirmed robustness (66.9%; 95% CI 56.1–77.7%). T1 mapping showed consistent detection rates (66–78%), whereas T2 mapping was highly variable (24–92%) and inversely associated with prior corticosteroid use. According to the 2018 Lake Louise criteria, 95% met non-ischemic injury criteria, but only 53% met edema criteria. T1 mapping independently predicted MACE (AUC 0.91; HR 1.44 per z-score), while septal LGE was the only morphological predictor (HR 2.7). LGE has limited sensitivity for ICI-associated myocarditis in real-world settings, particularly after early immunosuppression (fails in 35% of histologically confirmed cases). T2 mapping is highly variable and influenced by corticosteroid use. In contrast, T1 mapping is more stable and strongly associated with outcomes, supporting its role as the primary CMR diagnostic marker in this population.

3D CARDIAC MODELS WITH HIPSC-CMS IN HEREDITARY CARDIOMYOPATHIES AND ONCOLOGIC CARDIOTOXICITY: A SYSTEMATIC REVIEW

BEATRIZ DE LIMA VITORIO FERREIRA1; FLAVIA BEATRIZ DO CARMO MOREIRA2; EVELIN GABRIELLY DE VARGAS2; MARCOS AURELIO FONSECA MEDEIROS1; LUCAS MANOEL BORGES2; BIANCA RIBEIRO CORREIA LIMA3; PEDRO DE ARAUJO SANTOS1; FELIPE ANDREY DE CAMPOS BREGALDA2; CAMILA APATE2; MARIANA VIDAL MIYAZATO2; ANNE KAROLLYNE ALVARES SANTOS2;

(1) UNIFACISA - CAMPINA GRANDE - PB - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (3) UNINASSAU - RECIFE - PE - BRASIL;

Introdução/Fundamentos: Hereditary cardiomyopathies (hypertrophic and dilated cardiomyopathy, inherited arrhythmia syndromes) and chemotherapy-induced cardiotoxicity lack physiologically relevant human models. Human induced pluripotent stem cell–derived cardiomyocytes (hiPSC-CMs) in three-dimensional platforms (engineered heart tissues – EHTs, organoids, heart-on-a-chip – HoC) have emerged as alternatives to animal models. This review synthesizes evidence on their application in hereditary cardiac diseases and cancer therapy–related cardiotoxicity. Objetivos: To evaluate the ability of hiPSC-CM-based 3D cardiac models to recapitulate phenotypes of hereditary cardiomyopathies, inherited arrhythmia syndromes, and anticancer therapy–induced cardiotoxicity, and to identify underlying mechanisms. Métodos: Systematic review conducted according to PRISMA guidelines. Studies published between 2019 and 2026 were identified in PubMed using descriptors related to “hiPSC-CMs”, “heart-on-a-chip”, “engineered heart tissue”, “cardiomyopathy”, and “cardiotoxicity”. Inclusion criteria: studies using hiPSC-CMs from patients or controls in 3D platforms (EHTs, HoC, organoids); evaluation of hereditary cardiomyopathies, inherited arrhythmia syndromes (long QT, CPVT, Brugada), or anticancer-induced cardiotoxicity; and reporting functional outcomes or molecular mechanisms. Studies not meeting these criteria were excluded. Data were qualitatively synthesized. Resultados e Conclusões: hiPSC-CMs reproduced features of hypertrophic and dilated cardiomyopathy, long QT syndrome (types 1–3), CPVT, and Brugada syndrome. HoC systems modeled long QT and myocardial fibrosis. Cardiovascular disease is the second leading cause of death in cancer survivors. Mechanisms including oxidative stress, mitochondrial dysfunction, and apoptosis were replicated. Endothelial cells attenuated doxorubicin cardiotoxicity in tri-culture HoC. High-throughput platforms showed dose-dependent drug responses. Limitations include structural and electrophysiological immaturity. 3D hiPSC-CM platforms recapitulate hereditary cardiomyopathies and cancer therapy–related cardiotoxicity, enabling mechanistic insights and supporting their use in precision medicine and drug screening despite current limitations.

A 50% DECLINE WITH RISING CASE-FATALITY, PERSISTENT HOT SPOTS, AND LATITUDE-DEPENDENT SEASONALITY: BAYESIAN MAPPING OF 3.2 MILLION HEART FAILURE HOSPITALIZATIONS IN 5,570 BRAZILIAN MUNICIPALITIES (2010-2024)

GUSTAVO SKONETZKY1; AMANDA TEIXEIRA WATERMANN1; MILENA CHRISTINE POLLI1; LUIZA TREVISAN1; SIMONE TUCHTENHAGEN1; TIAGO VENDRUSCOLO1; ISADORA BIGOLIN1;

(1) UNIVERSIDADE REGIONAL INTEGRADA DO ALTO URUGUAI E DAS MISSÕES (URI) - ERECHIM - RS - BRASIL;

Introdução/Fundamentos: Heart failure (HF) is a leading cause of cardiovascular hospitalization worldwide, especially in low and middle-income countries. In Brazil, comprehensive municipal analyses of HF distribution and trends are still lacking. No prior study applied Bayesian spatial modeling to HF across all Brasilian municipalities. Objetivos: To analyse spatiotemporal trends and spatial clustering of HF hospitalizations across all 5,570 Brazilian municipalities from 2010 to 2024, stratified by sex, age, and municipality size. Métodos: Ecological time-series study using the Brazilian Hospital Information System (SIH-SUS). All HF admissions (ICD-10: I50) from 2010 to 2024 were included. Age-standardized rates (WHO standard population) were computed per municipality, year, sex, and population size stratum. Temporal trends were assessed using joinpoint regression. Spatial autocorrelation was evaluated by Moran’s I and LISA at municipal and state levels. Disease mapping used BYM2 models (R-INLA) to estimate posterior relative risks by quinquennium. Seasonality was assessed via STL decomposition. Data were publicly available and de-identified, ethics approval was waived per Resolution CNS 510/2016. Resultados e Conclusões: A total of 3,221,730 HF hospitalizations were analyzed. Age-standardized rates declined 50%, from 145.9 to 72.8 per 100,000 (APC - 6.8%, 2010–2021; p < 0.001), with non-significant increase post-2022 (APC +3.9%; p = 0.06). In-hospital case-fatality rose from 9.0% to 13.5% (2021 peak). Male-to-female rate ratio increased from 1.31 to 1.41. Small municipalities showed rates 62% higher than large centers (169.3 vs. 104.3/100,000) but lower case-fatality (7.6% vs. 10.8%), suggesting larger centers admit more severe cases. Moran’s I confirmed strong spatial clustering (I~0.40; p < 0.001) across all three quinquennia. BYM2 identified 2,110 municipalities (37.9%) with significantly elevated relative risk in 2020–2024, concentrated in the South and Central-West regions. LISA classified 28% of municipalities as high-high clusters, stable over time. Seasonal decomposition revealed winter peaks in the Southeast (index 108–112) absent in the equatorial North (94–102). HF hospitalizations in Brazil declined 50% over 15 years, yet persistent spatial clusters and an inverse relationship between admission rates and case-fatality across municipality sizes suggest ongoing disparities in primary care access. These findings provide actionable evidence for targeted resource allocation in continental-scale health systems.

ACUTE NEUROLOGICAL EVENTS AS TRIGGERS OF TAKOTSUBO SYNDROME: HIGHER INCIDENCE AND WORSE PROGNOSIS – A SYSTEMATIC REVIEW OF REGISTRIES AND COHORTS

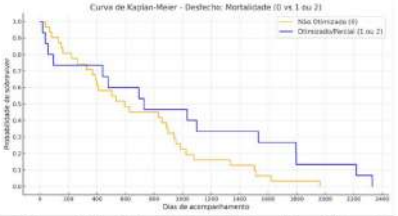
BEATRIZ DE LIMA VITORIO FERREIRA1; FLAVIA BEATRIZ DO CARMO MOREIRA2; MARIANA VIDAL MIYAZATO2; MARCOS AURELIO FONSECA MEDEIROS1; EVELIN GABRIELLY DE VARGAS2; GIOVANNA VILA REAL MARQUES BARRA DE GOUVEIA TREVISAN2; CAROLAINE BRENDA RIDOLFI2; MARIA EUGENIA RODRIGUES PAIVA2; ANNE KAROLLYNE ALVARES SANTOS2;

(1) UNIFACISA - CAMPINA GRANDE - PB - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Patients with acute brain injury, including stroke and traumatic brain injury (TBI), have an increased risk of cardiovascular (CV) events even without prior heart disease. The brain–heart axis involves autonomic dysfunction characterized by sympathetic overactivity and reduced vagal modulation. However, the association between injury severity and subsequent CV risk has not been systematically synthesized. Objetivos: To evaluate the association between brain injury severity in stroke and TBI and adverse cardiovascular outcomes, and the potential role of autonomic dysfunction. Métodos: PRISMA-based review. PubMed was searched from 2011–2026. Cohort studies and meta-analyses including patients with stroke or TBI were eligible if they reported follow-up ≥1 year, adjusted risk estimates (HR, OR, RR), and cardiovascular outcomes including MACE, stroke, coronary artery disease, hypertension or cardiac mortality. Injury severity was assessed using NIHSS or TBI classification (mild, moderate–severe, penetrating). Data on heart rate variability, baroreflex sensitivity, and troponin were extracted. Only studies with adjusted analyses were included. Resultados e Conclusões: Eight studies involving >5.6 million participants were included. In TBI, a dose–response association was observed for composite CVD: mild (HR 1.62; 95% CI 1.58–1.66), moderate–severe (HR 2.63; 2.51–2.76), and penetrating injury (HR 4.60; 4.26–4.96). Stroke risk also increased progressively (HR 2.53, 5.32, and 12.15). A meta-analysis showed increased CVD risk (OR 1.78; 95% CI 1.39–2.29) and cardiac mortality (RR 3.07; 2.17–3.98). In stroke, elevated rates of major CV events and troponin elevation (30–60%) were reported. Neurological severity correlated with autonomic dysfunction (ρ 0.29–0.47). Right insular lesions were associated with higher mortality (HR 2.11) and new-onset atrial fibrillation (39%). Reduced heart rate variability and impaired baroreflex sensitivity were consistently observed. Beta-blocker use in TBI was associated with lower in-hospital mortality (OR 0.39; 0.30–0.51). There is a consistent dose–response association between brain injury severity and cardiovascular risk, possibly mediated by autonomic dysfunction. Patients with more severe injury and insular involvement represent a high-risk group. Findings regarding beta-blockers should be interpreted cautiously given the observational nature of the data. Limitations include study heterogeneity and lack of causal inference data

16632

ANALYSIS OF PHARMACOLOGICAL TREATMENT AND FACTORS PREVENTING ITS OPTIMIZATION IN PATIENTS WITH HFREF



PEDRO AUGUSTO SOUZA1; CAROLINA CAMBI ANDRIETTA1; MICAEL OGURI REIS1; MARIA EDUARDA PEQUENO DA COSTA REIS1; MARCUS VINICIUS SIMÕES1;

(1) HOSPITAL DAS CLINICAS DA FACULDADE DE MEDICINA DE RIBEIRAO PRETO - USP - RIBEIRAO PRETO - SP - BRASIL;

Introdução/Fundamentos: Heart failure (HF) presents high morbidity and mortality, along with high rates of rehospitalization. The main studies on this syndrome indicate that optimizing drug therapy reduces decompensation and deaths Objetivos: This study evaluates the incorporation of new therapies, the factors associated with non-optimization, and the clinical outcomes of optimized versus non-optimized patients. Métodos: This is a retrospective study involving data collection from electronic medical records of stable outpatients with chronic Heart Failure with reduced Ejection Fraction (HFrEF), treated in 2022 at a high-volume specialized heart failure center, with at least 18 months of follow-up. Chi square tests assessed associations while graphs and Kaplan Meier curves illustrated outcomes Resultados e Conclusões: The study population included 304 patients, 62% of whom were male, with a mean age of 59.4 years. The primary etiologies were ischemic (30.26%) and hypertensive (13.49%). Regarding functional class (NYHA), 40.46% were in class II, 35.53% in class III. Notable comorbidities included systemic arterial hypertension (61.18%) and type 2 diabetes mellitus (34.86%). Regarding drug therapy, it was observed that: 99% were using beta-blockers, with 88.10% optimized; 84% were using mineralocorticoid receptor antagonists, with 93% optimization; and 36.51% were using SGLT2 inhibitors (SGLT2i), with financial constraints being the main limiting factor. Additionally, 89.47% were using ACE inhibitors/ARBs/ARNIs, and 37% were using Angiotensin Recepto rNeprilysin Inhibitors (ARNIs). The majority of hospitalizations occurred in non-optimized patients (71.01%). A lower frequency of hospitalizations was observed in the optimized group, though without a statistically significant association (p = 0.074). Event-free survival was numerically higher in optimized vs. non-optimized patients (HR 0.86; 95% CI 0.55–1.36; p = 0.37): “Kaplan-Meier Curve 2”. Overall survival was higher among optimized patients, with a relative reduction in the risk of death (HR 0.73; 95% CI 0.39–1.35; p = 0.088). The study demonstrates that, despite the use of the main drug classes in HFrEF patients, barriers to treatment optimization persist, primarily financial and clinical. Non-optimization was associated with higher rates of hospitalization and mortality. These results reinforce the need for strategies to expand access and adherence, with low influence from therapeutic inertia, indicating good clinical practice and the medical staff’s commitment to guidelines.

BENZODIAZEPINES IN HEART FAILURE: REASSURING THERAPY OR HIDDEN RISK? A SYSTEMATIC REVIEW AND META-ANALYSIS

RODRIGO VOIGT FILHO1; LARISSA SCHMITZ1; VITOR BAGATOLI1; CAROLINE OLIVEIRA FISCHER-BACCA1;

(1) UNIDAVI - CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL;

Introdução/Fundamentos: Anxiety and insomnia are common comorbidities in patients with heart failure (HF) and have been consistently associated with worse clinical outcomes. These conditions may share underlying pathophysiological mechanisms with HF, including heightened neurohormonal activation and autonomic imbalance. Benzodiazepines (BZDs) are among the most frequently prescribed therapies for anxiety and insomnia; however, their safety profile and prognostic impact in patients with HF remain uncertain. Objetivos: To systematically evaluate the association between benzodiazepine use and clinical outcomes in patients with heart failure through a meta-analysis. Métodos: A systematic search of PubMed, Embase, and the Cochrane Central Register of Controlled Trials (CENTRAL) was performed to identify studies assessing cardiovascular and clinical outcomes in patients with HF using benzodiazepines. Eligible studies included randomized and observational designs comparing BZD users versus non-users. Pooled effect estimates were calculated using a random-effects model, and results were reported as risk ratios (RRs) with 95% confidence intervals (CI). Statistical heterogeneity was assessed using the I² statistic. Resultados e Conclusões: Eight observational studies comprising 16,491 patients (61% male; 32.4% BZD users) were included. BZD use was associated with a higher risk of adverse clinical events (RR 1.16; 95% CI 1.04–1.29; p=0.008). Compared with non-users, BZD users had a significantly increased risk of HF hospitalization (RR 1.22; 95% CI 1.06–1.40; p=0.006). No significant differences were observed in all-cause mortality (p=0.38) or cardiovascular mortality (p=0.21). In a subgroup comparison, HF hospitalization rates were not significantly different between BZDs and Z-drugs (RR 1.36; 95% CI 0.78–2.36; p=0.28). Conclusions: In patients with HF, BZP use is associated with an increased risk of HF hospitalization without a significant impact on mortality. These findings raise concerns regarding the safety of BZDs in this population and highlight the need for cautious prescribing and further prospective evaluation.

BRIDGE TO TRANSPLANT OR DESTINATION THERAPY? A SYSTEMATIC REVIEW AND COMPARATIVE EFFECTIVENESS OF CONTEMPORARY LVADS VERSUS HEART TRANSPLANTATION IN ADVANCED HEART FAILURE

ISABELA DIEGUES VAZ MAROSTICA1; KAROLINE COELHO NEDEL1; CARLA ALBERICI PASTORE1; ANNA LAURA JAEGER2; NICOLE KLEIN MULLER3;

(1) UNIVERSIDADE FEDERAL DE PELOTAS - PELOTAS - RS - BRASIL; (2) UNIVERSIDADE FEEVALE - NOVO HAMBURGO - RS - BRASIL; (3) UNISINOS - SÃO LEOPOLDO - RS - BRASIL;

Introdução/Fundamentos: Advanced heart failure remains a major global health burden associated with high morbidity and mortality despite optimized guideline-directed medical therapy. Heart transplantation is considered the gold standard treatment, offering the best long-term survival and quality of life. However, its widespread application is limited by donor organ scarcity and strict eligibility criteria. In parallel, Left Ventricular Assist Devices (LVADs) have evolved from temporary bridge-to-transplant strategies into durable destination therapy options, particularly with the advent of fully magnetically levitated centrifugal-flow pumps, which have significantly improved hemocompatibility and clinical outcomes. Objetivos: To compare survival outcomes, major adverse events, and quality of life between contemporary LVAD therapy and heart transplantation in adults with advanced heart failure, and to assess whether the outcome gap between these two strategies has narrowed in the modern era. Métodos: A systematic review was conducted following PRISMA 2020 guidelines, with a structured search in PubMed covering January 2015 to March 2025. Of 132 studies identified, 21 met inclusion criteria, comprising randomized controlled trials, prospective cohort studies, and large-scale registry analyses. Key sources included the MOMENTUM 3 trial and data from the ISHLT registry. A qualitative synthesis was performed due to substantial heterogeneity across studies. Resultados e Conclusões: The MOMENTUM 3 trial demonstrated two-year survival of approximately 81% with HeartMate 3 while the ISHLT 2023 registry data report one-year post-transplant survival of 85–90% and five-year survival near 60%. Adverse event profiles differ markedly: LVADs carry higher risks of bleeding and device-related infections, while transplantation involves lifelong immunosuppression-related complications. Both therapies improve quality of life, with LVADs providing early functional gains and transplantation maintaining superior long-term physiological outcomes. Heart transplantation remains the gold standard, however, modern LVADs have significantly narrowed the survival gap, establishing themselves as a robust destination therapy, particularly for transplant-ineligible patients. These findings underscore the importance of individualized, multidisciplinary decision-making in advanced heart failure management.

Contemporary LVAD vs. Heart Transplantation in Advanced Heart Failure

Systematic Review — Comparative Effectiveness Summary

Parameter	Contemporary LVAD (HeartMate 3)	Heart Transplantation
1-year survival	~83%	85–90%
2-year survival	~81%	~80–85%
5-year survival	~58%	~60%
Main adverse events	Bleeding, device-related infection, stroke	Rejection, opportunistic infection, nephrotoxicity
Quality of life improvement	Early functional gains	Superior long-term physiological outcomes
Patient eligibility	Broader population, including transplant-ineligible patients	Donor scarcity and strict selection criteria
Immunosuppression	Not required	Lifelong
Destination therapy	Yes	N/A

Sources: MOMENTUM 3 Trial; ISHLT Registry Data (2015–2025)

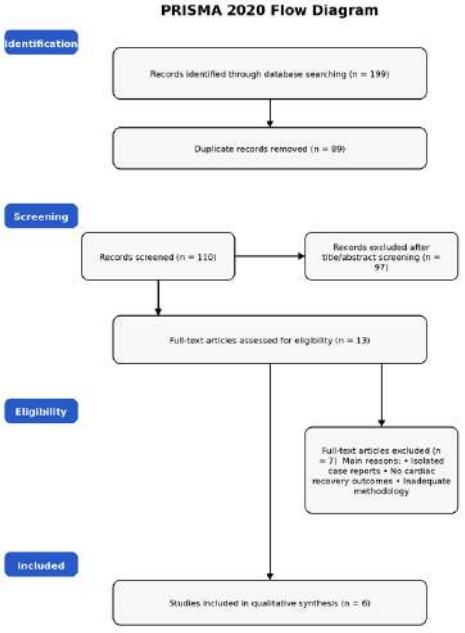
CA125 AND SGLT2 INHIBITORS IN HEART FAILURE: A SYSTEMATIC REVIEW AND META-ANALYSIS

JUAN PERES OLIVEIRA1; RAMON HUNTERMANN1; MARIA EDUARDA MOLINARI1; PEDRO GOMES BATISTA2; RAILLA RAQUEL ALBINO SANTOS SILVA3; MARCELA VASCONCELOS MONTENEGRO4; LARISSA ARAÚJO LUCENA5; GIULIA CALDEIRA GAELZER6; JULIANA GIORGI7; CAROLINE OLIVEIRA FISCHER-BACCA1;

(1) UNIDAVI - CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL; (2) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (3) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL; (4) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL; (5) UNIVERSIDADE FEDERAL DO RIO GRANDE DO NORTE - NATAL - RN - BRASIL; (6) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (7) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Carbohydrate antigen 125 (CA125) is a glycoprotein produced by mesothelial cells under mechanical stress and inflammation. It has emerged as a congestion biomarker and independent predictor of outcomes in heart failure (HF). SGLT2 inhibitors (SGLT2i) reduce HF events through mechanisms that may include extravascular decongestion. Whether SGLT2i reduces CA125 and whether baseline CA125 modifies their efficacy remain unclear, with no prior meta-analysis addressing this question. Objetivos: To evaluate the effect of SGLT2i versus placebo on CA125 levels in HF patients, and to assess the prognostic value of elevated CA125 in this population Métodos: Systematic review following PRISMA guidelines, searching PubMed, Cochrane Library, and Embase through April 2026. Studies derived from randomized controlled trials (RCTs) reporting serial CA125 in HF patients receiving SGLT2i versus placebo were included. Data were converted to log-ratio scale and pooled using inverse-variance random-effects models (DerSimonian-Laird). Heterogeneity was assessed with I² and Cochran Q. Leave-one-out sensitivity analysis was performed. Risk of bias was assessed using RoB 2. All analyses were conducted in R version 4.4 using the meta package. Resultados e Conclusões: Four RCT-derived studies were included (n=4,739). SGLT2i showed a trend toward CA125 reduction (pooled log-ratio: −0.057; 95%CI: −0.121 to 0.007; p=0.080; I²=53.2%). Leave-one-out analysis confirmed robustness, with pooled estimates ranging from −0.04 to −0.08 across iterations. In pooled prognostic analysis of 2 HFrEF studies, elevated CA125 independently predicted cardiovascular death or worsening HF (HR: 1.72; 95%CI: 1.29–2.28; I²=25.7%) after adjustment for NT-proBNP. CA125 was also predictive of worsening HF (HR: 1.87; 95%CI: 1.46–2.40), cardiovascular death (HR: 1.47; 95%CI: 1.11–1.94), and HF death (HR: 2.11; 95%CI: 1.29–3.45), but not of sudden cardiac death (HR: 1.04; 95%CI: 0.65–1.67). Conclusions: SGLT2i showed a borderline CA125 reduction. Elevated CA125 independently predicts adverse HF outcomes beyond natriuretic peptides, specifically congestion-related rather than arrhythmic mortality, reinforcing its complementary role in HFrEF risk stratification.



22089

CARDIAC FUNCTION RECOVERY AFTER PHEOCHROMOCYTOMA TREATMENT: A SYSTEMATIC REVIEW

BIANCA ARAÚJO HOLANDA1; ANA SOFIA ANDRADE OLIVEIRA DE FRANÇA LOPES1; LETÍCIA NUNES BENEVIDES1; SABRINA ARAÚJO LIMA MONTEIRO1; ISABELLA BOMFIM DE MELO DANTAS1; LEO NUNES BENEVIDES1;

(1) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Pheochromocytoma and paraganglioma (PPGL) may cause severe cardiovascular manifestations, including Takotsubo cardiomyopathy, catecholamine-induced dilated cardiomyopathy, cardiogenic shock, malignant ventricular arrhythmias, and subclinical myocardial dysfunction. Excess catecholamine exposure promotes myocardial stunning, oxidative stress, microvascular dysfunction, and ventricular remodeling, potentially leading to acute or chronic heart failure. However, the reversibility of cardiac dysfunction after treatment remains incompletely characterized. Objetivos: To evaluate cardiac function recovery and cardiovascular outcomes following treatment of PPGL-associated cardiomyopathy. Métodos: This systematic review was conducted according to PRISMA recommendations. Literature searches were performed in PubMed/MEDLINE, Scopus, and Web of Science using terms related to “pheochromocytoma”, “paraganglioma”, “cardiomyopathy”, “Takotsubo”, and “cardiac recovery”. Eligible studies included adult patients with PPGL-associated cardiac dysfunction reporting post-treatment functional outcomes. Isolated case reports, pediatric studies, and articles without cardiac recovery assessment were excluded. Resultados e Conclusões: The included studies demonstrated significant reversibility of cardiac dysfunction following catecholamine control and adrenalectomy. Patients with Takotsubo phenotype exhibited the highest recovery rates, with ventricular function normalization exceeding 90% in some cohorts. In contrast, chronic catecholamine-induced dilated cardiomyopathy showed lower recovery rates, suggesting persistent remodeling and myocardial fibrosis. In severe presentations with cardiogenic shock, temporary mechanical circulatory support, including extracorporeal membrane oxygenation (ECMO), Impella, and intra-aortic balloon pump, was associated with significant improvement in left ventricular ejection fraction and low in-hospital mortality. Speckle-tracking studies demonstrated reversal of subclinical myocardial dysfunction after adrenalectomy, even in patients with preserved LVEF. Early diagnosis and surgical treatment were consistently associated with better recovery and prognosis. PPGL-associated cardiomyopathy demonstrates high potential for reversibility following appropriate treatment, particularly in acute catecholamine-mediated phenotypes such as Takotsubo cardiomyopathy. Early recognition, hemodynamic stabilization, and adrenalectomy appear critical for cardiac recovery and improved cardiovascular outcomes.

CARDIAC REMODELING ASSOCIATED WITH THE USE OF ANABOLIC-ANDROGENIC STEROIDS AND ITS IMPLICATIONS FOR LEFT VENTRICULAR HYPERTROPHY AND THE RISK OF HEART FAILURE: A SYSTEMATIC REVIEW

MARIA EDUARDA BRAGA MARIN1; CAMILA KELLY PEREIRA1;

(1) CENTRO UNIVERSITÁRIO FAMESC - BOM JESUS DO ITABAPOANA - RJ - BRASIL;

Introdução/Fundamentos: The use of anabolic-androgenic steroids (AAS) has increased among athletes and the general population and is associated with adverse cardiovascular effects. Among these, left ventricular hypertrophy (LVH) stands out, as it may progress to the development of heart failure. AAS promote structural and functional cardiac remodeling, including increased ventricular mass and reduced systolic function. Objetivos: To analyze the association between AAS use, the development of left ventricular hypertrophy, and the subsequent risk of heart failure. Métodos: A systematic review based on the PRISMA protocol was conducted. The search was performed in the PubMed and SciELO databases up to December 2025, using descriptors such as “anabolic steroids,” “left ventricular hypertrophy,” and “heart failure,” combined with Boolean operators (AND/OR). Observational studies, clinical trials, and systematic reviews published in English and Portuguese that evaluated structural and functional cardiac parameters in AAS users were included. Study selection involved an initial screening of titles and abstracts, followed by full-text analysis. Duplicates and studies unrelated to the topic were excluded. A total of 10 studies were identified, of which 5 were included after exclusions. Resultados e Conclusões: A significant association between AAS use and cardiac impairment was observed. A retrospective cohort study including 1,189 AAS users and 59,450 controls, with a mean follow-up of 11 years, demonstrated an almost ninefold increased risk of developing cardiovascular disease (adjusted hazard ratio (aHR 8.90; 95% CI 4.99-15.88). The risk of heart failure was 3.63 times higher among AAS users (aHR 3.63; 95% CI 2.01-6.55). Additionally, another study reported an increase in left ventricular mass of +28.3 g during an average 16-week cycle of AAS use, with a positive correlation with weekly dose. Although partial reversibility was observed after months without use, prolonged exposure may lead to irreversible damage. Therefore, AAS use is associated with the development of LVH, an important risk factor for heart failure. These findings highlight the need for increased awareness, the implementation of public health strategies to reduce misuse of these substances, and rigorous cardiovascular assessment in individuals with a history of AAS use.

Authors (Year)	Study Design	Main Cardiac Findings	Key Findings
Windfeld-Mathiasen J, et al. (2025)	Comparison between steroid users vs controls	aHR 8.90 for cardiovascular diseases; aHR 3.63 for heart failure	Significantly higher risk of cardiovascular diseases and heart failure in AAS users.
Smit DL, et al. (2021)	Longitudinal follow-up of AAS users with echocardiography	Increase of 28.3 g in left ventricular mass; 4.9% reduction in LVEF	LVH and systolic dysfunction induced by AAS, with reversibility after cessation.
Cavalcante DN, et al. (2025)	Quantitative synthesis of observational studies	Reduction in LVEF (MD -2.25%); increased septal thickness (MD 1.24 mm) and posterior wall thickness (MD 1.09 mm); increase in LV mass (MD 13.29 g)	Adverse cardiac remodeling in AAS users.
Fyksen TS, et al. (2025)	Cross-sectional assessment of cardiac structure and function	Increased LV wall thickness; reduced GLS	Association between AAS use and structural and functional LV alterations.
Alhusban Z, et al. (2025)	Combined aggregated evidence + clinical illustration	Left ventricular hypertrophy, myocardial fibrosis, and diastolic dysfunction	Severe cardiac complications, including steroid-induced cardiomyopathy.

CHAGASIC VS. NON-CHAGASIC HFREF ON DOBUTAMINE: CLINICAL CHARACTERISTICS AND IN-HOSPITAL OUTCOMES

JOÃO GABRIEL PEIXOTO SANTANA1; IGOR ROCHA FREIRE1; GABRIEL YSHIDA ALVES BRANDÃO1; AGUINALDO FREITAS JUNIOR1; SALVADOR RASSI1; DANIELA DO CARMO RASSI1;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL;

Introdução/Fundamentos: Advanced heart failure with reduced ejection fraction (HFrEF) carries high in-hospital mortality. Patients requiring inotropic support with dobutamine represent a particularly high-risk population, heterogeneous in etiology. Chagas cardiomyopathy, still endemic in Latin America, may confer a distinct clinical profile compared to non-chagasic etiologies, with potential implications for management and prognosis. Objetivos: To compare clinical characteristics, comorbidities, in-hospital management and outcomes between HFrEF patients on dobutamine, according to chagasic vs. non-chagasic etiology. Métodos: Retrospective, single-center cohort of 67 hospitalized HFrEF patients on dobutamine. Continuous variables were compared using the Mann-Whitney U test and categorical variables using Fisher’s exact test, with a significance level of 5%. Resultados e Conclusões: Non-chagasic patients (n=26) had higher prevalence of coronary artery disease or prior myocardial infarction (42.3% vs. 9.8%; p=0.003) and systemic arterial hypertension (61.5% vs. 29.3%; p=0.012), reflecting a predominantly ischemic-hypertensive background. Chagasic patients (n=41) presented lower admission heart rate (68 vs. 77 bpm; p=0.036), higher amiodarone use (65.9% vs. 38.5%; p=0.043) and greater prevalence of pacemaker implantation (26.8% vs. 3.8%; p=0.021), consistent with conduction system involvement typical of Chagas disease. Left ventricular ejection fraction was lower in chagasic patients (25% vs. 32%; p=0.023). Non-chagasic patients required orotracheal intubation more frequently (30.8% vs. 7.3%; p=0.018) (Figure 1). In-hospital outcomes were similar: mortality (41.5% vs. 42.3%; p=1.000), composite endpoint of death or 3-month readmission (63.4% vs. 65.4%; p=1.000) and length of stay (20.0 vs. 15.5 days; p=0.444) (Figure 2). Chagasic and non-chagasic patients with HFrEF on dobutamine present distinct clinical profiles — greater ischemic-hypertensive burden in non-chagasic patients and greater conduction system involvement in chagasic patients. Despite these differences, in-hospital morbimortality was equally high in both groups, suggesting that at this advanced stage of disease, etiology alone does not determine prognosis.

CLINICAL OUTCOMES AND PREDICTORS OF IN-HOSPITAL MORTALITY IN ADVANCED HFREF REQUIRING DOBUTAMINE: A MULTIVARIATE ANALYSIS

GABRIEL YSHIDA ALVES BRANDÃO1; JOÃO GABRIEL PEIXOTO SANTANA1; IGOR ROCHA FREIRE1; AGUINALDO FREITAS JUNIOR1; SALVADOR RASSI1; DANIELA DO CARMO RASSI1;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL;

Introdução/Fundamentos: Advanced heart failure with reduced ejection fraction (HFrEF) requiring inotropic support represents the most severe end of the disease spectrum, with markedly elevated in-hospital mortality. Identifying independent predictors of death in this population is critical for risk stratification and therapeutic intensification before refractory decompensation, particularly in settings with heterogeneous access to optimized medical therapy. Objetivos: To identify independent predictors of in-hospital mortality and three-month composite morbimortality in patients with HFrEF receiving dobutamine. Métodos: Retrospective, single-center cohort of 67 consecutive adult patients with HFrEF on intravenous dobutamine. Clinical, echocardiographic, laboratory and pharmacological variables were analyzed. Candidate predictors were selected by p<0.10 in univariate analysis combined with biological plausibility; intubation and dialysis were excluded due to reverse causality. Standard multivariate logistic regression was performed; discrimination was assessed by AUC-ROC with bootstrap 95% CI (1,000 resamples) and calibration by Hosmer-Lemeshow test. Resultados e Conclusões: In-hospital mortality was 41.8% (n=28) and composite outcome 64.2%, in a severely ill population (median LVEF 26%; NYHA IV in 58.2%; 61.2% Chagas etiology). Only 20.9% received the four pillars of guideline-directed therapy and no patient used sacubitril/valsartan, likely reflecting hemodynamic contraindications and socioeconomic barriers to access in this public hospital cohort (Figure 1). The final model (AUC=0.804; 95% CI 0.695–0.901; H-L p=0.574) identified three independent predictors: mitral regurgitation grade (OR=3.13; 95% CI 1.43–6.84; p=0.004), reflecting advanced ventricular remodeling; serum sodium (OR=0.86 per mEq/L; 95% CI 0.75–0.98; p=0.023), a marker of neurohormonal activation; and dapagliflozin at admission (OR=0.20; 95% CI 0.06–0.70; p=0.012), suggesting a protective association, though limited by possible indication bias. All three predictors remained significant in sensitivity analysis (n=50) (Figure 2). The convergence of mechanical, neurohormonal and pharmacological predictors reflects multifactorial risk in this population. Early recognition of hyponatremia and mitral regurgitation may identify candidates for therapeutic intensification before the window of intervention is lost to dobutamine dependence. The marked undertreatment observed reinforces the urgent need for optimized medical therapy at earlier stages of disease progression.

COMBINED HEART-LIVER TRANSPLANTATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

EMMANUEL OBERDA NOMINATO1; JULIANA LUIZA PAULA DE ARAÚJO2; ANA FLÁVIA DE OLIVEIRA LELLES2; FELIPE OLIVEIRA ZICA MENDONÇA2; GABRIELLA NUNES FERNANDES GARCIA2; GUSTAVO SILVA RUOCCO2; KATHARINA SILVA BORGES2; GUILHERME GROSSI LOPES CANÇADO3; JOÃO BERNARDO SANCIO2; CLAUDIA ALVES COUTO2; CLAUDIO LEO GELAPE2;

(1) UNIVERSIDADE FEDERAL DE OURO PRETO - OURO PRETO - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: Combined heart–liver transplantation (CHLT) is an increasingly used strategy for selected patients with concomitant advanced cardiac and liver disease. However, outcome estimates remain limited by small observational cohorts and heterogeneous indications. Objetivos: To provide pooled estimates of patient survival, graft survival, and perioperative outcomes after CHLT. Métodos: PubMed, Embase, Web of Science, and Cochrane Library were searched from inception to March 2026. Full-text studies including adults undergoing CHLT and reporting at least one outcome of interest were eligible. Random-effects models estimated pooled proportions or means with 95% confidence intervals (95% CI). For overlapping cohorts, the study with the longest temporal coverage was prioritized. The review was prospectively registered in PROSPERO and reported according to PRISMA 2020. Resultados e Conclusões: Twelve observational studies comprising 735 patients were included, most of which reported mixed indications for CHLT. The most common cardiac indications were non-ischemic cardiomyopathy (n=293; 39.9%) and congenital heart disease (n=282; 38.4%). Among patients with available liver-specific indications, cardiac cirrhosis was the leading indication for liver transplantation (n=73; 51.4%), followed by amyloidosis (n=36; 25.4%). Overall, the majority of patients were male (n=480/682; 70.3%), with a mean age of 46.2 ± 16.8 years. Mean MELD and MELD-XI scores were 14.3 ± 6.7 and 14.3 ± 6.8, respectively, and mean ejection fraction was 34.5 ± 20.8%. Pooled patient survival was 85.7% at 1 year (95% CI, 77.1-91.4; I²=41.6%) and 78.3% at 5 years (95% CI, 74.2-82.0; I²=0.0%). Pooled combined graft survival was 90.4% at 1 year (95% CI, 48.3-99.0; I²=0.0%) and 77.5% at 5 years (95% CI, 69.2-84.2; I²=0.0%). In-hospital mortality was 6.8% (95% CI, 4.8–9.6; I²=0.0%). Postoperative resource use was substantial, with a mean ICU stay of 9.1 days (95% CI, 7.3–10.8; I²=0.0%) and a mean hospital stay of 31.2 days (95% CI, 16.9–45.5; I²=72.7%). Despite its complexity, CHLT was associated with preserved mid-term survival and apparently favorable graft survival, although the 1-year graft estimate was highly imprecise. These findings should be interpreted in light of clinical heterogeneity, center-level differences, and the observational nature of the included studies. Nevertheless, CHLT appears feasible in experienced centers with rigorous selection criteria and individualized multidisciplinary assessment.

COMPUTATIONAL DISSECTION OF THE TRANSCRIPTOMIC LANDSCAPE IN LIGHT-CHAIN AMYLOIDOSIS

CAMILA BEATRIZ FACHINI1; ULYSSES RAZIA CAVALCANTI1; GABRIELA CARMINATI LINO1; GABRIEL MELO ROTH DE OLIVEIRA1; GEOVANA CERESÉR DOS SANTOS1; LAURA HECK ZETTERMANN1; ROBERTA SCHULTZ MACHADO DOS SANTOS1; MANUELA TIMM1; VINICIUS MOLLING2; LUIZA SEIXAS MANSUR2; MARCELO RAVA DE CAMPOS3; NATASHA MALGAREZI2;

(1) UNISINOS - SÃO LEOPOLDO - RS - BRASIL; (2) UFCSPA - PORTO ALEGRE - RS - BRASIL; (3) HOSPITAL MOINHOS DE VENTO - PORTO ALEGRE - RS - BRASIL;

Introdução/Fundamentos: Cardiac amyloidosis is classified into light-chain (AL) and transthyretin forms. The former tends to result in fatal outcomes due to early systemic involvement preceding heart failure. The literature already acknowledges the influence of risk factors on clinical outcomes; however, bioinformatic analysis of gene expression may promote new hypotheses and study designs, opening possibilities for therapeutic interventions. Objetivos: To evaluate gene expression patterns and protein-protein interaction networks (PPINs) in cell lines expressing light-chains from patients with AL amyloidosis, aiming to identify Hub and Bottleneck genes with potential as therapeutic targets of interest. Métodos: Gene expression data were obtained from the National Center for Biotechnology Information (NCBI) at the Gene Expression Omnibus (GEO) datasets under the identification number GSE176119. Differentially expressed genes between the amyloidosis and control groups were evaluated using GEO2R. We used the resulting gene list as input for PPINs analysis performed with STRING. Hub and Bottleneck genes were subsequently identified using network topology algorithms implemented in CytoHubba, and the 10% most relevant genes were selected for further analysis. Resultados e Conclusões: The computational transcriptomic analysis in STRING generated 212 nodes and 3,351 edges. When imported into Cytohubba, it yielded 6 Hub genes (JUN, IL6, STAT3, IL1B, NFKB1 and TNF), 5 Bottleneck genes (CD4, HIF1A, TP53, EGR2 and SQLE), and 4 Hub-Bottleneck genes (MYC, AKT1, FOS and ACTB). Of these, 66.7%, 40% and 50%, respectively, were directly related to the pathophysiology of infiltrative heart diseases, cardiomyopathy, and heart failure. Among the Hub genes, JUN overexpression has been associated with cardiac hypertrophy, whereas its inhibition has been reported to reduce hypertrophic remodeling. Similarly, IL1B inhibition has been associated with attenuation of both cardiac hypertrophy and fibrosis. Among the Hub–Bottleneck genes, AKT1 expression has been documented as being involved in the induction of heart failure. The analysis demonstrates that the identified molecular interactions reinforce the relevance and potential of bioinformatics as a valuable tool for guiding pharmacogenetic and nanotechnology-based research strategies aimed at improving prognosis in patients with AL amyloidosis.

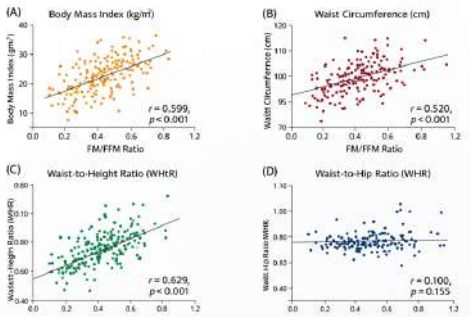
DXA-DERIVED FAT MASS TO FAT-FREE MASS RATIO AND ITS ANTHROPOMETRIC AND METABOLIC CORRELATES IN MIDDLE-AGED PATIENTS WITH HEART FAILURE

LUCIAN BATISTA DE OLIVEIRA1; BRENDA EDUARDA BAÍA DE ALENCAR2; RAISSA OSIAS TOSCANO DE BRITO1; GABRIELA ROCHA NASCIMENTO1; GABRIELA MARQUES MALHEIROS1; BEATRIZ GUIMARÃES AGUIAR1; FRANCISCO BANDEIRA1;



(1) UPE - RECIFE - PE - BRASIL; (2) UNIVERSIDADE FEDERAL DE CAMPINA GRANDE - UFCG - CAMPINA GRANDE - PB - BRASIL;

Introdução/Fundamentos: Adiposity plays a key role in the metabolic and clinical profile of patients with heart failure (HF), but conventional anthropometric measures may inadequately reflect body fat distribution. Dual-energy X-ray absorptiometry (DXA) provides a more accurate assessment, although its correlates remain unclear. Objetivos: To investigate DXA-derived adiposity in middle-aged patients with HF, emphasizing the fat mass to fat-free mass ratio (FM/FFM) as a marker of relative adiposity excess, and its association with anthropometric and metabolic parameters. Métodos: In this cross-sectional study, patients aged 40–64 years with established HF from a tertiary center were evaluated. DXA assessed body fat percentage (%BF) and FM/FFM, with high %BF defined as >25% in men and >35% in women. Anthropometric parameters included waist circumference (WC), waist-to-height ratio (WHtR), and waist-to-hip ratio (WHR). Laboratory measures included glycated hemoglobin (HbA1c) and triglyceride-to–high-density lipoprotein (HDL) ratio. HF phenotype was defined by New York Heart Association (NYHA) class, ejection fraction, and ischemic etiology. Spearman's correlation, one-way ANOVA, and linear regression were used for analyses, including trend assessment across FM/FFM quartiles. Resultados e Conclusões: A total of 203 patients were included (median age 57 years [IQR 51–61], 54.7% male). Reduced ejection fraction was present in 38.4%, 59.1% were NYHA III–IV, and 54.7% had ischemic etiology. Diabetes and prediabetes were observed in 46.3% and 33.5%, respectively, while 63.5% had high %BF. Mean FM/FFM was 0.48 ± 0.22. FM/FFM correlated with BMI (r = 0.599; p < 0.001), WC (r = 0.520; p < 0.001), and WHtR (r = 0.629; p < 0.001), but not with WHR (p = 0.155). HbA1c did not differ across FM/FFM quartiles (p = 0.679). In contrast, triglyceride-to-HDL ratio differed significantly (p = 0.001) and increased progressively across quartiles (B = 0.466; 95% CI 0.071–0.860; p for trend = 0.021). These findings indicate that FM/FFM captures metabolically relevant adiposity beyond traditional anthropometric measures and is associated with adverse lipid profile. Moreover, its consistent correlation with BMI, WC, and WHtR—but not WHR—suggests that waist-to-hip ratio may be a less reliable marker of adiposity in patients with HF.

Table 1 – Baseline characteristics of the study population (n = 203)

Variable	Value
Age, years	57 (IQR 51–61)
Male sex, n (%)	111 (54.7)
LVEF ≤40%, n (%)	91 (44.8)
NYHA class III–IV, n (%)	120 (59.1)
Ischemic etiology, n (%)	111 (54.7)
Diabetes, n (%)	94 (46.3)
Prediabetes, n (%)	68 (33.5)
High body fat, n (%)	129 (63.5)
FM/FFM ratio	0.48 ± 0.22

Note: Data are presented as median (interquartile range) or n (%). FM/FFM = fat mass to fat-free mass ratio; LVEF = left ventricular ejection fraction; NYHA = New York Heart Association.

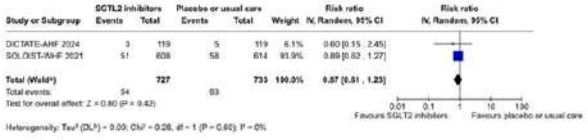
EARLY IN-HOSPITAL INITIATION OF SGLT2 INHIBITORS IN PATIENTS HOSPITALIZED FOR ACUTE DECOMPENSATED HEART FAILURE: A SYSTEMATIC REVIEW AND META-ANALYSIS

NATHÁLIA CRISTINA RODRIGUES1; MARTÍN RECH RAMOS1; JÚLIA MARQUES DA SILVA1; RAFAEL COLOMBO1; FÁBIO EDUARDO CAMAZZOLA1;

(1) UNIVERSIDADE DE CAXIAS DO SUL - CAXIAS DO SUL - RS - BRASIL;

Introdução/Fundamentos: Early initiation of sodium-glucose cotransporter 2 inhibitors (SGLT2i) during hospitalization for acute decompensated heart failure (ADHF) has emerged as a promising therapeutic strategy. However, evidence regarding its impact on clinical outcomes remains limited and heterogeneous. Objetivos: To evaluate the effects of early in-hospital initiation of SGLT2i on clinical outcomes in patients hospitalized for ADHF. Métodos: We conducted a systematic review and meta-analysis in accordance with PRISMA guidelines. Randomized controlled trials evaluating in-hospital initiation of SGLT2i (dapagliflozin, empagliflozin, or sotagliflozin), compared with placebo or usual care in adults hospitalized for ADHF, were included. PubMed, Embase, and the Cochrane Central Register of Controlled Trials were systematically searched through March 2026. The primary outcomes were all-cause mortality and heart failure events (HFE), including rehospitalization when available. Secondary outcomes included cardiovascular (CV) mortality. Risk ratios (RR) with 95% confidence intervals (CI) were pooled using a random-effects model. Risk of bias was assessed using the Cochrane RoB 2 tool. Resultados e Conclusões: We included 5 randomized controlled trials comprising 2,128 patients. Mean follow-up ranged from 1 to 9 months. Early in-hospital initiation of SGLT2 inhibitors was associated with a significant reduction in HFE, including rehospitalizations (RR 0.76; 95% CI 0.62–0.93; p=0.007). Reductions in all-cause mortality (RR 0.77; 95% CI 0.58–1.01; p=0.06) and CV mortality (RR 0.87; 95% CI 0.61–1.23; p=0.42) did not reach statistical significance, although effect estimates consistently favored SGLT2i. These findings support that early in-hospital initiation of SGLT2i reduces heart failure-related morbidity, particularly recurrent decompensation, without a significant impact on mortality. The effect on mortality in the acute setting remains uncertain and warrants further investigation.

Figure 1A. All-cause mortality was not significantly lower in the SGLT2 inhibitor group.



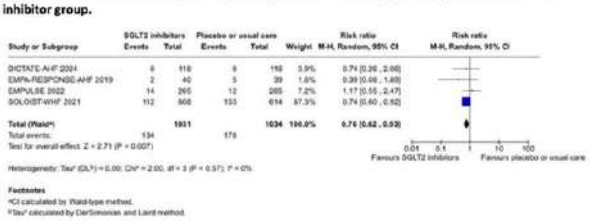


Figure 1B. Heart failure events, including rehospitalizations, were significantly lower in the SGLT2 inhibitor group.

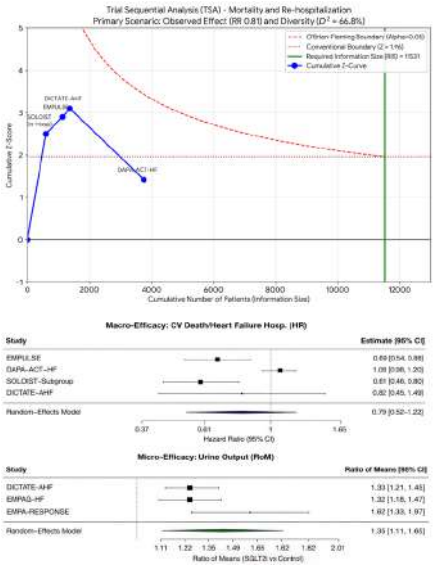

19046

EFFECT OF EARLY IN-HOSPITAL INITIATION OF SGLT2 INHIBITORS ON CLINICAL OUTCOMES AND DECONGESTION IN ACUTE HEART FAILURE: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CLINICAL TRIALS

HENZO IGLESIAS FRANCO MOREIRA1; MARCOS VINICIUS LOPES DE OLIVEIRA1; HANNAH UNGER1; ESTHER ELGRABLY DE MELO E SILVA ZATZ1; PEDRO HENRIQUE MENDOÇA DA SILVA1; BEATRIZ LEMOS LOPES1; JULIA ALENCAR FONSECA DIAS1; HELOIZA CORDEIRO PEREIRA2; CAROLINA CHAVES NOGUEIRA1; LUCAS CABRAL SOARES3; PALOMA PANZUTI RODRIGUES1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL; (3) CESUPA - BELEM - PA - BRASIL;

Introdução/Fundamentos: Acute heart failure (AHF) is associated with a high risk of early post-hospitalization events. Despite early incorporation of SGLT2 inhibitors (SGLT2i) into guidelines, their short-term clinical impact remains uncertain due to trial heterogeneity and limited sample size. It is also unclear whether benefits reflect prognostic effects or immediate physiological responses. Objetivos: To evaluate the clinical and decongestive efficacy of early SGLT2i initiation in AHF and assess the robustness of the available evidence. Métodos: Systematic review conducted according to PRISMA 2020. MEDLINE, Embase, and Cochrane were searched through March 2026. Randomized clinical trials evaluating SGLT2i initiation within 72 hours of admission were included. Risk of bias was assessed using RoB 2 and certainty of evidence using GRADE. Random-effects models (REML) with Knapp-Hartung adjustment were applied. Effect measures included HR, RR, and ratio of means (RoM) with 95% CI. Heterogeneity was assessed by I². Trial Sequential Analysis (α=5%, power=80%, RRR=20%) evaluated evidence robustness. Pre-specified subgroup analyses were performed according to timing of initiation (<24h vs 24–72h) and study size Resultados e Conclusões: Fourteen RCTs (n≈4.000) were included; 4 contributed to the primary outcome. No significant reduction in cardiovascular death or heart failure rehospitalization was observed (HR 0.79; 95% CI 0.52–1.22; I²=87%). Trial Sequential Analysis showed that only 32% of the required information size was achieved (RIS=11,531), indicating insufficient evidence and risk of type II error. Early diuresis significantly increased (RoM 1.33; 95% CI 1.21–1.45), with consistent direction but lower precision in subsequent analyses. No increased risk of renal dysfunction was observed (RR 1.04; 95% CI 0.90–1.21). No significant interaction was observed according to timing of initiation (p=0.445). Evidence certainty was low to moderate due to imprecision and heterogeneity. In conclusion, although SGLT2i improve early decongestion in AHF, they did not demonstrate robust clinical benefit during the in-hospital phase, suggesting predominance of physiological effects without consistent short-term clinical impact. These findings support the use of SGLT2i as adjunctive decongestive therapy rather than as a strategy for immediate prognostic improvement

20821

EFFECTIVENESS AND SAFETY OF SEQUENTIAL NEPHRON BLOCKADE IN HEART FAILURE PATIENTS FOLLOWED IN A SPECIALIZED OUTPATIENT CLINIC

CATARINA MARQUES MÜLLER PESSÔA1; RAFAELA MARQUES MÜLLER PESSÔA1; LUANA MONFERDINI1; PAULO MARÇAL SANTOS1; LARA LELLIS DA SILVA1; GIORGIA LOVATO CASSONE1; JULIA NOUMI MELLIS1; MARIA CLARA DEVITA1; LETÍCIA GIOVANNA FARIA DA SILVA1; BRUNO PIUNTI RIZZI1; RODRIGO NASCIMBENE SILVA1; NATHALIA DOS REIS DE MORAES1;

(1) PONTIFICIA UNIVERSIDADE CATOLICA DE CAMPINAS - CAMPINAS - SP - BRASIL;

Introdução/Fundamentos: Persistent congestion and diuretic resistance are associated with worse prognosis in heart failure (HF). Sequential nephron blockade (SNB), combining diuretics acting at different tubular sites, has emerged as a strategy to enhance natriuresis and decongestion, although evidence in outpatient and real-world settings remains limited. Objetivos: To evaluate the effectiveness and safety of SNB in HF patients followed in a specialized outpatient clinic. Métodos: This retrospective observational study included HF patients followed in a specialized outpatient clinic, divided according to the use of optimized HF therapy alone or additional SNB, defined as concomitant use of hydrochlorothiazide and/or acetazolamide. Among SNB patients, 93.1% received hydrochlorothiazide, 6.9% acetazolamide, and one patient received both agents. Median outpatient follow-up was 756 days in the SNB group and 511 days in the non-SNB group. Clinical, laboratory, and echocardiographic variables were assessed, including renal function, electrolyte abnormalities, NT-proBNP levels, and diuretic use. Continuous variables were compared using Student's t-test, while categorical variables were analyzed using chi-square or Fisher's exact tests, as appropriate. Statistical significance was set at 5%. Analyses were performed using Jamovi software. Resultados e Conclusões: A total of 191 patients were included, of whom 28 received SNB. Patients in the SNB group showed higher prevalence of atrial fibrillation (46.4% vs 26.1%; p=0.041), higher prevalence of furosemide use (92.9% vs 75.6%; p=0.047), higher prevalence of renal dysfunction defined as eGFR <60 mL/min/1.73m² (67.8% vs 37.3%; p=0.001), and higher NT-proBNP levels [2615 (814–6400) vs 1227 (506–2541) pg/mL; p=0.069], suggesting greater clinical severity and congestion burden. No significant difference was observed in hyperkalemia between groups (7.1% vs 7.3%; p=1.0). These findings suggest that SNB is predominantly used in patients with more advanced HF and possible diuretic resistance, without a substantial increase in laboratory complications. In a real-world outpatient setting, SNB demonstrated an acceptable safety profile, supporting its role as an adjunctive therapeutic strategy in selected HF patients.

Table 1. Clinical and laboratory comparison between patients with and without Sequential Nephron Blockade (SNB).

Variable	BNS (n=28)	No BNS (n=163)	p-value
Age (years), median (IQR)	64 (53.8–72.5)	62 (50.5–72.0)	0,430
Male sex, n (%)	19 (67.9%)	89 (54.3%)	0,219
LVEF (%), median (IQR)	30.5 (23.0–36.3)	32.0 (25.8–40.0)	0,490
Chronic kidney disease, n (%)	13 (46.4%)	57 (35.4%)	0,293
Atrial fibrillation, n (%)	13 (46.4%)	42 (26.1%)	0,041
Furosemide use, n (%)	26 (92.9%)	121 (75.6%)	0,047
eGFR (mL/min/1.73m²)	54.0 ± 25.8	66.7 ± 28.7	0,066
Hyperkalemia, n (%)	2 (7.1%)	12 (7.3%)	1,000
Weight gain, n (%)	13 (50%)	76 (52.4%)	0,835
NT-proBNP (pg/mL), median (IQR)	2615 (814–6400)	1227 (506–2541)	0,069
eGFR <60 mL/min/1.73m², n (%)	19 (67.8%)	60 (37.3%)	0,001

Note: Continuous variables were analyzed using Student's t-test and categorical variables using the chi-square or Fisher's exact test. Statistical significance was set at p<0.05. Analyses were performed using jamovi.

ELECTROCARDIOGRAPHIC FINDINGS AND VOLTAGE-TO-LEFT VENTRICULAR MASS RATIO IN PATIENTS WITH CARDIAC AMYLOIDOSIS: A TERTIARY CENTER COHORT ANALYSIS

AUGUSTO DE OLIVEIRA PERES1; ANA CLARA FARIAS DE NEGRI1; KAIQUE CABRAL DE OLIVEIRA1; KARINE DE SOUZA FALCÃO1; LUCAS ROCHA DA SILVA1; CAROLINE BITTAR-BRAUNE1; WILSON BRAZ CORRÊA FILHO1; ANDRÉ CASARSA MARQUES1; EDUARDO MARINHO TASSI1; FELIPE RODRIGUES BAPTISTA1; FABIO DE SOUZA1;

(1) UNIRIO - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Cardiac amyloidosis (CA) has gained increasing relevance due to population aging, advances in noninvasive diagnostic methods, and the availability of disease-modifying therapies, yet it remains underdiagnosed. The electrocardiogram (ECG) is a widely available tool that may raise clinical suspicion. The voltage-to-mass ratio (VMR) has been proposed as a complementary parameter to help differentiate CA from other hypertrophic phenotypes, although it is not routinely used in clinical practice. Objetivos: To describe electrocardiographic findings, including the voltage-to-mass ratio, in patients with confirmed CA followed at a specialized cardiology clinic. Métodos: Retrospective observational study including patients with confirmed CA (ATTRv, ATTRwt, or AL) evaluated between 2023 and 2026. ECG analysis included rhythm, heart rate, axis, PR interval, QTc (Bazett), QRS duration, low voltage criteria (<0.5 mV in limb leads, <1.0 mV in precordial leads), SV1+RV5, conduction disturbances, pseudo-infarction patterns, and R-wave progression. VMR was calculated as SV1+RV5 divided by left ventricular mass indexed to body surface area (mV/kg/m²), with lower values (previously reported as <17.9) suggesting a higher likelihood of CA. The study was approved by the local ethics committee. Resultados e Conclusões: Thirty-three patients were included: 66% ATTRv, 19% ATTRwt, and 15% AL; 66% were male, with mean age of 71 ± 12 years. Sinus rhythm was present in 70%, atrial fibrillation in 18%, and pacemaker rhythm in 12%. Mean heart rate was 72 ± 12 bpm, PR interval 212 ± 47 ms, QTc 446 ± 35 ms, QRS duration 101 ± 22 ms, and SV1+RV5 1.16 ± 0.5 mV. Low voltage was present in 42% of limb leads and 13% of precordial leads. First-degree atrioventricular block occurred in 44%, and left anterior fascicular block in 35%. Pseudo-infarction pattern was observed in 70%, and poor R-wave progression in 64%. Mean left ventricular ejection fraction was 55 ± 13%, with 61% preserved EF. Left ventricular mass index was 140 ± 66 g/m², and mean VMR was 8.9 ± 7.9 mV/kg/m². Pseudo-infarction patterns, low voltage, and conduction abnormalities were frequent findings in this cohort. The voltage-to-mass ratio was markedly reduced compared with previously reported reference values, supporting its potential role as a complementary noninvasive parameter to increase clinical suspicion and aid in the differential diagnosis of cardiac amyloidosis.

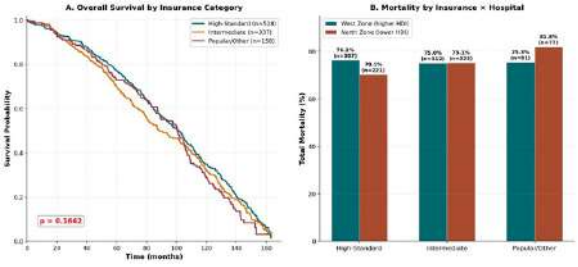
HEALTH INSURANCE AS A SOCIOECONOMIC PROXY IN DECOMPENSATED HEART FAILURE: MORTALITY GRADIENTS SHAPED BY HOSPITAL CONTEXT

DAVI DE VASCONCELLOS DIAS1; GIOVANNI POSSAMAI DUTRA2; BRUNO FERRAZ DE OLIVEIRA GOMES2; FABIANA CARDOSO DE OLIVEIRA1; JOÃO LUIZ FERNANDES PETRIZ2; PLINIO RESENDE DO CARMO JUNIOR2; EMILIA MATOS NASCIMENTO3; BASILIO DE BRAGANÇA PEREIRA1; GLAUCIA MARIA MORAES DE OLIVEIRA1;



(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) BARRA D`OR - RIO DE JANEIRO - RJ - BRASIL; (3) UNIVERSIDADE ESTADUAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: In the Brazilian supplementary healthcare system, health insurance tier reflects socioeconomic status and shapes access to specialized post-discharge care. Whether insurance category functions as an independent social determinant associated with differential mortality in DHF, and whether hospital context modifies this relationship remains underexplored. Objetivos: To analyze the association between health insurance category and mortality in DHF patients at two private tertiary centers in contrasting socioeconomic zones, and to evaluate the interaction between insurance tier and hospital context. Métodos: Retrospective cohort of 1,023 DHF patients (two centers, West Zone HDI 0.959 vs. North Zone HDI 0.814; median follow-up 6.9 years, IQR 4.4–9.9) classified by insurance: high-standard (n=528; 51.6%), intermediate (n=337; 32.9%), and popular/other (n=158; 15.4%). Estimated household income (derived from occupation, residential neighborhood, and PNAD survey data) validated the socioeconomic gradient. Kaplan-Meier curves, logistic regression, and hospital-stratified subgroup analyses were performed. Resultados e Conclusões: Median household income decreased progressively: R$5,512 (IQR 3,600–7,200), R$4,134 (IQR 3,465–4,500), and R$2,668 (IQR 2,079–2,700) for high-standard, intermediate, and popular/other, respectively. Total mortality increased across categories: 389/528 (73.7%) vs. 253/337 (75.1%; P=0.691) vs. 124/158 (78.5%; P=0.251 vs. reference). Insurance distribution differed markedly by hospital zone (P<0.001; Cramer's V=0.8), consistent with geographic socioeconomic clustering. The insurance–hospital interaction was numerically relevant: popular/other patients at the North Zone had 63/77 (81.8%) mortality vs. 61/81 (75.3%) at the West Zone (P=0.340). Although marginal p-values for insurance alone were non-significant, possibly reflecting confounding by hospital location, the progressive income gradient and institutional amplification of disadvantage support health insurance tier as a pragmatic marker of social vulnerability in DHF, particularly within the healthcare delivery context.

Table. Clinical and Mortality Profile by Health Insurance Category (n=1,023)

Characteristic	High-Standard (n=528)	Intermediate (n=337)	Popular/Other (n=158)	P-value
Income, median (IQR), R$	5,512 (3,600–7,200)	4,134 (3,465–4,500)	2,668 (2,079–2,700)	<0.001
Age, median (IQR), years	77 (67–85)	80 (71–86)	78 (69–84)	NS
LVEF, median (IQR), %	44 (33–58)	48 (36–59)	45 (34–54)	NS
BNP, median (IQR), pg/mL	2,120 (954–6,638)	3,500 (1,360–10,200)	2,045 (844–5,452)	NS
Follow-up, median (IQR), years	7.1 (4.7–9.9)	6.0 (4.0–9.8)	7.4 (4.5–9.7)	NS
North Zone, n (%)	221 (41.9%)	225 (66.8%)	77 (48.7%)	<0.001
Brown/Black, n (%)	52 (9.8%)	24 (7.1%)	4 (2.5%)	0.009
Total mortality, n (%)	389 (73.7%)	253 (75.1%)	124 (78.5%)	0.251*
In-hospital mortality, n (%)	61 (11.6%)	33 (9.8%)	16 (10.1%)	0.669*
Popular @ North Zone mort.	–	–	63/77 (81.8%)	–
Popular @ West Zone mort.	–	–	61/81 (75.3%)	0.340†

*vs. High-Standard (Fisher's exact). †North Zone vs. West Zone within Popular/Other. LVEF=left ventricular ejection fraction; BNP=B-type natriuretic peptide.

HEART FAILURE POST PULMONARY EMBOLISM: A PROSPECTIVE OBSERVATIONAL FOLLOW UP STUDY

HAKIM IRFAN SHOWKAT1; SADAF ANWAR1;

(1) SRINAGAR MEDCITY HEART INSTITUTE - INDIA;

Introdução/Fundamentos: Venous thromboembolism as DVT or PE, third most frequent acute cardiovascular syndrome .Heart failure secondary to pulmonary embolism is underdiagnosed and potentially life-threatening complication of deep vein thrombosis. Death usually occurs due to right ventricular failure in the setting of sustained hypotension and cardiogenic shock.The aim of this study was to evaluate & follow patients with Acute Pulmonary Embolism Objetivos: To Observe the effect of PE on RV and LV function on admission, discharge & follow up On Folow up - MACE or any Recurrent Venous thrombotic events Métodos: A prospective observational study entitled "Assessment of right & left ventricular functions in patients with Pulmonary embolism: An observational study" was conducted from Mar 2019 to April 2022 in the Department of Cardiology, Superspeciality hospital, North India.The study was conducted after securing informed consent from patients or attendants for participation in the study. Resultados e Conclusões: Patients were categorized as those (1) without RVD (125 patients [53.1%])(2) with RVD regression (RVD on admission but not at discharge or first follow up); 52 patients [22.1%])(3) with persistent RVD (RVD on admission, discharge & follow up; 26 patients [11.0%]), and (4) With both RVD & LVD at admission, discharge & follow up; 32 patients [13.6%]. After a mean ± SD of 2.1 ± 0.6 years, patients with RVD & LVD persistence showed an increased risk of recurrent VTE (12 patients, 5.1% patient-years) compared with those with only RVD (8 patients, 3.4% patient-years), without RVD (4 patients, 1.7% patient-years) or RVD regression (3 patients, 1.2% patient-years) (P = .001). 11of 18 deaths related to pulmonary embolism occurred in patients with RVD & LVD persistence. At multivariate analysis, adjusted by anticoagulant treatment duration, RVD persistence was an independent predictor of recurrent VTE (hazard ratio, 3.79; P<.001).

IMPACT OF ACCELERATED ADRENERGIC BLOCKADE ON LONG-TERM REVERSE VENTRICULAR REMODELING AND BNP KINETICS: A 12-MONTH MECHANISTIC ANALYSIS OF A RANDOMIZED TRIAL

VICTOR MATHEUS SOARES DA SILVA1; EMILLY MARIA SOARES DA SILVA2; MIGUEL ANGEL EUGENIO VELA1; CAMILY VITORIA DA SILVA DE MELO3; FRANCIELLY DE OLIVEIRA RODRIGUES1; THAYSA RAYANNA SANTOS BATISTA1; LUCAS HENRIQUE CHAVES CABRAL DA COSTA CAVALCANTI1; PEDRO HENRIQUE SIMÕES DE MELO BARBOSA BARBOSA1; DOMINGOS SAVIO BARBOSA DE MELO1;

(1) CENTRO UNIVERSITARIO MAURICIO DE NASSAU - RECIFE - PE - BRASIL; (2) FACULDADE DE MEDICINA DE OLINDA - OLINDA - PE - BRASIL; (3) UNINASSAU CARUARU - CARUARU - PE - BRASIL;

Introdução/Fundamentos: Left ventricular reverse remodeling (LVRR) is the definitive structural surrogate for improved prognosis in HFrEF. While beta-blockers are known catalysts for LVRR, the relationship between the speed of achieving target doses and the magnitude of structural recovery remains poorly defined. Furthermore, the role of B-type Natriuretic Peptide (BNP), as a marker of parietal stress, may serve as a biological guide for the safety and efficacy of this therapeutic progression, predicting long-term structural success. Objetivos: To investigate the impact of accelerated versus conventional beta-blocker titration on LVRR parameters and to assess the predictive value of early BNP kinetics over a 12-month follow-up. Métodos: In this longitudinal sub-analysis of 92 randomized patients (NYHA IV, LVEF <45%), we performed blinded transthoracic echocardiography and serial BNP measurements at admission, discharge, and 12 months. The primary structural endpoints were the absolute and percentage variations in Left Ventricular End-Systolic Diameter (LVESD) and End-Diastolic Diameter (LVEDD). Correlation between variables was assessed using Pearson's r, and the predictive accuracy for dose tolerance was determined via ROC curve analysis. Resultados e Conclusões: The accelerated titration group (IG) exhibited a significantly more pronounced reduction in BNP levels already at the time of discharge ($p<0.05$). At 12 months, the IG demonstrated robust structural recovery, with mean LVESD decreasing from 58.1 to 51.0 mm ($p<0.001$) and LVEDD from 66.7 to 62.3 mm ($p<0.001$). Conversely, the control group showed no statistically significant reduction in LVESD ($p=0.337$). A strong linear correlation ($r=0.72$) was identified between the magnitude of early BNP drop and the degree of LVESD reduction at one year. Furthermore, an early BNP reduction of >30% demonstrated high predictive accuracy for long-term full-dose tolerance (AUC-ROC 0.82). In conclusion, accelerated beta-blocker titration significantly catalyzes LVRR in advanced HFrEF. The early reduction in BNP reflects a vigorous decrease in parietal stress, predicting superior long-term structural recovery and modifying the natural history of the disease more effectively than conventional titration.

IMPACT OF EARLY SGLT2 INHIBITOR INITIATION ON RENAL FUNCTION IN ACUTE HEART FAILURE: A SYSTEMATIC REVIEW OF RANDOMIZED CONTROLLED TRIALS

IAN FERNANDINO SOUZA1; ARTUR MELO RODRIGUES1; DANIELLY RAMOS PEREIRA1; ANA CAROLYNE FERREIRA PESSOA1; RAFAEL RODRIGUES LOPES1; LAURA MUSTAFÁ UMBELINO VIEIRA1; GUSTAVO CAMPOS SABINO1; GABRIEL BRANT MOREIRA FERREIRA1; CHRISTIANO GONÇALVES DE ARAÚJO1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: Acute heart failure (AHF) is associated with high morbidity and an increased risk of worsening renal function. Although Sodium–Glucose Cotransporter 2 (SGLT2) inhibitors have demonstrated benefits in chronic heart failure, evidence regarding their early in-hospital use in AHF, particularly on renal outcomes, remains limited. Objetivos: To evaluate the effects of early (within the first 72 hours of hospitalization) initiation of SGLT2 inhibitors on renal outcomes and its safety in patients hospitalized with acute heart failure. Métodos: A systematic review was conducted in accordance with PRISMA guidelines. PubMed, Embase, and the Cochrane Library were searched in April 2026. The initial search identified 355 articles. After applying inclusion and exclusion criteria, 9 randomized controlled trials evaluating early (≤72 hours) SGLT2 inhibitor initiation in AHF were included. Data on renal outcomes and adverse events were extracted and qualitatively synthesized. Resultados e Conclusões: Across the included randomized controlled trials, early initiation of SGLT2 inhibitors in patients with AHF demonstrated a predominantly neutral impact on renal function. Baseline renal parameters were comparable between intervention and control groups. No significant differences were observed in eGFR decline or in the incidence of worsening renal function (WRF) during hospitalization. Mild, transient increases in serum creatinine were reported in some studies, without an increase in serious renal adverse events. Importantly, early SGLT2 inhibitor use was not associated with higher rates of acute kidney injury. Some trials suggested potential renal benefits, including increased 24-hour urine output and improved decongestion markers without compromising renal perfusion. Additionally, patients treated with SGLT2i required less loop diuretic dose escalation, suggesting a more efficient diuretic response. These findings were consistent across different SGLT2 inhibitors and patient subgroups, including those with chronic kidney disease. In conclusion, early initiation of SGLT2 inhibitors in AHF appears to be safe from a renal perspective, with neutral to mildly favorable effects. However, limitations include the relatively small number of studies, short follow-up periods, and methodological heterogeneity. Further large-scale studies with longer follow-up are warranted to better define long-term renal outcomes.

IMPACT OF OPTIMIZED DRUG THERAPY ON THE PROGNOSIS OF HEART FAILURE

CLARA TALITA SILVA LOBO1; FELIPE FREITAS COUTO2; TAINÁ TEIXEIRA VIANA2; ANA BEATRIZ BONFIM DE ALMEIDA1; PEDRO VOGEL ALMEIDA1; LÍVIA RODRIGUES SAMPAIO CAVALCANTE1; MARCUS VINICIUS BARBOSA VALE1; PAULO VICTOR ALMEIDA MARCHESINE2; MARIANA MARIA CARNEIRO MADEIRA2; RAÍSA MAINARTE FRANCO BARROS HAMILTON2; RODRIGO MOREL VIEIRA DE MELO1;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL; (2) INSTITUTO D'OR DE PESQUISA E ENSINO - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Hospitalization for heart failure (HF) represents a high-risk period for mortality and readmission, especially in the first months following discharge. Although guideline-directed medical therapy significantly reduces morbidity and mortality, its implementation in clinical practice at the time of hospital discharge remains suboptimal. Objetivos: To evaluate the association between optimized medical therapy at hospital discharge and the composite outcome of heart failure (HF) readmission or death within 180 days. Métodos: A retrospective, single-center observational study including 140 patients with HF and an ejection fraction ≤40%. Optimized therapy was defined as the prescription of the four prognosis-modifying classes (beta-blocker; Angiotensin-Converting Enzyme Inhibitor (ACEI), Angiotensin Receptor Blocker (ARB), or Angiotensin Receptor-Neprilysin Inhibitor (ARNI); mineralocorticoid receptor antagonist (MRA); and SGLT2 inhibitor). The primary outcome was HF readmission or death within 180 days. Resultados e Conclusões: Results: Forty-four patients (31.4%) received optimized therapy at hospital discharge. The composite outcome occurred in 53 (37.9%) patients during the 180-day follow-up. The absence of optimized therapy was associated with a higher risk of events in univariate analysis (RR 1.33; 95% CI 1.04–1.70; p=0.04) and maintained an independent association after multivariate adjustment (adjusted RR 2.48; 95% CI 1.12–5.49; p=0.025). A progressive reduction in the event rate was observed as the number of prescribed therapeutic classes increased (AUC 0.642; 95% CI 0.547–0.738; p=0.005). Conclusion: The absence of optimized medical therapy at hospital discharge was independently associated with a poorer 180-day prognosis, reinforcing hospital discharge as a critical moment for the full implementation of optimized therapy.

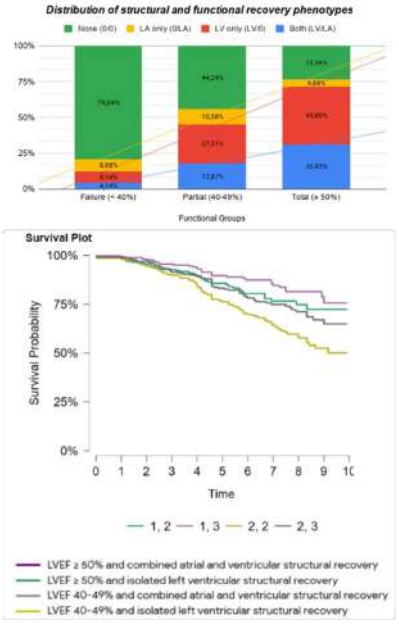
IMPACTS OF THE IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR ON BODY IMAGE AND IDENTITY: A SYSTEMATIC REVIEW

MURILO VALENTINNO FARIA DA SILVA1; GABRIEL MORAIS BRANDÃO1; RAFAELA DOS SANTOS ABUJAMRA1; ARIANE AUDREY FARIA1; RONALD DE SOUZA1;

(1) UNIVERSIDADE FEDERAL DE ALFENAS (UNIFAL) - ALFENAS - MG - BRASIL;

Introdução/Fundamentos: The implantable cardioverter-defibrillator (ICD) is an essential tool for preventing sudden cardiac death. However, alongside the survival guaranteed by the device, profound changes in the patient's self-image may also arise. Beyond the scars and the protrusion under the skin, which have an aesthetic impact, the feeling of constant dependence on a machine to stay alive can transform the individual's perception of life. Objetivos: To synthesize evidence regarding changes in identity and body image among ICD patients and their negative impacts. Métodos: This is a systematic review following the PRISMA methodology. PICO question: "What are the impacts of the ICD on patients' body image and identity?". The search strategy used descriptors such as "Implantable defibrillator", "Identity", and "Psychosocial Impact". Searches were conducted in April 2026 across the PubMed, CINAHL, and LILACS databases. Inclusion criteria were: primary studies, thematic adherence, and English or Portuguese languages. Secondary studies, editorials, and letters were excluded. After duplicate removal, title and abstract screening, and full-text review by two independent reviewers, 13 studies were included, totaling 1,219 patients. Data were subjected to thematic synthesis. Resultados e Conclusões: The ICD alters the patient's perception of body image through the device's protrusion under the skin and scars. The main negative impacts are feelings of embarrassment and being less attractive. This leads patients to restrict their clothing and avoid locations such as beaches or pools, in addition to avoiding physical proximity with sexual partners. Profound changes were observed in how patients perceive their own identity after the implant. One patient stated: "It's not the same!" "I feel deficient!" Patients reported a lack of doctor-patient communication and that the only alternative provided by physicians to the ICD was death. Thus, the presence of the ICD serves as a constant reminder of their finitude and loss of control over their own lives, as reported by one patient: "I am being controlled and regulated by a machine." Therefore, ICDs have the potential to alter the patient's self-perception and social relationships. The literature reveals a gap in doctor-patient communication prior to implantation, such that psychosocial aspects are often ignored. Studies suggest that psychosocial support and cardiac rehabilitation programs are effective in facilitating adaptation and improving the perception of self-image in ICD patients.



15377

IMPORTANCE AND SIGNIFICANCE OF LEFT ATRIAL REVERSE REMODELING IN THE FOLLOW-UP OF PATIENTS WITH HEART FAILURE ABSTRACT TEXT

LUANA BEATRIZ FAGUNDES SILVA1; SILAS RAMOS FURQUIM2; MARIA TEREZA SAMPAIO DE SOUSA LIRA2; DEBORAH DE SÁ PEREIRA BELFORT2; BRUNO BISELLI2; PAULO ROBERTO CHIZZOLA2; ROBINSON TADEU MUNHOZ2; EDIMAR ALCIDES BOCCHI2; SILVIA MOREIRA AYUB-FERREIRA2;

(1) HOSPITAL DAS CLINICAS USP - SÃO PAULO - SP - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Heart failure (HF) phenotypes are clinically classified based on left ventricular ejection fraction (LVEF). While cardiac reverse remodeling is a well-established marker of favorable outcome, clinical focus remains predominantly on the left ventricle (LV), which may underestimate significant structural changes in other chambers. The left atrium (LA) is a sensitive marker of hemodynamic burden and filling pressures; however, consensus is lacking regarding the prevalence and prognostic impact of left atrial reverse remodeling (LARR) in relation to left ventricular reverse remodeling (LVRR). Objetivos: To simultaneously analyze atrial and ventricular reverse remodeling to classify recovery phenotypes in patients with HF and evaluate the impact of structural dissociation on 10-year survival. Métodos: A retrospective cohort study (2006–2019) included 7,981 patients with baseline LVEF <40%. Subjects were stratified by functional recovery (Total: LVEF ≥50%; Partial: LVEF 40–49%) and by diameter normalization patterns: combined (LV/LA), isolated (LV or LA only), and absent. Statistical analysis included Pearson correlation and Kaplan–Meier survival curves with log-rank tests. Resultados e Conclusões: In the total functional recovery group (n=1,005), isolated ventricular normalization (LV only) was predominant (40.8%), surpassing the combined LV/LA profile (30.9%). A weak correlation was found between LVEF gain and atrial reduction (r=0.169). In the partial recovery group (n=1,494), absent structural improvement predominated (44.2%), with near-zero atrial variation (0.12%). Survival analysis at 5 and 10 years revealed that LA normalization significantly reduces mortality: in the total functional recovery group, mortality decreased from 20.2% (isolated LV) to 8.0% (combined LV/LA); in the partial recovery group, it fell from 31.1% (isolated LV) to 16.5% (combined LV/LA) (p < 0.001). Functional recovery is frequently independent of structural recovery; thus, current definitions of reverse remodelling may underestimate patient prognosis. Persistent atrial dilatation in patients with normalized LVEF suggests residual cardiac impairment, which maintains elevated mortality rates.

INDEPENDENT PROGNOSTIC VALUE OF THE NEUTROPHIL-TO-LYMPHOCYTE RATIO IN ACUTE HEART FAILURE: A SYSTEMATIC REVIEW.

CLARA SIMÕES NOBRE1; CLARA CARVALHO DE MORAIS LEITE1; MARIA EDUARDA OLIVEIRA SANTOS1; BEATRIZ BARSI CUNHA1; LETICIA LIMA FELIX MARINHO1; GIOVANA PAZ LIMA1; GIOVANA SIEBRA DE OLIVEIRA1; MARINA CALADO LIMA1; JULIA SIEBRA DE OLIVEIRA1; BÁRBARA MAIA FERNANDES LYRA1; ANE KAROLINE MEDINA NÉRI1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Acute heart failure (AHF) is associated with high morbidity and mortality, and early risk stratification remains a major clinical challenge. Systemic inflammation is recognized as a key mechanism in its pathophysiology, and the neutrophil-to-lymphocyte ratio (NLR) at admission has emerged as a cost-effective prognostic biomarker. Elevated NLR has been associated with worse clinical outcomes, including increased in-hospital and long-term mortality. However,the prognostic reliability of NLR is often challenged by non-cardiac inflammatory triggers, and cut-off variability limits comparability and clinical applicability across studies. Therefore, a synthesis focusing on the independent role of this marker is necessary. Objetivos: This review aims to analyze the independent prognostic impact of high versus low admission NLR on mortality and major clinical outcomes in patients with acute heart failure, both de novo and Acute Decompensated Heart Failure cases (ADHF), while specifically accounting for major inflammatory confounders. Métodos: The systematic review followed PRISMA guidelines. A literature search was conducted in Embase, Cochrane, LILACS and PubMed, covering studies up to April 2026. MeSH and DeCS terms used include “Acute Heart Failure”, “Neutrophil-to-Lymphocyte Ratio”, “Mortality”, and “Prognosis”, combined with AND/OR. Resultados e Conclusões: A total of 16 studies were included in this review with the selection process detailed in the PRISMA flow diagram. The studies were primarily retrospective cohort studies, encompassing 22,250 patients with AHF, including both de novo cases and ADHF. Although thresholds varied, most studies found that an NLR above the range of 3.0 to 5.5 is associated with a significantly higher risk of in-hospital and long-term all-cause mortality. The predictive value of the NLR remained significant even in populations specifically screened to exclude active infections, the use of corticosteroids, or other primary inflammatory confounders, suggesting that in the context of AHF, the NLR serves as a marker of immune-metabolic stress associated with cardiac decompensation. Notably, integrating NLR into the AHEAD score (Atrial fibrillation, Hemoglobin, Elderly, Abnormal renal function, Diabetes) improved Net Reclassification Improvement (NRI), outperforming standard scores. These findings highlight that elevated admission NLR is a robust predictor of both acute and long-term adverse clinical outcomes in AHF, helping identify patients requiring intensive monitoring.

(1) UNIVERSIDADE FEDERAL DO PARANÁ (UFPR) - CURITIBA/PR - CURITIBA - PR - BRASIL; (2) UNIVERSIDADE FEDERAL FLUMINENSE - NITEROI - RJ - BRASIL; (3) HOSPITAL DE CLINICAS DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL; (4) UNIVERSIDADE FEDERAL DE GOIAS - GOIÂNIA - GO - BRASIL; (5) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (6) UNICAMP - CAMPINAS - MT - BRASIL;

Introdução/Fundamentos: Chagas cardiomyopathy (CCM) is a major public health problem in endemic countries, associated with a distinct clinical profile and worse prognosis than other etiologies. The Meta-Analysis Global Group in Chronic Heart Failure (MAGGIC) score is a widely used prognostic tool; however, its applicability in CCM remains uncertain. Objetivos: To evaluate MAGGIC's performance in predicting 12-month mortality in CCM patients, comparing discrimination and calibration with non-CCM patients. Métodos: This was a prospective, multicenter cohort of outpatients with chronic heart failure (aged ≥18 years and left ventricular ejection fraction [LVEF] <50%) from 30 specialized centers in Brazil between June 2021 and June 2025. Baseline data and variables required for MAGGIC calculation were obtained through standardized in-person questionnaires and chart reviews. Chagas etiology was defined by serological testing, and patients were categorized as CCM or non-CCM; undetermined cases were excluded. Follow-up via telephone interviews concluded in September 2025. The outcome was 12-month all-cause mortality. Resultados e Conclusões: Of 2,128 patients, 263 (12.4%) had CCM and, of those, 162 (7.6%) died. Mean age was similar between groups (63±12 years in CCM vs. 61±14 in non-CCM; p=0.08), as was the proportion of female sex (40% vs. 35%; p=0.113). CCM patients were less frequently White (25% vs. 34%; p=0.002) and had lower LVEF (31±8% vs. 34±9%; p<0.001), higher MAGGIC scores (20.1±6.7 vs. 18.4±6.8; p<0.001), worse New York Heart Association functional class (34% vs. 26% in III-IV; p=0.008), lower systolic blood pressure (108±18 vs. 121±23; p<0.001) and body mass index (25 [22; 28] vs. 27 [24; 30]; p<0.001). MAGGIC showed moderate discrimination, with similar performance in both groups (AUC 0.65 vs. 0.69; p=0.398; Figure A). Calibration was overall adequate in both groups (Hosmer–Lemeshow test: p=0.087 vs. p=0.152; Figure B), although discrepancies between observed and predicted mortality across risk deciles were evident in the bar plot, particularly among CCM patients. In conclusion, In this large contemporary cohort, the MAGGIC score demonstrated acceptable overall performance in patients with CCM, with moderate discrimination and similar performance compared with non-CCM. However, variability in risk estimation across strata suggests potential limitations of the score in this population.

Figure A. Receiver operating characteristic (ROC) curves of the MAGGIC score for predicting 12-month mortality by etiology group.

MELD AND MELD-XI AS PREDICTORS OF MORTALITY AFTER HEART TRANSPLANTATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

EMMANUEL OBERDA NOMINATO1; JULIANA LUIZA PAULA DE ARAÚJO2; IGOR DA CRUZ SILVA2; JOÃO GABRIEL FRANCISCO GABRIEL FRANCISCO RODA2; LUANA LINS SILVA TÉRCIO2; CAIO LOUREIRO GIL1; GUSTAVO ELIAS LOPES SANTIAGO2; LUIZ GUSTAVO CÂNDIDO TÔRRES2; CLAUDIO LEO GELAPE2;

(1) UNIVERSIDADE FEDERAL DE OURO PRETO - OURO PRETO - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: Liver dysfunction is common in end-stage heart failure and may affect outcomes after heart transplantation (HTx). The Model for End-Stage Liver Disease (MELD) and MELD excluding INR (MELD-XI) are the most commonly used hepatic risk scores in this setting, with MELD-XI offering a potential advantage by excluding INR, which may be affected by anticoagulation. However, the prognostic utility of both scores in HTx remains uncertain. Objetivos: To separately evaluate the prognostic utility of preoperative MELD and MELD-XI for post-HTx mortality and to compare their discriminatory performance. Métodos: PubMed, Embase, Cochrane Library, and Web of Science were searched from inception to March 2026. We included studies of adults undergoing isolated HTx with preoperative MELD or MELD-XI assessment, excluding patients with Fontan circulation because of their distinct liver pathophysiology and prognosis. The primary outcome was the hazard ratio (HR) for post-HTx mortality per one-point increase in the score. Discriminatory performance comparing MELD and MELD-XI was defined as a secondary outcome. Data were synthesized using a random-effects model with REML and Hartung-Knapp confidence intervals (CI). The review was reported in accordance with PRISMA 2020. Resultados e Conclusões: Eleven observational studies comprising 38,466 patients were included. Three studies reported continuous HRs for MELD and five for MELD-XI. Among studies reporting continuous HRs, all individual estimates exceeded 1.0, indicating higher mortality risk per additional score point. However, neither pooled estimate reached statistical significance. The pooled HR was 1.06 per additional point for MELD (95% CI 0.96-1.16; I^2=50.7%; p=0.120) and 1.17 for MELD-XI (95% CI 0.95-1.44; I^2=84.3%; p=0.109). The remaining studies reported categorical analyses only, using heterogeneous cut-offs that precluded meta-analysis, although they generally suggested worse prognosis in higher-score groups. The secondary outcome could not be synthesized because discriminatory metrics were inconsistently reported, preventing direct comparison between MELD and MELD-XI. Thus, despite a consistent directional signal, wide confidence intervals around the pooled HRs, substantial heterogeneity and incomplete reporting prevent either score from being established as a robust independent predictor of post-HTx mortality. More consistent reporting of effect estimates and discriminatory metrics is needed to clarify the prognostic role of MELD and MELD-XI in HTx.

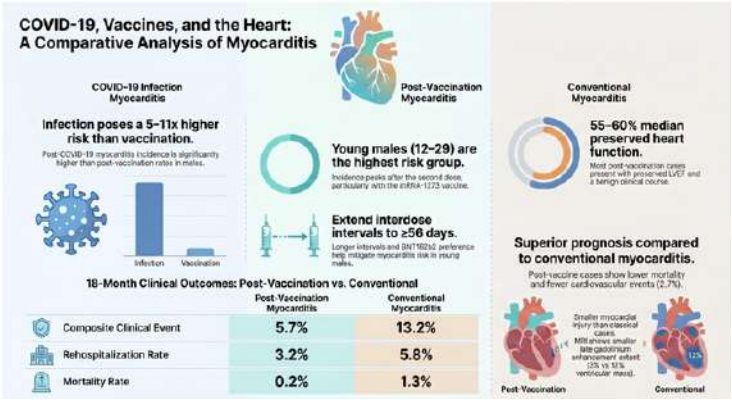
MORTALITY AND ICU OUTCOMES IN SEPSIS PATIENTS WITH LEFT VENTRICULAR SYSTOLIC DYSFUNCTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

JOAO VICTOR SILVA CORREIA1; ANA BEATRIZ VALVERDE RAMOS2; RAÍSSA VITÓRIA ALVES ESTEVAM3; LUCCA MOREIRA LOPES4; MARIANA MERIGHI MOREIRA SALLES5; PEDRO LAWALL DE CARVALHO6; RICARDO ORMANES MASSOUD7; RAFAEL HORTENCIO MELO8;

(1) DEPARTMENT OF ARTS AND SCIENCES, UNIVERSITY OF SOUTH FLORIDA - UNITED STATES; (2) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (3) UNIVERSIDADE ESTADUAL DE CIÊNCIAS DA SAÚDE DE ALAGOAS - MACEIO - AL - BRASIL; (4) UNIVERSITY OF KANSAS MEDICAL CENTER - UNITED STATES; (5) UNIVERSIDADE DO OESTE PAULISTA - UNOESTE - PRESIDENTE PRUDENTE - SP - BRASIL; (6) UNIVERSIDADE FEDERAL DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL; (7) UNIVERSIDADE ESTADUAL DO PARA (UEPA) - BELÉM - PA - BRASIL; (8) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Left ventricular systolic dysfunction (LVSD) is frequently observed in patients with sepsis, but its prognostic significance remains unclear due to inconsistent diagnostic definitions. While some studies assess LVSD by left ventricular ejection fraction (LVEF), others employ global longitudinal strain (GLS), leading to heterogeneous findings. Objetivos: To evaluate the association between left ventricular systolic dysfunction and mortality and ICU outcomes in patients with sepsis through a systematic review and meta-analysis of observational studies. Métodos: This systematic review and meta-analysis was conducted in accordance with PRISMA guidelines. We systematically searched PubMed, Embase, and the Cochrane Library for studies reporting outcomes of sepsis patients with LVSD. Random-effects models were used to pool estimates of mortality and intensive care unit (ICU) length of stay (LOS). Subgroup analyses stratified results by LVSD severity (based on LVEF) and by diagnostic method (LVEF vs GLS). Resultados e Conclusões: A total of 44 studies encompassing 4,781 patients were included. Pooled mortality was 40.8% (95% CI, 35.4–46.6; Fig. 1.1) in LVEF-defined LVSD and 37.6% (95% CI, 29.6–46.3; Fig. 1.2) in GLS-defined LVSD. Stratification by LVEF severity revealed the highest mortality in severe LVSD (48.9%), compared with moderate (33.9%) and mild dysfunction (37.7%; Fig. 1.3). Mean ICU LOS was approximately 9 days (95% CI, 6.7–11.4; Fig. 1.4), with no significant difference between GLS- and LVEF-defined LVSD. In this meta-analysis of nearly 5,000 patients, LVSD in sepsis was consistently associated with high mortality and prolonged ICU stay. Mortality was greatest among patients with severe LVSD, underscoring its prognostic relevance. These findings highlight the need for standardized criteria to define LVSD in the context of sepsis.



17453

MYOCARDITIS ASSOCIATED WITH COVID-19 AND MRNA VACCINATION: A SYSTEMATIC REVIEW OF CLINICAL OUTCOMES, DIAGNOSTIC FINDINGS, AND LONG-TERM PROGNOSIS.

MARCELA LINS REMOR1; MATHEUS LOPES BITAR MESQUITA2; DAVID STEINER LARRAT1; NICOLE PEREIRA MONTEIRO DA CRUZ1; GIULIA LINS REMOR1; LUIZA LAMARTINE NOGUEIRA ARAÚJO1; GIOVANA LINS REMOR3; RICARDO ORMANES MASSOUD2; ANTONIO MARIA ZACARIAS ARAÚJO MONTEIRO1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (3) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Myocarditis has been reported after both SARS-CoV-2 infection and mRNA COVID-19 vaccination, but evidence on its clinical course, cardiac magnetic resonance (CMR) findings, and long-term prognosis remains fragmented. Objetivos: To systematically review myocarditis associated with COVID-19 and mRNA vaccination, synthesizing evidence on incidence, risk factors, clinical presentation, diagnostic findings, treatment, and long-term cardiovascular outcomes. Métodos: We performed a PRISMA 2020-compliant systematic review of PubMed/MEDLINE, Embase, Cochrane CENTRAL, and Web of Science from January 2020 to March 2026, without language restrictions. Eligible studies included randomized, observational, population-based, and case-series designs with diagnostic confirmation. Two reviewers independently screened studies and extracted data. Risk of bias was assessed with RoB 2, Newcastle-Ottawa Scale, and JBI tools, and certainty of evidence for incidence and risk factors was evaluated with GRADE. Owing to major heterogeneity in populations, diagnostic criteria, and outcomes, findings were synthesized narratively. Resultados e Conclusões: Of 8,742 records, 68 studies were included, comprising approximately 487 million mRNA vaccine doses, 6,847 confirmed post-vaccination myocarditis cases, 1,294 post-COVID-19 cases, and 3,779 conventional myocarditis comparators. Post-vaccination myocarditis occurred predominantly in males aged 12-29 years, especially after the second dose, with highest incidence after mRNA-1273. Main risk factors were male sex, younger age, second dose, short interdose interval, and mRNA-1273 versus BNT162b2. Typical presentation included chest pain, symptom onset within 2-4 days, troponin elevation, abnormal ECG, and preserved LVEF. CMR usually showed subepicardial inferolateral late gadolinium enhancement with smaller scar burden than conventional myocarditis; LGE often persisted despite edema resolution. Available long-term data suggest that post-vaccination myocarditis generally follows a mild clinical course and has more favorable outcomes than conventional myocarditis, whereas post-COVID-19 myocarditis appears closer to conventional disease. Overall, post-vaccination and post-COVID-19 myocarditis show distinct epidemiological, clinical, and prognostic profiles. Although post-vaccination myocarditis is rare, it disproportionately affects young males and may be mitigated by longer interdose intervals and preferential BNT162b2 use in higher-risk groups.

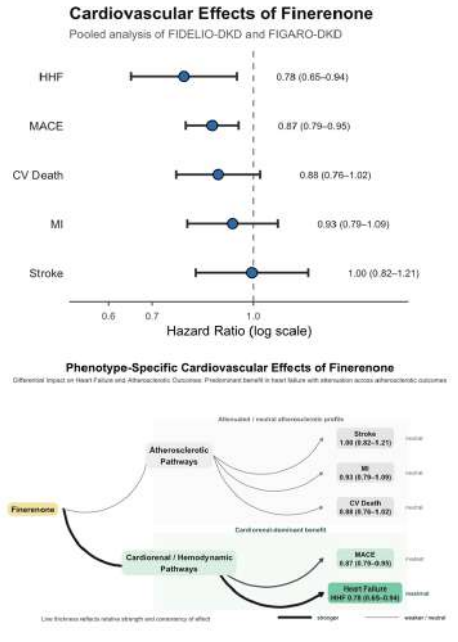
MYOSIN INHIBITORS REDEFINE TREATMENT IN OBSTRUCTIVE HYPERTROPHIC CARDIOMYOPATHY: A BAYESIAN NETWORK META-ANALYSIS

JULIA CREMONINI BERNARDI1; VITOR BAGATTOLI1; NICOLY FIORESE ANDRADE1; GABRIEL OLIVO LEANDRO1; MARIA EDUARDA MOLINARI1; JULIANA GIORGI2; CAROLINE OLIVEIRA FISCHER-BACCA1;

(1) UNIDAVI - CENTRO UNIVERSITARIO PARA O DESENVOLVIMENTO DO ALTO VALE DO ITAJAI - RIO DO SUL - SC - BRASIL; (2) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Obstructive hypertrophic cardiomyopathy (oHCM) is characterized by left ventricular outflow tract obstruction and debilitating symptoms. Although beta-blockers remain first-line therapy, their disease-specific efficacy is limited. Novel cardiac myosin inhibitors, including aficamten and mavacamten, have emerged as targeted therapies; however, comparative evidence among available pharmacologic strategies remains scarce. Objetivos: To compare the efficacy of aficamten, mavacamten, metoprolol, and placebo in patients with symptomatic oHCM through a Bayesian network meta-analysis. Métodos: A systematic review and Bayesian network meta-analysis were conducted according to PRISMA guidelines. Randomized controlled trials evaluating aficamten, mavacamten, metoprolol, or placebo in adults with symptomatic oHCM were included. Outcomes assessed comprised Kansas City Cardiomyopathy Questionnaire (KCCQ), N-terminal pro-B-type natriuretic peptide (NT-proBNP), ≥1 New York Heart Association (NYHA) functional class improvement, resting left ventricular outflow tract (LVOT) gradient, and post-Valsalva LVOT gradient. Effect estimates were pooled as mean differences (MD), risk ratios (RR), and 95% credible intervals (CrI). Resultados e Conclusões: Six randomized controlled trials involving 918 patients were included. Both aficamten and mavacamten significantly improved KCCQ, reduced NT-proBNP, increased the likelihood of NYHA functional improvement, and reduced resting and post-Valsalva LVOT gradients compared with metoprolol and/or placebo. Mavacamten demonstrated the greatest improvement in KCCQ (MD 9.07; 95% CrI 5.78–12.2), whereas aficamten showed the highest probability of benefit for NYHA improvement (RR 2.33; 95% CrI 1.73–3.21), resting LVOT reduction (MD −39.9 mmHg; 95% CrI −46.4 to −33.2), and post-Valsalva LVOT reduction (MD −43.8 mmHg; 95% CrI −62.6 to −20.8). No statistically significant differences were observed between aficamten and mavacamten across outcomes. Metoprolol did not demonstrate significant benefit in most comparisons versus placebo. Overall, these findings suggest consistent superiority of myosin inhibitors over conventional beta-blockade, supporting their potential as a preferred therapeutic strategy in patients with symptomatic oHCM.



14278

PHENOTYPE-SPECIFIC CARDIOVASCULAR EFFECTS OF FINERENONE IN TYPE 2 DIABETES AND CHRONIC KIDNEY DISEASE: DIFFERENTIAL IMPACT ON HEART FAILURE AND ATHEROSCLEROTIC OUTCOMES

THALES DA FONSECA DORNELLES1; MARIA FERNANDA BRÊTAS FRANZINI1; LETÍCIA VIEIRA GUIMARÃES1; THIAGO CASALI ROCHA1;

(1) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL;

Introdução/Fundamentos: Finerenone reduces cardiovascular events in patients with type 2 diabetes and chronic kidney disease (CKD). However, whether these benefits are consistent across cardiovascular outcomes or vary by event type remains unclear. Prior trials have reported heterogeneous effects across heart failure–related and atherosclerotic outcomes, but this pattern has not been formally evaluated as a primary analytical focus. Objetivos: To determine whether the cardiovascular effects of finerenone differ across clinically relevant outcomes and are consistent with a phenotype-specific pattern between heart failure–related and atherosclerotic events. Métodos: A systematic review and meta-analysis of randomized controlled trials comparing finerenone versus placebo in patients with type 2 diabetes and CKD was conducted (PRISMA; PROSPERO-registered). PubMed, Embase, and Cochrane Library were searched through April 2026. Risk of bias was assessed using RoB2. Hazard ratios (HRs) and 95% confidence intervals (CIs) were extracted for hospitalization for heart failure (HHF), major adverse cardiovascular events (MACE), cardiovascular (CV) death, myocardial infarction (MI), and stroke. Analyses prioritized outcome-specific effects rather than composite estimates using random-effects models (REML). Given the limited number of trials, analyses were prespecified as pattern-oriented, focusing on consistency and gradients of effect. Certainty of evidence was assessed using GRADE. Resultados e Conclusões: Two large-scale randomized trials (>13,000 participants) were included. Finerenone reduced HHF (HR 0.78, 95% CI 0.65–0.94) and modestly reduced MACE (HR 0.87, 95% CI 0.79–0.95), with no significant effects on CV death (HR 0.88, 95% CI 0.76–1.02), MI (HR 0.93, 95% CI 0.79–1.09), or stroke (HR 1.00, 95% CI 0.82–1.21). A graded, consistent pattern was observed, with maximal benefit in heart failure outcomes and attenuation across atherosclerotic events. Heterogeneity and risk of bias were low. Finerenone appears to demonstrate a phenotype-specific cardiovascular profile, with more pronounced effects on heart failure outcomes and attenuated or neutral effects on atherosclerotic events. This pattern is consistent with differential modulation of cardiorenal and hemodynamic pathways rather than indicating a strong direct anti-atherosclerotic effect. These findings support outcome-specific interpretation of cardiometabolic therapies and may have implications for therapeutic positioning and trial design.

PREDICTION OF MORBIDITY AND MORTALITY USING THE BAN-ADHF SCORE IN PATIENTS HOSPITALIZED FOR ACUTE DECOMPENSATED HEART FAILURE

CLARA TALITA SILVA LOBO1; PAULO VICTOR ALMEIDA MARCHESINE2; PEDRO VOGEL ALMEIDA1; ANA BEATRIZ BONFIM DE ALMEIDA1; LÍVIA RODRIGUES SAMPAIO CAVALCANTE1; MARCUS VINICIUS BARBOSA VALE1; FELIPE FREITAS COUTO2; TAINÁ TEIXEIRA VIANA2; MARIANA MARIA CARNEIRO MADEIRA2; RAISA MAINARTE FRANCO BARROS HAMILTON2; RODRIGO MOREL VIEIRA DE MELO1;

(1) UNIVERSIDADE FEDERAL DA BAHIA - SALVADOR - BA - BRASIL; (2) INSTITUTO D'OR DE PESQUISA E ENSINO - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Prognostic stratification in acute decompensated heart failure (ADHF) is essential for guiding resource allocation and clinical decision-making. The BAN-ADHF score has been proposed as a simple tool for predicting adverse events; however, its utility in different clinical settings requires validation. Objetivos: To evaluate the performance of the BAN-ADHF score as a predictor of morbidity and mortality in patients with ADHF hospitalized at a tertiary center. Métodos: A retrospective observational study of patients hospitalized for acute decompensated heart failure (ADHF). The primary outcome was a composite of in-hospital mortality and/or 30-day readmission. The secondary outcome was the length of hospital stay. The association between the BAN-ADHF score and the outcomes was evaluated through bivariate analyses and multivariate logistic regression, with estimates of relative risk (RR) and 95% CI. The score's discrimination was assessed using the ROC curve (AUC). Resultados e Conclusões: Results: Three hundred patients were analyzed, with 50 events (16.7%) of the primary composite outcome. The occurrence of the outcome was higher in the high-risk group according to the BAN-ADHF score (>12) compared to the low-risk group (≤12). The BAN-ADHF score maintained an independent association with the primary outcome in the multivariate model, with additional influence from age and creatinine. The score's discrimination was moderate (AUC 0.642; 95% CI 0.558–0.735; p=0.001). The length of hospital stay was longer in the high-risk group (median 11 days [IQR 6–18] vs. 8 days [IQR 4.8–13.2]; p=0.003). Conclusion: The BAN-ADHF score showed moderate discrimination and an independent association with morbidity and mortality in ADHF, in addition to being related to a longer length of stay. Therefore, it may contribute to initial risk stratification in the hospital setting.

PRIMARY PREVENTION IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR USE IN HEART FAILURE WITH REDUCED EJECTION FRACTION

LUCAS CESAR PERIN-GUIMARÃES1; LUCAS YUGI DE SOUZA TERUI1; AMYR DANTAS OMAR1; SARA RIBEIRO BICUDO1; GIULIA LAMIM NASCIMENTO LEAL1; GABRIELA YUMI KONNO SAITO1; GABRIELA LUIZA SEZNE1; LUCAS FERNANDES MODESTO1; BRUNA CZELUSNIAK GOULART1; GUSTAVO ALEX ASSUNÇÃO DOS SANTOS1; HELLEN JOST EVALDT1; MIGUEL MORITA FERNANDES-SILVA1;

(1) UNIVERSIDADE FEDERAL DO PARANÁ - CURITIBA - PR - BRASIL;

Introdução/Fundamentos: Heart failure with reduced ejection fraction (HFrEF) is associated with high mortality, and sudden cardiac death remains one of its leading causes. Implantable cardioverter-defibrillators (ICDs) are recommended for primary prevention in selected patients according to contemporary guidelines. However, ICD utilization in real-world practice remains suboptimal, particularly in middle-income countries. Objetivos: To evaluate ICD utilization for primary prevention in patients with HFrEF and to identify clinical factors associated with device implantation. Métodos: This was an observational study including 70 patients with HFrEF followed at a tertiary referral center in Brazil. Patients with left ventricular ejection fraction ≤35% were evaluated regarding clinical, laboratory, therapeutic, and socioeconomic characteristics. Comparisons between patients with and without ICD were performed using parametric and nonparametric tests. Multivariable logistic regression analysis was conducted to identify independent predictors associated with ICD implantation. Resultados e Conclusões: Mean age was 63.1±12.3 years, and 54.3% of patients were female. Overall, only 9 patients (12.9%) had an ICD implanted. Among the 21 patients with clear guideline-based indication for primary prevention, only 4 (19.0%) received the device. Patients with ICD had a significantly higher number of hospital admissions since heart failure diagnosis (p<0.001), higher prevalence of Chagas cardiomyopathy (33.3% vs. 4.9%; p=0.014), and more frequent use of SGLT2 inhibitors (77.8% vs. 42.6%; p=0.049). They also presented lower systolic blood pressure (104.1±17.0 vs. 120.5±21.8 mmHg; p=0.034) and diastolic blood pressure (64.8±13.1 vs. 75.4±13.1 mmHg; p=0.025). In multivariable analysis, a higher number of hospitalizations was independently associated with ICD implantation (OR 5.16; 95% CI 1.84–14.44; p=0.002), whereas hypertension was negatively associated with device use (OR 0.07; 95% CI 0.008–0.69; p=0.023). ICD utilization for primary prevention was low even among patients with clear guideline-based indications, highlighting a substantial gap between recommendations and real-world practice. Device implantation appeared to occur preferentially in patients with greater clinical severity and perceived arrhythmic risk, particularly those with Chagas cardiomyopathy and recurrent hospitalizations. These findings reinforce the need for strategies aimed at improving access to device therapy in patients with HFrEF in Brazil.

Table 1. Baseline Characteristics According to ICD Status

Variable	No ICD (n=61)	ICD (n=9)	p-value
Age, years	63.1 ± 12.8	62.8 ± 8.9	0.94
Female sex, n (%)	31 (50.8)	7 (77.8)	0.13
Hypertension, n (%)	47 (77.0)	4 (44.4)	0.040
Diabetes mellitus, n (%)	30 (49.2)	5 (55.6)	0.72
Previous myocardial infarction, n (%)	19 (31.1)	4 (44.4)	0.43
Chagas etiology, n (%)	3 (4.9)	3 (33.3)	0.014
Left ventricular ejection fraction, %	28.3 ± 5.7	25.7 ± 3.6	0.20
>3 hospital admissions since HF diagnosis, n (%)	5 (8.2)	6 (66.7)	<0.001
Systolic blood pressure, mmHg	120.5 ± 21.8	104.1 ± 17.0	0.034
Diastolic blood pressure, mmHg	75.4 ± 13.1	64.8 ± 13.1	0.025
SGLT2 inhibitor use, n (%)	26 (42.6)	7 (77.8)	0.049

Abbreviations: HF, heart failure; ICD, implantable cardioverter-defibrillator; SGLT2, sodium–glucose cotransporter 2.

Table 2. ICD Eligibility and Predictors of ICD Implantation

Variable	Result		
Patients with ICD, n (%)	9 (12.9)		
Patients with guideline-based indication for ICD, n	21		
Eligible patients receiving ICD, n (%)	4 (19.0)		
Multivariable Logistic Regression for ICD Implantation			
Variable	Odds Ratio (95% CI)		p-value
Number of hospital admissions	5.16 (1.84–14.44)		0.002
Hypertension	0.07 (0.008–0.69)		0.023

Abbreviations: ICD, implantable cardioverter-defibrillator.

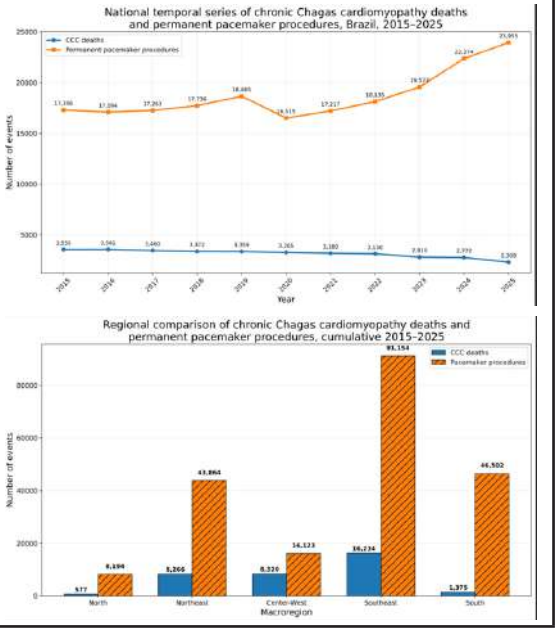
PROGNOSTIC ROLE OF HEART RATE IN HEART FAILURE WITH REDUCED EJECTION FRACTION: THE INFLUENCE OF ATRIAL FIBRILLATION

HELLEN JOST EVALDT1; SARA RIBEIRO BICUDO2; LEONARDO SANDRI3; BRUNO CALDEIRA ANTÔNIO1; AMYR DANTAS OMAR1; RICARDO D'OLIVEIRA VIEIRA4; RICARDO D'OLIVEIRA VIEIRA4; CAMILA NOGUEIRA LEANDRO LIRA5; CAMILA NOGUEIRA LEANDRO LIRA5; FÁTIMA ELIZABETH FONSECA DE OLIVEIRA NEGRI NEGRI6; FÁTIMA ELIZABETH FONSECA DE OLIVEIRA NEGRI NEGRI6; MARCELY GIMENES BONATTO7; SABRINA BERNARDEZ PEREIRA8; WILSON NADRUZ9; MIGUEL M FERNANDES-SILVA10;

(1) UNIVERSIDADE FEDERAL DO PARANÁ - CURITIBA - PR - BRASIL; (2) UNIVERSIDADE FEDERALDO PARANÁ - CURITIBA - PR - BRASIL; (3) UNIVERSIDADE FEDERAL DO PARANÁ - CURITBA - PR - BRASIL; (4) HOSPITAL E CLÍNICA SÃO ROQUE - SAO ROQUE - SP - BRASIL; (5) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL; (6) UNIVERSIDADE FEDERAL DE PERNAMBUCO - RECIFE - PE - BRASIL; (7) HOSPITAL SANTA CASA DE MISERICÓRDIA DE CURITIBA - CURITIBA - PR - BRASIL; (8) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL; (9) UNICAMP - CAMPINAS - SP - BRASIL; (10) UNIVERSIDADE FEDERAL DO PARANÁ, CURITIBA-PR - CURITIBA - PR - BRASIL;

Introdução/Fundamentos: The prognostic value of heart rate (HR) in patients with heart failure with reduced ejection fraction (HFrEF) may differ according to cardiac rhythm; however; this relationship may differ in patients with atrial fibrillation (AF) or flutter. Objetivos: To assess the association between HR and a composite endpoint of cardiovascular (CV) death or HF hospitalization in HFrEF, and to evaluate whether this relationship is modified by cardiac rhythm. Métodos: This prospective cohort included patients with chronic HFrEF from June 2021 to June 2024 across 30 sites in Brazil. Patients were followed for 6 and 12 months. HR was measured during outpatient visit at baseline and analyzed stratified by rhythm (sinus vs AF/flutter) as a continuous variable per 10 bpm increase. Patients with pacemaker were excluded. The primary endpoint was the composite of HF hospitalization or CV death. Associations between HR and outcomes were assessed using Cox models adjusted for age, sex, LVEF, MAGGIC score and beta-blocker dose. Resultados e Conclusões: Among 1314 patients (mean age 59.6 years, 35% women, mean LVEF 29.7%, 16% with AF/flutter), 247 experienced the primary endpoint. Patients in sinus rhythm had lower HR (72±13 vs 77±18 bpm, p<0.001), despite similar use of betablocker at target dose (35% vs 41%, p=0.12) compared to those in AF/flutter. In sinus rhythm, higher HR was independently associated with increased risk of the composite outcome (HR=1.17 per 10 bpm increase (95% CI 1.06-1.29); p=0.002). In patients with AF/Flutter, this association was attenuated and not statistically significant (HR=1.08 (95% CI 0.92-1.26); p=0.34; Figure). However, there was no significant interaction between HR and rhythm (p for interaction=0.45), indicating no effect modification. In this large contemporary cohort of patients with HFrEF, increased HR was associated with worse prognosis, irrespective of cardiac rhythm.



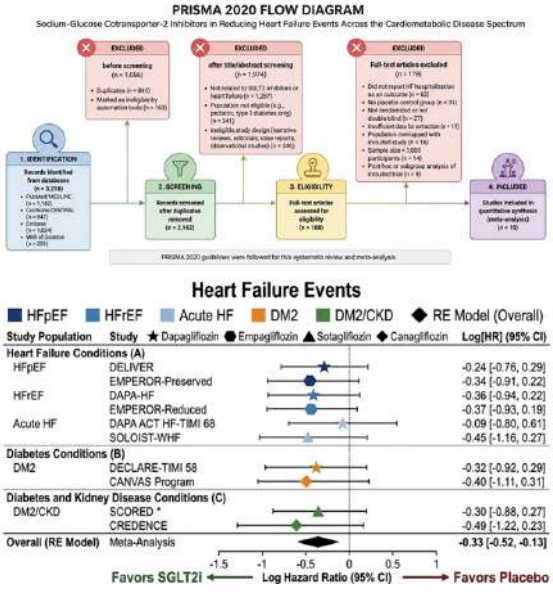
22006

REGIONAL MISMATCH BETWEEN CHRONIC CHAGAS CARDIOMYOPATHY MORTALITY BURDEN AND PERMANENT PACEMAKER PROCEDURES IN BRAZIL: AN ECOLOGICAL TIME-SERIES ANALYSIS, 2015–2025

MELINA CONDE MAUES LIMA1; FABRICIO BACELAR MARINHO FILHO2; KELLY CRISTINA COSTA GUEDES NASCIMENTO1; DILMA COSTA DE OLIVEIRA NEVES2; MARCUS VINICIUS SETUBAL MODESTO DE ABREU2;

(1) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL; (2) CESUPA - BELEM - PA - BRASIL;

Introdução/Fundamentos: Chronic Chagas cardiomyopathy (CCC) is an important cause of conduction system disease and permanent pacemaker implantation in Brazil. Although Chagas disease burden is historically concentrated in specific Brazilian regions, it remains unclear whether the regional distribution of definitive cardiac stimulation procedures corresponds to the distribution of CCC-related mortality burden. Objetivos: To compare, across Brazilian macroregions from 2015 to 2025, the distribution of deaths due to chronic Chagas cardiomyopathy and the distribution of permanent pacemaker implantation procedures, in order to assess whether the supply of definitive cardiac stimulation corresponds to the regional burden of disease. Métodos: This ecological time-series study used nationwide secondary data from the Mortality Information System and the Hospital Information System of the Brazilian Unified Health System. Deaths with underlying cause ICD-10 code B57.2 were extracted by year and macroregion. Permanent pacemaker procedures were identified by combining seven SIGTAP codes related to definitive single-chamber, dual-chamber, and multi-site devices, excluding temporary pacemakers. Absolute frequencies and proportional regional distributions were analyzed over time. Data from 2025 were considered preliminary. Resultados e Conclusões: From 2015 to 2025, 34,772 deaths due to CCC and 205,837 permanent pacemaker procedures were recorded in Brazil. The Southeast concentrated the highest cumulative number of CCC deaths (16,234), followed by the Center-West (8,320) and Northeast (8,266), whereas the North and South accounted for the lowest totals. Over the same period, the Southeast also recorded the largest number of pacemaker procedures (91,154), followed by the South (46,502) and Northeast (43,864). A marked geographic mismatch was observed between mortality burden and procedure distribution: the Center-West showed a high CCC mortality burden but comparatively modest pacemaker volume, whereas the South displayed the opposite pattern, with relatively low mortality burden but high procedural concentration. Nationally, CCC deaths declined over time, from 3,555 in 2015 to 2,308 in 2025, while pacemaker procedures increased from 17,306 to 23,955. These findings suggest persistent regional disparity between CCC-related mortality burden and the distribution of definitive cardiac stimulation procedures in Brazil, supporting further analyses adjusted for population size, age structure, and access to specialized cardiovascular care.



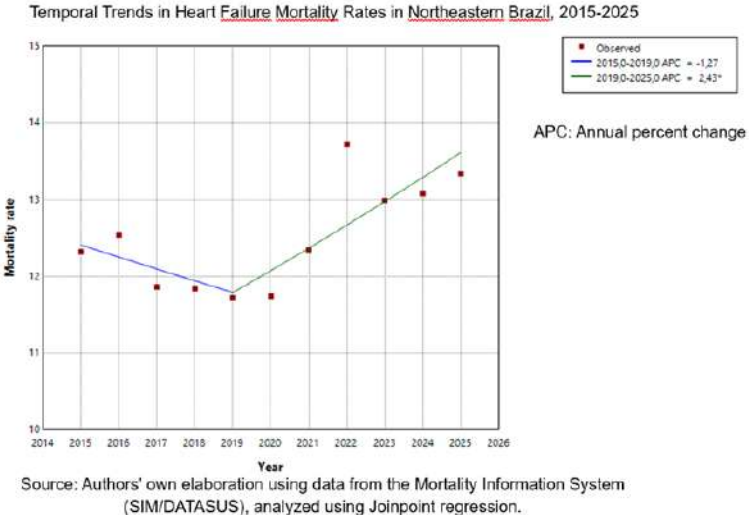
20303

SODIUM-GLUCOSE COTRANSPORTER-2 INHIBITORS IN REDUCING HEART FAILURE EVENTS ACROSS THE CARDIOMETABOLIC DISEASE SPECTRUM: A META-ANALYSIS OF 10 RANDOMIZED CLINICAL TRIALS INCLUDING 66,635 PATIENTS

GUSTAVO RODRIGUES SAMPAIO1; EMILY BITTENCOURT DE SOUZA MARTINS2; ANGÉLICA PAIXAO DE MENEZES2; FABIO DE FARIAS LEITE FILHO2; SAMUEL FERNANDES VIERA AMARAL2; MARIA FERNANDA PIMENTEL DE AGUIAR2; DAVI CASTRO SÁ DE LIMA2; PAULA FRANSSINETTI CASTELO BRANCO2; WALLISON SILVA TELES2;

(1) UECE - UNIVERSIDADE ESTADUAL DO CEARÁ CAMPUS FORTALEZA - FORTALEZA - CE - BRASIL; (2) UECE - FORTALEZA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Heart failure (HF) remains a leading cause of hospitalization and cardiovascular mortality worldwide. SGLT2 inhibitors (SGLT2i) have shown consistent cardiovascular benefits, but prior meta-analyses focused predominantly on HF with reduced ejection fraction. Consequently, a comprehensive synthesis across type 2 diabetes (T2D), chronic kidney disease (CKD), and acute HF populations is lacking to inform clinical practice. Objetivos: To quantify the effect of SGLT2i on HF-related events, including hospitalization, urgent visits, and worsening HF, through a meta-analysis of randomized clinical trials spanning diverse cardiometabolic populations, and to assess heterogeneity, publication bias, and result stability. Métodos: A PRISMA 2020-compliant systematic review was conducted across PubMed, Cochrane Library, Embase, and Web of Science (2017–2025). Ten randomized, double-blind, placebo-controlled trials (DAPA-HF, EMPEROR-Reduced, DELIVER, EMPEROR-Preserved, DECLARE-TIMI 58, SCORED, SOLOIST-WHF, CREDENCE, CANVAS, DAPA ACT HF-TIMI 68) totaling 66,635 patients were included. Drugs analyzed were dapagliflozin, empagliflozin, canagliflozin, and sotagliflozin. Endpoints varied across studies (first HF hospitalization, urgent visits, worsening HF). HRs were pooled via random-effects model (REML) using JAMOVI with the MAJOR module. Bias was assessed with Cochrane RoB 2, heterogeneity with I² and Cochran's Q, publication bias with Egger's test and Fail-Safe N and stability via leave-one-out analysis. Resultados e Conclusões: Among 66,635 patients, 2,264 HF events occurred with SGLT2i versus 3,020 with placebo (pooled HR 0.72; 95% CI 0.59–0.87; p 0.001). I² was 0% (Q p = 1.000). No publication bias was detected (Egger's p = 0.789; Fail-Safe N = 32). By subgroup: HF trials (HR 0.71; 95% CI 0.64–0.79), T2D trials (HR 0.71; 95% CI 0.61–0.83) and T2D/CKD trials (HR 0.72; 95% CI 0.59–0.87) showed consistent benefit. Acute HF trials showed a non-significant trend (HR 0.75; 95% CI 0.53–1.06). Benefits were consistent across dapagliflozin, empagliflozin, canagliflozin, and sotagliflozin. SGLT2i reduced HF-related events by 28% across the cardiometabolic spectrum, with consistent benefit in chronic HF, T2D, and CKD populations. The benefit in acute HF was directionally favorable but not statistically significant. Endpoint heterogeneity across trials and early termination of SOLOIST-WHF and SCORED are limitations. These findings support a class effect of SGLT2i, reinforcing their role in cardiometabolic disease management.



21665

TEMPORAL ANALYSIS OF HEART FAILURE MORTALITY DURING THE PRE- AND POST-COVID-19 PANDEMIC PERIODS IN NORTHEASTERN BRAZIL

DÉBORA OLIVEIRA DA SILVA1; GABRIEL CARDOSO DA CUNHA1; ANA CLARA SEPULVIDA DE OLIVEIRA1; ANDRÉ PEREIRA DE OLIVEIRA1; LILIAN FREITAS CARDOSO DE ALENCAR SOARES1; NAYANE ARAÚJO CARDOSO1; GENEZY DOS SANTOS COSTA1; RAYSSA GABRIELLE PEREIRA DE CASTRO BUENO1;

(1) FACULDADE DE MEDICINA DE AÇAILÂNDIA - AÇAILÂNDIA - MA - BRASIL;

Introdução/Fundamentos: Heart failure (HF) is a common outcome of several cardiomyopathies and one of the leading causes of cardiovascular mortality in Brazil and worldwide, particularly among older adults. Additionally, the COVID-19 pandemic had substantial impacts on healthcare delivery, affecting the follow-up and clinical outcomes of patients with HF. Objetivos: To analyze the epidemiological profile and temporal trends of heart failure mortality in Northeastern Brazil during the pre- and post-COVID-19 pandemic periods. Métodos: This ecological study of time series evaluated the mortality due to heart failure in northeastern Brazil between 2015 and 2025. The data were obtained from the Mortality Information System (SIM/DATASUS), and the Brazilian Institute of Geography and Statistics (IBGE), were used to calculate the mortality rates per 100,000 inhabitants. Time trends were evaluated using Joinpoint regression to estimate the Annual Percentage Change (APC) and the corresponding 95% confidence intervals (95% CI). Resultados e Conclusões: During the study period, the highest heart failure mortality rate was observed in 2022, with 13.72 deaths per 100,000 inhabitants, predominantly among individuals aged ≥60 years (85.7%). Joinpoint regression identified an inflection point in mortality trends in 2019. From 2015 to 2019, a non-significant decreasing trend was observed (APC = -1.27%; 95% CI: -6.03 to 0.59; p = 0.21). However, from 2019 to 2025, there was a statistically significant increase in mortality rates, with an annual growth of 2.43% (95% CI: 1.40–6.15; p = 0.002). Sex-stratified analysis revealed distinct temporal patterns. Among women, mortality increased steadily throughout the study period (APC = 1.29%; 95% CI: 0.04–2.52; p = 0.039). Among men, mortality remained stable until 2019, followed by a significant increase in the post-pandemic period (APC = 2.65%; 95% CI: 1.42–6.52; p = 0.009). The predominance of deaths among older adults highlights the persistent burden of heart failure in vulnerable populations. Furthermore, the observed increase in mortality, together with sex-specific temporal patterns after the pandemic, suggests recent changes in the epidemiological profile of heart failure in Northeastern Brazil.

Source: Authors' own elaboration using data from the Mortality Information System (SIM/DATASUS), analyzed using Joinpoint regression.

THE EFFICACY AND SAFETY OF LEVOSIMENDAN IN PATIENTS WITH ADVANCED HEART FAILURE: AN UPDATED META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

GABRIEL BALBI FERNANDES SILVA1; GIOVANA DE SOUSA FERRO BARBOSA1; HIAGO CRAVINHO CABRAL2;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) UNIVERSIDADE ESTADUAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: This study aims to examine efficacy and safety of intermittent levosimendan compared to a placebo control group in advanced heart failure patients Objetivos: This study aims to examine efficacy and safety of intermittent levosimendan compared to a placebo control group in advanced heart failure patients Métodos: PubMed, Embase Cochrane, SCOPUS and Web of Science were searched for randomized controlled trials comparing levosimedan to a placebo in patients with advanced heart failure. Risk ratios (RR) and Mean Differences (MD) with 95% confidence intervals [CI] were pooled with a random-effects model. Endpoints were the all cause mortality rate, Improved left ventricular ejection and all cause rehospitalization rate. R 4.4.2 was used for all statistical analyses. Resultados e Conclusões: 17 randomized controlled trials with 1299 patients were included. Intermittent levosimendan was significantly associated with an improved left ventricular ejection fraction compared with placebo (MD 4.75 [95% CI 1.24–8.26], P = 0.008; I2 = 100, P <0.00001), with cumulative z-score of change after ≤ 1 week passing the monitoring boundaries, favoring the levosimendan, but did not cross the required information size. Additionally, we found no difference between levosimendan and placebo in all-cause rehospitalization rate (RR 0.75 [95% CI 0.46–1.22], P = 0.25; I2 = 70, P = 0.04) and in all-cause mortality rate (RR 0.65 [95% CI 0.33–1.30], P = 0.19; I2 = 39, P = 0.12). In ambulatory patients with advanced Heart Failure (left ventricular ejection fraction ≤35%, New York Heart Association Classes III and IV), repetitive levosimendan 24h infusion might be an additional therapeutic option but observed deaths may raise its safety issue. Although the new study suggests a higher rate of observed deaths, it has inherent design limitations which may affect the generalizability of the findings

ANTICOAGULANT MONOTHERAPY VERSUS DUAL THERAPY IN PATIENTS WITH ATRIAL FIBRILLATION AND STABLE CORONARY ARTERY DISEASE: AN UPDATED SYSTEMATIC REVIEW AND META-ANALYSIS

ANA LUISA COSTA ALENCAR1; LUÍS FELIPE CARVALHO PEREIRA1; REBECA SOARES ALMEIDA2; PEDRO HENRIQUE SANT'ANNA DE MORAES3; THAÍS PEREIRA BELO4; AILTON CÉSAR DE ARAÚJO FILHO4; EMILY BITTENCOURT DE SOUZA MARTINS5; YURI FELIX BRANDÃO6; BENJAMIM ANTÔNIO PINHEIRO VIEIRA5; LUIZ GUSTAVO DA SILVA CASTELO BRANCO5; ANNA LETÍCIA ALVES BOMFIM5; JAMES NOBRE DE SENA6;

(1) UNIVERSIDADE FEDERAL DO CARIRI - BARBALHA - CE - BRASIL; (2) UNIVERSIDADE FEDERAL DO OESTE DA BAHIA - BARREIRAS - BA - BRASIL; (3) UNIVERSIDADE TIRADENTES - ARACAJU - SE - BRASIL; (4) UNIVERSIDADE ESTADUAL DO CEARÁ - QUIXERAMOBIM - CE - BRASIL; (5) UNIVERSIDADE ESTADUAL DO CEARÁ - FORTALEZA - CE - BRASIL; (6) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Atrial Fibrillation (AF) and Coronary Artery Disease (CAD) are frequently associated in high-risk patients, presenting a complex clinical challenge. Traditionally, management requires anticoagulation to prevent cardioembolic strokes and antiplatelet therapies to reduce ischemic events. However, this combination substantially increases major bleeding risk. In light of new evidence, an updated meta-analysis is needed to reassess the efficacy and safety of monotherapy or combination regimens. Objetivos: To compare the efficacy and safety of anticoagulant monotherapy versus dual therapy in patients with AF and CAD. Métodos: A systematic search of PubMed, Embase, and Scopus was conducted following the PRISMA guidelines to identify randomized controlled trials (RCTs) and observational studies comparing efficacy and safety of anticoagulant monotherapy vs dual therapy in patients with AF and stable coronary artery disease. Statistical analysis was performed using R 4.5.3 software with random-effects models. Risk of bias was assessed using the Cochrane RoB 2 tool and Newcastle-Ottawa Scale. Resultados e Conclusões: Seven studies (4 RCTs, 3 cohorts) were selected, including 9,549 patients (mean age 73.3 years, 73.16% male), of whom 4,831 (50.6%) underwent anticoagulant monotherapy, with a median follow-up of 2.76 years. There were no significant differences between both groups regarding major bleeding, myocardial infarction, stroke, systemic embolism, cardiovascular death and all-cause death. RCT-only subanalysis demonstrated that anticoagulant monotherapy reduced major bleeding compared to dual therapy (RR=0.57, 95% CI 0.38–0.87, $p<0.05$, $I^2=49.9\%$), with no significant differences in other outcomes. However, no other significant differences were identified regarding the outcomes. In conclusion, in patients with AF and stable CAD, anticoagulant monotherapy appears safe and may reduce major bleeding compared to dual therapy, without a statistically significant increase in ischemic events, although the limited sample size may preclude detection of modest differences in these outcomes. Heterogeneity among the studies, the inclusion of observational studies and limited sample sizes restrict the generalizability of the findings. Thus, individualized therapy, balancing hemorrhagic and ischemic risks for each patient profile, remains essential until targeted clinical trials with greater statistical power are conducted to consolidate the evidence.

17719

BEYOND GLYCEMIC CONTROL: CARDIOVASCULAR BENEFITS OF SGLT2 INHIBITORS IN NON-DIABETIC HEART FAILURE PATIENTS.

LUCCAS YASIER DE ASSIS CANEIRO1; GUILHERME ANSELMO NOCRATO1; HERALDO GUEDIS LOBO FILHO1; MATHEUS DUARTE PIMENTEL1; LIVIAN QUIRINO BAIA1; ISADORA MARIA FURTADO BARBOSA LOBO1; CAMILA SOUSA MATOS1; FELIPE CELESTINO MARTINS LOPES1; SARAH BRAGA DE CASTRO1; ERICK SOUSA PORTELA1; ANTONIA RAFAELA LIMA DE SOUZA1; HANIEL FELIPE DE OLIVEIRA SAMPAIO1;

(1) UFC - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Heart failure (HF) is a major cause of global morbidity and mortality, affecting over 60 million people, with poor prognosis, especially in patients with preserved ejection fraction, who historically had limited therapeutic options. Sodium-glucose cotransporter 2 inhibitors (SGLT2 inhibitors), initially developed for type 2 diabetes mellitus, have shown cardiovascular and renal benefits beyond glycemic control, including reductions in HF hospitalizations and cardiovascular death across different phenotypes. These effects appear independent of diabetes, suggesting non-glycemic mechanisms. Objetivos: Evaluate the effects of SGLT2 inhibitors in HF patients, comparing outcomes between individuals with and without diabetes, focusing on cardiovascular death, HF hospitalization, renal outcomes, and consistency across ejection fraction phenotypes. Métodos: Systematic review conducted in PubMed including studies up to 2025, using the descriptors "SGLT2 inhibitors," "heart failure," and "non-diabetic." Five randomized clinical trials were included, assessing SGLT2 inhibitors in HF patients regardless of ejection fraction, with subgroup analyses by diabetes status. Observational studies, reviews, mechanistic studies, populations without HF, and those lacking relevant clinical outcomes were excluded. Resultados e Conclusões: SGLT2 inhibitors reduced the composite outcome of cardiovascular death or HF hospitalization across phenotypes. In HF with preserved ejection fraction, empagliflozin reduced the primary outcome (13.8% vs. 17.1%; HR 0.79), mainly driven by fewer hospitalizations. Dapagliflozin showed similar results (16.4% vs. 19.5%; HR 0.82) in preserved or mildly reduced EF. Benefits were consistent regardless of diabetes. In non-diabetic patients, empagliflozin reduced the primary outcome (HR 0.78) without interaction with glycemic status. There was also a reduction in total HF hospitalizations (HR 0.73) and slower decline in renal function, with smaller reductions in estimated glomerular filtration rate. SGLT2 inhibitors consistently reduce cardiovascular death and HF hospitalization across phenotypes, regardless of diabetes, with similar effect magnitude in diabetic and non-diabetic patients. They also improve renal outcomes, reinforcing their role in the cardiorenal axis. These findings support SGLT2 inhibitors as a cornerstone therapy in HF management, independent of glycemic status.

CARDIOVASCULAR EFFECTS OF GLP-1 RECEPTOR AGONISTS IN OVERWEIGHT AND OBESE PATIENTS WITHOUT DIABETES: A SYSTEMATIC REVIEW

OLGA GIOVANNA DANELON1; ANNE ALVAREZ CLAUDINO1; FABIANA VERONEZ GIMENEZ1;

(1) FACULDADE DE MEDICINA DE MARILIA - MARÍLIA - SP - BRASIL;

Introdução/Fundamentos: To this day, cardiovascular diseases remain the leading cause of mortality worldwide, accounting for approximately 17.9 million deaths annually. Among the main modifiable risk factors, obesity stands out due to its strong association with adverse cardiovascular outcomes. In Brazil, where over 60% of adults are overweight and 25% live with obesity, this relationship further highlights the urgent need for strategies targeting both weight reduction and cardiovascular risk. In this context, glucagon-like peptide-1 receptor agonists (GLP-1 RAs), initially developed for type 2 diabetes, have shown benefits beyond glycemic control, including reductions in major adverse cardiovascular events (MACE), even in non-diabetics. Despite these findings, the mechanisms of cardiovascular protection aren't fully understood. Therefore, this study aims to address the following research question: What are the cardiovascular effects of GLP-1 receptor agonists in overweight and obese patients without diabetes? Objetivos: To evaluate cardiovascular effects of GLP-1 RAs in overweight and obese individuals without diabetes. Métodos: This systematic review was conducted in accordance with PRISMA guidelines. Studies were included if they aligned with the research objective, including MACE, cardiovascular mortality, and abdominal circumference. Only randomized, double-blind clinical trials published in English within the last five years and with full-text availability were considered. Exclusion criteria included duplicates, renal or diabetes-focused studies, non-human studies, abstracts, case reports, descriptive studies, theses, editorials, and reviews. Data from the studies were extracted for qualitative analysis and narrative synthesis of the main results. Resultados e Conclusões: Among the seven studies, six showed a consistent reduction in MACE and overall cardiovascular risk with GLP-1 RAs in overweight or obese individuals without diabetes. One study found that these benefits were independent of weight loss, suggesting additional metabolic, anti-inflammatory, and vascular effects. Only one study reported treatment discontinuation due to gastrointestinal adverse effects (16%), while the overall safety profile remained favorable. These findings support a cardioprotective effect of GLP-1 receptor agonists beyond weight reduction. The search in only two databases constitutes a limitation of this study; it's recommended to expand the sources and evaluate the performance of a meta-analysis for greater strength of the evidence

Combined Abatacept and Ruxolitinib Therapy in Immune Checkpoint Inhibitor–Associated Myocarditis: A Systematic Review of Published Cases

ANA LUISA COSTA ALENCAR1; CARLA VIDA FAÇANHA QUEZADO1; CARLOS EMANUEL NUNES MARTINS1; LUÍS FELIPE CARVALHO PEREIRA1; BIANCA COSTA ANDRADE1; FRANCISCO CARLEIAL FEIJO DE SÁ1;

(1) UNIVERSIDADE FEDERAL DO CARIRI - BARBALHA - CE - Brasil;

Introdução/Fundamentos: The oncological treatment landscape has been revolutionized by the use of Immune Checkpoint Inhibitors (ICI), which function by increasing T-lymphocyte-mediated antitumoral activity. However, this heightened immune expression can trigger adverse responses, such as immune-related myocarditis, which carries a high mortality rate, specially when refractory to conventional treatment with high-dose corticosteroids. Given this scenario, combined therapy with Abatacept and Ruxolitinib emerges as a promising approach. Objetivos: To evaluate the efficacy and safety of combined abatacept and ruxolitinib therapy in the treatment of ICI-induced myocarditis. Métodos: A systematic search of PubMed, Embase, and Scopus was conducted following the PRISMA guidelines to identify case reports and case series describing the use of abatacept and ruxolitinib for the treatment of ICI–induced myocarditis. Resultados e Conclusões: A total of 36 cases of ICI-induced myocarditis were identified. The majority of patients were male (n=22), with a median age of 70.1 years. Patients received anti-PD(L)1 (n=26) or anti-PD(L)1 plus anti-CTLA-4 (n=10). Median onset of symptoms was 33.6 days (range 14–168) after a median of 2 ICI cycles. The most common presenting symptoms were muscle weakness (n=26), dyspnea (n=19), diplopia (n=12), and dysphagia (n=12). 31 cases were promptly initiated on combined therapy of abatacept (10–20 mg/kg) and ruxolitinib (10–20 mg BID), and 5 cases received secondary immunosuppressive therapy prior to the initiation of combined therapy. Concomitant immunosuppressive agents were used in 19 cases alongside the primary protocol. Overall, 33 cases (91.7%) demonstrated clinical improvement and resolution of acute myotoxicity over a follow-up period of up to 1 year. One case experienced a recurrence of myocarditis, which was successfully retreated with abatacept and ruxolitinib. The myotoxicity-specific fatality rate was 2.7% (n=1). All-cause mortality over a follow-up period of up to 1 year was 33% (n=12), due to unrelated causes. No adverse events were reported in association with the combined use of Abatacept and Ruxolitinib. In conclusion, combined abatacept and ruxolitinib therapy demonstrated promising results in published cases of ICI-induced myocarditis. However, curente evidence is limited. Controlled prospective studies are needed to establish specific dosing protocols, treatment duration, and potential oncological outcomes in patients receiving this combination.

COMPARATIVE EFFICACY AND SAFETY OF ASUNDEXIAN VERSUS APIXABAN IN ATRIAL FIBRILLATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

THIAGO BONAFÉ1; ANA VITÓRIA RODRIGUES MONTANHA1; BRUNA MEDEIROS GOMES1; GABRIEL FALCÃO OLIVEIRA2; GABRIELA CARVALHO LIMA1; ISABELLA CUNHA SILVA1; JÉSSICA BRITO BARROSO1; LETÍCIA MOREIRA SERIGIOLLI1; MATHEUS SOUZA RIBEIRO1; NAYAD SILVERIO BRAGA1; SARA YASMIN SILVA DURÃES1; PAULA PEXE ALVES MACHADO3;

(1) CENTRO UNIVERSITARIO DE VARZEA GRANDE - UNIVAG - CUIABÁ - MT - BRASIL; (2) UNIVERSIDADE DE CUIABA - UNIC - CUIABÁ - MT - BRASIL; (3) UFMT - CUIABÁ - MT - BRASIL;

Introdução/Fundamentos: Anticoagulation in Atrial Fibrillation (AF) is mandatory for the prevention of stroke and systemic embolism. Apixaban is a consolidated therapy, yet its application remains limited by the intrinsic risk of bleeding complications. Asundexian, a novel Factor XIa inhibitor, proposes a pharmacological decoupling of hemostasis and thrombosis, theoretically aiming for greater clinical safety. This meta-analysis evaluates the comparative efficacy and safety profiles of these therapies. Objetivos: To evaluate the comparative efficacy and safety of asundexian versus apixaban for the prevention of stroke and systemic embolism, as well as the risk of major bleeding in adult populations with AF. Métodos: A systematic review and meta-analysis was conducted in accordance with PRISMA guidelines, systematically searching the PubMed and Embase databases. Clinical trials evaluating adult patients with AF requiring oral anticoagulation were included. The intervention involved the administration of asundexian compared directly to a control group receiving apixaban. Analyzed clinical outcomes encompassed the incidence of major bleeding events, all-cause mortality, and cardiovascular mortality. The screening process removed duplicate records and excluded studies with inadequate methodological designs, incorrect populations, or inappropriate interventions. Statistical analyses calculated the pooled Relative Risk (RR) with 95% Confidence Intervals (CI) and assessed inter-study heterogeneity using the I^2 statistic. Resultados e Conclusões: Three clinical trials comprising a total cohort of 16,247 participants were included. Asundexian demonstrated a statistically significant reduction in the risk of bleeding events compared to apixaban, yielding a pooled Relative Risk of 0.52 (95% CI: 0.46–0.60; I^2=0%). Conversely, the intervention did not demonstrate a significant reduction in all-cause mortality (RR=0.82; 95% CI: 0.59–1.12; I^2=0%) or cardiovascular mortality (RR=0.75; 95% CI: 0.42–1.33; I^2=67.6%). In conclusion, asundexian presents a superior safety profile, effectively reducing the bleeding risk by nearly half. However, this distinct hemostatic advantage does not translate into an overall survival or cardiovascular mortality benefit. Given the lack of superiority in fatal clinical outcomes, further studies are required to define the definitive therapeutic role of Factor XIa inhibition in the routine management of AF.

22042

COMPARATIVE PHARMACOLOGICAL ASSESSMENT OF THE DIURETIC AND ELECTROLYTE-MODULATING EFFECTS OF SYAGRUS COCOIDES EXTRACT VERSUS HYDROCHLOROTHIAZIDE

JOÃO VICTOR CUNHA SILVA1; JHONATA COSTA MOURA1; ELLEN CAROLINE DA SILVA PENHA1; ANDRESSA COELHO FERREIRA1; RAPHAEL FURTADO MARQUES1; MATHEUS BASTOS VASCONCELOS1; MARIA EDURADA DE CASTRO PEREIRA1; MARIA CLARA SANTOS ARAUJO1; MARIA JÚLIA DE SENA LOPES1; LARA LUIZA PITOMBEIRA ROCHA1; BIANCA DE FATIMA ASSUNÇÃO SODRÉ1; RACHEL MELO RIBEIRO1;

(1) UFMA - CAMPUS SAO LUIS - SÃO LUÍS - MA - BRASIL;

Introdução/Fundamentos: Thiazide diuretics remain first-line agents in hypertension management; however, their adverse metabolic effects underscore the need for alternative compounds with distinct renal mechanisms. Plant-derived bioactive substances represent a promising source of novel diuretic candidates, yet their comparative pharmacological profiles remain insufficiently explored. Objetivos: This study aimed to evaluate the acute diuretic and electrolyte effects of the hydroalcoholic extract of Syagrus cocoides (SYA) and hydrochlorothiazide (HCTZ), with emphasis on temporal patterns of renal response. Métodos: S. cocoides kernels were dried, milled, and macerated in 70% hydroalcoholic solution, concentrated under reduced pressure (40°C), lyophilized, and stored at 5°C. Male, young, normotensive Wistar rats (200–250 g) were maintained under controlled conditions (24–25°C; 12 h light/dark cycle) with food and water ad libitum. Following 15 days of acclimatization, animals were randomized into four groups (n=5): vehicle, HCTZ (25 mg/kg), SYA (100 mg/kg), and SYA (300 mg/kg). Urinary output was measured over 24 hours, and sodium, potassium, and chloride excretion were quantified at 6 and 24 hours. Data were expressed as mean ± SEM and analyzed by one-way ANOVA followed by Tukey's test ($p<0.05$). Resultados e Conclusões: SYA induced a significantly faster onset of diuresis compared with HCTZ, particularly at 300 mg/kg, with sustained urine output persisting up to 24 hours. HCTZ exhibited a delayed but pronounced early-phase diuretic effect. Regarding electrolyte handling, HCTZ enhanced early natriuresis, consistent with distal tubular sodium reabsorption inhibition, whereas SYA promoted delayed yet robust sodium excretion at 24 hours, suggesting alternative tubular mechanisms. SYA also induced a marked and persistent increase in chloride excretion surpassing HCTZ, while potassium excretion was moderately elevated across all treated groups. The divergent temporal and electrolyte profiles indicate that S. cocoides extract likely acts through renal mechanisms distinct from thiazide diuretics, supporting the hypothesis that SYA modulates tubular ion transport via non-thiazide pathways. These findings highlight its potential as a novel natural candidate for diuretic drug discovery and translational nephrology research.

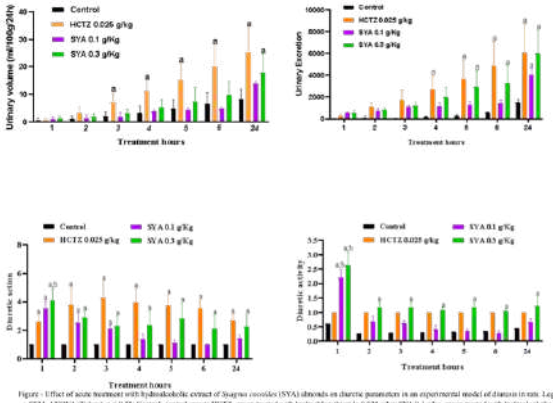

Figure - Effect of acute treatment with hydroalcoholic extract of *Syagrus cocoides* (SYA) almonds on diuretic parameters in an experimental model of diuresis in rats. Legend: Mea ± SEM, ANOVA (Tukey), $p \leq 0.05$; Control, control group; HCTZ, group treated with hydrochlorothiazide 0.025 g/kg; SYA 0.1 g/kg, group treated with hydroalcoholic extract of Syagrus cocoides almonds 0.1 g/kg; SYA 0.3 g/kg, group treated with hydroalcoholic extract of Syagrus cocoides almonds 0.3 g/kg; a comparison with the control group, b comparison with the hydrochlorothiazide group; c comparison with the SYA 0.1 g/kg group.

18471

EFFECT OF GLP-1 RECEPTOR AGONISTS (GLP-1RAS) ON THE REDUCTION OF MAJOR ADVERSE CARDIOVASCULAR EVENTS (MACE) IN PATIENTS AT HIGH CARDIOVASCULAR RISK.

MARIELLY ALVES SILVEIRA1; MOISÉS DE SOUSA VELOSO2; JARBAS MURILO GOMES DA SILVA1; MARCELO DANTAS CAMPOS1; JOÃO PAULO ARAÚJO DA SILVA1; MARIELLA MARTINS VIEIRA DE FARIA1;

(1) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (2) FACULDADE DE ENSINO SUPERIOR DA AMAZONIA REUNIDA - REDENÇÃO - PA - BRASIL;

Introdução/Fundamentos: Glucagon-like peptide-1 receptor agonists (GLP-1RAs) are antidiabetic agents that stimulate glucose-dependent insulin secretion and delay gastric emptying, promoting satiety and weight loss. Given the high cardiovascular risk associated with metabolic syndrome, this drug class has gained attention for its potential to reduce adverse cardiovascular events. Objetivos: To analyse the protective effect of GLP-1RAs on major adverse cardiovascular events (MACE) in patients at high cardiovascular risk. Métodos: A systematic review was conducted in accordance with PRISMA guidelines, with a search performed in PubMed using descriptors related to “GLP-1 receptor agonists” and “cardiovascular outcomes.” Studies including patients with type 2 diabetes mellitus, obesity, or cardiovascular diseases using GLP-1RAs and evaluating cardiovascular outcomes, including MACE, were selected based on predefined eligibility criteria. After screening, 12 studies were included in the final analysis. Resultados e Conclusões: GLP-1RAs were shown to reduce ischemia–reperfusion injury and promote favorable modulation of cardiovascular risk factors. An observational study demonstrated a 21% reduction in the risk of MACE, corroborated by clinical trials. Obese patients showed greater benefit in reducing hospitalizations due to heart failure. Functional improvement was observed in patients with heart failure and chronic kidney disease, including reduction in NYHA functional class, increased distance in the 6-minute walk test, and greater response to cardiac resynchronization therapy, as well as benefits in heart failure with preserved ejection fraction. There was also a reduction in atherosclerotic events, such as myocardial infarction, stroke, and cardiovascular death, in addition to a decrease in arrhythmic events. In secondary prevention, meta-analyses demonstrated a reduced risk of total stroke (RR 0.85; 95% CI 0.77–0.93) and non-fatal stroke (RR 0.87; 95% CI 0.79–0.95). The combination with SGLT2 inhibitors showed a synergistic effect. GLP-1RAs provide consistent benefits in reducing cardiovascular events and mortality across the cardiometabolic spectrum. Despite this, their use remains suboptimal in eligible populations, highlighting the need for greater implementation in clinical practice, with potential to reduce major adverse cardiovascular events and cardiovascular mortality.

20866

EFFECT OF GLP-1 RECEPTOR AGONISTS ON CARDIOVASCULAR EVENTS REDUCTION: A SYSTEMATIC REVIEW

YASMIN DE MELO SILVA1; MARILIA GOMES ROCHA BACELAR1; THAYANE DE MELO SILVA E SILVA1; ISABELLA SEABRA LOPES1; REMBRANT WILLY OLIVEIRA SANTOS1; AMANDA DIELY BULHÕES REZENDE1; BEATRIZ FERREIRA SANTIAGO KATO1; RYAN FROHLICH MOREIRA1; DAVI DE SA ROQUE1; HELOISA HELENA MESQUITA SILVA1; RHANA MARIELA ROGUIGUES YACHIMURA LIRA1; LUIZ MARIO PARA RODRIGUES1;

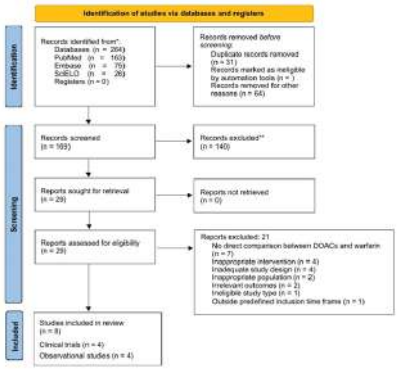
(1) FACULDADE DE MEDICINA ESTÁCIO DE CASTANHAL - FMEC - CASTANHAL - PA - BRASIL;

Introdução/Fundamentos: GLP-1 receptor agonists were developed for type 2 diabetes but demonstrated consistent cardiovascular benefits, reducing myocardial infarction, stroke, and cardiovascular death. Recent evidence suggests expansion of this benefit to populations without T2D - individuals with obesity and/or high cardiovascular risk. Objetivos: To evaluate the efficacy of GLP-1 agonists in reducing MACE-3 in patients with and without T2D, including primary and secondary prevention. Métodos: Qualitative systematic review based on eight articles from 2016 to 2026, selected from PubMed, Embase, and Cochrane. Search used descriptors “GLP-1 receptor agonists”, “liraglutide”, “semaglutide”, “cardiovascular outcomes” and “MACE” (Boolean “AND”/”OR”). Inclusion: RCTs, meta-analyses, cohorts with MACE-3 outcome, full text, English/Portuguese. Exclusion: sample <500 patients, follow-up <12 months, narrative reviews, letters. Risk of bias assessed with RoB 2 (RCTs) and ROBINS-I (observational), following PRISMA guidelines. To better organize the levels of evidence, studies were classified as primary evidence (LEADER, SUSTAIN-6, SELECT), secondary evidence (meta-analyses), and observational evidence (real-world cohort SCORE). Strategies were adopted to avoid redundancies and ensure each study was analyzed at its respective hierarchical level. Primary outcome: MACE-3 composite. Resultados e Conclusões: Studies revealed significant MACE-3 reduction with GLP-1 agonists, in patients aged 61-64 years. Meta-analyses: 12-14% reduction (IRR 0.87; 95%CI 0.83-0.91; HR 0.86; 95%CI 0.80-0.92; HR 0.86; 95%CI 0.80-0.93; RR 0.86; 95%CI 0.78-0.95). RCTs: LEADER (HR 0.87; 0.78-0.97), SUSTAIN-6 (HR 0.74; 0.58-0.95), SELECT (HR 0.80; 0.72-0.90). SCORE (primary prevention): 41% reduction (HR 0.59; 0.48-0.73). Benefit extended to all-cause mortality, myocardial infarction, stroke, and heart failure hospitalization, with no significant differences across age, sex, and race subgroups. Safety: gastrointestinal events were more frequent with GLP-1 agonists, with discontinuation rates ranging from 9% to 16% compared to 5% to 8% with placebo. There was no increase in pancreatitis or neoplasms. GLP-1 agonists consistently reduce MACE-3 in T2D at high cardiovascular risk, obesity with prior cardiovascular disease, and primary prevention of obese individuals with multiple risk factors, transcending glycemic control, with robust evidence suggesting a consistent cardioprotective benefit and acceptable safety profile.

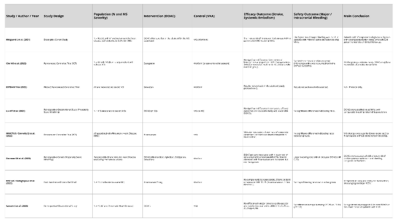
Table 1: Characteristics of included studies.

Year	Study / Design	Population	Intervention	N	MACE-3 (HR/RR/IRR; 95%CI)
2025	Meta-analysis (21 RCTs)	T2D + high CV risk	Various GLP-1 RAs	99,599	IRR 0.87 (0.83-0.91)
2025	Meta-analysis (11 RCTs)	T2D + high CV risk	Various GLP-1 RAs	85,373	HR 0.86 (0.80-0.92)
2021	Meta-analysis (8 RCTs)	T2D + high CV risk	Various GLP-1 RAs	60,080	HR 0.86 (0.80-0.93)
2025	Meta-analysis (5 RCTs)	T2D	Oral semaglutide	13,875	RR 0.86 (0.78-0.95)
2023	SELECT (RCT)	Obesity + CVD (no DM)	Semaglutide 2.4 mg/w	17,604	HR 0.80 (0.72-0.90)
2016	LEADER (RCT)	T2D + high CV risk	Liraglutide 1.8 mg/d	9,340	HR 0.87 (0.78-0.97)
2016	SUSTAIN-6 (RCT)	T2D + high CV risk	Semaglutide SC	3,297	HR 0.74 (0.58-0.95)
2026	SCORE (Cohort)	Obesity (Prim Prev)	Semaglutide 2.4 mg/w	144,552	HR 0.59 (0.48-0.73)

RCT: randomized clinical trial; T2D: type 2 diabetes; CV: cardiovascular; CVD: cardiovascular disease; GLP-1 RA: GLP-1 receptor agonist; MACE: major adverse cardiovascular events; HR: hazard ratio; RR: risk ratio; IRR: incidence rate ratio; 95% CI: 95% confidence interval.



19272



EFFICACY AND SAFETY OF DIRECT ORAL ANTICOAGULANTS VERSUS VITAMIN K ANTAGONISTS FOR STROKE PREVENTION IN ATRIAL FIBRILLATION WITH MITRAL STENOSI: A SYSTEMATIC REVIEW

GIULIA OLIVEIRA RAMALHO1; DAVI DANTAS FREIRE1; EDER OLIVEIRA COSTA1; JULIA VASCONCELOS DA SILVEIRA1; RODRIGO GOUVEIA AZEVEDO BORGES1; RODRIGO ALVES DE SOUZA GALVÃO2;

(1) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL; (2) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Patients with mitral stenosis (MS) and atrial fibrillation (AF) constitute a high-risk population for cardioembolism. Although vitamin K antagonists (VKAs) are the established therapy, their narrow therapeutic window and the need for frequent INR monitoring motivate the search for more practical alternatives, such as direct oral anticoagulants (DOACs). This systematic review evaluates current evidence given the lack of consensus on off-label DOAC use. Objetivos: To synthesize current evidence on the efficacy and safety of DOACs versus VKAs for stroke prevention in patients with MS and AF. Métodos: Following PRISMA guidelines, a systematic review of PubMed, SciELO, and EMBASE was conducted, restricted to articles from the last 5 years. Using PICOT criteria, RCTs and observational studies comparing DOACs to VKAs for preventing thromboembolic events in adults with MS and AF were included. Two independent reviewers screened 264 initial records; conflicts were resolved by a third author. After duplicate removal and full-text review of 29 articles, 8 studies were selected. Methodological quality was evaluated using a risk of bias tool. Resultados e Conclusões: The 8 included studies (4 RCTs, 4 observational) yielded divergent findings based on study design. Observational cohorts indicated DOACs had a lower or equivalent risk of stroke/systemic embolism (HR 0.28-0.70) and lower bleeding risk (HR 0.72) compared to VKAs. Pilot RCTs (e.g., RISE MS) showed no symptomatic strokes and acceptable silent ischemia rates. Conversely, the largest RCT (INVICTUS), focusing on rheumatic heart disease, demonstrated significant superiority of VKAs over rivaroxaban in reducing the composite of cardiovascular events and mortality, without increasing bleeding rates. In conclusion, evidence on DOACs in MS with AF is conflicting. While observational data suggest a promising efficacy and safety profile, robust randomized trials establish VKAs as the undisputed gold standard, particularly in rheumatic disease. Routine DOAC use in this population should not be encouraged until ongoing clinical trials definitively clarify their role.

EFFICACY AND SAFETY OF FERRIC CARBOXYMALTOSE IN PATIENTS WITH HEART FAILURE WITH REDUCED EJECTION FRACTION AND IRON DEFICIENCY: A SYSTEMATIC REVIEW OF RECENT EVIDENCE

RAFAEL CARRARO DE REZENDE1; JOÃO PAULO CALEGARO SALVARANI1; PEDRO ARTHUR PAZDZIORNY PADILHA1; MARSELHA MARQUES BARRAL MONTESSI1;

(1) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL;

Introdução/Fundamentos: Iron deficiency occurs in 30-50% of heart failure with reduced ejection fraction (HFrEF) cases, being associated with higher hospitalization rates and mortality. In the IRONMAN trial, there was no significant difference in cardiovascular death (CVD) or heart failure hospitalizations (HFHs) between the group assigned to ferric derisomaltose and the usual care-only group, although safety endpoints were met; as an alternative, ferric carboxymaltose (FCM) has been tested for its efficacy and safety in subsequent trials. Objetivos: To evaluate the efficacy and safety of FCM in patients with HFrEF and iron deficiency. Métodos: Randomized controlled clinical trials published in the last five years encompassing patients with left ventricular ejection fraction < 50% and serum ferritin level < 100 ng/mL (or serum ferritin level 100 ng/mL–300 ng/mL and transferrin saturation < 20%) were included in the review. Studies that did not meet these criteria were excluded. The outcomes analyzed were CVD, HFHs, and incidence of adverse effects. Initial research was conducted in the MEDLINE and Google Scholar databases using the entry terms “ferric carboxymaltose”, “heart failure with reduced ejection fraction”, “cardiovascular death”, and “heart failure hospitalization”. The articles found were exported to Rayyan in order to remove duplicates, and the PRISMA 2020 checklist was used to systematize the review. Resultados e Conclusões: Three studies were included, comprising 5032 patients, of whom 2657 (52.8%) were assigned to FCM and 2375 (47.2%) were assigned to placebo. The AFFIRM-AFH trial showed no significant difference in CVD between the groups (HR 0.96; 0.70–1.32, p = 0.81), but HFHs were significantly reduced in the FCM group (HR 0·74; 0.58–0.94, p = 0.013). In the HEART-FID trial, no significant difference was observed between the groups in the composite outcome of CVD or HFHs (HR 0.93; 0.81–1.06). In the FAIR-HF2 trial, FCM did not reduce HFHs when compared to placebo (RR 0.80; 0.60–1.06, p = 0.12). In all three studies, no significant difference was observed in the incidence of adverse effects between the groups. The latter two studies were affected by the COVID-19 pandemic. Recent evidence regarding the use of FCM in HFrEF patients with iron deficiency still appears to be controversial, with one study showing a reduction in HFHs; however, it should be noted that two of the studies were impacted by COVID-19, raising the need for further clinical trials.

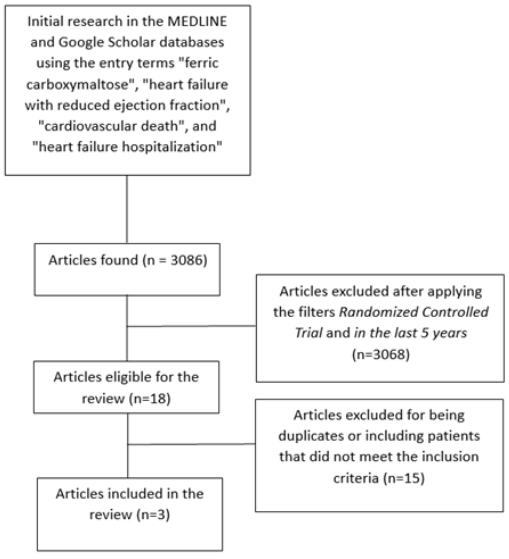

Figure 1. Flowchart of the study selection process

EFFICACY OF SGLT2 INHIBITORS IN NON-DIABETIC PATIENTS WITH HEART FAILURE: A SYSTEMATIC REVIEW

FERNANDO MARQUES MAIA1; RYAN CEZÁRIO DOS SANTOS1; LÍVIA KAROLINE BARRETO WERNCKE SILVA2; PAULO HENRIQUE DA SILVA MARQUES2; HEITOR RODRIGUES VAZ1; LUIS AUGUSTO AIRES FREIRE PERUZZO2; CARLOS EDUARDO PIMENTA DIAS2; MARIA BÁRBARA DE HOLANDA CAVALCANTE UBALDO MONTEIRO E BARBOSA2; MARCUS DE FRANÇA BARROS FILHO3; PAULO SERGIO RODRIGUES DE MELO1; OSVANIR VIEIRA DOS SANTOS JUNNIOR1; VINICIUS MAIA DE OLIVEIRA4;

(1) AFYA FACULDADE DE CIENCIAS MEDICAS DE PALMAS - PALMAS - TO - BRASIL; (2) INSTITUTO TOCANTINENSE PRESIDENTE ANTONIO CARLOS - CAMPUS PORTO NACIONAL - TO - PORTO NACIONAL - TO - BRASIL; (3) UNINOVAFAPI - TERESINA - PI - BRASIL; (4) CENTRO UNIVERSITARIO UNICESUMAR - MARINGA - PR - BRASIL;

Introdução/Fundamentos: Sodium-glucose cotransporter 2 inhibitors (SGLT2i) have revolutionized the management of type 2 diabetes by demonstrating significant reductions in major adverse cardiovascular events. Emerging evidence suggests that these benefits extend beyond glycemic control, impacting cardiac structure and function through non-hypoglycemic pathways such as improved ion homeostasis, reduced inflammation, and optimized myocardial energetics. However, while the cardioprotective effects in diabetic populations are well-established, there is a need for a contemporary systematic synthesis of high-quality evidence focusing specifically on outcomes in non-diabetic patients to define their role as a foundational therapy in broader cardiology practice. Objetivos: To systematically evaluate the impact of SGLT2 inhibitors on cardiovascular mortality and heart failure outcomes in patients without diabetes mellitus. Métodos: This systematic review was conducted in accordance with PRISMA guidelines. A comprehensive search was performed in PubMed and Scopus in April 2026, including studies published between 2020 and 2026. The search strategy used the terms “SGLT2 inhibitors,” “cardiovascular mortality,” and “non-diabetic,” with appropriate filters applied, such as full-text availability and restriction to the medical field. Eligible studies were selected based on predefined inclusion and exclusion criteria. Two independent reviewers conducted study selection and data extraction. A total of 30 studies were initially identified, of which 14 were included in the final analysis. Resultados e Conclusões: SGLT2 inhibitors significantly reduce the risk of cardiovascular mortality and hospitalizations for heart failure in non-diabetic patients. These clinical benefits are consistent across the spectrum of left ventricular ejection fraction and are directly supported by mechanisms independent of glucose-lowering, including the modulation of the cardiac sodium-interactome and the reduction of oxidative stress. The results confirm that SGLT2 inhibitors provide robust cardioprotection regardless of glycemic status, supporting their implementation as a foundational treatment for heart failure in the non-diabetic population.

IMPACT OF INHALED TREPROSTINIL ON CARDIOVASCULAR AND HEMODYNAMIC OUTCOMES IN PH-ILD: A SYSTEMATIC REVIEW

GUILHERME COSTA DINIZ1; DAVI DE HOLANDA MARTINS ACSELRAD1; MARINA CALADO LIMA1; MARIA VITÓRIA COUTINHO CORDEIRO DA SILVA1; JÚLIA CAMBRAIA DANTAS1; MARINA CARVALHO LIMA MENDONÇA1; GABRIELA FONTELES CONRADO1; BIANCA SENA MACEDO1; LUCAS VITOR ARAGÃO MOREIRA1; MARIA EDUARDA TELMOS DE LIMA1; MARIANA DE PAULA PESSOA BEZERRA1; NILCYELI LINHARES ARAGÃO1;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Pulmonary hypertension associated with interstitial lung disease (PH-ILD) carries high morbidity and mortality, with limited effective therapies. Inhaled treprostinil has recently emerged as a targeted treatment with potential benefits extending beyond vasodilation. Objetivos: To systematically assess the effects of inhaled treprostinil on hemodynamic, cardiovascular, functional, and clinical outcomes in PH-ILD. Métodos: This systematic review was conducted according to PRISMA guidelines. PubMed, Embase, Cochrane Library, and Scopus were searched through April 2026 for randomized controlled trials and observational studies evaluating inhaled treprostinil in PH-ILD. Relevant outcomes included pulmonary vascular resistance (PVR), cardiac biomarkers (BNP/NT-proBNP), 6-minute walk distance (6MWD), and clinical endpoints such as hospitalization and disease progression. Data were qualitatively synthesized. Resultados e Conclusões: Five studies were included. Inhaled treprostinil demonstrated consistent hemodynamic benefit, with reductions in PVR of up to 40.1% and decreases in NT-proBNP of approximately 15%. Functional capacity improved in randomized trials, with gains of up to 31 m in 6MWD, while real-world data revealed a more variable response, with 38.5% of patients achieving a clinically meaningful improvement (≥30 m) at 6 months. Across studies, treatment was associated with reduced clinical worsening and lower healthcare utilization, including an estimated 30% reduction in hospitalization risk. Notably, the magnitude and consistency of benefit were greater in controlled trial settings compared with observational cohorts. Taken together, Inhaled treprostinil provides robust and consistent hemodynamic improvement in PH-ILD and contributes to stabilization of functional capacity, with signals of reduced clinical worsening. However, the attenuation and variability of benefit in real-world settings underscore the importance of patient selection, early initiation, and treatment optimization. These findings support its role as a cornerstone therapy in PH-ILD while highlighting the need for strategies to enhance effectiveness beyond clinical trial populations.

PREDICTIVE ANALYSIS OF THE CARDIOVASCULAR THERAPEUTIC POTENTIAL OF PHYTOCHEMICAL COMPOUNDS FROM HIBISCUS SABDARIFFA: AN IN SILICO STUDY

STELLANNY CILENE RODRIGUES CASTRO1; ADRIA DA SILVA SANTOS2; ADRIELLE BARBOSA MARTINA1; HUGO COIMBRA DE OLIVEIRA1; JAYNARA DA SILVA ESTEVES1; JULLE KELE PEREIRA GONÇALVES1; LUÍS HENRIQUE CIRQUEIRA DA SILVA1; FELIPE CAPELA DO CARMO1; JOAO VITOR DOS SANTOS BENJAMIN3; DILMA DO SOCORRO MORAES DE SOUZA4;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE FEDERAL DE RONDÔNIA - PORTO VELHO - RO - BRASIL; (3) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (4) FUNDACAO HOSPITAL DE CLINICAS GASPAR VIANNA PA - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases represent a global health problem. They are associated with oxidative stress and alterations in the renin-angiotensin-aldosterone system. Hibiscus sabdariffa has a high content of anthocyanins and phenolic acids. These compounds may have effects on the cardiovascular system. They may act through modulation of the NO/cGMP pathway and inhibition of the angiotensin-converting enzyme. Nevertheless, its clinical application is limited. This is mainly due to the lack of studies on its molecular interactions. Objetivos: To analyze in silico the propensity of the pharmacological response of volatile compounds from Hibiscus sabdariffa in cardiovascular activities. Métodos: This is an in silico study conducted in sequential steps. Initially, the main phytochemicals present in Hibiscus sabdariffa were identified through a literature review using PubMed, SciELO, and Google Scholar databases. Next, the chemical structures of the selected compounds were obtained from the PubChem® database. A predictive analysis of pharmacological potential was then performed using the Prediction of Activity Spectra for Substances (PASS) software, focusing on cardiovascular-related activities, including angiotensin-converting enzyme inhibition, antioxidant effects, and vasodilatory action. Only compounds with a probability of activity (Pa) greater than 0.5 were considered, and the data were organized for analysis. Resultados e Conclusões: Ten phytochemicals were analyzed, including organic acids (citric, hydroxycitric, hibiscus, malic, tartaric, and caffeic), flavonoids (hibiscitrin and myricetin), and ellagic acid. All compounds demonstrated significant cardiovascular potential (Pa>0.5). Tartaric acid showed the highest probability for lipid metabolism regulation (Pa=0.838) and vasoprotective activity (Pa=0.731). Regarding vascular homeostasis, malic and caffeic acids exhibited peripheral vasodilatory activity (Pa=0.659 and 0.639, respectively). Hibiscitrin (Pa=0.709) and tartaric acid (Pa=0.712) stood out for their antithrombotic and fibrinolytic potential. Furthermore, citric and hibiscus acids demonstrated relevant activity in cholesterol antagonism (Pa=0.583 and 0.542) alongside antioxidant properties, suggesting a multi-target effect across multiple pathophysiological pathways associated with cardiovascular diseases. We conclude that these compounds have therapeutic potential, though robust preclinical and clinical trials remain essential for experimental validation.

SS-31 AS A MITOCHONDRIAL MODULATOR IN THE TREATMENT OF HEART FAILURE AND ACUTE KIDNEY INJURY

VICTOR FONTES QUADRINI1; GIULLIA SAORI TAKAGAKI1; DANIELA CRISTINA ISHY1; FERNANDA LEDIMUTH GOMES DE MELO1;

(1) UNIVERSIDADE MUNICIPAL DE SAO CAETANO DO SUL - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: SS-31 is a synthetic tetrapeptide that selectively binds to cardiolipin, stabilizing the inner mitochondrial membrane and preserving its structure and function under cellular stress. It has emerged as a potential therapeutic strategy to attenuate tissue injury in high-energy-demand organs such as the heart and kidneys, where mitochondrial dysfunction plays a key role in the pathophysiology of acute kidney injury (AKI) and heart failure (HF). Heart failure and acute kidney injury are closely linked conditions with high morbidity and mortality. Mitochondrial dysfunction and oxidative stress play a central role in their pathophysiology. Current therapies remain limited, highlighting the need for new approaches. In this context, SS-31 emerges as a promising mitochondrial-targeted therapy, although its clinical benefits are still not fully established. Objetivos: To collect, evaluate and summarize the role of SS-31 as a mitochondrial-targeted therapy in heart failure and acute kidney injury, with emphasis on functional, bioenergetic, and inflammatory outcomes. Métodos: Systematic review based on the PICO strategy (P: patients with kidney injury and/or heart failure; I: SS-31; C: standard treatment; O: improvement in clinical outcomes and reduction of oxidative stress). Following PRISMA, a search was conducted in PubMed/MEDLINE (March–April/2026) using the descriptors “Elamipretide”, “SS-31”, “MTP-131”, “Heart Failure”, “Acute Kidney Injury”, “Mitochondrial Dysfunction”, “Oxidative Stress” and “Reactive Oxygen Species”. Of 57 studies, 14 were included after screening. Resultados e Conclusões: Results: Included studies comprised preclinical and clinical models. SS-31 demonstrated dose-dependent effects, with acute administration improving hemodynamic parameters and reducing renal injury, while chronic use promoted sustained structural benefits. Mechanistically, it stabilized cardiolipin, increased ATP production, and reduced oxidative stress. Improvements in cardiac and renal function were observed, with a favorable safety profile and predominantly mild adverse effects. Conclusion: SS-31 shows potential as a mitochondrial modulator in the cardiorenal axis, promoting improved bioenergetics, reduced oxidative stress, and both cardiac and renal benefits. Despite these promising findings, clinical evidence remains limited, requiring larger studies to confirm its efficacy and safety.

THE ROLE OF SGLT2 INHIBITORS BEYOND DIABETES: CARDIOVASCULAR IMPLICATIONS

BEATRZ BRILHANTE DE SOUSA1; LAURA COSTA DA COSTA1; EVA VITÓRIA FERREIRA VIANA1; DIOGO MACOLA FELIX1; EDUARDO MACHADO DA SILVA ZAMIAN1; MAGNUM DIAS COELHO1; ROBERTO MARCIO DE OLIVEIRA JUNIOR1;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Sodium-glucose cotransporter 2 inhibitors (SGLT2i), also known as gliflozins, are widely used in the treatment of type 2 diabetes mellitus. Beyond glycemic control, recent evidence has demonstrated significant cardiovascular and renal benefits, including reductions in hospitalizations for heart failure, major adverse cardiovascular events (MACE), and preservation of renal function. Objetivos: To synthesize contemporary evidence regarding the cardiovascular effects of SGLT2 inhibitors on heart failure, cardiovascular mortality, and major adverse cardiovascular events (MACE). Métodos: This systematic review was conducted in accordance with the PRISMA 2020 guidelines and based on the PICO strategy. Searches were performed in the PubMed/MEDLINE, EMBASE, Scopus, and Cochrane Library databases, including studies published between April 24, 2025, and April 24, 2026. The following descriptors were used: “SGLT2 inhibitors,” dapagliflozin, empagliflozin, canagliflozin, ertugliflozin, “Heart Failure,” “cardiovascular death,” “hospitalization for heart failure,” and MACE. Phase III/IV randomized controlled trials and subanalyses of RCTs with a minimum follow-up of 12 weeks and cardiovascular outcome assessment were included. Study selection was performed through blinded peer review, with a third reviewer resolving disagreements. Of the 527 records identified, 10 studies were included in the final synthesis. Risk of bias was assessed using the RoB 2.0 tool, and a descriptive synthesis was conducted due to methodological heterogeneity. The protocol was registered in PROSPERO. Resultados e Conclusões: The studies consistently demonstrated cardiovascular and renal benefits associated with SGLT2 inhibitors, including reductions in hospitalizations for heart failure, improvements in echocardiographic parameters, reductions in NT-proBNP levels, preservation of renal function, and decreased incidence of MACE. Large clinical trials reported an approximate 25–35% reduction in hospitalizations for heart failure, along with lower cardiovascular mortality. Landmark studies such as DAPA-HF, EMPEROR-Reduced, EMPEROR-Preserved, and DELIVER demonstrated benefits even among patients without diabetes mellitus, reinforcing cardioprotective mechanisms independent of glycemic control. These findings consolidate SGLT2 inhibitors as cardioprotective and nephroprotective therapeutic strategies across multiple clinical settings, although further studies are still needed to better define their effects in specific populations.

ASSOCIATION BETWEEN PEDIATRIC HEART SURGERY AND NEURODEVELOPMENTAL ALTERATIONS IN PATIENTS WITH CONGENITAL HEART DISEASE: A SYSTEMATIC REVIEW OF EVIDENCE

EMANUEL CARVALHO AMARAL1; CLARA STEINER FERNANDES DE SOUSA MOULIN LIMA1; MARIA EDUARDA CARVALHO LOBO1; MARIA APARECIDA ALMEIDA SOUZA RODRIGUES1;

(1) UNIVERSIDADE DE VASSOURAS (UNIVASSOURAS) - VASSOURAS - RJ - BRASIL;

Introdução/Fundamentos: Congenital heart disease is the most frequent malformation at birth, frequently requiring surgical intervention in the first years of life. In recent decades, advances in surgical techniques and pediatric intensive care have promoted a significant reduction in mortality. However, the increase in survival has brought greater relevance to non-cardiac outcomes, especially neurological and cognitive alterations, which directly impact the functionality and quality of life of these patients. Objetivos: This study aimed to analyze the association between pediatric heart surgery and neurocognitive development alterations in children with congenital heart disease. Métodos: A systematic review was conducted according to PRISMA guidelines, searching the PubMed and Virtual Health Library databases using the descriptors “Heart Surgery”, “Neurodevelopment”, and “Children”. The review included studies published in the last five years, with a clinical or observational design, available in full text, and involving a pediatric population undergoing heart surgery in free full text. Duplicate and out-of-scope articles were excluded. After screening 499 records and applying eligibility criteria, 25 studies were selected for qualitative analysis. Resultados e Conclusões: The results indicate that functional impairment is multifactorial. In the preoperative period, structural brain alterations stand out, such as immaturity and lesions associated with fetal hypoxia. During the intraoperative period, especially during cardiopulmonary bypass, episodes of hypotension and hypoxia increase the risk of neurological damage, making NIRS monitoring relevant for prevention. In the postoperative period, complications such as delirium, metabolic disorders, and kidney injury also negatively influence outcomes. The main deficits include alterations in executive functions, language delay, and motor impairments, with repercussions that may persist into adolescence. Furthermore, environmental factors, such as family stimulation and multidisciplinary follow-up, play an important role in recovery. It is concluded that the impairments observed in children undergoing heart surgery result from the interaction between pre-, intra-, and postoperative factors. Strategies aimed at maintaining cerebral perfusion, combined with multidisciplinary follow-up and adequate environmental support, are fundamental to minimize sequelae and improve long-term outcomes.

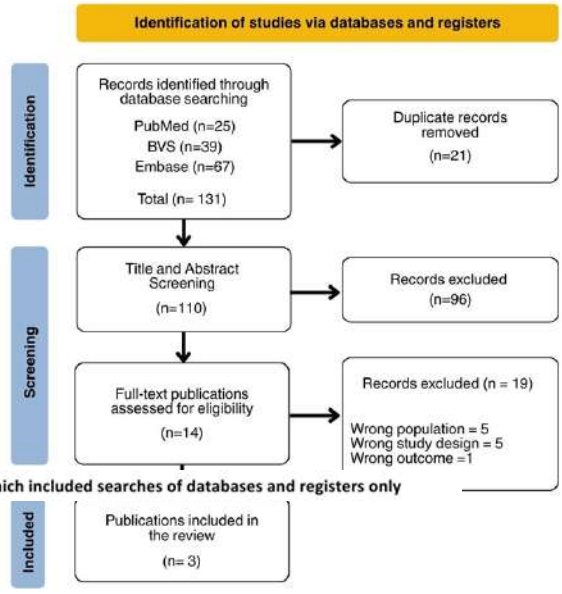
COMPARATIVE OUTCOMES OF SHUNT TYPES IN THE NORWOOD I PROCEDURE FOR PEDIATRIC CARDIOVASCULAR SURGERY: A SYSTEMATIC REVIEW AND META-ANALYSIS

ANTONIO JHONATA ALVES LIMA1; JAMES NOBRE DE SENA2; MARIAL CLARA AGUIAR TOMAZ3; YURI FELIX BRANDÃO2; NEWTON DIÓGENES PINHEIRO NETO2; AILTON CÉSAR DE ARAÚJO FILHO1; ROBERTO VICTOR PAIVA CAMURÇA4; EMILY BITTENCOURT DE SOUZA MARTINS4; ANNA LETÍCIA ALVES BOMFIM4; BENJAMIN ANTÔNIO PINHEIRO VIEIRA4;

(1) UECE - QUIXERAMOBIM - CE - BRASIL; (2) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (3) UNICHRISTUS - FORTALEZA - CE - BRASIL; (4) UECE - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: In the Norwood procedure (Stage I) for hypoplastic left heart syndrome, the shunt strategy influences coronary perfusion and hemodynamic stability. The modified Blalock–Taussig shunt (mBTs) may increase diastolic “runoff” and systemic load, while the right ventricle-to-pulmonary artery (RV-PA) shunt reduces runoff but involves a ventriculotomy and higher pulmonary intervention rates. A quantitative synthesis is essential to guide surgical selection and interstage care in high-complexity centers. Objetivos: To compare mBTs vs. RV-PA regarding Stage I hospital mortality, death/transplant by Stage II, interstage reinterventions, and severe acute kidney injury (AKI). Métodos: Systematic review and meta-analysis of comparative observational studies in pediatric patients. Risk of bias was assessed for non-randomized studies. Effect measures were expressed as risk ratios (RR) with 95% confidence intervals (CI), synthesized via restricted maximum likelihood random-effects models with Hartung–Knapp adjustment. Sensitivity was tested via one-study-out exclusion. Resultados e Conclusões: For Stage I hospital mortality, five studies (7,740 patients) showed a robust reduction with RV-PA: RR 0.72 (95% CI: 0.63–0.82), with zero heterogeneity and stable effects, suggesting cross-center reproducibility. For death or transplant by Stage II, three studies (3,822 patients) showed no difference: RR 0.83 (95% CI: 0.55–1.26). Conversely, two studies (1,000 patients) revealed a significant increase in pulmonary reinterventions for the RV-PA group: RR 4.39 (95% CI: 2.67–7.23), with zero heterogeneity, indicating a higher interstage burden. One study (355 patients) found no significant difference in severe AKI. The RV-PA shunt consistently reduces Stage I hospital mortality but substantially increases pulmonary reinterventions by Stage II, defining a clear clinical trade-off. Findings support individualizing shunt strategies based on anatomy and the center’s capacity for interstage surveillance. These estimates assist in family counseling and the implementation of structured protocols for early hemodynamic monitoring, integrating early survival with long-term care planning in pediatric surgery.



21393

COMPARISON OF PULSATILE AND CONTINUOUS FLOW PERFUSION DURING EXTRACORPOREAL CIRCULATION IN PEDIATRIC CARDIAC SURGERY: A SYSTEMATIC REVIEW OF HEMODYNAMIC IMPACTS AND CLINICAL OUTCOMES

CARLA VIDA FAÇANHA QUEZADO1; ANA LUISA COSTA ALENCAR1; LUÍS FELIPE CARVALHO PEREIRA1; BIANCA COSTA ANDRADE1; CARLOS EMANUEL NUNES MARTINS1; CAIO DANTAS VERAS LUCIO1; ISRAEL CASTRO RABELO1; FRANCISCO CARLEIAL FEIJÓ DE SÁ1; ARTHUR MOISES CABRAL CRUZ1; MARIA ANTONIA LINARD DE MACÊDO1; TAÍSSA THÁTYLA DE CASTRO1;

(1) UFCA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Introduction: Cardiopulmonary bypass (CPB) constitutes a fundamental aspect in pediatric cardiac surgeries, especially correcting congenital heart defects while maintaining the body's perfusion. Although CPB systems traditionally operate via Non-Pulsatile Flow (NPF), Pulsatile Flow (PF) has been proposed as a physiologically superior alternative. Objetivos: Objectives: This study aims to compare hemodynamic impacts and clinical outcomes of pulsatile flow versus non-pulsatile flow perfusion during CBP in pediatric patients undergoing cardiac surgery. Métodos: Methods: A search was conducted across the PubMed, Embase, and BVS using DeCS/MeSH descriptors, following the PRISMA guidelines. The selection included randomized clinical trials and a retrospective cohort evaluating the Pulsatility Index (PI) and post-surgical recovery. Resultados e Conclusões: Results: The study included a total of 443 pediatric patients with congenital heart defects undergoing CPB with either pulsatile flow (n=215) or non-pulsatile flow (n=228). PRISM-III scores (NPF: 5.4±2.1; PF: 5.8±2.8) were similar between groups, according to the randomized clinical trial, indicating comparable baseline severity. At the retrospective cohort, both groups exhibited similar pre-CPB plasma free hemoglobin levels, however, the pulsatile group demonstrated significantly lower post-CPB levels (p=0.04). Transcranial Doppler ultrasound analysis revealed better-maintained results in the pulsatile group regarding the PI at the right middle cerebral artery and the arterial line (p<0.05) at the randomized trial. Conversely, the cohort demonstrated arterial line pressures were higher in the non-pulsatile group (p=0.003), possibly driven by higher vascular resistance. However, PI returned to baseline values post-CPB in both groups. No statistically significant differences were observed in regional cerebral oxygen saturation or gaseous microemboli counts (GME) between groups at the retrospective study (NPF=176±47; PF=337±74; p=0.079). Likewise, there were no significant di overall hospital stay. C has proven to be safe, the prognoses of CPB using PF and NPF showed similar aspects in both PI and GME scores and clinical outcomes. However, due to the small sample size for comparison between these approaches, further studies on this topic are needed for a more definitive conclusion

EFFICACY AND SAFETY OF CRYOPRESERVED VERSUS LIQUID-PRESERVED PLATELETS IN CARDIAC SURGERY: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CLINICAL TRIALS

MARCUS VINÍCIUS VIEIRA TORQUATO1; ROBERTO VICTOR PAIVA CAMURÇA1; ARTHUR VITOR COUTO DE SOUSA1; EDUARDA LIMA VERDE FERREIRA1; PEDRO VINICIUS POMPEU DE OLIVEIRA1; MARIO SERRANO BARBOSA FILHO1; VINICIUS GALVÃO PARENTE RAFAEL1; YURI FELIX BRANDÃO2; NEWTON DIÓGENES PINHEIRO NETO2; HENRIQUE GABRIEL VIEIRA SANTOS1; EMILY BITTENCOURT DE SOUZA MARTINS1; FLÁVIO DUARTE CAMURÇA3;

(1) UNIVERSIDADE ESTADUAL DO CEARÁ - FORTALEZA - CE - BRASIL; (2) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (3) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Conventionally stored platelets (liquid-preserved at 22°C) have a limited shelf life of 5–7 days, resulting in high discard rates and limited availability in remote areas. Cryopreservation with dimethyl sulfoxide (DMSO) extends this period to up to 2 years, but its in vivo hemostatic efficacy and clinical safety remain controversial, especially following large recent trials. Objetivos: To compare the hemostatic efficacy and clinical safety of cryopreserved platelets versus liquid-preserved platelets in adult patients undergoing cardiac surgery with cardiopulmonary bypass. Métodos: Following PRISMA, a systematic review of randomized clinical trials (RCTs) comparing the two preservation methods was conducted. The search included PubMed, Embase, Cochrane, ScienceDirect, Scopus, and Web of Science databases. Data were extracted, and the meta-analysis was performed using fixed- and random-effects models. Five main outcomes were analyzed: intraoperative bleeding, BARC (Bleeding Academic Research Consortium) bleeding, reoperation for bleeding control, length of hospital stay, and mortality. Results were expressed as Mean Difference (MD) or Odds Ratio (OR) with 95% Confidence Interval (CI). Resultados e Conclusões: A total of 222 articles were identified in the initial search. After duplicate removal, 53 records were excluded. Ultimately, 4 randomized clinical trials were included, comprising 319 patients for hemostatic efficacy analysis and 266 for safety and length of hospital stay outcomes. For intraoperative bleeding, no significant difference was observed between groups (MD 43.67 mL; 95% CI -160.58 to 247.92; p = 0.68), with high heterogeneity (I^2 = 75%). Similar findings were observed for clinically significant bleeding (BARC) incidence (OR 1.19; 95% CI 0.38 to 3.75; p = 0.76; I^2 = 65%) and reoperation for bleeding (OR 0.74; 95% CI 0.34 to 1.61; p = 0.45; I^2 = 12%), with no significant differences between strategies. Length of hospital stay was also comparable (MD -1.36 days; 95% CI -6.08 to 3.36; p = 0.57; I^2 = 62%). However, pooled analysis of mortality showed a significantly higher risk of death in the cryopreserved platelet group (OR 5.54; 95% CI 1.38 to 22.22; p = 0.02), with no heterogeneity (I^2 = 0%). Although cryopreserved platelets offer logistical advantages, they were not superior to liquid-preserved platelets in controlling bleeding in cardiac surgery, and the observed increase in mortality raises critical safety concerns requiring further investigation before routine clinical implementation.

ENDOVASCULAR VS OPEN REPAIR IN ABDOMINAL AORTIC ANEURYSM: A CONSISTENT EARLY SURVIVAL–LATE DURABILITY TRADE-OFF ACROSS CLINICAL SETTINGS

MARIA FERNANDA BRETAS FRANZINI1; THALES DA FONSECA DORNELLES1; ALESSANDRO MOTTA FRANZINI2;

(1) FACULDADE DE CIENCIAS MEDICAS E DA SAUDE DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL; (2) HOSPITAL SAO JOSE DO AVAI - ITAPERUNA - MG - BRASIL;

Introdução/Fundamentos: Endovascular aneurysm repair (EVAR) has transformed abdominal aortic aneurysm (AAA) management by improving perioperative outcomes versus open repair. However, whether this early survival advantage is offset by reduced long-term durability, and how this relationship manifests across clinical presentations, remains incompletely defined, particularly regarding its implications for clinical decision-making. Objetivos: To characterize the relationship between early survival and long-term durability after EVAR versus open repair in elective and ruptured AAA, integrating short-term mortality and long-term reintervention outcomes. Métodos: A systematic review and meta-analysis were conducted according to PRISMA guidelines. Randomized controlled trials and prospective cohort studies comparing EVAR versus open repair were identified through PubMed, Embase, and the Cochrane Library (inception to April 2026). The primary outcomes were 30-day and perioperative mortality. The secondary outcome was reintervention, defined as any secondary procedure related to the index aneurysm repair. Pooled risk ratios (RRs) with 95% confidence intervals (CIs) were estimated using random-effects Mantel–Haenszel models. Heterogeneity was assessed using the I² statistic, and subgroup analyses were performed by clinical presentation. Certainty of evidence was evaluated using the GRADE system. Resultados e Conclusões: Ten studies (7 RCTs and 3 prospective cohorts), including 55,633 patients, were analyzed. Median follow-up ranged from 2.1 to 15 years. For early outcomes, EVAR was associated with lower perioperative mortality in elective AAA (RR 0.32, 95% CI 0.17–0.57; I² = 32%) and reduced 30-day mortality in ruptured AAA (RR 0.65, 95% CI 0.47–0.89; I² = 0%). For long-term outcomes, EVAR was associated with higher reintervention rates in elective AAA (RR 1.86, 95% CI 1.08–3.22; I² = 28%). This pattern likely reflects a clinically meaningful balance between lower procedural invasiveness and reduced long-term structural durability of EVAR compared with open surgery. EVAR provides a consistent early survival benefit across clinical settings, offset by reduced long-term durability. These findings support a consistent and clinically coherent early survival–late durability trade-off framework and highlight the importance of individualized treatment decisions based on patient characteristics and long-term procedural considerations.

IMPACT OF ATRIAL FIBRILLATION ON HOSPITAL OUTCOMES IN PATIENTS UNDERGOING CORONARY ARTERY BYPASS GRAFTING: A SYSTEMATIC REVIEW OF BRAZILIAN STUDIES

ANNA BEATRIZ DE OLIVEIRA NOGUEIRA1; VICTOR MEDEIROS REBOUÇAS1; THIAGO HENRIQUE DUARTE MOREIRA1; LUCAS HORTÊNCIO RIBEIRO DE OLIVEIRA1; GERSON BARBOSA DO NASCIMENTO1;

(1) ESCOLA MULTICAMPI DE CIENCIAS MEDICAS - CAICÓ - RN - BRASIL;

Introdução/Fundamentos: Atrial fibrillation (AF) is the most common arrhythmic complication in the postoperative period of coronary artery bypass grafting (CABG). Quantifying the impact of this arrhythmia on hospital outcomes is essential to optimize protocols aimed at reducing morbidity and mortality. Objetivos: To perform a systematic review on the impact of AF on hospital outcomes in patients undergoing CABG in Brazil, focusing on in-hospital mortality, length of stay, and incidence of complications. Métodos: This is a systematic review conducted in accordance with the PRISMA guidelines, based on the selection of publications from the PubMed, LILACS, and SciELO databases. The Health Sciences Descriptors used were “Atrial Fibrillation” and “Coronary Artery Bypass Grafting.” Randomized clinical trials and observational studies conducted in Brazil, published between 2015 and 2026, were included if they evaluated patients undergoing CABG and compared outcomes between groups with and without AF. The outcomes analyzed were hospital mortality, length of stay in the intensive care unit (ICU) and total hospitalization, stroke, and acute kidney injury. The final sample comprised six studies. Resultados e Conclusões: The incidence of AF among 7,428 patients undergoing CABG was 15.4% (ranging from 11.4% to 19%). In-hospital mortality in the group that developed the arrhythmia was 9.54%, compared to 3.59% in the sinus rhythm group ($p < 0.05$). AF was associated with an increased need for prolonged mechanical ventilation and longer ICU stay, with total hospitalization ranging from 11 to 14.5 days. Regarding multisystem impact, the incidence of stroke was up to four times higher (4.0% vs. 1.1%), and acute kidney injury was up to five times higher (12.0% vs. 2.4%) in patients with AF. Concerning prophylaxis, analysis of 140 patients using colchicine did not demonstrate a reduction in AF incidence (7.04% vs. 13.04%, $p = 0.271$) and was associated with a higher infection rate. In contrast, maintaining central venous pressure ≤ 15 cmH_2O reduced AF incidence from 22.86% to 8.57% ($p = 0.03$). Factors such as advanced age (>64.5 years), increased left atrial diameter (>40.5 mm), and elevated inflammatory markers were identified as predictors of postoperative AF. The implementation of targeted prophylactic and therapeutic protocols for AF is essential to optimize CABG outcomes in the national setting.

IMPACT OF CARDIOPULMONARY BYPASS ON SYSTEMIC INFLAMMATORY RESPONSE SYNDROME IN PATIENTS UNDERGOING CORONARY ARTERY BYPASS GRAFTING.

EVILLY CUTRIM VAZ1; MARCEL PORTELA SILVA MATTEUCCI1; VINICIUS JOSÉ DA SILVA NINA1; WILKER FRAINKYLI SILVA MENDONÇA1; ISABELA MIRANDA MELO1; FERNANDO RIBEIRO SILVA1; DAVI HENRIQUE PALÁCIO SILVA1; PAULO GABRIEL SILVA CASTRO CAMPOS1; RAMON FABRÍCIO DE AMORIM NEVES E FRANÇA1;

(1) UFMA - CAMPUS SAO LUIS - SÃO LUÍS - MA - BRASIL;

Introdução/Fundamentos: Cardiopulmonary bypass (CPB), although indispensable for myocardial revascularization, induces a complex inflammatory cascade that contributes to systemic inflammatory response syndrome (SIRS) and may influence postoperative recovery. The Systemic Immune-Inflammation Index (SII), derived from peripheral blood cell counts, has been proposed as an integrative marker of inflammatory and immune status. However, its role as a predictor of clinically relevant outcomes after coronary artery bypass grafting (CABG) remains insufficiently defined. Objetivos: This study aimed to evaluate the association between SII and postoperative outcomes in patients undergoing CABG with CPB. Métodos: A retrospective analytical cohort was conducted including adult patients submitted to isolated CABG with CPB between 2022 and 2023. Preoperative and postoperative SII values, as well as their variation (Delta SII), were analyzed. Statistical evaluation included correlation analysis, ROC curves, and multivariate regression models, with adjustment for clinical variables and CPB duration ($p < 0.05$). Resultados e Conclusões: A total of 104 patients were included (mean age 63.6 ± 8.8 years; 77.9% male). The mean ICU length of stay was 5.8 ± 5.1 days, and hospital mortality reached 7.7%. SII and Delta SII showed limited discriminatory capacity for mortality and major cardiovascular complications (AUC < 0.60), and were not independent predictors of death in adjusted analyses. In contrast, both markers demonstrated a consistent positive association with ICU length of stay ($r \approx 0.31$), remaining significant predictors in linear regression models ($p = 0.001$). These findings suggest that, although not useful for mortality prediction, SII may reflect the intensity of postoperative inflammatory response and be associated with prolonged ICU stay, indicating potential value in assessing postoperative morbidity and recovery trajectory in CABG patients.

IMPACT OF FASCIAL PLANE BLOCKS ON POSTOPERATIVE INFLAMMATORY MARKERS FOLLOWING CARDIAC SURGERY VIA MEDIAN STERNOTOMY: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

EMMANUEL OBERDA NOMINATO1; ARTHUR ÁVILA REIS RONCARATI MIRANDA1; THIAGO MACEDO RIBEIRO1; IAGO MARCOS ROCHA LOPES1; CAIO TOMITA FERREIRA2; JOÃO LUCAS SILVA PEREIRA3; VICTOR LIMA AMARAL3; GUSTAVO ANDRÉ PEDRAL DINIZ LEITE2; GABRIEL ANDRÉ PEDRAL DINIZ LEITE2; CLAUDIO LEO GELAPE2;

(1) UNIVERSIDADE FEDERAL DE OURO PRETO - OURO PRETO - MG - BRASIL; (2) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (3) FACULDADE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Figure 1 - PRISMA flow diagram

Introdução/Fundamentos: Cardiac surgery via sternotomy triggers a robust systemic inflammatory response involving synthesis of IL-6, TNF-α and CRP. Fascial plane blocks (FPB) have emerged as a multimodal analgesia component with preliminary evidence suggesting attenuation of the surgical stress response, yet their impact on inflammatory markers remains poorly synthesized. Objetivos: To evaluate the impact of FPB on inflammatory response and clinical outcomes in cardiac surgery via median sternotomy. Métodos: We searched PubMed, Embase, and Cochrane Library through March 2026 for randomized controlled trials (RCTs) comparing FPB versus placebo or usual care in adults undergoing cardiac surgery via median sternotomy. Primary outcomes were IL-6 (pg/mL), TNF-α (pg/mL), and CRP (mg/L). Secondary outcomes were ICU stay (hours), hospital stay (days), and extubation time (hours). Inflammatory markers were analyzed in predefined postoperative time windows. A random-effects model was used to estimate mean differences (MDs) with 95% confidence intervals (CIs). Heterogeneity was assessed by I^2. Subgroup analysis was performed based on the use of cardiopulmonary bypass (CPB). The protocol was prospectively registered in PROSPERO (CRD420261364869). Resultados e Conclusões: We included six RCTs involving 440 patients, of whom 224 (50.9%) were allocated to the FPB group. FPB was associated with significantly lower IL-6 levels at 12–24h (MD 21.51; 95% CI 8.01 to 35.02; I^2=46.9%), although no significant differences were observed at 0–1h (MD 10.51; 95% CI −13.10 to 34.12; I^2=69.8%) or 24–48h (MD 16.63; 95% CI −7.83 to 41.10; I^2=33.0%). TNF-α at 12–24h (MD 10.37; 95% CI −8.23 to 28.97; I^2=99.1%) and CRP at 24–48h (MD 18.95; 95% CI −9.84 to 47.74; I^2=92.8%) showed no significant differences; high heterogeneity limits reliability. Regarding secondary outcomes, FPB significantly reduced time to extubation (MD 2.83; 95% CI 0.12 to 5.55; I^2=97.6%) and ICU stay (MD 6.51; 95% CI 1.43 to 11.59; I^2=93.3%), though high heterogeneity limits these estimates. Hospital stay did not differ significantly (MD 0.73; 95% CI −0.37 to 1.83; I^2=92.6%). In the CPB subgroup, findings remained consistent for IL-6 at 0–1h, 12–24h, and hospital stay, whereas ICU stay and extubation time lost significance. Overall, FPB was associated with reduced IL-6 at 12–24h and improved clinical recovery outcomes, suggesting a potential anti-inflammatory role in cardiac surgery via median sternotomy. These findings warrant confirmation in larger RCTs.

Figure 2: Pooled analysis

OUTCOME	PARTICIPANTS	EFFECT ESTIMATE [95% CI]	I^2	P-VALUE
IL-6: 0-1h	185	MD 10.51 [-13.10 – 34.12]	69.8%	0.3831
IL-6: 12-24h*	288	MD 21.51 [8.01 – 35.01]	46.9%	0.0018
IL-6: 24-48h	155	MD 16.63 [-7.83 – 41.10]	33.0%	0.1827
TNF-α: 12-24h	213	MD 10.37 [-8.23 – 28.97]	99.1%	0.2744
CRP: 24-48h	178	MD 18.95 [-9.84 – 47.74]	92.8%	0.1970
ICU stay*	321	MD 6.51 [1.43 – 11.59]	93.3%	0.0120
Hospital stay	326	MD 0.73 [-0.37 – 1.83]	92.6%	0.1963

IMPACT OF PULMONARY VALVE REPLACEMENT ON MORTALITY AND ARRHYTHMIC RISK IN REPAIRED TETRALOGY OF FALLOT: A SYSTEMATIC REVIEW AND META-ANALYSIS

PEDRO VINÍCIUS SANTOS DE MEDEIROS1; BRUNO VIEIRA GAIA1; PEDRO HENRIQUE GORRI CUSTÓDIO DE MELO BRITES2; CRISTHIAN MONTEIRO DE OLIVEIRA3; YAN LUIZ FARIAS DA SILVA1; GABRIEL FERREIRA ROSENDO1; CAMILA CAVALCANTE LOPES DE GÓES4; ALFREDO AURÉLIO MARINHO ROSA FILHO5; GUILHERME JOSÉ TEIXEIRA DE SOUZA1;

(1) UNCISAL - MACEIÓ - AL - BRASIL; (2) UNIVERSIDADE ESTADUAL DE MARINGA - MARINGÁ - PR - BRASIL; (3) UNIVERSIDADE DA REGIAO DE JOINVILLE - JOINVILLE - SC - BRASIL; (4) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (5) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Pulmonary valve regurgitation is a frequent long-term complication after tetralogy of Fallot (TOF) repair, resulting in progressive right ventricular remodeling and dysfunction. Although pulmonary valve replacement (PVR) is frequently performed in this population, its association with long-term survival remains uncertain. Objetivos: To quantify the association between PVR and the incidence of all-cause mortality, sustained ventricular tachycardia (VT), and atrial tachyarrhythmias (SVT) compared to conservative management in patients with repaired TOF. Métodos: Quantitative synthesis was performed using a Random-effects model with the Mantel-Haenszel (MH) method. To ensure data independence and avoid cohort overlap, four independent studies were consolidated. Pooled effects were expressed as Risk Ratios (RR) with 95% confidence intervals (CI). Heterogeneity was quantified by I^2. Resultados e Conclusões: The final analysis included 4 studies (Bokma 2023, He 2019, Therrien 2001, Gengsakul 2007) totaling 1,252 patients (PVR: 637; Control: 615). Median/mean follow-up ranged from 1.9 to 9.1 years, with a weighted average follow-up of 7.8 years, corresponding to a cumulative exposure exceeding 9,800 patient-years. • All-Cause Mortality: PVR was associated with a numerical reduction in mortality risk, although the result did not reach statistical significance (RR 0.58 [95% CI 0.16–2.07]; I2 = 38.4%). • Ventricular Arrhythmias (VT): A consistent protective trend was observed, with PVR accounting for a 51% reduction in the risk of sustained ventricular tachycardia (RR 0.49 [95% CI 0.23–1.04]; I2 = 0%). • Atrial Tachyarrhythmias (SVT): No protective effect was observed for atrial arrhythmias, with a higher incidence in the surgical group (RR 1.15 [95% CI 0.72–1.84]; I2 = 0%). In patients with repaired TOF, PVR demonstrates a consistent clinical trend toward reducing all-cause mortality and sustained ventricular tachycardia. The RR of 0.49 for ventricular arrhythmias suggests a strong potential for electrical stabilization despite the wide confidence interval. Conversely, the increased risk of atrial arrhythmias (RR 1.15) likely reflects surgical sequelae. These findings support PVR as a strategy for ventricular protection, though optimal timing remains critical to translate remodeling into survival benefits.

IMPACT OF TRANSCATHETER AORTIC VALVE IMPLANTATION VERSUS SURGICAL AORTIC VALVE REPLACEMENT ON THE INCIDENCE OF STROKE IN LOW-RISK PATIENTS WITH AORTIC STENOSIS: A SYSTEMATIC REVIEW

ALANNE RYLLARI DA SILVA DOS SANTOS1; GABRIELA PIXUNA DIAS1; GLÓRIA ALBUQUERQUE FRANCO1; FERNANDA NEVES VILHENA MATOS1; CLÁUDIA LORENA XAVIER DA SILVA2; JULIANA OLIVEIRA DE ALMEIDA1; MARIA GIOVANNA DA CRUZ TOCANTINS1; ANA CAROLINA RODRIGUES NASCIMENTO3; ANTONIO MARIA ZACARIAS ARAÚJO MONTEIRO2;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (3) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Aortic stenosis (AS) is one of the most prevalent valvular heart diseases associated with population aging, highlighting the need for continuous evaluation of therapeutic strategies according to clinical severity and operative risk. Currently, transcatheter aortic valve implantation (TAVI) is the preferred treatment for patients with severe AS at high or intermediate surgical risk compared with surgical aortic valve replacement (SAVR). However, there is no consensus regarding its use as first-line therapy in low-risk patients. In this population, often characterized by longer life expectancy, stroke remains a major concern due to its significant impact on quality of life. Objetivos: To evaluate the incidence of stroke following TAVI compared with SAVR in patients with severe AS and low surgical risk. Métodos: A systematic review of randomized controlled trials (RCTs) published between 2022 and March 2026, investigating the incidence of stroke after TAVI compared to SAVR in low-risk patients with severe AS. Secondary analyses of RCTs and incomplete articles were excluded. The literature search was conducted across PubMed, Embase, and Scopus databases using DeCS/MeSH descriptors and free-text terms such as “Transcatheter Aortic Valve Replacement”, “Surgical Aortic Valve Replacement”, and “Low Surgical Risk”. Resultados e Conclusões: From 107 studies identified in the databases, 4 RCTs (n = 4,187) were included in the review, with a mean follow-up of approximately 4 years. The population was predominantly male, with low surgical risk evidenced by a mean Society of Thoracic Surgeons (STS) score of 1.7%. Regarding the incidence of stroke, none of the analyzed studies showed a statistically significant difference between TAVI and SAVR, as 95% confidence intervals crossed the unit and p-values were greater than 0.05. Two studies observed a higher frequency of non-disabling stroke in the TAVI group (HR = 1.93 and 1.22); however, this difference was also not statistically significant. Therefore, the findings of this updated review indicate that there is no consistent evidence supporting the superiority of TAVI over SAVR in low-risk patients with AS. Further multicenter studies with long-term follow-up are required to confirm these findings.

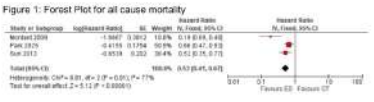
IMPACT OF TRUE LUMEN RATIO ON REINTERVENTION AND AORTIC REMODELING AFTER FROZEN ELEPHANT TRUNK SURGERY FOR AORTIC DISSECTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

EMMYLAINE MENDES DE SOUSA1; HILLARY FERNANDA ROBERTO DOS SANTOS1; LEINA YUKARI ETTO1;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL;

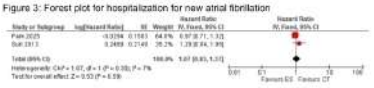
Introdução/Fundamentos: The Frozen Elephant Trunk (FET) technique has become a standard strategy for the treatment of complex aortic dissections involving the aortic arch and descending thoracic aorta. Despite technical advances, persistent false lumen patency and distal remodeling failure remain associated with aneurysmal degeneration and late reinterventions. Traditionally, prognosis has been based on anatomical inference and chronicity of dissection. However, recent evidence suggests that geometric parameters, particularly the True Lumen Ratio (TLR), may provide superior prognostic value. Objetivos: To evaluate the impact of true lumen ratio and anatomical medidors as predictors on distal reintervention rates and aortic remodeling after FET surgery. Métodos: A systematic review and meta-analysis were conducted according to PRISMA guidelines. Searches were performed in PubMed, Scopus, and Web of Science using the terms (“aortic dissection”) AND (“frozen elephant trunk” OR “FET”). A total of 388 articles were identified,68 underwent full-text assessment. 15 studies were included in the systematic review and 6 in the meta-analysis. Observational studies and clinical trials were included.Methodological quality and risk of bias were assessed using the ROBINS-I tool for observational studies and the Cochrane RoB 2 tool for randomized clinical trials.Quantitative analysis was performed using RevMan 5.4 with a random-effects Mantel-Haenszel model, calculating Odds Ratio and 95% confidence intervals. Resultados e Conclusões: The systematic review included 845 patients, while the meta-analysis comprised 692 individuals. Overall analysis demonstrated that unfavorable remodeling or reduced true lumen geometry was significantly associated with increased distal reintervention risk (OR 5.61; 95% CI 1.95–16.15; p = 0.001).The subgroup based on anatomical inference and dissection chronicity demonstrated a trend toward increased distal reintervention (OR 3.27; 95% CI 0.65–16.48; p = 0.15).High heterogeneity (I^2=88%) due to variations in devices.The subgroup based on direct geometric remodeling demonstrated a strong and statistically significant association between reduced true lumen geometry and distal reintervention (OR 9.93; 95% CI 2.55–38.71; p = 0.0009). Volumetric studies identified higher rates of distal aneurysmal degeneration and dSINE among patients with reduced True Lumen Ratio.Reduced postoperative true lumen (<0.30) was a significant predictor of distal failure after FET, increasing reintervention risk nearly 10-fold.

17479

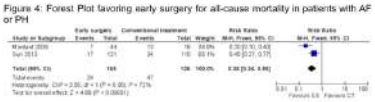


MANAGEMENT OF SEVERE ASYMPTOMATIC MITRAL REGURGITATION: EARLY SURGERY OR WATCHFUL WAITING? A SYSTEMATIC REVIEW AND META-ANALYSIS

JUAN LUKA DIAS MOTA1; CAMILLY CHRISTINE DE LIMA FERREIRA1; ISADORA MARIA COELHO QUEIROZ1; JOÃO PEDRO TEIXEIRA BENTES MONTEIRO1; JOÃO DA SILVA FERREIRA MARINHO1; JOÃO MACEDO COELHO NETO1; LEONARDO BRITO DE SOUZA1; LUCAS MACÊDO AURÉLIO PAIVA1; IASMIN SALDANHA FAÇANHA1; ISABELA THOMAZ TAKAKURA1;



(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL;



Introdução/Fundamentos: Mitral regurgitation (MR) is a valvular heart disorder that impacts significantly in cardiovascular morbidity and mortality, increasing its prevalence with age. In severe cases, surgery becomes the only definitive therapeutic option, yet the optimal timing for intervention in asymptomatic patients remains controversial. Objetivos: To compare early surgical intervention versus conservative management in adults with severe asymptomatic primary MR and preserved left ventricular function. Métodos: A systematic review and meta-analysis was conducted in accordance with PRISMA 2020 guidelines. Searches were performed in MEDLINE, Embase, and Web of Science without restrictions in language or publication date, using the descriptors “Mitral Valve Insufficiency” AND severe AND ‘early surgery’ AND asymptomatic. Primary outcomes were all-cause and cardiac mortality; secondary outcomes included hospitalization for heart failure and new-onset atrial fibrillation. Final data was pooled using a random-effects model. Resultados e Conclusões: There were 3 studies included, comprising 2,276 patients (1,116 early surgery; 1,160 conservative management), with a mean follow-up of 10–12 years. The mean age of the intervention and control group were 57.2 and 59.5 years, respectively, with 67.0% being males in the intervention arm and 69.1% in the control arm. Smoking prevalence was similar, with 23.6% in the intervention group and 25.0% in the control group. Early surgery was associated with a significant reduction in all-cause mortality (HR = 0.53; 95% CI: 0.41–0.67; p < 0.00001) and cardiac mortality (HR = 0.19; 95% CI: 0.10–0.37; p < 0.00001). Hospitalization for heart failure was also significantly lower in the early surgery group (HR = 0.38; 95% CI: 0.25–0.57; p < 0.00001). No significant difference was observed in the incidence of new-onset atrial fibrillation (HR = 1.07; 95% CI: 0.83–1.37; p = 0.59). In patients already with atrial fibrillation or pulmonary hypertension, early surgery conferred additional survival benefit (RR = 0.36; 95% CI: 0.24–0.56; p < 0.00001). The meta-analysis supports that early surgical intervention in patients with severe asymptomatic mitral regurgitation significantly improves long-term outcomes, reducing all-cause and cardiac mortality as well as heart failure hospitalizations compared with conservative management. However, further prospective and randomized studies are warranted to confirm these benefits and to refine patient selection criteria and timing of intervention.

20243

NEUTROPHIL-LYMPHOCYTE-PLATELET RATIO AS A PREDICTOR OF ACUTE KIDNEY INJURY AFTER CORONARY ARTERY BYPASS GRAFTING

Introdução/Fundamentos: Acute kidney injury (AKI) is a frequent and clinically significant complication after coronary artery bypass grafting (CABG), associated with increased morbidity and mortality. Its pathophysiology is multifactorial and strongly related to the systemic inflammatory response triggered by cardiopulmonary bypass (CPB). However, early identification of patients at higher risk remains a major challenge in clinical practice. The neutrophil-lymphocyte-platelet ratio (N/LPR) has emerged as a simple and accessible inflammatory marker, potentially useful for risk stratification, although its role in predicting AKI in this setting remains incompletely established. Objetivos: To evaluate the association between N/LPR and the occurrence of AKI in patients undergoing CABG with CPB. Métodos: A retrospective convenience cohort was conducted including 98 adult patients submitted to CABG with CPB between January 2022 and July 2023. Quantitative variables were expressed as mean ± standard deviation or median and interquartile range according to data distribution, assessed by the Shapiro-Wilk test. Comparisons were performed using Chi-square or Fisher's exact tests, and Student's t-test or Mann-Whitney test, as appropriate. Variables associated with AKI in univariate analysis were further evaluated in multivariate logistic regression models to identify independent predictors (p < 0.05). Resultados e Conclusões: AKI occurred in 23.47% of patients, most frequently in early stages (13 cases in KDIGO stage 1, 7 in stage 2, and 3 in stage 3). Among 13 recorded deaths, 9 occurred in patients who developed AKI, reinforcing its clinical impact. In univariate analysis, both diabetes mellitus (p = 0.042) and N/LPR (p = 0.001) were significantly associated with AKI, and N/LPR remained independently associated in adjusted models. These findings suggest that N/LPR may serve as a practical and low-cost biomarker for early identification of patients at increased risk of AKI after CABG, supporting its potential role in perioperative risk stratification and timely implementation of nephroprotective strategies.

OFF-PUMP VS ON-PUMP CORONARY ARTERY BYPASS GRAFTING IN ISCHEMIC CARDIOMYOPATHY WITH REDUCED EJECTION FRACTION: SYSTEMATIC REVIEW AND META-ANALYSIS OF SHORT- AND LONG-TERM MORTALITY

ALEXANDRE KEN ROSSINI MURAKAMI1; LARA ALVES TAVARES2; AUGUSTO BORGES LIBONI2; HELENA BORGES DA SILVEIRA2; JOÃO PEDRO VASCONCELOS2; ALEXANDRE NOBORU MURAKAMI3;

(1) UNIVERSIDADE ESTADUAL DE LONDRINA - LONDRINA - PR - BRASIL; (2) PONTIFÍCIA UNIVERSIDADE CATÓLICA DO PARANÁ - CAMPUS LONDRINA - LONDRINA - PR - BRASIL; (3) HOSPITAL HONPAR - ARAPONGAS - PR - BRASIL;

Introdução/Fundamentos: Although landmark trials such as ROOBY and CORONARY compared off-pump coronary artery bypass grafting (OPCABG) and on-pump coronary artery bypass grafting (ONCABG), evidence remains limited in higher-risk patients, particularly those with ischemic cardiomyopathy and heart failure with reduced ejection fraction (HFrEF), in whom the prognostic impact of surgical strategy is still unclear. Objetivos: To compare short- and long-term mortality between OPCABG and ONCABG in patients with ischemic cardiomyopathy and HFrEF. Métodos: We conducted a systematic review and meta-analysis according to PRISMA 2020 and Cochrane guidelines, with protocol registration in PROSPERO (CRD420261324102). PubMed, Embase, CENTRAL, and LILACS were searched for studies published from January 2010 onward. Randomized controlled trials and propensity-score matched cohort studies including adults with left ventricular ejection fraction <40%, undergoing isolated OPCABG or ONCABG, and reporting outcomes up to 30 days or up to 10 years were eligible. Two reviewers independently screened studies and extracted data. Methodological quality was assessed using RoB 2 and the Newcastle-Ottawa Scale. Random-effects models were used to estimate risk ratios (RR) and hazard ratios (HR) with 95% confidence intervals. Heterogeneity was assessed using Cochran's Q and I^2 statistics, and robustness was examined by leave-one-out sensitivity analysis. Resultados e Conclusões: Twelve studies were included, totaling 18,113 patients (OPCABG n = 9,700; ONCABG n = 8,413). For short-term mortality, based on 9 studies, OPCABG was associated with a 33% lower risk of death compared with ONCABG (RR = 0.67; 95% CI 0.58–0.77; p < 0.00001), with no significant heterogeneity (I^2 = 0%). Funnel plot inspection did not suggest publication bias. For long-term survival, 7 studies showed no statistically significant difference between techniques (HR = 0.97; 95% CI 0.82–1.14; p = 0.70), with moderate heterogeneity (I^2 = 56%), mainly attributable to between-study variability and one lower-precision study. Overall, in patients with ischemic cardiomyopathy and HFrEF, OPCABG was associated with lower early mortality without compromising long-term survival, supporting it as a potentially preferred strategy in this high-risk subgroup.

RIGHT VERTICAL INFRA-AXILLARY THORACOTOMY VERSUS MEDIAN STERNOTOMY IN PEDIATRIC PATIENTS WITH CONGENITAL HEART DEFECTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

LUANNA PAULA GARCEZ1; BUENA AZIRI2; EDIN BEGIC3; OSCAR BISNETO4; CAMILA MOTA GUIDA5; ANTÔNIO JANDERSON RODRIGUES DA SILVA1; ANTONIO OSMAN DA SILVA6; ADNALDO DA SILVEIRA MAIA7;

(1) CENTRO UNIVERSITÁRIO FAMETRO - MANAUS - AM - BRASIL; (2) SARAJEVO MEDICAL SCHOOL, SARAJEVO SCHOOL OF SCIENCE AND TECHNOLOGY, - BOSNIA HERZEGOVINA; (3) DEPARTMENT OF CARDIOLOGY, GENERAL HOSPITAL "PRIM. DR. ABDULAH NAKAS", FACULTY OF MEDICINE, UNIVERSITY OF SARAJEVO - BOSNIA HERZEGOVINA; (4) UFCG - CAMPINA GRANDE - PB - BRASIL; (5) INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA - SAO PAULO - SP - BRASIL; (6) UNIVERSIDADE FEDERAL DO AMAZONAS - MANAUS - AM - BRASIL; (7) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Median sternotomy (MS) remains the standard approach for congenital heart defect repair, however, minimally invasive techniques, such as right vertical infra-axillary thoracotomy (RVIAT), are increasingly used for simple lesions, including atrial septal defect (ASD) and ventricular septal defect (VSD), despite still limited comparative perioperative evidence in this population. Objetivos: To compare clinical and perioperative outcomes between the RVIAT approach and MS for ASD and VSD repair. Métodos: PubMed, Embase and Cochrane database were searched for randomized and nonrandomized studies comparing thoracotomy with sternotomy in pediatric patients with ASD or VSD. Cochrane's Review Manager Version 7.2.0 (RevMan, 2024) was used for all statistical analyses. Heterogeneity was examined with I² statistics. Mean differences (MD) and risk ratios (RR) with 95% confidence intervals (CIs) were pooled under a random-effects model. Resultados e Conclusões: 14 studies were included, totaling 4,585 pediatric patients (mean age 2.32 ± 2.29 years) undergoing ASD/VSD correction. Of these, 2,508 underwent RVIAT and 2,077 underwent MS. There was no statistically significant difference between RVIAT and sternotomy regarding operative time (MD 3.84 minutes; 95% CI -4.00 to 11.68; p = 0.34; I²=96%; Figure 1A) and aortic cross-clamp time (MD 1.36 minutes; 95% CI -1.24 to 3.84; p = 0.32; I²=84%; Figure 1B), findings corroborated by tests of differences between ASD and VSD subgroups (p = 0.08 and p = 0.94, respectively). On the other hand, RVIAT was associated with shorter hospital length of stay (MD -1.24 days; 95% CI -2.28 to -0.20; p = 0.02; I²=97%; Figure 1C) and lower chest drainage volume (MD -17.20 mL; 95% CI -24.88 to -9.52; p < 0.0001; I²=97%; Figure 1D), compared with MS, with a significant difference in the analysis between subgroups (ASD and VSD). Additionally, in patients undergoing VSD correction, there was no statistically significant difference in the risk of residual shunt between approaches (RR = 0.77, 95% CI 0.50 to 1.19; p = 0.24; I²=0%; Figure 1E). This meta-analysis demonstrated that RVIAT is a safe, effective alternative to MS for ASD and VSD repair. Operative and aortic cross-clamp times were comparable, while RVIAT was associated with shorter hospital stay and lower postoperative chest tube drainage, without increased residual shunt risk. These findings support RVIAT as a safe approach with aesthetic advantages, although randomized studies are still needed for definitive confirmation.

SAPHENOUS VEIN GRAFT FAILURE IN FAMILIAL HYPERCHOLESTEROLEMIA: A SYSTEMATIC REVIEW AND META-ANALYSIS SUPPORTING ARTERIAL REVASCULARIZATION STRATEGIES

EMANOEL DE BRITO SOUSA1; LUCAS PINA RODRIGUES1; HELOISA HORIE SANTOS DA COSTA1; ISAAC JEFFERSON AGUIAR SANTOS1; LUISA MEDEIROS VISENTINI2; GABRIELA CAMURI FIRMINO CARLOS3; VITORIA MARIA MESQUISTA PESSOA1; GEYSA DARLET GONÇALVES SILVA4; NELSON AMÉRICO HOSSNE JUNIOR5;

(1) UNIVERSIDADE SANTO AMARO (UNISA) - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE DO OESTE PAULISTA - UNOESTE - PRESIDENTE PRUDENTE - SP - BRASIL; (3) CENTRO UNIVERSITARIO SAO CAMILO - GUARULHOS - SP - BRASIL; (4) CENTRO UNIVERSITÁRIO DAS FACULDADES METROPOLITANAS UNIDAS - SÃO PAULO - SP - BRASIL; (5) UNIVERSIDADE FEDERAL DE SAO PAULO - UNIFESP - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Familial hypercholesterolemia (FH) exposes the cardiovascular bed to lifetime elevations of LDL-cholesterol, accelerating atherosclerosis. In patients undergoing coronary artery bypass grafting (CABG), the aggressive metabolic environment of FH drastically compromises saphenous vein graft patency, increasing the risk of structural graft failure and recurrent ischemic events in the long term. Objetivos: To analyze the long-term clinical impact of FH and evaluate coronary graft integrity following CABG. Métodos: A systematic review structured according to the PICO strategy, eligibility criteria, and PRISMA 2020 flowchart (Figure 1). A systematic search was performed across PubMed, Embase, Scopus, Web of Science, BVS/Lilacs, and Cochrane Library databases, including 13 studies (9 cohorts in the meta-analysis). Risk of bias was assessed using the Newcastle Ottawa Scale. A random-efects model (REML, I²=52.35%, p=0.013) and Inverse Variance method were applied, with funnel plot symmetry and absence of publication bias confirmed by Egger and Begg tests (p>0.05). Study registered under the OSF platform. Resultados e Conclusões: The Forest Plot (Figure 2) demonstrates that FH doubles the risk of post-CABG MACE (OR 1.96; 95% CI: 1.53–2.51; p<0.0001), driven by recurrent myocardial infarction (OR 2.05; 95% CI: 1.40–3.00) and the need for repeat revascularization (OR 2.11; 95% CI: 1.45–3.08). Meta-regression signaled a trend of positive association between follow-up time and clinical failure (beta=0.0035; p=0.9397), suggesting progressive graft deterioration under cumulative lipid exposure ("cholesterol-years"), though formal mathematical significance is attenuated by the high weight of contemporary short-term cohorts. This biological vulnerability corroborates landmark findings by Kawasuji (2000), which documented saphenous vein patency of only 35% at 8 years in FH (vs. 87% for internal mammary arteries), demonstrating that arterialized hemodynamic stress triggers intimal hyperplasia and accelerated atherosclerosis specifically in venous conduits. These findings align with contemporary evidence from Deconinck (2025) showing persistent high residual risk despite intensive lipid-lowering therapies (OR 2.52). Big Data registries (NIS-USA, n>3.7 million) confirm that FH imposes widespread multivessel disease and highly complex surgeries. In conclusion, FH is a strong predictor of long-term vein graft failure. Multiarterial grafting and aggressive lipid control prevent structural failure and genetic risk.

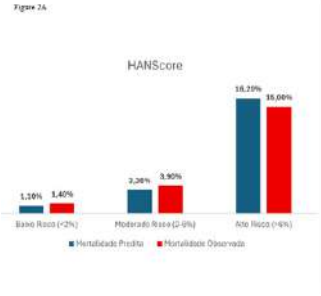
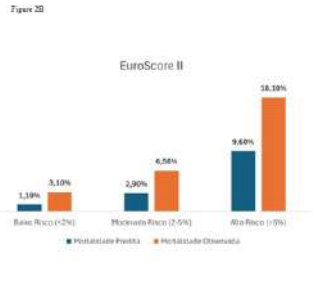
SCORE FOR PREDICTING POSTOPERATIVE MORTALITY IN CARDIAC SURGERY DEVELOPED WITH THE AID OF ARTIFICIAL INTELLIGENCE



MATEUS GOMES DA SILVA SERRA1; JULIA REBECA MENDES VIEIRA1; ANA BEATRIZ GABRIE SILVA RODRIGUES1; GUSTAVO PINHEIRO SANTANA1; CLARA SALES FIGUEIREDO1; CAIO REBOUCAS FONSECA CAFEZEIRO1; LUIZ CARLOS PASSOS1; OSVALDEMAR REGIS DO NASCIMENTO JUNIOR1; JACKSON BRANDÃO LOPES1; RAFAEL FERNANDES ALMEIDA1; EDUARDO LUIZ MATOS FERNANDES1; RODRIGO MOREL VIEIRA MELO1;



(1) HOSPITAL ANA NERY - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Cardiac surgery is an essential therapeutic strategy for several cardiovascular diseases and is widely performed in Brazil. Risk prediction models such as EuroSCORE and STS Score are used to estimate mortality and complications; however, they show limited performance in the Brazilian population due to epidemiological and socioeconomic differences. Objetivos: In this context, the present study aimed to develop a local predictive model for in-hospital mortality in cardiac surgery, named HANScore, using artificial intelligence tools. Métodos: This is an observational, single-center, ambispective study conducted at a tertiary hospital in Northeastern Brazil. A total of 2,768 adult patients who underwent cardiovascular surgery between January 2022 and July 2025 were included. The development cohort consisted of prospective data (2023–2025), while validation was performed using retrospective data from 2022. The primary outcome was in-hospital mortality. The model was built using multivariable logistic regression, with variable selection assisted by artificial intelligence, and validated through calibration (Hosmer-Lemeshow test) and discrimination (AUC-ROC), being compared with EuroSCORE Resultados e Conclusões: The sample had a median age of 58 years, with a predominance of females (53.9%) and a high prevalence of hypertension (64.5%) and diabetes (24.2%). Valve surgeries were the most frequent procedures (57%). Factors associated with higher mortality included renal dysfunction, anemia, advanced age, previous surgery, and complex procedures. The HANScore, composed of 11 variables and stratified into three risk levels, demonstrated superior performance compared to EuroSCORE, with better discriminative ability (AUC 0.774 vs. 0.732) and improved calibration (p=0.250 vs. 0.032). The HANScore demonstrated good accuracy and superiority over EuroSCORE in the studied population, highlighting the importance of local predictive models. Despite limitations such as its single-center design and the relatively low number of events, the model proved adequate in reflecting regional characteristics. Future multicenter studies are required for external validation and to expand its applicability.

ACUTE MYOCARDIAL INFARCTION IN YOUNG ADULTS: ANALYSIS OF IN-HOSPITAL MORTALITY IN BRAZIL (2015–2025)

IGOR MELLO NASCIMENTO1; TÁSSIA CAMILLY FERNANDES2; CAMILA VITÓRIA MAGNAVITA DOS SANTOS3; KAIQUE FONSECA DOS SANTOS2; JÚLIA LOPES SEIXAS PEREIRA1; JÚLIA ROCHA GALVÃO1; ISABELLA HAJ BARBOSA SANTOS3; FERNANDO AMIN SOARES FERREIRA4; LUÍSA VAZ NEPOMUCENO TANAN2; JÉSSICA FEITOSA DE ALMEIDA4;

(1) ESCOLA BAHIANA DE MEDICINA E SAUDE PUBLICA (EBMSP) - SALVADOR - BA - BRASIL; (2) CENTRO UNIVERSITARIO UNIDOMPEDRO - SALVADOR - BA - BRASIL; (3) UNIFACS - SALVADOR - BA - BRASIL; (4) ZARNS - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Lower in-hospital mortality from acute myocardial infarction (AMI) in young adults is often attributed to a lower burden of comorbidities. However, reduced prior exposure to ischemic episodes, related to the hypothesis of ischemic preconditioning described in the literature, raises questions about the mechanisms underlying these more favorable outcomes. Objetivos: To analyze the profile of hospitalizations and in-hospital mortality due to AMI in Brazil from 2015 to 2025, comparing young adults (20–49 years) and individuals aged ≥50 years. Métodos: Ecological, retrospective study using data from the Brazilian Hospital Information System (SIH/SUS), obtained via DATASUS. Hospitalizations due to AMI (ICD-10: I21) under urgent admission were included. Variables analyzed included hospitalizations, in-hospital deaths, and age group. Chi-square test and logistic regression were used, with calculation of odds ratios (OR) and 95% confidence intervals (95% CI). Resultados e Conclusões: Between 2015 and 2025, in-hospital mortality due to acute myocardial infarction (AMI) decreased from 12.27% to 7.53%, with a transient increase in 2020 (10.04%), possibly associated with the COVID-19 pandemic. Hospitalizations totaled 1,396,316, with a decrease in 2020 and subsequent increase. Individuals aged ≥80 years presented the highest mortality rates, although declining over the period. Young adults presented lower mortality (4.40%) compared to those aged ≥50 years (10.62%) (p<0.001). Age ≥50 years was associated with a higher chance of in-hospital death (OR=2.56; 95% CI: 2.50–2.62; p<0.001), with a narrow interval, indicating high precision of the estimate and low influence of random error. A global reduction in mortality is observed, with maintenance of advanced age as the main prognostic factor. The findings suggest that the superiority of cardiovascular reserve and the lower burden of comorbidities prevail over the lack of ischemic preconditioning in young individuals, acting as the main mechanisms for the maintenance of favorable outcomes. The evidence reinforces the need for differentiated healthcare strategies according to age profile. Limitations include the use of secondary data.

APIXABAN VS RIVAROXABAN FOR VENOUS THROMBOEMBOLISM TREATMENT: A SYSTEMATIC REVIEW AND META-ANALYSIS OF SAFETY AND EFFICACY.

JOÃO GABRIEL PALOMARES MENDES1; WESLEY CARDOSO WENDT1; LUIZ DIEGO BRITO PEDROSO1; RICARDO ESTEVÃO MATOS SOUTO2; RENAN DANTAS ANDRADE1; DAVI DE CAMPOS CLEMENTE1; GUILHERME COMNISKY MEZZOMO1; GUSTAVO JABBAR VERGARA1; ALEXANDRE MANFROI PALADINO1; JOÃO MARCOS HOCKMULLER3; RENATO GARCIA LISBOA2;

(1) UNIVERSIDADE DA REGIAO DE JOINVILLE - JOINVILLE - SC - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (3) CENTRO UNIVERSITARIO DE VARZEA GRANDE - UNIVAG - CUIABÁ - MT - BRASIL;

Introdução/Fundamentos: Rivaroxaban and apixaban are direct oral anticoagulants (DOACS) with the function of inhibiting the factor Xa on coagulation cascade. Both drugs have been widely used in treatment of Venous Thromboembolism (VTE). However, direct comparative evidence between these modalities remains conflicting regarding efficacy and safety, with divergent findings regarding bleeding and Thromboembolism recurrency. Objetivos: To conduct a systematic review with meta-analysis to compare the efficacy and safety of apixaban versus rivaroxaban, in the treatment of VTE evaluating critical outcomes such as mortality, bleeding complications, and recurrence on overall population and subgroups. Métodos: A systematic review was conducted, with searches performed in the PubMed, Embase and Cochrane Library (February/2026). Randomized clinical trials and cohort studies were included. In the comparison between rivaroxaban and apixaban on patients diagnosed with VTE, the following outcomes were evaluated: (1) Major Bleeding (MB), (2) VTE recurrence, (3) all case mortality. The meta-analysis was performed using RevMan (v5.4.1) software, study heterogeneity was assessed using Cochran's Q test and I² statistic. Resultados e Conclusões: 40 studies were included, totaling 346.909 patients. VTE had less recurrence on apixaban when compared to rivaroxaban (HR 0.80; 95% CI 0.69-0.93; P<0.05; Fig. 1). Major blending was significantly lower on the apixaban group (RR 0.63; 95% CI 0.45-0.89; P<0.05; Fig. 2). On subgroup analyses, the cancer only population showed no statistical differences on MB between apixaban and rivaroxaban (RR 0.56; 95% CI 0.45-0.89; P=0.39; Fig. 2) however, in the non-cancer subgroup the incidence of MB was significantly lower in apixaban group (RR 0.78; 95% CI 0.61-0.99; P<0.05; Fig. 2); The Overweight subgroup showed no statistical differences (RR 0.71; 95% CI 0.29-1.74; P=0.45) Also, subgroup analyses according to follow-up duration showed no significant differences in studies with follow-up > 6 months (RR 1.10; 95% CI 0.87–1.39; P=0.41) or ≤ 6 months (RR 0.66; 95% CI 0.36–1.22; P=0.18); All case mortality showed no statistical differences between apixaban and rivaroxaban (RR 1.05; 95% CI 0.93–1.19; P=0.42). Conclusion: Apixaban was associated with a lower risk of major bleeding and VTE recurrence compared to rivaroxaban, with no difference in all-cause mortality. The bleeding benefit was more evident in non-cancer patients, with no significant differences across other subgroups.

ARE BIORESORBABLE STENTS AS SAFE AND EFFECTIVE AS CONVENTIONAL DRUG-ELUTING STENTS IN PATIENTS WITH CORONARY ARTERY DISEASE?

BEATRIZ ALMEIDA BERBET1; GUILHERME JOSÉ BRAGA DE PAULA1; CAIO RESENDE SIQUEIRA SANTOS1; ERICO RIBEIRO NETTO1;

(1) UFJF - JUIZ DE FORA - MG - BRASIL;

Introdução/Fundamentos: Chronic stable coronary artery disease (CAD) results from a transient imbalance between myocardial oxygen supply and demand, leading to reversible ischemia. Management is based on comorbidity control, lifestyle modifications, optimized medical therapy, and, when indicated, myocardial revascularization. In this context, percutaneous coronary intervention (PCI) with stent implantation, particularly drug-eluting stents (DES), plays a central role in restoring coronary flow and relieving symptoms. Objetivos: The objective of this systematic review was to synthesize the scientific evidence from studies that compared the efficacy of drug-eluting stents and bioresorbable stents in patients with coronary artery disease. Métodos: A systematic review was conducted based on the PubMed, Cochrane and BVS databases in March 2026. The following descriptors were used: ("Bioresorbable Vascular Scaffold" OR "bioabsorbable stent" OR "bioresorbable scaffold") AND ("Drug-Eluting Stent" OR "everolimus stent") AND ("coronary artery disease" OR "percutaneous coronary intervention"). A total of 231 studies were identified, of which 56 were included in this review. Resultados e Conclusões: It was observed that, over a five-year follow-up period, the use of bioresorbable vascular scaffolds (BVS) was associated with worse outcomes compared to drug-eluting stents (DES), with a higher incidence of target lesion failure and device thrombosis. BVS showed higher rates of subacute thrombosis, which may be associated with a higher rate of residual intra-device stenosis after the procedure. BVS implantation was associated with a significant reduction in intra-arterial myocardial necrosis (cIMR) compared to DES implantation. Both BVS and DES implantation showed comparable rates of target lesion revascularization at 1 year. BVS demonstrated frequent vascular remodeling, with an increase in mean lumen and vessel area compared to DES. Although a slightly greater lumen loss was observed in segments treated with BVS, this difference did not translate into worse clinical outcomes, as no significant differences were found in major adverse cardiovascular events, revascularization, or stent thrombosis in the short term. Both devices demonstrated comparable long-term clinical safety and perfusion efficacy. There was no significant difference between the BVS and metallic stent groups regarding target vessel failure or mortality rates.

ARMENIAN NATIONAL REGISTRY OF MYOCARDIAL INFARCTION (ARMI): FIRST NATIONAL BENCHMARK FOR STEMI CARE, REPERFUSION PRACTICES, AND ONE-YEAR OUTCOMES

HAMLET HAYRAPETYAN1; HAMAYAK SISAKYAN2; MAYRANUSH DRAMBYAN3; MIKAYEL ADAMYAN4; ZARA KARTOYAN5; TIGRAN ASTVATSATRYAN6; SEROB MANUKYAN7; ARAM CHILINGARYAN8; HARUTYUN GHRMAJYAN8; LEVON HAYRAPETYAN1; MARINE SARGSYAN9; ARTUR STEPANYAN10;

(1) EREBUNI MC - ARMENIA; (2) - ARMENIA; (3) ARMENIAN REPUBLICANS MC - ARMENIA; (4) NORK MARASH MC - ARMENIA; (5) ASTGHIK MC - ARMENIA; (6) SHENGAVIT MC - ARMENIA; (7) BEST LIFE MC - ARMENIA; (8) YEREVAN SCIENTIFIC MC - ARMENIA; (9) YEREVAN STATE MEDICAL UNIVERSITY - ARMENIA; (10) GYUMRI MC - ARMENIA;

Introdução/Fundamentos: Coronary artery disease remains the primary driver of mortality in Armenia. Prior to December 2023, no national prospective data existed on reperfusion strategies or STEMI outcomes. The ARMI registry was launched to address this critical evidence gap and establish a foundation for quality benchmarking and improvement. Objetivos: The primary aim was to determine in-hospital mortality across all national STEMI centers. Secondary objectives included evaluating cardiovascular and all-cause mortality, rehospitalization at 30 days and 12 months, the prognostic influence of time-to-treatment delays, and adherence to guideline-recommended reperfusion therapy. Métodos: ARMI is a prospective nationwide registry enrolling consecutive adults (18–93 years) presenting with STEMI within 48 hours of symptom onset across 13 specialized centers. Clinical, procedural, and outcome data were captured using a standardized REDCap platform. All patients underwent structured follow-up at 30 days and 12 months. Enrollment spanned December 2023 through July 2025. Resultados e Conclusões: Results A total of 2,222 patients were enrolled; 1,392 with complete follow-up data were included in this analysis. The cohort was predominantly male (81.1%). Primary PCI was performed in 99.6% of revascularized patients, reflecting near-universal guideline adherence. Overall in-hospital mortality was 3.1%, with cardiovascular etiology accounting for 91% of deaths. LVEF ≤40% was present in nearly two-thirds of in-hospital deaths, underscoring its prognostic significance. Acute heart failure (Killip class 3–4) at presentation was observed in 8.0% of patients and carried substantially worse outcomes: in-hospital mortality of 9.0% and a 12-month all-cause mortality rate of 32%, compared to 8% in the overall cohort. HF-related rehospitalization affected 13% of Killip class 3–4 patients versus 36% overall, reflecting a sustained morbidity burden. Conclusions ARMI provides the first national benchmark for STEMI management in Armenia, demonstrating primary PCI rates and in-hospital mortality comparable to European registries. Acute heart failure at presentation and depressed LV systolic function identify a high-risk population with disproportionately poor short- and long-term outcomes. These data support targeted quality improvement initiatives and lay the groundwork for translational cardiovascular research at the national level.

ASSOCIATED FACTORS OF IN-HOSPITAL DEATH AND PROLONGED STAY IN ACS: A MULTICENTER BRAZILIAN REGISTRY ANALYSIS STRATIFIED BY SUBTYPE

PEDRO CÉSAR REZENDE SEGURADO1; ANA CLARA PIERROTE RODRIGUES VASCONCELOS1; GABRIEL CARVALHO FIUSA2; RODRIGO GÓES DE OLIVEIRA GALVÃO3; NATAN TEIXEIRA DA SILVA3; ANTONIO AURELIO FAGUNDES JÚNIOR1;

(1) UNIVERSIDADE DE BRASILIA - BRASÍLIA - DF - BRASIL; (2) UNIVERSIDADE CATOLICA DE BRASILIA - BRASÍLIA - DF - BRASIL; (3) ESCOLA SUPERIOR DE CIENCIAS DA SAUDE - BRASÍLIA - DF - BRASIL;

Introdução/Fundamentos: Acute coronary syndrome (ACS) remains a leading cause of in-hospital mortality and healthcare resource use worldwide. In middle-income countries, real-world data on factors associated with adverse outcomes across ACS subtypes are scarce. Identifying factors independently associated with in-hospital death and prolonged length of stay (LOS >7 days), overall and by subtype, may refine risk stratification and guide resource allocation. Objetivos: To identify clinical and demographic factors independently associated with in-hospital death and prolonged hospitalization (>7 days) in patients with ACS, both overall and stratified by subdiagnosis (STEMI, NSTEMI, unstable angina [UA]). Métodos: Multicenter retrospective study using a national registry from the largest private hospital network in Brazil, covering 14 states between January 2020 and June 2024. A total of 7,171 ACS patients were analyzed overall and stratified as STEMI, NSTEMI and UA. Multivariable logistic regression models identified factors independently associated with each outcome. Analyses were performed in RStudio. Resultados e Conclusões: Overall, 91 in-hospital deaths and 649 prolonged hospitalizations occurred. Independent factors associated with were age (OR 1.06, 95%CI 1.04–1.08), STEMI (OR 12.41, 95% CI 6.34–25.83), NSTEMI (OR 4.24, 95% 2.28–8.50), heart failure (HF; OR 3.18, 95% CI 1.51–6.25) and chronic kidney disease (CKD; OR 2.35, 95% CI 1.34–3.99). Factors associated with LOS >7d were age (OR 1.02), STEMI (OR 2.06), NSTEMI (OR 1.52), HF (OR 1.55) and CKD (OR 2.38), all p<0.05. By subtype: in STEMI, age was associated with both outcomes. In NSTEMI, age and smoking (OR 1.96, 95% CI 1.00–3.70) were associated with death, while age, CKD (OR 2.31) and HF (OR 1.90) were associated with prolonged LOS. In UA, GRACE score was the sole predictor of death (OR 1.04, 95% CI 1.02–1.05); age, hypertension (OR 1.67) and CKD (OR 2.68) predicted LOS >7d. Taken together, in this large-scale, real-world registry, clinical profiles and factors associated with severity diverged significantly across ACS subtypes. While traditional risk factors like CKD and HF were consistent across the board, the specific impact of smoking in NSTEMI and the GRACE score in UA highlights the need for personalized risk assessment.

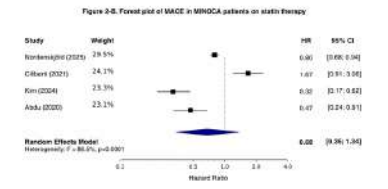
ASSOCIATION BETWEEN STATIN THERAPY AND CLINICAL OUTCOMES IN MINOCA: A SYSTEMATIC REVIEW AND META-ANALYSIS



LEONARDO VILLATORE1; LUIGI AZEVEDO1; FELIPE QUADROS1; PIETRO SANT'ANA1; NICOLE BRANCO1; HELOISA BORAZO1; DANIELA TENIUS1; IASMIM LEMOS1; ALINE BRANCO1; VINICIUS DA SILVEIRA1; LUCAS AZEVEDO2; MARCO AURELIO BORAZO3;

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (2) PONTIFICIA UNIVERSIDADE CATOLICA DE SAO PAULO - SÃO PAULO - SP - BRASIL; (3) HOSPITAL SAO VICENTE DE PAULA - GUARAPUAVA - PR - BRASIL;

Introdução/Fundamentos: Myocardial infarction with non-obstructive coronary arteries (MINOCA) is a complex syndrome affecting 5–10% of acute myocardial infarction patients. Despite lacking obstructive lesions, MINOCA carries a substantial risk of all-cause mortality and major adverse cardiovascular events (MACE). Currently, specific randomized trials are lacking, and secondary prevention relies on empirical observational data, such as the SWEDEHEART registry. However, the efficacy of statins remains debated due to MINOCA's heterogeneous etiology, highlighting the need to quantify their impact on clinical outcomes. Objetivos: To evaluate the impact of statin therapy in patients with MINOCA, focusing on all-cause mortality as the primary outcome and MACE as the secondary outcome. Métodos: This systematic review and meta-analysis was conducted in accordance with PRISMA and prospectively registered in an international database (PROSPERO). A systematic search was conducted in PubMed/MEDLINE and Cochrane CENTRAL to identify observational and randomized studies comparing statin users versus non-users with confirmed MINOCA. Methodological quality was assessed using the Newcastle-Ottawa Scale (NOS). Outcomes were analyzed using Relative Risk (RR) for mortality and Log Hazard Ratios (Log HR) for MACE, with 95% Confidence Intervals (95% CI), employing a random-effects model. Statistical heterogeneity was assessed using the I^2 statistic, and certainty of evidence via the GRADE approach. Resultados e Conclusões: Four studies were included, encompassing 10,383 patients (5,084 in the statin group and 5,299 in the control group). Statin therapy was associated with a statistically significant 50% reduction in the relative risk of all-cause mortality (RR 0.50; 95% CI 0.35–0.72; I^2 = 37.4%; moderate certainty of evidence). Conversely, the numerical benefit of statins in reducing MACE did not reach statistical significance (HR 0.68; 95% CI 0.35–1.34), accompanied by profound heterogeneity (I^2 = 86.5%; very-low-certainty evidence) likely stemming from varied operational definitions across studies. In conclusion, statin therapy is associated with a significant reduction in all-cause mortality in MINOCA patients. Despite the inconclusive data regarding MACE, the overall survival benefit supports the routine use of statins in this population.

ATTENUATION OF THE ASSOCIATION BETWEEN DIABETES AND IN-HOSPITAL MORTALITY IN STEMI AFTER ADJUSTMENT FOR BASELINE CLINICAL SEVERITY

VIVIANE DE OLIVIERA DANTAS1; ANDREA DIAS STEPHANUS1; LUIZ SÉRGIO FERNANDES DE CARVALHO1;

(1) UNIVERSIDADE CATOLICA DE BRASILIA - BRASÍLIA - DF - BRASIL;

Introdução/Fundamentos: Type 2 diabetes is associated with higher in-hospital mortality in ST-elevation myocardial infarction. However, diabetic patients often present with worse clinical status at admission, and it remains unclear whether this association reflects an independent effect or greater baseline severity. Objetivos: To evaluate whether the association between T2DM and in-hospital mortality in STEMI is attenuated after sequential adjustment for baseline clinical severity and to assess its association with in-hospital cardiac complications. Métodos: This retrospective cohort included 2,510 consecutive STEMI patients from two tertiary centers. The association between T2DM and in-hospital mortality was assessed using multivariable logistic regression in three models: Model 1 (diabetes alone), Model 2 (age and sex), and Model 3 (additionally adjusted for LVEF, Killip class, creatinine clearance, heart rate, and SBP at admission). Attenuation across models was quantified on the log-odds scale using the change-in-estimate approach. Model discrimination and calibration were assessed by AUC and Hosmer-Lemeshow test. As a secondary analysis, the association between diabetes and a composite of in-hospital cardiac complications (heart failure, cardiogenic shock, cardiac arrest) was evaluated using similarly adjusted models. Resultados e Conclusões: Among 2,510 patients, 763 (30.4%) had T2DM. In-hospital mortality was higher in diabetics (7.99% vs. 3.66%; p<0.001). The OR for mortality was 2.29 (95% CI 1.59 to 3.28) in Model 1, 2.03 (95% CI 1.40 to 2.93) in Model 2, and 1.34 (95% CI 0.88 to 2.04; p=0.172) in Model 3, corresponding to a 64.7% attenuation. In the fully adjusted model, independent predictors of mortality were LVEF (OR 0.895 per %; 95% CI 0.877 to 0.913; p<0.001), creatinine clearance (OR 0.978 per mL/min; 95% CI 0.970 to 0.986; p<0.001), and age (OR 1.022 per year; 95% CI 1.009 to 1.035; p=0.001). The model showed good discrimination with an AUC of 0.882 and adequate calibration (Hosmer-Lemeshow p=0.109). Composite complications were more frequent in diabetics (51.9% vs 40.9%; OR 1.56; 1.31–1.85; p<0.001), but not after adjustment (OR 1.20; 0.96–1.51; p=0.116). In STEMI, higher in-hospital mortality in patients with diabetes is attenuated after adjustment for baseline clinical severity, particularly ventricular and renal function. A similar pattern is observed for in-hospital cardiac complications, suggesting these differences are explained by baseline clinical severity rather than an independent effect of diabetes.

BETA-BLOCKER THERAPY AFTER ACUTE MYOCARDIAL INFARCTION IN PATIENTS WITH PRESERVED OR MILDLY REDUCED LEFT VENTRICULAR EJECTION FRACTION: AN UPDATED META-ANALYSIS

MARIA EUGÊNIA RODRIGUES PAIVA1; GIOVANNA VILA REAL MARQUES BARRA DE GOUVEIA TREVISAN1; GABRIEL APARECIDO RODRIGUES1; CAROLAINE BRENDA RIDOLFI1; LARISSA DUARTE DE MELO1; SOFIA ANTONIA COHEN COUTO1; LAIANE RODRIGUES MACEDO1; LETICIA RODRIGUES SIMON1; FLÁVIA BEATRIZ DO CARMO MOREIRA1; BEATRIZ DE LIMA VITÓRIO FERREIRA2; BEATRIZ HELENA CERMARIA SOARES DA SILVA1;

(1) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (2) UNIFACISA - CAMPINA GRANDE - PB - BRASIL;

Introdução/Fundamentos: Beta-blockers (BBs) have historically been recommended following acute myocardial infarction (AMI), including in patients with preserved left ventricular ejection fraction (LVEF), based largely on pre-reperfusion era evidence. However, in the contemporary reperfusion era, with widespread adoption of early percutaneous coronary intervention and modern antithrombotic therapies, the incremental benefit of routine long-term BB therapy in patients with preserved or mildly reduced LVEF has become increasingly uncertain. Objetivos: To evaluate the impact of beta-blocker therapy on all-cause mortality and recurrent myocardial infarction in post-AMI patients with preserved or mildly reduced LVEF. Métodos: A systematic review was performed according to PRISMA criteria in the PubMed, Embase, and Cochrane databases. Search strategy included terms “beta blocker therapy,” “myocardial infarction”, “Preserved Ejection Fraction” and “mildly reduced left ventricular ejection fraction”. Studies enrolling post-AMI patients with LVEF ≥40% comparing long-term BB therapy versus standard care were included; studies with reduced LVEF or non-randomized designs were excluded. A total of 442 articles were identified; 19 studies underwent full-text review and 5 were selected. Resultados e Conclusões: The pooled analysis included 5 RCTs comprising 23,531 post-AMI patients with preserved or mildly reduced LVEF, with median follow-up ranging from 3.0 to 3.8 years. Among them, 11,749 received beta-blockers and 11,782 received standard care. All-cause mortality occurred in 477 patients (4.06%) in the beta-blocker group versus 482 (4.09%) in controls, showing no significant difference between groups (RR 0.99; 95% CI 0.87–1.12; p=0.90). Recurrent MI occurred in 468 patients (3.98%) receiving beta-blockers compared with 524 patients (4.45%) in the control group, without statistically significant reduction in risk. Overall, long-term beta-blocker therapy demonstrated neutral clinical outcomes in this population. In post-AMI patients with preserved or mildly reduced LVEF, long-term beta-blocker therapy was not associated with significant reductions in all-cause mortality or recurrent MI, questioning the routine long-term use of beta-blockers in contemporary clinical practice.

CLINICAL IMPACT OF SEX-SPECIFIC HIGH-SENSITIVITY TROPONIN THRESHOLDS IN SUSPECTED ACUTE CORONARY SYNDROME: A SYSTEMATIC REVIEW

MARIA LAURA LUCAS QUEIROZ DE PINHO BARROSO1; BERNARDO LUCAS DE OLIVEIRA1; JULIA KROEHLING GIL1; MARCOS REIS2; ISABELA GALIZZI FAE1;

(1) UNIVERSIDADE FEDERAL DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL; (2) FACULDADE CIENCIAS MEDICAS DE MINAS GERAIS - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: Women presenting with suspected acute coronary syndrome (ACS) typically exhibit lower cardiac troponin concentrations than men, leading to underdiagnosis when universal high-sensitivity cardiac troponin (hs-cTn) thresholds are applied. Sex-specific thresholds have been proposed to improve diagnostic accuracy in women, however, their use remains controversial in current guidelines. Objetivos: To systematically evaluate the impact of sex-specific versus universal hs-cTn thresholds in adults presenting to the emergency department with suspected ACS regarding diagnostic reclassification, diagnostic accuracy (sensitivity and specificity), one-year prognosis and treatment disparities. Métodos: A systematic review was conducted according to PRISMA guidelines. PubMed/MEDLINE was searched for studies comparing universal versus sex-specific hs-cTn thresholds in adults with suspected acute coronary syndrome. Screening involved a blinded dual-review process with a third reviewer for consensus, followed by full-text assessment based on a predefined PICO question. Risk of bias was assessed using the QUADAS-2 tool (Figure 1). Resultados e Conclusões: Sixteen observational studies involving 95,897 patients, including 38,988 women (40.7%), were included (6 hs-cTnI, 8 hs-cTnT, and 2 comparative studies) (Figure 2). Sex-specific thresholds for women increased diagnostic sensitivity, with values ranging from 3.2% to 9.1% across studies, but reduced specificity, with reported values ranging from 3.3% to 17.2%, demonstrating a trade-off between improved detection and reduced specificity. Diagnostic reclassification among women was consistently higher than in men, although most studies reported small absolute changes. Despite increased diagnostic detection, one-year cardiovascular outcomes remained largely unchanged. Overall, evidence supporting routine implementation remained inconclusive. Notably, several studies reported that sex-related disparities in invasive management and evidence-based therapies persisted despite increased ACS detection in women. Sex-specific hs-cTn thresholds increase diagnostic sensitivity and reclassification among women with suspected ACS. However, current evidence does not consistently demonstrate improved clinical outcomes. Routine implementation remains uncertain due to limited clinical benefits, reduced specificity, and persistent sex-related disparities in downstream cardiovascular care.

COMPARATIVE EFFICACY AND SAFETY OF ANTIPLATELET STRATEGIES AFTER CORONARY ARTERY BYPASS GRAFTING: A BAYESIAN NETWORK META-ANALYSIS

WELLGNER FERNANDES OLIVEIRA AMADOR1; MARIA JOSÉ DIAZ-GUTIERREZ2; PANDORA ELOA OLIVEIRA FONSECA1; CAINÃ ARAÚJO SARAIVA1; MARIANO GALLO RUELAS3; GIOVANNA MACANHÃ SCREMIN4; JULIANA GIORGI5;

(1) UNIVERSIDADE FEDERAL DE CAMPINA GRANDE - UFCG - CAMPINA GRANDE - PB - BRASIL; (2) GEORGE WASHINGTON UNIVERSITY - UNITED STATES; (3) INSTITUTO DE INVESTIGACIÓN NUTRICIONAL - PERU; (4) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (5) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Antiplatelet therapy after coronary artery bypass grafting (CABG) is essential to prevent graft failure and adverse cardiovascular events. However, the optimal regimen remains uncertain, particularly regarding the balance between ischemic protection and bleeding risk. Objetivos: To compare the efficacy and safety of different antiplatelet strategies following CABG using a bayesian network meta-analysis of randomized controlled trials (RCTs). Métodos: PubMed, Embase, and Cochrane databases were systematically searched from inception to March 31, 2026, for RCTs comparing antiplatelet strategies after CABG. This systematic review and network meta-analysis followed PRISMA guidelines. The outcomes assessed were graft occlusion, major adverse cardiovascular events (MACE; composite of cardiovascular death, myocardial infarction, stroke, or repeat revascularization), and major bleeding. Risk ratios (RRs) with 95% credible intervals (CrIs) were estimated using a Bayesian random-effects model. Treatments were ranked using the surface under the cumulative ranking curve (SUCRA). Resultados e Conclusões: A total of 31 RCTs including 10,460 patients (mean age, 62.7 years; 87.5% male; 27.5% with diabetes; 64.4% hypertensive) who underwent CABG were included, with a mean follow-up of 14,7 months. Compared with low-dose (LD, 75–100 mg) aspirin, aspirin LD plus clopidogrel loading dose followed by 75 mg daily (RR 0.21; 95% CrI 0.03–0.83; SUCRA 0.97), aspirin LD plus ticagrelor 90 mg twice daily (RR 0.52; 95% CrI 0.33–0.80; SUCRA 0.89), and ticagrelor 90 mg twice daily monotherapy (RR 0.63; 95% CrI 0.44–0.91; SUCRA 0.72) significantly reduced graft occlusion (Figure 1). No strategy demonstrated statistical superiority over aspirin LD for MACE; however, SUCRA rankings favored aspirin LD plus ticagrelor 90 mg twice daily, aspirin LD plus clopidogrel, and aspirin 75–160 mg daily (all SUCRA ≈0.74). For major bleeding, aspirin 81 mg twice daily ranked as the safest strategy (SUCRA 0.97), followed by aspirin LD plus ticagrelor 180 mg (SUCRA 0.57) and aspirin LD monotherapy (SUCRA 0.55). In conclusion, dual antiplatelet therapy reduced graft occlusion without improving MACE compared with aspirin alone. Aspirin-based regimens showed the best safety profile for major bleeding (Figure 2).

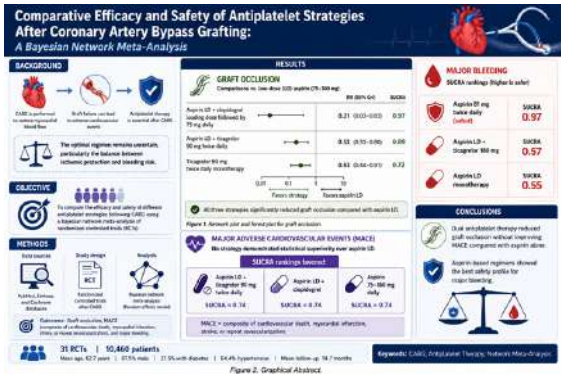

Figure 2. Graphical Abstract.

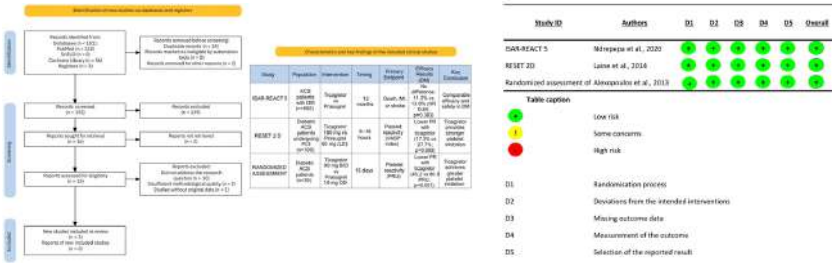


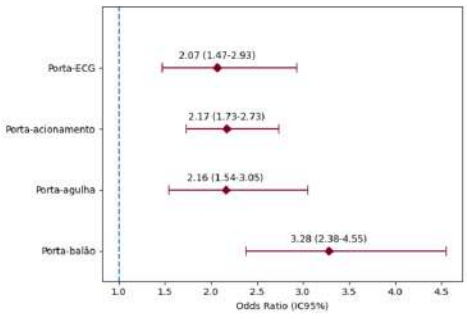
16404

COMPARATIVE EFFICACY AND SAFETY OF TICAGRELOR VERSUS PRASUGREL IN PATIENTS WITH ACUTE CORONARY SYNDROME AND TYPE 2 DIABETES: A SYSTEMATIC REVIEW

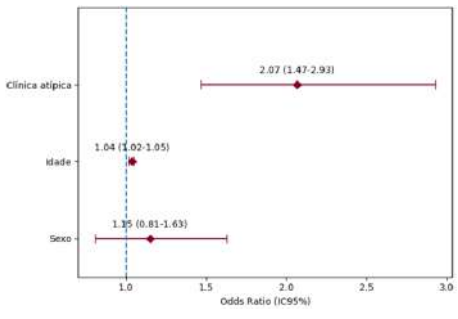
DAVID STEINER LARRAT1; NICOLE PEREIRA MONTEIRO DA CRUZ1; MATHEUS LOPES BITAR MESQUITA2; PEDRO JOSÉ MONTEIRO AOUN COURI3; MARCELA LINS REMOR1; ISABELA NOLETO NOBRE1; ANA CAROLINA WOSNY GUIMARÃES1; RAFAEL PERES MORAIS1; THEO AGUIAR BRITO1; WALTHER AUGUSTO DE CARVALHO1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (3) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Acute coronary syndrome (ACS) in patients with type 2 diabetes mellitus (T2DM) is associated with a higher risk of ischemic events. Platelet hyperreactivity and reduced responsiveness to antiplatelet therapy contribute to this high-risk profile. In this context, P2Y12 receptor inhibitors, such as ticagrelor and prasugrel, represent the cornerstone of antiplatelet therapy, with distinct efficacy and safety profiles. However, the optimal strategy balancing major adverse cardiovascular events (MACE), platelet function, and bleeding risk remains uncertain. Objetivos: To evaluate the comparative efficacy and safety of ticagrelor versus prasugrel in reducing MACE and modulating platelet function in patients with ACS and T2DM, based on evidence from randomized controlled trials (RCTs). Métodos: A systematic review was conducted in accordance with PRISMA 2020 guidelines. Searches were performed in PubMed, SciELO, and the Cochrane Library using DeCS/MeSH descriptors. RCTs assessing the comparative efficacy of these therapies in patients with ACS and T2DM were included. Studies that did not address the research question, were preclinical, conducted in animals, incomplete, or lacked original data were excluded. Study selection was performed independently by three reviewers. Risk of bias was assessed using the RoB 2 tool. Due to heterogeneity, data synthesis was qualitative. Resultados e Conclusões: A total of 181 records were identified, of which three RCTs were included after screening. No significant difference in MACE was observed between ticagrelor and prasugrel in patients with T2DM (HR up to 0.84; 95% CI, 0.58–1.24), with no difference in bleeding risk. In contrast, among patients without T2DM, prasugrel was associated with a lower incidence of MACE (HR 1.70; 95% CI, 1.29–2.24; p<0.001), with a significant interaction according to diabetic status (p=0.0035). Ticagrelor was associated with greater inhibition of platelet reactivity following loading dose compared with prasugrel (p=0.009), without significant differences in high on-treatment platelet reactivity. No consistent superiority was observed in T2DM. The heterogeneity of outcomes and the limited number of studies restrict the generalizability of these findings. The findings do not demonstrate consistent superiority between ticagrelor and prasugrel in patients with T2DM, contrasting with the benefit observed with prasugrel in the overall population. Despite greater platelet inhibition with ticagrelor, its clinical impact remains uncertain.



18037



COMPARISON BETWEEN TYPICAL AND ATYPICAL CLINICAL PRESENTATIONS IN THE JOURNEY OF STEMI PATIENTS: A RETROSPECTIVE COHORT STUDY

VEREDA LINAY DE ALMEIDA COUTO1; HELOISA MARTINS QUADROS2; ANDRÉA SAMPAIO DE OLIVEIRA2; MATEUS XAVIER DOS ANJOS1; EMERSON RAÍ ARAÚJO AZEVEDO1; BRUNA SANTANA RAMOS2; HERBERT FAGUNDES DE SOUZA1; HUGO CARDOSO DE SOUZA FALCON1; POLLIANNA DE SOUZA RORIZ1;

(1) SAMU - SALVADOR - BA - BRASIL; (2) UNIFACS - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: Although certain guidelines discourage the dichotomization between typical and atypical clinical presentations, non-classic manifestations of ST-segment elevation myocardial infarction (STEMI) still lead to delays in patient management and mortality repercussions. Objetivos: This study evaluates the impact of atypical presentation on care timelines and outcomes within a regional STEMI assistance network in Salvador, Brazil. Métodos: The analyzed data includes 1360 STEMI patients enrolled in the regional STEMI care database between May 2021 and March 2026. Patients were scanned for typical pain, described as retrosternal or central chest, tightening, dull, crushing, or heavy. Outcomes include door-to-electrocardiogram (ECG), door-to-activation, door-to-needle, and door-to-balloon times, and mortality rates. Patients assisted outside Salvador, previously hospitalized, or with incomplete data were excluded. Continuous variables were expressed as median [interquartile range] and compared using the Mann–Whitney test; categorical variables were analyzed using the chi-square test. Multivariable logistic regression was used to assess associations, adjusted for age and sex. Resultados e Conclusões: Patients with atypical symptoms are older (64 [57–71] versus(vs.) 61 [53–68] years; p<0.001) and more frequently female (46.4% vs. 35.5%; p<0.001). Significant delay was observed when compared to the typical presentation, with higher door-to-ECG (24.5 [12-62] vs. 14 [8-27] minutes (min); p<0.001), door-to-activation (54 [27.25-121.5] vs 33 [19-59] min; p<0.001), door-to-needle (139 [95-207] vs 110.5 [77.59-159] min; p<0.001) and door-to-balloon times (227.5 [175.25-347] vs 173 [143-224.5] min; p<0.001). In multivariable analysis, atypical presentations remain independently associated with a higher chance of delay in door-to-ECG (OR=2.07; 95% CI: 1.47-2.93; p<0.001), door-to-activation (OR=2.17; 95% CI: 1.73-2.73; p<0.001), door-to-needle (OR=2.16; 95% CI: 1.54-3.05; p<0.001), and door-to-balloon times (OR=3.28; 95% CI: 2.38-4.55; p<0.001). Mortality rates relate to atypical presentations (OR=2.07; 95% CI: 1.47–2.93; p < 0.001) and age (OR=1.04; 95% CI: 1.02–1.05; p < 0.001), but not sex (OR=1.15; 95% CI: 0.81–1.63; p = 0.42). Atypical symptoms in STEMI patients are associated with significant delays in every step of assistance and a marked increase in mortality, reinforcing the need for earlier recognition strategies and sustained clinical vigilance.

CORONARY PLAQUE INSTABILITY: ARE NON-SIGNIFICANT LESIONS THE REAL CULPRIT OF ACUTE CORONARY SYNDROMES?

HANIEL FELIPE DE OLIVEIRA SAMPAIO1; FELIPE CELESTINO MARTINS LOPES1; PEDRO GONÇALVES NOGUEIRA NETO1; SARAH BRAGA DE CASTRO1; CAMILA SOUSA MATOS1; AMANDA LIMA CARVALHO1; ANTÔNIA RAFAELA LIMA DE SOUZA1; ISADORA MARIA FURTADO BARBOSA LOBO1; MARIA FERNANDA FREITAS NUNES1; CAIO CÉSAR FARIAS LIMA MELO1; MATHEUS DUARTE PIMENTEL1; HERALDO GUEDIS LOBO FILHO1;

(1) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Patients with acute coronary syndromes (ACS) may present with obstructive coronary artery disease (CAD) or non-obstructive coronary artery disease (NOCAD). Although obstructive CAD predominates, a consistent proportion of ACS occurs without significant stenosis. Thus, evaluating the incidence and outcomes according to lesion type is essential. Objetivos: To evaluate the incidence and clinical outcomes of ACS according to the presence or absence of obstructive CAD. Métodos: A systematic review was conducted in accordance with PRISMA guidelines. Searches were performed in PubMed, Embase, and Cochrane using predefined descriptors and free-text terms. Eligibility criteria were defined according to the PICO framework. Studies including adult patients with ACS, comparing outcomes between obstructive CAD and NOCAD, were included. Screening was conducted by two reviewers, with discrepancies resolved by consensus. Data extraction focused on ACS incidence and presentation, followed by qualitative synthesis. Resultados e Conclusões: Four studies including 10,200 patients were analyzed. Obstructive CAD accounted for most ACS presentations, while NOCAD was identified in 5–10% of myocardial infarctions and up to 10% of NSTEMI, representing a clinically relevant subgroup despite lower prevalence compared with obstructive CAD. In NSTEMI, mortality was similar at 30 days (1.3% vs 1.0%) and 1 year (2.4% vs 2.6%). However, obstructive CAD showed higher rates of recurrent myocardial infarction (7.6% vs 0.9% at 30 days; 9.8% vs 3.6% at 1 year; HR 0.35, 95% CI 0.12–0.98; p=0.04). Conversely, 1-year mortality was higher in NOCAD (5.2% vs 1.6%; HR 3.44, 95% CI 1.05–11.28; p=0.04). In STEMI, NOCAD was associated with lower mortality (0.8% vs 2.4% at 30 days; 0.8% vs 4.0% at 3 years) and lower major adverse cardiovascular event (MACE) rates (1.6% vs 5.7%; 7.7% vs 22.2%). High-risk plaques were associated with increased event rates (6.4% vs 2.4%), enhancing their prognostic relevance even in absence of significant stenosis. Although obstructive CAD accounts for most ACS presentations, NOCAD represents a clinically relevant subgroup. In NSTEMI, NOCAD is associated with lower rates of recurrent ischemic events but similar all-cause mortality, suggesting a distinct risk profile not driven by coronary events alone. In STEMI, NOCAD is consistently associated with lower mortality and MACE. Additionally, high-risk plaque features are linked to increased adverse events, underscoring the role of plaque vulnerability beyond stenosis severity.

CRITICAL LATE-NIGHT WINDOW IN STEMI CARE: A 3,704-PATIENT ANALYSIS OF MORTALITY AND REPERFUSION DELAYS

JOÃO GABRIEL BATISTA SIMON VIANA1; JEFFERSON HEBER MARQUES FONTES1; MATEUS XAVIER DOS ANJOS1; DANIEL NASCIMENTO MACHADO1; LUIZA CARDOSO ALMEIDA1; CAMILA SAMPAIO SILVA1; EMERSON RAÍ ARAÚJO AZEVEDO1; HERBERT FAGUNDES DE SOUZA1; FRANCISCO MOREIRA CASTRO1; GRACCHO CARDOSO DA SILVA NETO1; RAFAEL HUMMES MULLER1; POLLIANNA DE SOUZA RORIZ1;

(1) SERVIÇO DE ATENDIMENTO MÓVEL DE URGÊNCIA (SAMU) - SALVADOR - BA - BRASIL;

Introdução/Fundamentos: In ST-segment elevation myocardial infarction (STEMI), timely diagnosis and rapid reperfusion are essential determinants of prognosis. However, care processes may be affected by the time of hospital admission. Objetivos: To evaluate whether a critical late-night admission window, identified through hourly mortality distribution, was associated with higher mortality and delays in STEMI care within a regional public reperfusion network. Métodos: Cross-sectional study using a regional STEMI care database (January 2017–April 2026). Patients with STEMI admitted to public healthcare units in Salvador, Bahia, and its metropolitan region were included. Suspected STEMI cases are reported to a multidisciplinary STEMI response team for ECG review, cardiology supervision, and reperfusion guidance. An exploratory hour-by-hour mortality analysis suggested concentration of deaths after midnight; therefore, the 00:00–02:59 window was compared with all other admission times. Hospital mortality, age, sex, Killip class, GRACE score, and care-time intervals were analyzed, including ECG-to-team activation, door-to-needle, door-to-balloon, and total ischemic time. Chi-square, Mann-Whitney, and logistic regression were used, controlling for clinical variables. Resultados e Conclusões: Among 3,704 patients with valid admission-time data, 401 were admitted between 00:00 and 02:59. Groups had similar age (62.7 vs. 62.2 years), male sex distribution (62.6% vs. 60.1%; p=0.344), and mean GRACE score (108.9 vs. 108.0), while Killip III–IV was more frequent in the 00:00–02:59 group (5.5% vs. 3.0%; p=0.011). Mortality was higher during this period (19.4% vs. 13.0%; OR 1.60; 95%CI 1.23–2.10; p=0.001). In logistic regression, the association remained significant after adjustment for age, sex, and Killip class (OR 1.59; 95%CI 1.19–2.11; p=0.001), and after adjustment for GRACE score (OR 1.77; 95%CI 1.17–2.68; p=0.007). The 00:00–02:59 group also had longer ECG-to-team activation time (19 vs. 15 min; p=0.005), door-to-team activation time (80 vs. 46 min; p<0.001), door-to-balloon time (p=0.002), and total ischemic time (198 vs. 182 min; p=0.011). Admission between 00:00 and 02:59 was associated with higher mortality and delays in team activation and reperfusion-related care, suggesting a critical operational vulnerability window in the regional STEMI network.

Table 1. Baseline characteristics, outcomes, and care-time intervals according to admission time

Variable	Other admission times	00:00-02:59	p-value
Patients, n	3303	401	
Age, years, mean ± SD	62.2 ± 12.3	62.7 ± 12.3	0.382
Male sex, n (%)	1 986 (60.1)	251 (62.6)	0.344
GRACE score, mean +/- SD	108.0 ± 28.3	108.9 ± 28.3	0.441
Killip III-IV, n (%)	97 (3.0)	21 (5.5)	0.011
Hospital mortality, n (%)	427 (13.0)	77 (19.4)	0.001
ECG-to-team activation time, min, median [Q1-Q3]	15 [7-33]	19 [8-40.5]	0.005
Door-to-team activation time, min, median [Q1-Q3]	46 [25-99.8]	80 [27.5-667.5]	<0.001
Door-to-needle time, min, median [Q1-Q3]	131 [97-209]	144 [99-227.5]	0.094
Door-to-balloon time, min, median [Q1-Q3]	217 [153-338]	257 [180-386]	0.002
Total ischemic time, min, median [Q1-Q3]	182 [129-260]	198 [122.3-364]	0.011

Note: Care-time intervals are reported as median [Q1-Q3] minutes. ECG, electrocardiogram; GRACE, Global Registry of Acute Coronary Events; SD, standard deviation.

Table 2. Logistic regression for hospital mortality associated with 00:00-02:59 admission

Model	OR	95% CI	p-value
Unadjusted	1.60	1.23-2.10	0.001
Adjusted for age, sex, and Killip class	1.59	1.19-2.11	0.001
Adjusted for GRACE score	1.77	1.17-2.68	0.007

CULPRIT-ONLY VERSUS COMPLETE REVASCULARIZATION IN NSTEMI WITH MULTIVESSEL DISEASE: A BAYESIAN NETWORK META-ANALYSIS

WELLGNER FERNANDES OLIVEIRA AMADOR1; MARIA JOSÉ DIAZ-GUTIERREZ2; PANDORA ELOA OLIVEIRA FONSECA1; CAINA ARAUJO SARAIVA1; MARIANO GALLO RUELAS3; GIOVANNA MACANHÃ SCREMIN4; MRUNALINI DANDAMUDI5;

(1) UNIVERSIDADE FEDERAL DE CAMPINA GRANDE - UFCG - CAMPINA GRANDE - PB - BRASIL; (2) GEORGE WASHINGTON UNIVERSITY - UNITED STATES; (3) INSTITUTO DE INVESTIGACIÓN NUTRICIONAL - PERU; (4) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL; (5) ADVANCED HEART FAILURE AND TRANSPLANT CARDIOLOGY DEPT MONTEFIORE MEDICAL CENTER - UNITED STATES;

Introdução/Fundamentos: Complete revascularization may improve outcomes in non–ST-segment elevation myocardial infarction (NSTEMI) patients with multivessel disease. However, the optimal timing and comparative effectiveness among available strategies remain uncertain. Objetivos: To compare the efficacy of culprit-only versus different complete revascularization strategies in NSTEMI patients with multivessel disease. Métodos: PubMed, Embase, and Cochrane databases were systematically searched from inception to March 31, 2026, for randomized controlled trials (RCTs) and observational studies. This systematic review and Bayesian network meta-analysis followed PRISMA guidelines. The interventions included culprit-only revascularization (COR), immediate complete revascularization (ICR), staged complete revascularization (SCR), and multivessel percutaneous coronary intervention (MV-PCI). The outcomes were: all-cause mortality, myocardial infarction, unplanned revascularization, and major adverse cardiovascular events (MACE). Risk ratios (RRs) with 95% credible intervals (CrIs) were estimated using a Bayesian random-effects model. Treatments were ranked using the surface under the cumulative ranking curve (SUCRA). Resultados e Conclusões: A total of 18 studies (2 RCTs, 16 observational) including 71,033 patients (mean age 71.2 years; 60.5% male; 34.2% diabetes; 59.8% hypertension) were included. No strategy significantly reduced all-cause mortality compared with COR (Figure 1); however, ranking analysis favored ICR as the most effective (RR 0.66; 95% CrI 0.41–1.09; SUCRA 0.77), followed by MV-PCI and SCR, while COR ranked lowest. For MACE, no statistically significant differences were observed; nevertheless, MV-PCI ranked highest (SUCRA 0.64), followed by ICR, COR, and SCR. Regarding unplanned revascularization, MV-PCI showed the greatest probability of benefit (RR 0.21; 95% CrI 0.05–1.04; SUCRA 0.95), followed by ICR, whereas COR consistently ranked worst. For myocardial infarction, ICR was the only strategy associated with a significant reduction compared with COR (RR 0.60; 95% CrI 0.40–0.89), with SUCRA ranking favoring MV-PCI first (SUCRA 0.92), followed by ICR, SCR, and COR. In conclusion, although most pairwise comparisons were not statistically significant, ranking analyses consistently suggest that complete revascularization strategies, particularly ICR and MV-PCI, are associated with more favorable outcomes across clinically relevant endpoints, whereas COR showed the lowest performance (Figure 2).

DIAGNOSTIC PERFORMANCE OF CORONARY CALCIUM SCORE AND EXERCISE STRESS TEST COMPARED WITH CORONARY CORONARY COMPUTED TOMOGRAPHY ANGIOGRAPHY IN THE DETECTION OF CORONARY ARTERY DISEASE.

GIOVANNA ALVAREZ BAGGIO PEREIRA1; LÍVIA PIETSCH CAMILO1; GUSTAVO RIZ1; LUIZ CÉSAR GUARITA-SOUZA1; MARIA ISABEL GOMES TOMASELLI VISENTAINER1; CLAUDIO JOSÉ BELTRÃO JOSÉ BELTRÃO1;

(1) PONTIFICIA UNIVERSIDADE CATOLICA PUC - CURITIBA - PR - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases account for approximately 32% of global deaths, with Coronary Artery Disease (CAD) being the leading cause, often silent and difficult to detect early. Exercise stress testing (EST), widely used due to its low cost, demonstrates sensitivity ranging from 50–72% and specificity from 69–74%. The 2025 Brazilian Guideline for Chronic Coronary Syndrome downgraded EST to a class IIb/B recommendation for CAD investigation, restricting its use to settings without imaging methods. Coronary computed tomography angiography (CCTA) demonstrates sensitivity of 97.8% and specificity of 95.6%, while coronary artery calcium (CAC) scoring is an independent marker of cardiovascular risk. Objetivos: To evaluate the diagnostic accuracy of EST and CAC scoring in identifying CAD using CCTA as the gold standard and analyze the incremental value of combining these methods. Métodos: This observational, cross-sectional, retrospective study was approved by the corresponding Research Ethics Committee. A total of 1,897 patients who underwent CCTA were assessed, with final analysis including 1,550 individuals (764 with CAD and 786 without CAD). CAC was analyzed as a binary variable (≥100 considered positive) and ordinally, while EST was classified as positive or negative for ischemia. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and area under the curve (AUC) from ROC curves were calculated. Initially, isolated analyses of EST and CAC were performed. Subsequently, the model was expanded to include clinical and laboratory variables (age, sex, BMI, HbA1c, lipid profile, hs-CRP, and creatinine), using 5-fold cross-validation and 95% confidence intervals. Resultados e Conclusões: EST (n=204) demonstrated sensitivity of 7.3%, specificity of 94.7%, PPV of 61.5%, NPV of 47.1%, and AUC of 0.51. CAC (n=211) showed sensitivity of 25%, specificity of 85%, PPV of 67.3%, NPV of 48.2%, and AUC of 0.61. The combined model (n=91) demonstrated sensitivity of 70.7%, specificity of 54.5%, PPV of 73.2%, NPV of 51.4%, and AUC of 0.66. The expanded model achieved a mean AUC of 0.66, sensitivity of 40%, and specificity of 87%, showing improvement over isolated tests. In multivariate analysis, hs-CRP was the strongest predictor of CAD, followed by age and CAC, whereas EST contributed minimally. EST demonstrated poor performance for CAD screening, CAC showed a confirmatory role, and inclusion of clinical variables improved risk stratification without replacing anatomical imaging methods.

DOES CT-DERIVED FRACTIONAL FLOW RESERVE REDUCE UNNECESSARY INVASIVE CORONARY ANGIOGRAPHY IN PATIENTS WITH SUSPECTED CORONARY ARTERY DISEASE? A SYSTEMATIC REVIEW OF RANDOMIZED CONTROLLED TRIALS

JOÃO GABRIEL ALVES BARROS1; RUBEM CANTAO DA SILVA NETO1; LARISSA ESPINDOLA LOBATO1; ANA LYGIA DOS SANTOS CORREA PRADO1; JOAO PEDRO RUFFEIL OLIVA1; MAYANA MARQUES LISBOA1; GIOVANNA BARCELOS FONTENELE PEREIRA2;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Coronary artery disease (CAD) is the leading global cause of death, affecting 197 million people worldwide. Coronary computed tomography angiography (CCTA) is a first-line diagnostic test, but its moderate specificity leads to high rates of invasive coronary angiography (ICA) without functionally significant obstructive disease, accounting for up to 45% of elective catheterizations. CT-derived fractional flow reserve (CT-FFR) was developed to overcome this limitation by noninvasively estimating the hemodynamic significance of coronary stenosis. However, evidence supporting its clinical impact is limited to a few randomized controlled trials (RCTs). This systematic review aimed to synthesize these findings. Objetivos: To qualitatively assess the effectiveness of CT-FFR combined with CCTA versus standard care in adult patients with suspected CAD. Métodos: This study is a systematic review of RCTs conducted in accordance with PRISMA guidelines. Searches were performed in the PubMed, Cochrane, and Embase databases. Of the 187 records identified, 4 RCTs were included, comparing CT-FFR combined with CCTA versus isolated CCTA or standard care in adult patients with suspected CAD. The outcomes assessed were the reduction of unnecessary referrals for ICA and the safety of the method based on rates of Major Adverse Cardiovascular Events (MACE) and mortality. Risk of bias assessment was performed using the Cochrane RoB2 tool. Resultados e Conclusões: The 4 RCTs included 9,261 participants: FORECAST (UK, n=1,400, 2021), PRECISE (international, n=2,103, 2023), Guo et al. (China, n=5,297, 2024), and Qian et al. (China, n=461, 2025). Significant reductions in ICA rates were observed in the CT-FFR groups across all studies evaluating this outcome, with absolute reductions ranging from 2.4% to 19.3%. In PRECISE, the CT-FFR-based strategy reduced catheterizations without obstructive CAD by 76% (HR 0.24; 95% CI 0.16–0.36). No statistically significant differences in MACE rates were observed between groups, suggesting the strategy's safety. Limitations included heterogeneity among comparators and a maximum follow-up of 2 years. Overall, CT-FFR combined with CCTA consistently reduced unnecessary ICA while maintaining clinical safety by not increasing adverse events. Further studies with longer follow-up and cost-effectiveness analyses across healthcare systems are needed to strengthen these findings.

EARLY ADMINISTRATION OF PCSK9 INHIBITORS COMBINED WITH HIGH-INTENSITY STATINS VERSUS HIGH-INTENSITY STATINS ALONE IN PATIENTS WITH ACS: A SYSTEMATIC REVIEW

JULIA DE ANDRADE MELLO BRASIL MONTEIRO1; JULIA SCHNEIDER SANTIAGO2; EDUARDO COIMBRA COELHO DE ASSIS2; JOÃO CARLOS DA COSTA MENDES FILHO2; VICENZO LORENZONI VALE3; JOÃO VITOR DOS SANTOS VASCONCELOS3; GIOVANNA BARCELOS FONTENELE PEREIRA1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (3) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Reducing low-density lipoprotein cholesterol (LDL-C) in patients with acute coronary syndromes (ACS) is directly associated with a lower incidence of ischemic events. Currently, the earliest possible administration of high-intensity statin therapy is the gold standard for ACS treatment. However, achieving therapeutic LDL-C targets remains challenging in this population. In this clinical setting, proprotein convertase subtilisin/kexin type 9 (PCSK9) inhibitors have emerged as a potential adjunct to high-intensity statins to reduce LDL-C levels more rapidly and effectively. Objetivos: To evaluate the clinical benefit of in-hospital administration (within 24–72 hours of presentation) of PCSK9 inhibitors combined with high-intensity statin therapy in ACS patients, focusing on LDL-C level assessment and the impact during the post-ACS vulnerable period. Métodos: A systematic review was conducted following the PRISMA guidelines, based on searches in PubMed, Embase, and Cochrane databases. The MeSH terms used were: "Acute Coronary Syndrome", "PCSK9 Inhibitors", "Standard of Care", "Cholesterol, LDL", and "Myocardial Infarction/prevention and control", covering the period from 2019 to April 2026. Only randomized clinical trials (RCTs) were included. Eleven articles were screened, of which three met the inclusion criteria, the most recent being from February 2026. Inclusion was based on a rigorous assessment of eligibility criteria and methodological quality certification using the RoB 2 tool. Resultados e Conclusões: All evaluated studies demonstrated that early administration of PCSK9 inhibitors, alongside high-intensity statins, resulted in a sustained and more efficient reduction of LDL-C levels compared to high-intensity statin monotherapy, enabling up to 95% of patients to reach recommended therapeutic targets. Consequently, LDL-C reduction promotes vulnerable plaque stabilization and reduces total atheroma volume, decreasing the likelihood of major adverse cardiovascular events (MACE), such as acute myocardial infarction. Despite promising data, further large-scale, long-term randomized clinical trials are essential to confirm these findings.

21111

EARLY INITIATION OF PCSK9 INHIBITORS AFTER ACUTE CORONARY SYNDROME: EFFECTS ON LDL REDUCTION AND CLINICAL OUTCOMES – A SYSTEMATIC REVIEW

LETICIA HELENA DOS SANTOS SILVA1; RAFAELLA DE LISIEUX GAIA OLIVEIRA1; CARLA FERNANDA VEIGA PIMENTEL1; PAULA RAPHAELLA DA SILVA MELO1; FRANCISCO DE ASSIS COSTA1;

(1) CENTRO UNIVERSITARIO DE MACEIO - UNIMA / AFYA - MACEIO - AL - BRASIL;

Introdução/Fundamentos: Patients with Acute Coronary Syndrome are at high risk for recurrent cardiovascular events, especially in the early phase after the initial event. Although intensive statin therapy is the standard treatment, many patients do not achieve the recommended LDL levels. Early initiation of PCSK9 inhibitors may provide rapid LDL reduction and potential clinical benefits; however, evidence regarding their impact on cardiovascular outcomes in this setting remains limited. Objetivos: To evaluate the efficacy and safety of the early initiation of PCSK9 inhibitors in patients with Acute Coronary Syndrome, focusing on LDL reduction and cardiovascular outcomes. Métodos: The proposed study is a systematic review whose searches were conducted in the PubMed scientific database, including articles published within the last 10 years. The search was carried out using the descriptors: “acute coronary syndrome” OR “myocardial infarction” AND “PCSK9 inhibitors” OR “evolocumab” OR “alirocumab” AND “early” OR “acute phase”. Studies without theoretical reflection, theses, dissertations, and review articles were excluded. Selection was performed through titles, abstracts, and full-text reading. In the end, eleven studies were analyzed. Resultados e Conclusões: Early administration of PCSK9 inhibitors after Acute Coronary Syndrome is associated with rapid and significant reductions in LDL-C and other atherogenic markers, including lipoprotein(a) and apolipoprotein B, allowing most patients to achieve recommended lipid targets early. This strategy also appears to reduce major adverse cardiovascular events in the short term without increasing adverse effects, suggesting a favorable safety and efficacy profile. However, further large-scale randomized studies are needed to confirm their impact on long-term clinical outcomes.

EARLY RISK STRATIFICATION IN ACUTE CORONARY SYNDROME: PERSPECTIVES FROM EMERGING BIOMARKERS

KAREN CRISTINA ADELINO PINTO1; KIARA ADELINO PINTO1; EMILLY MEDEIROS RICARTE1; LARISSA FARIAS SOUSA2; ANA KARINE ROCHA DE MELO LEITE1;

(1) UNIVERSIDADE ESTADUAL DO CEARÁ (UECE) - QUIXERAMOBIM - CE - BRASIL; (2) UNIVERSIDADE ESTADUAL DO CEARÁ (UECE) - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Acute Coronary Syndrome (ACS), caused by a marked reduction or interruption of cardiac blood flow—as seen in Myocardial Infarction (MI) and Unstable Angina—represents the leading cause of global mortality and disability, requiring precision diagnostic strategies to mitigate fatal outcomes. Currently, markers such as troponin T and B-type natriuretic peptide (BNP), associated with the GRACE score, are used for diagnosis and risk stratification. However, some biomarkers exhibit low specificity or delayed release, hindering early management. Thus, the investigation of new markers represents a significant advancement in cardiology. Objetivos: To analyze the efficiency of new cardiac biomarkers in the diagnosis and early risk stratification of ACS. Métodos: Qualitative systematic review conducted according to PRISMA guidelines. The search was performed in the Scopus (n=10), Embase (n=73), and PubMed (n=184) databases between 2021 and 2026, using the descriptors “Acute Coronary Syndrome” AND Biomarkers AND Troponin AND “Risk Score”. Reviews and research focused exclusively on troponin, isolated diagnosis, or non-laboratory markers were excluded. Selection, performed by two independent reviewers using Rayyan, resulted in the inclusion of 9 studies. Resultados e Conclusões: Urea-to-creatinine ratio, albumin-to-creatinine ratio, albumin activity index, NT-proBNP, Apo AI, KIM-1, and DPP3 were identified as predictors of in-hospital mortality in ACS. Growth Differentiation Factor-15 (GDF-15) stood out among inflammatory cytokines as an independent predictor of MI and death, surpassing BNP with accuracy comparable to high-sensitivity troponin T (hs-cTnT). The association of hs-cTnT with cMyBP-C or copeptin showed high reliability for diagnostic rule-out, especially in patients with chronically elevated troponin. The marker S100A8/A9 stood out for directly assisting in therapeutic guidance. Furthermore, factors such as sex, age, and comorbidities influence biomarker cutoff values. Unlike other markers, the reduction of miR-30c-5p presented diagnostic and prognostic value in ACS. Combining multiple biomarkers with the GRACE score improved risk discrimination, reinforcing ACS as a multi-organ stress condition and allowing the incorporation of inflammatory, hepatic, renal, cardiac, and hematologic markers into early stratification, favoring clinical decisions and better outcomes.

ECONOMIC AND CLINICAL BURDEN OF CORONARY ANGIOPLASTY WITH STENT IN THE BRAZILIAN PUBLIC HEALTH SYSTEM: A NATIONWIDE ANALYSIS FROM 2020 TO 2025

MELINA CONDE MAUES LIMA1; FABRICIO BACELAR MARINHO FILHO2; MARIA FERNANDA CAMPOS NEVES DOS SANTOS2; KELLY CRISTINA COSTA GUEDES NASCIMENTO1; GIOVANNI MONTEIRO MATOS3; DILMA COSTA DE OLIVEIRA NEVES3; SOFIA OLIVEIRA DA COSTA1;

(1) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (3) CESUPA - BELEM - PA - BRASIL;

Introdução/Fundamentos: Coronary angioplasty with stent is a cornerstone of contemporary management of coronary artery disease, especially in acute and high-risk ischemic settings. In publicly funded health systems, understanding its temporal and regional burden is essential to guide resource allocation and cardiovascular care planning. Objetivos: To analyze temporal trends and regional disparities in hospital admissions, costs, in-hospital mortality, and length of stay related to coronary angioplasty with stent in the Brazilian Unified Health System (SUS) from 2020 to 2025. Métodos: This was an ecological, retrospective, nationwide study based on secondary data from the Hospital Information System of SUS. The procedure analyzed was coronary angioplasty with stent implantation. Approved hospital admission authorizations, total reimbursed values, in-hospital deaths, and mean length of stay were assessed by year and region. Descriptive analysis was performed, including temporal variation and proportional in-hospital mortality. Resultados e Conclusões: From 2020 to 2025, 299,192 hospital admissions for coronary angioplasty with stent were approved in SUS, totaling R$1,757,816,033.27, with 4,393 in-hospital deaths and an overall mean length of stay of 3.2 days. Admissions increased from 45,758 in 2020 to 60,349 in 2025 (+31.9%), while total costs rose from R$257,849,156.55 to R$402,537,005.65 (+56.1%), indicating growth disproportionate to procedural volume. Mean cost per admission also increased from R$5,635.06 to R$6,670.15 (+18.4%). Absolute in-hospital deaths increased from 740 to 826 (+11.6%), although proportional mortality fell from 1.62% to 1.37%, alongside a slight reduction in mean length of stay from 3.3 to 3.1 days. Across the 2020–2025 period, the Southeast concentrated the greatest burden, accounting for 48.7% of admissions and 48.7% of total expenditure, whereas the Midwest showed the highest cumulative proportional mortality (2.21%) and the Northeast the longest cumulative mean stay (3.8 days). These findings suggest increasing financial pressure of interventional cardiology on SUS, with persistent regional inequalities. Although selected performance indicators modestly improved over time, these findings highlight the growing procedural and economic burden of coronary angioplasty with stent in SUS and support further planning strategies to reduce regional inequalities and optimize high-complexity cardiovascular care.

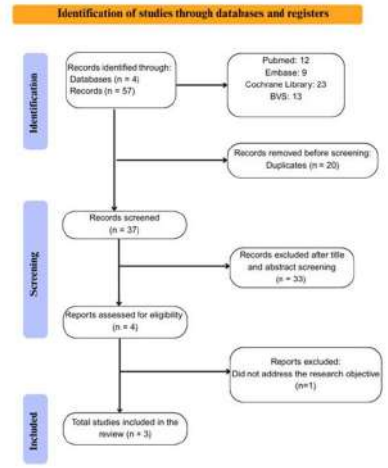
20295

EFFICACY AND SAFETY OF SECONDARY PREVENTION IN MINOCA: A MECHANISM-ORIENTED SYSTEMATIC REVIEW AND META-ANALYSIS

BEATRIZ DE LIMA VITORIO FERREIRA1; FLAVIA BEATRIZ DO CARMO MOREIRA2; MARCOS AURELIO FONSECA MEDEIROS1; EVELIN GABRIELLY DE VARGAS2; MARIANA VIDAL MIYAZATO2; PEDRO DE ARAUJO SANTOS1; BIANCA RIBEIRO CORREIA LIMA3; LUCAS MANOEL BORGES DOURADO2; ANNE KAROLLYNE ALVARES SANTOS2;

(1) UNIFACISA - CAMPINA GRANDE - PB - BRASIL; (2) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (3) UNIPE - JOÃO PESSOA - PB - BRASIL;

Introdução/Fundamentos: Myocardial infarction with non-obstructive coronary arteries (MINOCA) accounts for 6–15% of myocardial infarctions and is associated with substantial risk of major adverse cardiovascular events (MACE) and mortality. The role of standard secondary prevention therapies remains uncertain, as these patients were largely excluded from randomized trials. Objetivos: To evaluate the efficacy (mortality and MACE) and safety (etiology-specific adverse events) of statins, ACE inhibitors/angiotensin receptor blockers (ACEi/ARB), beta-blockers, dual antiplatelet therapy (DAPT), and aspirin in MINOCA patients. Métodos: This systematic review and meta-analysis followed PRISMA guidelines. A structured PubMed search identified observational cohorts and post-hoc analyses of randomized trials. Studies were screened independently using predefined criteria: (1) clear MINOCA definition, (2) follow-up ≥1 year, and (3) reporting adjusted hazard ratios (HR) for mortality or MACE and/or safety outcomes. Extracted data included HRs with 95% confidence intervals and adverse events stratified by mechanisms (e.g., vasospasm, Takotsubo syndrome, microvascular dysfunction). Heterogeneity was assessed using I^2, and pooled estimates calculated with a random-effects model. Resultados e Conclusões: Seven studies (n = 39,273) were included. Statins showed the most consistent benefit, reducing mortality (HR 0.60–0.71) and MACE (HR 0.77). ACEi/ARB were associated with reduced MACE (HR 0.65–0.82), without significant mortality benefit. Beta-blockers showed benefit in subgroups, especially Takotsubo syndrome, but borderline overall effects. Antiplatelet strategies raised concerns: although DAPT reduced mortality in pooled analyses, intensified regimens increased adverse events, and aspirin was associated with increased MACE and potential harm in vasospastic mechanisms. Treatment effects varied by etiology. Statins provide the most consistent mortality benefit in MINOCA, while ACEi/ARB reduce MACE. Beta-blockers may benefit selected subgroups. Routine antiplatelet strategies—especially aspirin and intensified DAPT—may be harmful in non-atherosclerotic mechanisms. These findings challenge uniform secondary prevention and support a mechanism-guided approach. Results should be interpreted considering heterogeneity and predominance of observational data.



20194

EFFICACY OF EZETIMIBE COMBINED WITH ATORVASTATIN COMPARED TO ATORVASTATIN MONOTHERAPY IN PATIENTS WITH CORONARY ARTERY DISEASE AND TYPE 2 DIABETES MELLITUS: A SYSTEMATIC REVIEW OF RANDOMIZED CONTROLLED TRIALS.

MARIA GIOVANNA DA CRUZ TOCANTINS1; LUANA KAORI KAORI SAKAGUCHI SAKAMOTO1; STER MARQUES DE LIMA SILVA1; CAREN SILVA SANCHES1; EVA LUDMILA DO SOCORRO DA CRUZ MARQUES1; FLÁVIA SOEIRO SALGADO1; IRIA VICTORIA BARRETO MAIA1; VITÓRIA CAMPOS CORDEIRO1; LEONARDO GOUVÊA DE OLIVEIRA1; LEONAN SILVA DA SILVA1; ALANNE RYLLARI DA SILVA DOS SANTOS1; DANILLO MONTEIRO PORFÍRIO2;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL;

Figure 1. PRISMA flow diagram

Introdução/Fundamentos: Coronary artery disease (CAD) is frequently associated with type 2 diabetes mellitus (T2DM) and may lead to serious complications. Traditionally, treatment involves statins, particularly atorvastatin. However, this population has greater difficulty achieving LDL targets due to the limited reduction provided by these drugs. In this context, the combination of atorvastatin and ezetimibe emerges as an alternative therapeutic strategy. Objetivos: To evaluate the efficacy of ezetimibe added to atorvastatin compared with atorvastatin monotherapy in patients with coronary artery disease (CAD) and type 2 diabetes mellitus (T2DM). Métodos: Systematic review conducted in accordance with PRISMA guidelines. Searches were performed in April 2026 in PubMed, Cochrane Library, Embase, and BVS using the descriptors (DeCS/MeSH) “Coronary Artery Disease,” “Diabetes Mellitus,” “Atorvastatin,” and “Ezetimibe,” combined with the Boolean operator AND. Only randomized controlled trials (RCT) were included. The primary outcome was LDL reduction; outcomes related to atherosclerotic plaque and inflammatory markers were also assessed. Study selection was performed by two independent reviewers, and risk of bias was assessed using the RoB 2 tool. Resultados e Conclusões: A total of 57 articles were identified, of which three comprised the final sample (Figure 1). All studies demonstrated a reduction in LDL levels in both groups, as summarized in Table 1. In the study by Wang et al., the reduction was significantly greater in the intervention group ($p < 0.05$), as was the case for high-sensitivity C-reactive protein (hs-CRP) and atherosclerotic plaque area ($p < 0.05$). Similarly, Uemura et al. observed a greater reduction in LDL in the intervention group, with no assessment of inflammatory or plaque-related outcomes. In contrast, Koshelskaya et al. reported reductions in LDL and inflammatory markers in both groups, with no significant difference between them. A non-significant increase in endothelin-1 was observed in the control group, and no plaque-related outcomes were assessed. Risk of bias analysis indicated high risk in two studies (Uemura et al. and Koshelskaya et al.) and some concerns in Wang et al. Therefore, combination therapy appears to promote greater LDL reduction compared with monotherapy, particularly in this population. However, these findings should be interpreted with caution due to the risk of bias, and larger studies with quantitative analyses are needed for confirmation.

Table 1. Data presented as reported in the original studies. # Uemura et al. corresponds to a crossover RCT; follow-up duration is presented per intervention period. *Baseline value of the sample. Note: Data were presented as reported in the original studies, without standardization or additional statistical analyses.

Author, Year, and Country of Publication	Intervention	Control	Sample characteristics	Follow-up duration	LDL (Intervention)	LDL (Control)	Secondary outcomes	Statistical significance intergroup
Wang *et al.*, 2017; China	Ezetimibe 10 mg/day + atorvastatin 20 mg/day	Atorvastatin 20 mg/day	n = 100; age: 57.2 ± 16.6 years; men: 61%	12 months	LDL reduction : 3.53 → 1.67 mmol/L ($p < 0.05$)	LDL reduction : 3.45 → 2.04 mmol/L ($p < 0.05$)	Reduction in hs-CRP and atherosclerotic plaque area in both groups, more pronounced in the intervention group ($p < 0.05$).	$P < 0,05$
Uemura *et al.*#; 2012; Japan	Ezetimibe 10 mg/day + atorvastatin 10 mg/day	atorvastatin 20 mg/day	n = 39; age: 67.8 ± 9.7 years; men: 76.9%	crossover RCT: 12 weeks per period (total: 24 weeks)	LDL reduction : 111.6* → 82.9 mg/dL ($p < 0.05$)	LDL reduction : 111.6* → 98.4 mg/dL ($p < 0.05$)	Inflammatory or atherosclerotic plaque-related outcomes were not assessed.	$P < 0,05$
Koshelskaya *et al.*, 2014; Russia	Ezetimibe 10 mg/day + atorvastatin 10–20 mg/day	atorvastatin 10–40 mg/day	n = 60; age (range): 43–78 years; men: not reported	6 months	LDL reduction : 4.09 → 2.30 mmol/L ($p \leq 0.01$; 49.2% reduction)	LDL reduction : 4.24 → 2.42 mmol/L ($p \leq 0.001$; 42.5% reduction)	hs-CRP, TNF-α, and IL-1β decreased significantly in both groups; endothelin-1 showed a non-significant increase only in the control group (0.31 → 0.42; $p = 0.06$).	Between-group comparison not reported.

EFFICACY OF PATHOPHYSIOLOGICAL MECHANISM-GUIDED PHARMACOLOGICAL TREATMENT IN PATIENTS WITH MYOCARDIAL ISCHEMIA WITH NON-OBSTRUCTIVE CORONARY ARTERIES: A SYSTEMATIC REVIEW.

INGRA MOREIRA DE ARAÚJO ROCHA1; ALICE PETROLA BEZERRA SAYÃO1; ISABELA PERINI TEIXEIRA1; RYAN LUCAS CRUZ AGUIAR1; ISABELLE DE MORAIS VERAS HOLANDA1; CLARA DE ANDRADE SOUZA1; CELINA CASTRO RIBEIRO1; LUCAS ROMERO CARVALHO1; OTAVIO PEREIRA SILVA FILHO1; LÍDIA DE CASTRO BRITO1; RAFAELA ALBUQUERQUE OTHON SIDOU1; DAVI LIMA RABÊLO DE MELO2;

(1) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL; (2) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Myocardial ischemia without coronary obstruction (INOCA) affects up to 50% of patients with angina who undergo coronary angiography, impacting quality of life and the use of healthcare services. Its heterogeneous pathophysiology requires mechanism-specific therapeutic approaches; however, the available evidence remains fragmented, hindering the guidance of individualized management and reinforcing the need for a systematic synthesis. Objetivos: To evaluate the efficacy of pharmacological treatment guided by pathophysiological mechanisms in patients with INOCA, focusing on symptom reduction and improvement in quality of life and cardiovascular parameters. Métodos: A systematic review conducted in accordance with the PRISMA guidelines and registered in the PROSPERO database (CRD420261359282). The search was conducted in the PubMed, Embase, and Cochrane Library databases. After removing duplicates, 222 studies were identified, of which 93 were selected for full-text review, and 19 were included in the final analysis. Resultados e Conclusões: Approximately 3,200 patients were included. Mechanism-guided treatment demonstrated an improvement of +11.7 points on the SAQ (95% CI 5.0–18.4; $p = 0.001$), with a 35.5% loss of diagnostic accuracy in the control group compared to 2.7% in the intervention group. Regarding microvascular dysfunction, ranolazine showed no benefit in the general population, but was effective in the subgroup with CFR < 2.5: improvement in MPRI ($p = 0.0137$) and angina frequency ($p = 0.027$), with symptomatic variation correlated with myocardial perfusion reserve ($r = 0.25$; $p = 0.005$). In vasospasm, fasudil resulted in the absence of ischemia in 85% of patients; cilostazol promoted an improvement of ≥ 10 points on the SAQ in 86% of patients refractory to two calcium channel blockers (CCBs), with a 54% reduction in emergency department visits. Prolonged use of nitrates was associated with a higher incidence of cardiovascular events (19.8% vs. 8.3%; HR 5.18). In conclusion, pharmacological treatment guided by pathophysiological mechanisms demonstrated greater efficacy than empirical approaches in patients with INOCA, with benefits in symptoms, quality of life, and functional parameters, particularly in subgroups with microvascular dysfunction and coronary vasospasm. Non-targeted therapies may be ineffective or associated with worse outcomes. However, the scarcity of consistent prospective studies reinforces the need for new clinical trials to consolidate this strategy.

Introdução/Fundamentos: Chest pain requires rapid risk stratification. The HEART score is the standard tool for predicting MACE, but inflammation plays a key role in plaque pathophysiology. This study evaluates the Systemic Immune-Inflammatory Index (SII), calculated using the formula Platelets×Neutrophils/Lymphocytes, as a potential adjunct in risk stratification. Objetivos: To assess whether the addition of the SII to the HEART Score improves the predictive accuracy for 30-day MACE in patients with NSTE-ACS. Métodos: Retrospective, observational, single-center study. Patients aged >18 years with a diagnosis of NSTE-ACS who underwent cardiac catheterization and had complete clinical data were included. Exclusion criteria were stable angina, hepatic failure, hematological, oncological, inflammatory and infectious diseases, creatinine clearance <60 ml/min/m², and incomplete medical records. Of 985 patients screened, 169 met the inclusion criteria. The primary endpoint was a composite of death, new MI, PCI, CABG at 30 days, and the presence of a critical coronary lesion on clinical treatment, with individual components also analyzed separately. Statistical analysis was performed using ROC curves with AUC calculation to assess model discrimination and logistic regression, with a significance level of 5%. Artificial intelligence was used to support literature review, proofreading, and translation. Resultados e Conclusões: In the ROC analysis for the primary endpoint, the HEART Score alone yielded an AUC of 0.620 (P = 0.077), and the SII alone yielded an AUC of 0.574 (P = 0.218), both without statistical significance. The SII × HEART Score interaction product demonstrated superior and statistically significant discriminatory performance (AUC = 0.636; P = 0.044), with a sensitivity of 74.2% and specificity of 54.6% at a cutoff of >34.09. In logistic regression analysis for individual endpoints, the SII × HEART Score was an independent predictor of 30-day mortality (OR = 3.4; 95% CI 1.09–10.59; P = 0.034) and of new MI at 30 days (OR = 1.57; 95% CI 1.12–20.77; P = 0.034). The SII alone was not a significant independent predictor in any of the logistic regression analyses. In conclusion, The SII × HEART Score product outperformed either index alone, serving as an independent predictor of 30-day mortality and PCI, suggesting additional value of the SII in risk stratification.

HEALTHCARE QUALITY OF ST-SEGMENT ELEVATION MYOCARDIAL INFARCTION PATIENTS IN PUBLIC VS. PRIVATE HEALTH SYSTEMS IN BRAZIL

GIOVANA RECH1; LARISSA HABCKOST MAZZOLA SILVA1; CRISTINA KLEIN WEBER1; JOAO PAULO BEILNER HOLZ1; THIAGO DE ALMEIDA SALLES1; GIULIA BONATTO REICHERT1; EDUARDO TARASCONI RUSCHEL1; MARCIA MOURA SCHMIDT1; ALEXANDRE SCHAAN DE QUADROS1;

(1) INSTITUTO DE CARDIOLOGIA / FUNDAÇÃO UNIVERSITARIA DE CARDIOLOGIA - PORTO ALEGRE - RS - BRASIL;

Introdução/Fundamentos: The Brazilian public healthcare system is free and available to all Brazilian citizens, but individuals may choose to contract private healthcare. The association between type of healthcare with clinical characteristics and outcomes in patients with ST-segment elevation myocardial infarction (STEMI) in Brazil has not been adequately investigated. Objetivos: To compare clinical characteristics and outcomes among ST-segment elevation myocardial infarction patients who received public care versus those receiving private care. Métodos: Prospective cohort with all STEMI patients submitted to primary percutaneous coronary intervention (pPCI) in a tertiary cardiology center, from January 2010 to December 2024. T-test and Chi-square were performed. A p < 0.05 was considered statistically significant. Resultados e Conclusões: 6.864 patients were included, 80% from public health care and 20% from private. Public patients were younger, more frequently female, less frequently white, and had lower educational levels and income. They presented more smoking and less hypertension, dyslipidemia and family history of CAD (Coronary Artery Disease), as demonstrated in Table 1. They presented later to the hospital (4.83 hours [3-7] vs. 3 hours [1.55-5.56]; p<0.001), but had a lower door-to-balloon time (63 minutes [46 ; 87] vs. 71 minutes [51 ; 98]; p<0.001). The total ischemic time (5.84 hours [3.98 –8.50] vs 4.33 hours [2.83–6.96]; p<0.001) was higher in patients from the public system. Baseline angiographic characteristics and success rates of pPCI were similar between groups with a 98% angiographic success rate in the public system and 97% in the private system (p = 0.232). Medications administered in the first 24 hours of hospital admission were in accordance with current CAD guidelines, and did not significantly differ between groups. At hospital discharge, patients in the public were less likely to receive prescriptions of ticagrelor, prasugrel, and angiotensin II receptor blockers than private patients. Long-term follow-up was obtained in 90% of patients, with a mean duration of 328 ± 216 days. There were no significant differences in-hospital and long-term outcomes between STEMI patients attended by public or private assistance in a reference center in Brazil (Table 2). However, clinical characteristics and medical treatment differed significantly. In conclusion, despite worse socioeconomic profile and longer total ischemic time among public patients, clinical outcomes were similar between groups.

Table 1 – Clinical characteristics of the study patients.

HETEROGENEOUS OUTCOMES OF DUAL VERSUS SINGLE ANTIPLATELET THERAPY IN SPONTANEOUS CORONARY ARTERY DISSECTION: A SYSTEMATIC REVIEW

GABRIELA MENDONÇA DE OLIVEIRA1; JOSÉ JORGE DE PAIVA RÍSPOLI NETO1; BIANCA OLIVEIRA DE SIMONI1; GABRIEL VOLPATO ROCHA1; FLÁVIA BITTAR BRITTO ARANTES1;

(1) UNIVERSIDADE FEDERAL DE UBERLÂNDIA - UBERLÂNDIA - MG - BRASIL;

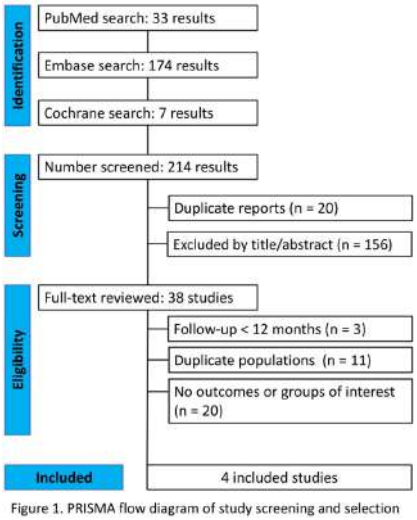

Figure 1. PRISMA flow diagram of study screening and selection

Introdução/Fundamentos: Spontaneous coronary artery dissection (SCAD) is an increasingly recognised cause of acute coronary syndrome (ACS). However, the optimal antiplatelet treatment in this scenario remains controversial. Objetivos: To synthesise the comparison between dual versus single antiplatelet therapy (DAPT vs SAPT) on major adverse cardiovascular events (MACE) in SCAD. Métodos: Systematic review conducted in accordance with PRISMA 2020 guidelines and prospectively registered in PROSPERO (Figure 1). Eligible studies included cohorts of adults with angiographically confirmed, non-iatrogenic SCAD. Four reviewers independently performed study screening. Resultados e Conclusões: Among 214 records identified, four observational cohort studies were included, comprising 1,675 patients with SCAD. The pooled weighted mean age was 52.3 (±10) years, and 88.7% were women. DAPT was used in approximately 61% of patients. The pooled MACE incidence was 12.4% across follow-up windows ranging from 12 to 36 months (study-level range 8.6%–14.6%). The association between DAPT and MACE was heterogeneous. In DISCO, DAPT was associated with a higher incidence of MACE compared with SAPT (18.9% vs 6.0%; HR 2.62, 95% CI 1.22–5.61). Similarly, in SR-SCAD, DAPT was independently associated with increased risk of adverse events (HR 2.18; p=0.042). In the CanSCAD subanalysis, 12-month MACE did not differ significantly between DAPT and SAPT (4.6% vs 3.4%, p=0.53). ANZ-SCAD suggested an increased risk specifically associated with aspirin plus ticagrelor (aHR 1.8, 95% CI 1.04–3.2). No study demonstrated a reduction in MACE with DAPT compared with SAPT. In patients with SCAD, observational evidence suggests no benefit of DAPT over SAPT, with some cohorts indicating a potential increase in MACE associated with DAPT, particularly with more potent regimens. These findings, together with SCAD pathophysiology, support the need for randomised trials, ideally with stratification by sex and antiplatelet regimen, to define the optimal antiplatelet strategy in this population.

Table 1. Baseline characteristics and outcomes of included studies

Study	Design	Population	Conservative treatment	Follow-up (median, months)	No. of patients (DAPT / SAPT / Total)	Female sex	Age	MACE/MACCE (per-study follow-up)
ANZ-SCAD, 2025	Prospective & retrospective cohort	818 y; ACS due to confirmed SCAD	88.5% (469)	21	DAPT: 64% (325) SAPT: 36% (184) Total: 505	88.7% (448)	52.2 ± 10.4 y	Aspirin + ticagrelor aHR 1.8 (1.04–3.2); p = 0.037
SR-SCAD, 2022	Prospective cohort	SCAD by Saw angiographic classification	78% (305)	29	DAPT: 58% (221) SAPT: 41.4% (161) Total: 389	88% (344)	53 y (IQR 47–60)	DAPT at discharge HR 2.18 (1.10–4.68); p = 0.042
DISCO, 2021	Retrospective cohort	Non-atherosclerotic SCAD; 918 y	100% (199)	12	DAPT: 66.3% (132) SAPT: 33.2% (67) Total: 199	88.9% (177)	52.1 ± 9.3 y	SAPT: 6.0% DAPT: 18.9% HR 2.62 [1.22–5.61]; p = 0.013
CanSCAD*, 2022	Prospective cohort	Non-atherosclerotic SCAD-confirmed angiographically; acute ACS; 918 y	100% (562)	36	DAPT: 56.6% (347) SAPT: 40.4% (235) Total: 582	88.8% (517)	51.7 ± 10.5 y	SAPT: 3.4% DAPT: 4.6% p = 0.53

DAPT, dual antiplatelet therapy; SAPT, single antiplatelet therapy; SCAD, spontaneous coronary artery dissection; ACS, acute coronary syndrome; HR, hazard ratio; aHR, adjusted hazard ratio; CI, confidence interval; IQR, interquartile range; MACE/MACCE, composite of all-cause mortality, non-fatal myocardial infarction (including SCAD-related or recurrent MI), stroke or TIA, heart failure, unplanned coronary revascularisation, and recurrent SCAD.
*CanSCAD figures refer to the RCT-MO subanalysis of conservatively managed patients (n = 562); the parent CanSCAD cohort (n = 750) had 84.1% conservatively managed.

IMPACT OF ANEMIA ON MORTALITY IN PATIENTS WITH MYOCARDIAL INFARCTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

MARCOS PAULO JORGE DE SALES1; LOUISE ARAÚJO JASSÉ SANTOS1; ANTONIO MARIA ZACARIAS ARAÚJO MONTEIRO1; RAFAEL ARAÚJO DE BRITO NOBRE2; GABRIEL SANTARÉM JORGE PINTO DOS REIS1; RENATA GOMES DE ARAÚJO TEIXEIRA CYPRIANO3;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO FIBRA (FACULDADE INTEGRADA BRASIL AMAZONIA) - BELÉM - PA - BRASIL; (3) UNIVERSIDADE DA AMAZONIA - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases, including myocardial infarction (MI), remain the leading cause of mortality worldwide. Anemia is highly prevalent in this population and may impair oxygen delivery, contributing to higher mortality. However, evidence on its prognostic impact remains heterogeneous and inconsistent. This study aimed to systematically evaluate the association between anemia and mortality in patients with MI. Objetivos: To evaluate the impact of anemia on mortality in patients with myocardial infarction. Métodos: A systematic review and meta-analysis were conducted using PubMed, Google Scholar, and EBSCO, according to PRISMA guidelines. The search combined terms related to anemia and myocardial infarction with terms describing outcomes and effect estimates. Studies focused on transfusion, treatment, surgical, perioperative, anesthesia, or ICU settings were excluded. Observational studies assessing anemia and outcomes in MI were included. Two separate meta-analyses were performed: dichotomous data (OR) and adjusted hazard ratios (HR, generic inverse variance). Studies reporting only risk ratios were not included in quantitative synthesis. Analyses were conducted using RevMan with random-effects models due to expected clinical and methodological heterogeneity. Resultados e Conclusões: A total of 46 studies (n >160,161) were included. Most demonstrated worse outcomes in patients with anemia. In pooled dichotomous analysis, anemia was associated with increased mortality (OR 3.64, 95% CI 2.66–4.99; p < 0.00001; I^2 = 75%). In adjusted analysis, anemia remained significantly associated with mortality (HR 2.08, 95% CI 1.73–2.51; p < 0.00001; I^2 = 84%), although with attenuation of effect. Therefore, anemia was consistently associated with increased mortality in MI, even after adjustment for confounders, supporting anemia as an independent and clinically relevant prognostic marker for risk stratification in MI. Heterogeneity likely reflects differences in anemia definition (baseline vs hospital-acquired), patient populations (STEMI, ACS, or MI), outcome definitions, and follow-up duration. Random-effects models accounted for this expected variability. Overall, these results support incorporating anemia into clinical decision-making and risk assessment strategies in patients with MI.

IMPACT OF BETA-BLOCKERS ON CLINICAL OUTCOMES IN PATIENTS WITH PRESERVED EJECTION FRACTION AFTER ACUTE MYOCARDIAL INFARCTION: A SYSTEMATIC REVIEW

MARIANA ALENCAR DE ARAUJO1; LARA PONTES COELHO2; MARIA CLARA PINHEIRO LIMA BRASILEIRO2; MARIA EDUARDA MACHADO NOGUEIRA3; NICOLE BARROSO MENDONÇA4; ANA SOPHIA PINHO DE SOUZA5; MARIA CLARA FIALHO BORGES2; MARÍLIA BEATRIZ RODRIGUES ARAÚJO2; SOPHIA ALENCAR ARRAIS DE SOUZA2; DAVI LIMA RABÊLO DE MELO2;

(1) UNIVERSIDADE CHRISTUS - FORTALEZA (CE) - BRASIL - FORTALEZA - CE - BRASIL; (2) CENTRO UNIVERSITÁRIO CHRISTUS - FORTALEZA (CE) - BRASIL - FORTALEZA - CE - BRASIL; (3) CENTRO UNIVERSITÁRIO CHRISTUS - FORTALEZA - CE - BRASIL; (4) CENTRO UNIVERSITÁRIO CHRISTUS - FORTALEZA (CE) - BRASIL - FORTLEZA - CE - BRASIL; (5) CENTRO UNIVERSITÁRIO CHIRSTUS - FORTALEZA (CE) - BRASIL - FORTLEZA - CE - BRASIL;

Introdução/Fundamentos: The benefit of beta-blockers in patients after acute myocardial infarction (AMI) was widely established in the pre-reperfusion era. However, in the contemporary era of reperfusion and optimized medical therapy, their impact on patients with preserved left ventricular ejection fraction (LVEF ≥50%) remains uncertain. Objetivos: To evaluate the impact of beta-blockers on major adverse cardiovascular events (MACE) and mortality in post-AMI patients with preserved LVEF. Métodos: A systematic review was conducted in accordance with the PRISMA guidelines, structured using the PICO framework (P: post-AMI adults with LVEF ≥50%; I: beta-blockers; C: control/placebo; O: MACE and mortality) and registered in PROSPERO (No. XXXX). Searches were performed in PubMed, SciELO, LILACS, Cochrane Library, and ScienceDirect, including studies from 2022 to 2026. Randomized clinical trials and contemporary observational studies were included. Studies involving patients with prior heart failure or reduced ejection fraction were excluded. Of 275 references identified, after removal of duplicates and screening by title and abstract, 15 articles were assessed in full text, of which four were included. Resultados e Conclusões: Four contemporary multicenter clinical trials were included (ABYSS, REDUCE-AMI, BETAMI, and REBOOT), totaling 21,710 patients with AMI and preserved or mildly reduced LVEF. Most studies did not demonstrate a significant benefit of beta-blockers in reducing MACE. The REDUCE-AMI and REBOOT trials showed no significant reduction in mortality or MACE. Conversely, the BETAMI trial demonstrated a modest reduction in the composite outcome of death or MACE (14.2% vs. 16.3%; HR 0.85; 95% CI 0.75–0.98; p=0.03), primarily driven by a lower incidence of reinfarction (HR 0.73; 95% CI 0.59–0.92). The ABYSS trial evaluated therapy discontinuation and demonstrated that interruption of beta-blockers did not meet non-inferiority criteria compared with treatment continuation (HR 1.16; 95% CI 1.01–1.33), suggesting increased risk with discontinuation. There were no consistent differences in mortality, hospitalization for heart failure, or adverse events between groups. Contemporary data suggest no consistent benefit of beta-blockers in reducing mortality or MACE in post-AMI patients with preserved LVEF. However, routine discontinuation should be undertaken with caution, as it may be associated with worse outcomes, and the decision should be individualized according to the patient's clinical profile.

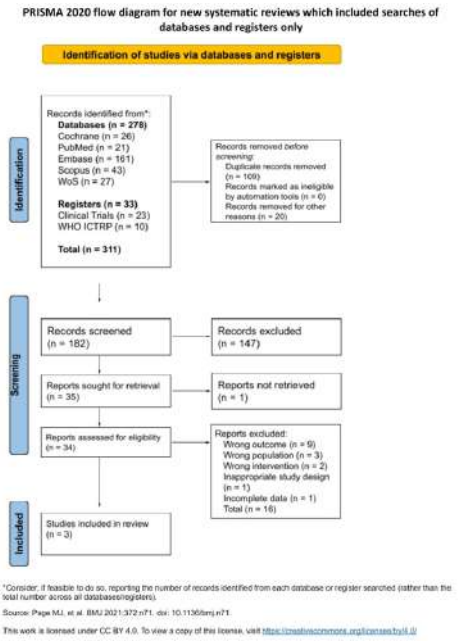
19135

IMPACT OF COLCHICINE USE ON THE REDUCTION OF MAJOR CARDIOVASCULAR EVENTS IN PATIENTS AFTER ACUTE MYOCARDIAL INFARCTION: A SYSTEMATIC REVIEW OF RANDOMIZED CLINICAL TRIALS.

ENRICO MAGELA BATALHA FALCAO1; JONATHAS ADRIEL TAVARES AMARAL2; ELIONAI FELIPE ROCHA DE LIMA SOUZA2; ANNA CHRISTINA LORENZONI FERREIRA1; LUCAS GABRIEL CARDOSO DE SOUZA2; JOÃO PAULO MONTEIRO RODRIGUES2; VICTOR PAMPLONA MENESCAL DE SOUZA2; DANGILLA RIBEIRO DOS SANTOS2; JOÃO LUCAS LALOR TAVARES2; ANA LUIZA NEPOMUCENO SAMPAIO2; JOÃO GABRIEL PORTILHO GOMES BRITO2; VIVIANE PATRÍCIA LOPES CARDOSO2;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (2) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Acute myocardial infarction (AMI) remains an important cause of cardiovascular morbidity and mortality. After the ischemic event, the inflammatory response contributes to the progression of atherosclerosis and the occurrence of new events. In this context, colchicine, an anti-inflammatory drug, has been investigated as a strategy for secondary prevention due to its ability to modulate inflammatory pathways associated with plaque instability. Thus, it is relevant to evaluate its impact on reducing major cardiovascular events in post-AMI patients. Objetivos: To evaluate the efficacy and safety of colchicine administration in reducing major adverse cardiovascular events (MACE) in patients following AIM, through a systematic review of randomized clinical trials. Métodos: Systematic review conducted according to PRISMA 2020 guidelines, with searches in PubMed, Virtual Health Library, and Cochrane Library using DeCS/MeSH descriptors related to "colchicine", "myocardial infarction", and "cardiovascular events", combined with AND/OR operators. Randomized clinical trials published in the last 10 years, in English or Portuguese, evaluating colchicine use in patients after AIM or acute coronary syndrome were included. Preclinical studies, reviews, and those with high risk of bias were excluded. Screening was performed by independent reviewers using the Rayyan software. Outcomes included major cardiovascular events (cardiovascular death, reinfarction, and stroke), as well as hospitalization for heart failure and adverse events. Data synthesis was qualitative, with risk of bias assessed using the RoB 2 tool. Resultados e Conclusões: After screening, four randomized clinical trials were included. In post-AMI patients, colchicine reduced major cardiovascular events ($p<0.05$), suggesting benefit in secondary prevention. Similar results were observed in stable coronary artery disease, with a significant reduction in events ($p<0.01$). However, early administration in acute settings did not demonstrate benefit in ventricular remodeling or periprocedural outcomes ($p>0.05$). Overall, colchicine showed a favorable safety profile, without increased serious adverse events, although mild gastrointestinal effects were reported. These findings suggest benefit in chronic and post-infarction settings, with less consistent results in the acute phase, highlighting the need for larger studies.



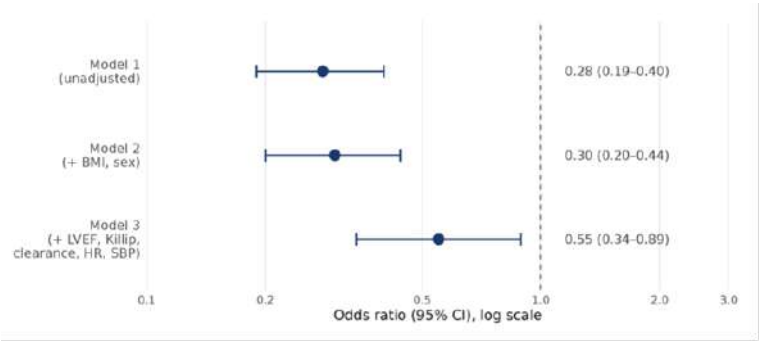
20164

INCRETIN-BASED THERAPIES PROMOTE PLAQUE STABILIZATION IN CORONARY ARTERY DISEASE: A SYSTEMATIC REVIEW

WILKER FRAINKYLI SILVA MENDONCA1; EVILLY CUTRIM VAZ1; PAULO VICTOR DE AGUIAR RIBEIRO1; KAUÃ MANUEL COSTA ARAÚJO1; ISABELA MIRANDA MELO1; EVELYN BEZERRA DOS SANTOS1; MARCEL PORTELA SILVA MATTEUCCI1; DANIELA SERRA DE ALMEIDA1;

(1) UNIVERSIDADE FEDERAL DO MARANHAO - SÃO LUIS - MA - BRASIL;

Introdução/Fundamentos: Glucagon-like peptide-1 receptor agonists (GLP-1RAs) reduce major cardiovascular events and mortality. However, their direct mechanisms in modulating coronary plaque remain incompletely understood, representing an important knowledge gap. Objetivos: This study aims to evaluate the efficacy of incretin-based therapies (IBTs) in the compositional modulation of atherosclerotic plaques in patients with coronary artery disease (CAD). Métodos: A systematic review was conducted to address the PICO question: in patients with coronary artery disease (CAD), are IBTs, compared with standard treatment or placebo, effective in modulating coronary atherosclerotic plaques as assessed by intracoronary imaging? The search for records was performed in major databases, including studies published from 2016 onwards. Studies involving adult patients with CAD and longitudinal follow-up were included. Study selection and data extraction were performed independently by two reviewers, followed by risk of bias assessment, certainty of evidence evaluation, and qualitative synthesis. Resultados e Conclusões: A total of 311 records were initially identified, with 3 studies ultimately included. A consistent reduction in lipid content of atherosclerotic plaques was observed, with a decrease of 85.6% in maximum lipid burden in the GLP-1RA group compared to 42.0% in the control group (p=0.01), along with reductions in fibro-fatty volume and plaque thickness. These therapies were also associated with plaque stabilization, with an increase in fibrous components under liraglutide use (34±129 mm³ vs. −2±101 mm³ in the control group; p=0.04), as well as improvements in endothelial function and inflammatory modulation. In patients following acute coronary syndrome, a mean regression of 5.8% was observed compared to a progression of 1.1% in the control group (p=0.041), with a greater reduction in percent atheroma volume (PAV) (-6.1% vs. -0.7%; p=0.039). However, in the OPTIMAL study subanalysis, no significant differences in PAV reduction were observed at 48 weeks, despite consistent improvements in plaque composition. Incretin-based therapies promote stabilization of coronary atherosclerotic plaque, with improvement in composition and reduction in inflammation. Despite inconsistent effects on plaque volume, consistent benefits are observed in plaque vulnerability. These findings suggest a cardiovascular effect independent of luminal regression in patients with CAD.



20196

LOWER IN-HOSPITAL MORTALITY IN YOUNGER STEMI PATIENTS AFTER PHARMACOINVASIVE STRATEGY: CONTRIBUTION OF BASELINE CLINICAL SEVERITY

VIVIANE DE OLIVEIRA DANTAS1; ANDREA DIAS STEPHANUS2; LUIZ SERGIO FERNANDES DE CARVALHO1;

(1) UNIVERSIDADE CATOLICA DE BRASILIA - BRASÍLIA - DF - BRASIL; (2) ARAMARI APO INSTITUTE - BRASÍLIA - DF - BRASIL;

Introdução/Fundamentos: Younger STEMI patients have lower in-hospital mortality, but typically present with a more favorable clinical profile. The extent to which baseline severity explains this association in pharmacoinvasive cohorts remains unclear. Objetivos: To assess the association between younger age and in-hospital mortality in STEMI patients treated with a pharmacoinvasive strategy, and to evaluate how this association changes after sequential adjustment for baseline clinical severity. Métodos: This retrospective cohort study included 2,510 consecutive STEMI patients admitted to two tertiary centers. Premature STEMI was defined as age <55 years. The association with in-hospital mortality was assessed using multivariable logistic regression with a sequential adjustment approach and change-in-estimate evaluation. Model 1 included premature STEMI alone, Model 2 added BMI and sex, and Model 3 added LVEF, pre-fibrinolysis Killip class, creatinine clearance, HR and SBP. Discrimination was assessed with the area under the receiver operating characteristic curve (AUC) and calibration with the Hosmer-Lemeshow test. As a sensitivity analysis, age was modeled as a continuous variable using natural cubic splines. Resultados e Conclusões: Of the 2,510 patients, 1,587 (63.2%) had premature STEMI. In-hospital mortality was 2.6% in younger patients and 9.0% in older patients (p<0.001). In model 1, premature STEMI was associated with lower in-hospital mortality (OR 0.28; 95%CI 0.19–0.40; p<0.001), and the estimate was largely unchanged after adjustment for BMI and sex (OR 0.30; 95%CI 0.20-0.44; p<0.001). After full adjustment, the association persisted with attenuated magnitude (OR 0.55; 95%CI 0.34-0.89; p=0.015), corresponding to a 54.2% attenuation in the log-odds (Figure 1). The model showed good discrimination (AUC 0.901) and adequate calibration (Hosmer-Lemeshow p=0.875). Continuous age modeling demonstrated a linear association with mortality (p for non-linearity=0.93) and similar discrimination (AUC 0.902), supporting the dichotomized analysis. Stratified analyses suggested a stronger association in Killip I and reduced LVEF, without significant interactions. In this cohort, the lower in-hospital mortality observed in younger STEMI patients was largely attenuated after adjustment for baseline clinical severity, indicating that differences in admission profile account for a substantial portion of this association. A residual effect persisted, suggesting that age adds prognostic information beyond measured clinical variables.

MACHINE LEARNING MODEL TO PREDICT LONG-TERM MORTALITY IN CHRONIC CORONARY SYNDROME: AN ELASTIC NET-DERIVED CLINICAL SCORE

ANISIO UCHOA LEITE SANTANA1; ALFREDO ROGÉRIO DIAS DALCOMUNI1; JOÃO VITOR BIANCALANA FERREIRA PERES CALIL1; VITOR BATALHA DE CAMARGO1; ARTHUR PINHEIRO SILVEIRA FREITAS1; EDUARDO MARTELLI MOREIRA2; FABIO GRUNSPUN PITTA2; EDUARDO GOMES LIMA2; FABIANA HANNA RACHED2; HENRIQUE TROMBINI PINESI2; CARLOS VICENTE SERRANO JR2;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Predicting long-term mortality in chronic coronary syndrome (CCS) is challenging. While machine learning (ML) offers high accuracy, its complexity often hinders clinical use. Objetivos: To compare three ML algorithms predicting 5-year mortality in a CCS cohort and translate the best-performing model into a practical clinical nomogram. Métodos: Baseline clinical, laboratory, and echocardiographic data were analyzed. The cohort was dynamically split into training (70%) and validation (30%) sets. Three algorithms—Elastic Net (Cox Penalized), Random Survival Forest (RSF), and Extreme Gradient Boosting (XGBoost)—were trained and compared using Harrell's C-index. Internal validation used 500 bootstrap resamples. Risk stratification was evaluated using Kaplan-Meier (KM) curves with Hazard Ratios (HR), and clinical utility was assessed via Decision Curve Analysis (DCA). Resultados e Conclusões: The Elastic Net model outperformed tree-based algorithms in the hold-out test set (C-index 0.759; 95% CI: 0.700-0.819), compared to RSF (0.751; 95% CI: 0.690-0.811) and XGBoost (0.731; 95% CI: 0.668-0.793). Elastic Net selected key predictors (age, left ventricle mass, ejection fraction, hemoglobin, creatinine, NYHA class, and peripheral artery disease) to build the nomogram. Bootstrapping confirmed robust internal validation (corrected C-index 0.766). KM analysis stratified the unseen validation cohort into risk cohorts; compared to the low-risk reference, mortality was significantly higher in the high-risk group (HR: 6.26; 95% CI: 2.93-13.37, p<0.001). DCA confirmed superior clinical utility: at a 20% risk threshold, the nomogram provided a higher net benefit (0.105) than the "treat-all" strategy (0.039), effectively avoiding 26.6 unnecessary interventions per 100 patients. In conclusion, among the evaluated ML models, the Elastic Net provided the best predictive performance. Its translation into a clinical nomogram successfully bridges the gap between advanced methodology and transparent risk stratification, optimizing medical decisions for patients with CCS.

MINOCA IS NOT BENIGN: EARLY STABILITY MASKS PROGRESSIVE RISK ACCUMULATION AND TREATMENT-RESISTANT EVENT TRAJECTORIES

FURKAN DOLAP1; NURCAN NURCAN ARAT1; ZEYNEP DEMIRCI1; KUDRET KESKIN1; AHMET GURDAL GURDAL1;

(1) SISLI HAMIDIYE ETFAL EDUCATION AND RESEARCH HOSPITAL, ISTANBUL, TURKIYE - TÜRKIYE;

Introdução/Fundamentos: Myocardial infarction with non-obstructive coronary arteries (MINOCA) is often perceived as a relatively benign condition. However, the temporal pattern of adverse events and the impact of conventional therapies remain poorly defined. Objetivos: This study aims to define the timing of adverse events in MINOCA and to evaluate the influence of cardiovascular risk factors and treatment strategies on both the incidence and progression of MACE and mortality. Métodos: We analyzed 370 consecutive patients with MINOCA (190 men, 180 women) in a retrospective single-center cohort (2015–2025). Baseline risk factors and medical therapies were assessed at diagnosis. The primary endpoint was MACE, defined as a composite of non-fatal myocardial infarction, stroke, and cardiovascular hospitalization. All-cause mortality was analyzed separately. Time-to-event analyses were performed with a prespecified 12-month landmark to distinguish early and late events. Resultados e Conclusões: MACE occurred in 66 patients (17.8%) over a median follow-up of 36 months (IQR 30–44). Early events were uncommon but not absent, with only a small proportion occurring within the first year, whereas the vast majority occurred beyond 12 months. This pattern indicates an early phase of relative clinical stability followed by progressive accumulation of both non-fatal and fatal events over time. Median time to MACE was 28.4 months and to death 22.5 months. Risk profiles showed sex-specific patterns. In men, risk factors remained relatively stable across age strata, with smoking predominating. In contrast, women demonstrated a shift toward metabolic risk with aging, as diabetes and hyperlipidemia became more prevalent. This transition was associated with both higher incidence and earlier occurrence of MACE in women. Diabetes showed a stronger association with MACE and earlier event timing in older women, whereas no comparable effect was observed in men. Conversely, smoking showed a more pronounced, age-dependent association with MACE in men. Treatment analyses revealed no significant association between conventional therapies and outcomes. Dual antiplatelet therapy (12.4%) was not associated with differences in MACE incidence, timing, or mortality, consistent across definitions. Similarly, other standard therapies showed no significant relationship with outcomes. In contrast, colchicine use was associated with lower mortality without affecting MACE, suggesting a role in modulating disease progression rather than preventing initial events.

MORTALITY OF RESTRICTIVE VERSUS LIBERAL BLOOD TRANSFUSION STRATEGIES IN ANEMIC PATIENTS WITH ACUTE CORONARY SYNDROME: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

LEONARDO ROSA MONJELÓ1; MATHEUS AUGUSTO CAMBRAIA MENDES FERREIRA1; PEDRO AUGUSTO PIMENTA DE ALMEIDA1; ÉRICO RIBEIRO NETTO1;

(1) UFJF - JUIZ DE FORA - MG - BRASIL;

Introdução/Fundamentos: There is limited evidence regarding blood transfusion (BT) strategies in anemic patients with acute coronary syndrome (ACS). While the myocardial injury caused by ischemia in the ACS could be mitigated by BT in anemic patients, BT may also worsen prognosis, due to adverse events such as fluid overload and thrombosis. Therefore, a synthesis of the clinical evidence is needed to support clinical decision-making. Objetivos: To compare the mortality rates associated with a liberal (LS)(Hb ≤ 10 g/dL) versus a restrictive (RS)(Hb ≤ 8 g/dL) BT strategy among anemic patients with ACS. Métodos: This systematic review and meta-analysis were conducted in accordance with PRISMA guidelines. A comprehensive search was conducted in Embase, PubMed, and Web of Science using a search strategy based on MeSH terms. Two authors independently screened the studies and any discrepancies were resolved by a third author. Reference lists of included studies were also hand-searched for eligible trials. Only original randomized controlled trials (RCTs) that investigated different strategies of BT in anemic ACS patients were included. The Cochrane Risk of Bias (RoB 2.0) tool was used to assess the included studies. Statistical analysis was performed using R Studio software. Resultados e Conclusões: A total of 229 articles were identified from Embase (39), PubMed (137), and Web of Science (53). After title and abstract screening, ten articles underwent full-text review. Two studies (REALITY, 2021, n=666; MINT, 2023, n=3504) met the eligibility criteria, totaling 4170 participants. The meta-analysis showed no significant difference in mortality between the LS and RS of BT [RR 1.00, CI 95%; 0,63-1,60]. Substantial heterogeneity was observed (I2=61%), suggesting inconsistent effects across studies. The overall certainty of evidence may be limited by concerns regarding deviations from intended interventions across included studies. These data suggest that blood transfusion decisions should not rely solely on hemoglobin thresholds but should also consider individualized clinical evaluation. There is no evidence that supports an LS of BT in ACS patients. An LS might increase unnecessary healthcare costs and adverse effects, without a benefit in mortality rates. This study shows some limitations such as the limited number of RCTs and data inconsistency. Therefore, further large-escale RCTs are needed for the optimal evidence based management for these patients.

NON-OBSTRUCTIVE LEFT MAIN CORONARY ARTERY DISEASE (<50%): LEFT VENTRICULAR EJECTION FRACTION AS THE PRIMARY PROGNOSTIC DETERMINANT - A PRELIMINARY SINGLE-CENTER ANALYSIS

VICTOR CARLOS LUZ DE OLIVEIRA1; VICTOR ARRAIS ARAÚJO2; NAILTON GAMA DE CASTRO1; CARLOS VICENTE SERRANO2; ANDRÉ VICTOR DE ARAÚJO CLEMENTINO1; MARIANA KIMURA MARTINEZ1; EDUARDO GOMES LIMA2;

(1) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Non-obstructive left main coronary artery disease (LMCAD <50%) represents a therapeutic blind spot: excluded from landmark randomized trials and lacking evidence-based management guidance. Revascularization in this population is typically driven by concomitant multivessel disease rather than the left main lesion itself, leaving its prognostic determinants undefined. Objetivos: To identify, in a preliminary analysis, predictors of major adverse cardiovascular events (MACE) and evaluate whether therapeutic strategy influences long-term prognosis in non-obstructive LMCAD. Métodos: Retrospective single-center cohort of 91 patients with angiographically confirmed LMCAD <50% (2018-2024), managed with optimal medical therapy (OMT, n=51), coronary artery bypass grafting (CABG, n=22), or percutaneous coronary intervention (PCI, n=18); revascularization was indicated by overall coronary anatomy. MACE was defined as death, myocardial infarction, or stroke. Left ventricular ejection fraction (LVEF) was assessed continuously and dichotomized (preserved ≥50% vs. reduced <50%); LVEF analyses excluded four patients with missing data (n=87). Kaplan-Meier survival analysis, Cox proportional hazards regression, and multivariable logistic regression were performed as appropriate. Resultados e Conclusões: Over a median follow-up of 3.5 years, 15 MACE occurred (16.5%). Diabetes mellitus (DM) was the only baseline characteristic differing significantly across groups (p=0.005). On multivariable logistic regression, both DM and reduced LVEF independently predicted surgical referral (p=0.012 and p=0.048, respectively), whereas triarterial disease and severe angina showed no significant association (p>0.05). Nonetheless, no difference in MACE-free survival was observed across therapeutic strategies (log-rank p=0.275), though power was limited in this preliminary cohort. Notably, LVEF emerged as the sole independent predictor of MACE across all analytical approaches: multivariable Cox adjusted for DM (HR=0.179, 95%CI 0.049–0.661, p=0.010; C-statistic=0.734); continuous Cox (HR=0.926 per 1%, p=0.004); categorical Cox (HR=0.266, 95%CI 0.083–0.857, p=0.027); and Kaplan-Meier (log-rank p=0.019). At five years, preserved LVEF was associated with markedly higher MACE-free survival (87.0% vs. 57.1%). These hypothesis-generating findings suggest LVEF as the primary prognostic determinant in non-obstructive LMCAD, independent of therapeutic strategy, though larger prospective studies are warranted to validate this observation.

PREGNANCY-ASSOCIATED VERSUS NONPREGNANCY SPONTANEOUS CORONARY ARTERY DISSECTION: A SYSTEMATIC REVIEW

GABRIELLA FRAIJI MELO1; MARCELA VASCONCELOS MONTENEGRO2; RAILLA ALBINO SILVA3; PEDRO GOMES BATISTA4; MIGUEL A SAMANIEGO-LAGUNA5; JULIANA GIORGI6;

(1) FACULDADE DE CIENCIAS MEDICAS DA SANTA CASA DE SAO PAULO - SÃO PAULO - SP - BRASIL; (2) UNIVERSIDADE DE PERNAMBUCO - RECIFE - PE - BRASIL; (3) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL; (4) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (5) UNIVERSIDAD AUTÓNOMA METROPOLITANA - MEXICO; (6) HOSPITAL SIRIO-LIBANES - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: Spontaneous coronary artery dissection (SCAD) is a major nonatherosclerotic cause of acute coronary syndrome in young women. Pregnancy-associated SCAD (P-SCAD) has been linked to more severe presentation and greater clinical instability than nonpregnancy SCAD (NP-SCAD), but comparative evidence remains limited. Objetivos: To systematically compare the clinical presentation, management, and outcomes of P-SCAD and NP-SCAD. Métodos: PubMed, Embase, and CENTRAL were searched through November 2025. This systematic review followed PRISMA guidelines and was registered in PROSPERO (CRD420251237308). Observational studies including women aged 18 years or older with confirmed SCAD were eligible. Outcomes of interest included mortality, major adverse cardiovascular events, SCAD recurrence, left ventricular dysfunction, rehospitalization, cardiac arrest, and percutaneous coronary intervention. Resultados e Conclusões: Four observational studies including 21,672 women, of whom 824 had P-SCAD, were included. Across studies, P-SCAD was consistently associated with a more severe phenotype, characterized by clustering in late pregnancy or the early postpartum period, more extensive coronary involvement, greater left ventricular dysfunction, and higher short-term morbidity, including readmission and adverse cardiovascular events. Long-term survival appeared broadly similar where reported, although recurrence risk and markers of clinical instability were more pronounced in P-SCAD. Differences in reproductive history, hormonal exposure, and extracoronary vascular findings further supported a distinct pregnancy-associated phenotype. Available evidence supports P-SCAD as a higher-risk form of SCAD with more severe early presentation and greater short-term morbidity than NP-SCAD. These findings reinforce the likelihood of pregnancy-specific pathophysiologic mechanisms and support the need for tailored risk assessment and multidisciplinary management. Given the limited number of observational studies, further prospective comparative research is needed.

PROPHYLACTIC LOW-DOSE RIVAROXABAN FOR PREVENTION OF LEFT VENTRICULAR THROMBUS AFTER ANTERIOR ST-ELEVATION MYOCARDIAL INFARCTION: A SYSTEMATIC REVIEW

JOÃO VITOR DOS SANTOS VASCONCELOS1; FELIPE TORRES NORMANDES2; JULIA DE ANDRADE MELLO BRASIL MONTEIRO2; LUANA RODRIGUES ECKER2; NICOLE PEREIRA MONTEIRO DA CRUZ2; RODRIGO ORMANES MASSOUD1; MATHEUS LOPES BITAR MESQUITA1; GIANLUCA CERQUEIRA GRISOLIA1; JOAO PEDRO RUFFEIL OLIVA1; MAYANA MARQUES LISBOA1; ANTONIO MARIA ZACARIAS ARAÚJO MONTEIRO2;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Left ventricular (LV) thrombus is a well-recognized complication of anterior ST-segment elevation myocardial infarction (STEMI), occurring in 12% to 25% of patients when assessed by cardiac magnetic resonance imaging (CMR). Despite this risk, the role of prophylactic anticoagulation added to dual antiplatelet therapy (DAPT) remains uncertain, with current guidelines providing only weak recommendations due to limited evidence. This systematic review aimed to systematically evaluate and qualitatively synthesize the available evidence on the efficacy and safety of adding low-dose rivaroxaban to DAPT for prevention of LV thrombus in patients with anterior STEMI. Objetivos: To evaluate whether DAPT plus rivaroxaban reduces LV thrombus formation compared with DAPT alone in patients with anterior STEMI. Métodos: A systematic review without meta-analysis was conducted following PRISMA guidelines. PubMed, Cochrane CENTRAL, and Embase were searched for randomized controlled trials (RCTs) and cohort studies comparing DAPT plus rivaroxaban versus DAPT alone in anterior STEMI patients. The primary outcome was LV thrombus detected by imaging (CMR or echocardiography). Risk of bias in randomized trials was assessed using the RoB 2 tool. Due to significant methodological heterogeneity — particularly in imaging modalities— a qualitative synthesis was performed rather than meta-analysis. Resultados e Conclusões: Two RCTs enrolling 839 patients were identified; no cohort studies met inclusion criteria. Zhang et al. (2022, n=279) used echocardiography and reported lower LV thrombus rates with rivaroxaban (0.7% vs 8.6%). The APERITIF trial (2026, n=560) used CMR and found no significant difference in LV thrombus formation (13.7% vs 16.6%, difference −2.9%, 95% CI −8.9% to 3.2%). Minor bleeding was increased with rivaroxaban in APERITIF. The discordant results may be partially explained by differences in imaging modality sensitivity, as CMR detects approximately four times more thrombi than echocardiography. Due to the availability of only two studies with significant methodological heterogeneity, no definitive conclusions can be drawn regarding the efficacy of prophylactic rivaroxaban for LV thrombus prevention after anterior STEMI. However, the statistically significant benefit observed in one study suggests a potential true effect that cannot be excluded and warrants further investigation. Larger, multicenter trials using standardized CMR-based detection are needed to clarify this association.

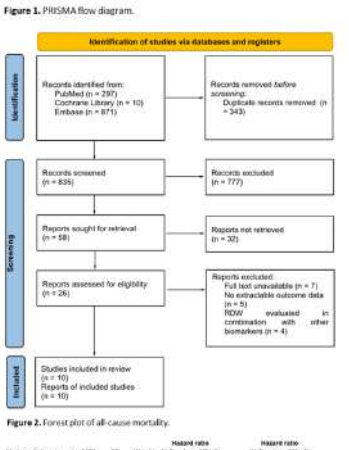
QUALITY OF LIFE AND ITS PREDICTIVE FACTORS IN PATIENTS WITH REFRACTORY ANGINA: A 10-YEAR FOLLOW-UP STUDY

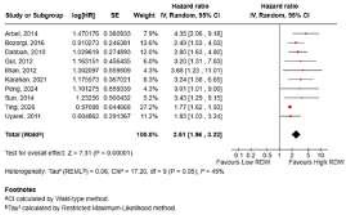
KÉTLIN LUIZA OLIVEIRA1; CAMILA PAIXÃO JORDÃO2; LUCIANA OLIVEIRA CASCAES DOURADO2;

(1) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (2) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL;

Introdução/Fundamentos: Refractory angina (RA) severely impacts quality of life (QoL). Understanding its long-term evolution and the factors that influence it is fundamental for clinical management. Objetivos: The objective of this study was to evaluate the evolution of QoL in patients with RA and to identify predictive variables for clinical improvement. Métodos: This cohort study was designed to evaluate patients with RA (CCS angina ≥2) before (pre) and after (post) an average interval of 10 years. The Seattle Angina Questionnaire (SAQ) was used to measure QoL, assessing the overall mean score and domain-specific scores (angina stability, symptom frequency, disease perception, treatment satisfaction, and physical limitation). For pre- and post-comparisons, the paired Student's t-test was applied. Multiple linear regression analysis was used to identify independent variables associated with the variation in QoL scores. Resultados e Conclusões: Thirty patients were included between 2015-2018; 9 patients died and 2 patients were lost to follow-up until the 10-year reassessment (2025-2026). Among the 19 reassessed patients, a significant improvement in overall QoL was observed (pre = 42.51± 15.88 vs. post = 59.80±19.99; p=0.0162). In the domain analysis, significant improvement was observed in angina stability (pre = 35.38 vs. post = 45.61; p=0.0002), symptom frequency (pre = 31.58 vs. post = 57.89; p=0.0002), and disease perception (pre = 39.91 vs. post = 77.96; p<0.0001). Linear regression analysis indicated that the model explained 86% of the variance in results. Among the analyzed variables, the reduction in glycated hemoglobin and fasting blood glucose were statistically significant predictors (Intercept, p=0.02; Glycated Hemoglobin, p=0.001; and Fasting Blood Glucose, p=0.03) of QoL improvement.Patients with RA presented a long-term improvement in QoL. Metabolic control, represented by glycated hemoglobin and fasting blood glucose, proved to be a predictive factor for QoL improvement.



16814

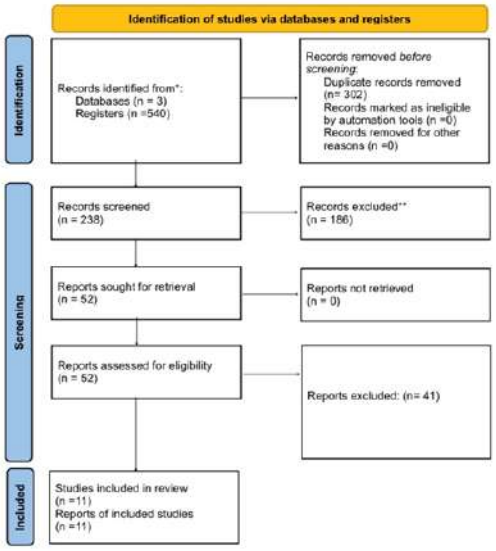


RED CELL DISTRIBUTION WIDTH AND MORTALITY IN PATIENTS WITH ACUTE CORONARY SYNDROME: A SYSTEMATIC REVIEW AND META-ANALYSIS

GABRIELA TEIXEIRA MAIA1; JULIA BRAUN1; RAFAELLA VALLI SANTANNA1; DIEGO CHEMELLO1;

(1) UNIVERSIDADE FEDERAL DE SANTA MARIA - SANTA MARIA - RS - BRASIL;

Introdução/Fundamentos: Acute coronary syndrome (ACS), including ST-segment elevation myocardial infarction (STEMI), non–ST-segment elevation myocardial infarction (NSTEMI), and unstable angina, remains a major cause of cardiovascular mortality. Red cell distribution width (RDW), derived from a routine complete blood count, has emerged as a potential prognostic biomarker in cardiovascular disease. Although prior individual studies and meta-analyses have suggested an association between elevated RDW and adverse outcomes, the evidence in patients with ACS remains heterogeneous, highlighting the need for a systematic synthesis. Objetivos: To analyze the association between elevated RDW at hospital admission and all-cause mortality in patients with ACS. Métodos: This systematic review and meta-analysis was conducted in accordance with the PRISMA guidelines. A comprehensive literature search was performed in PubMed, Embase and the Cochrane Library from inception to April 2026. The search strategy combined terms related to RDW and ACS. Data extraction was performed by two reviewers, including study characteristics and hazard ratios (HR) with 95% confidence intervals. The primary outcome was all-cause mortality. Meta-analysis was conducted using pooled hazard ratios, calculated through the inverse variance method under random-effects model. Statistical analysis were performed using Review Manager. Resultados e Conclusões: Ten observational studies comprising 70,894 patients were included. The studies enrolled heterogeneous ACS populations, including STEMI, NSTEMI, unstable angina pectoris, and broader AMI cohorts, with follow-up ranging from the in-hospital period to 5 years. Most cohorts included patients undergoing PCI or primary PCI, and the cutoff used to define elevated RDW varied between 13.0% and 14.8%. In the random-effects meta-analysis, elevated RDW was significantly associated with increased all-cause mortality (HR, 2.51 [95% CI, 1.96–3.22]; p<0.00001) (Figure 2). The direction of effect was consistent across all included studies, with individual hazard ratios ranging from 1.77 to 4.35. Moderate heterogeneity was observed among studies (Tau²=0.06; χ^2=17.20, df=9; p=0.05; I^2=45%). Elevated RDW was associated with a higher risk of all-cause mortality in patients with ACS. Although moderate heterogeneity was observed across studies, these findings support the potential role of RDW as an accessible and low-cost prognostic biomarker for risk stratification in this population.



17050

RED CELL DISTRIBUTION WIDTH AS A PREDICTOR OF MORTALITY IN ACUTE MYOCARDIAL INFARCTION: A SYSTEMATIC REVIEW

LAURA AZEVEDO DE MORAES1; YURI FÉLIX BRANDÃO1; LARA DAMASCENO DUARTE1; LUCAS CARTAXO TAVARES1; GIOVANNA MARIA SARAIVA CRUZ1; MARINA ALMEIDA SIMÕES1; BEATRIZ BARSI CUNHA1; MARIA EDUARDA SANTOS DE OLIVEIRA1; CLARA SIMÕES NOBRE1; THAÍS FACÓ DE CASTRO1; VICTÓRIA STEPHANE TESSARO1; RENATO NOGUEIRA BARRETO DE MELO2;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (2) UFC - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Acute myocardial infarction (AMI) is a major cause of hospitalization and death worldwide. Despite advances in treatment, mortality remains high, highlighting the need for early risk stratification. Red cell distribution width (RDW), a routine blood parameter, has been associated with worse outcomes and mortality in AMI. However, evidence remains heterogeneous, supporting the need for a comprehensive synthesis of its prognostic value. Objetivos: To evaluate the prognostic value of RDW in adults with AMI, assessing its association with mortality and major adverse cardiovascular events (MACE). Métodos: This PRISMA-based systematic review was registered in PROSPERO (CRD420261368312) and conducted using PubMed, Embase, and LILACS in April 2026, including studies published from 2020 to 2026. Randomized and observational studies assessing RDW as a prognostic marker in adults with acute myocardial infarction were included. Study selection and data extraction were performed independently by two reviewers using Rayyan, with disagreements resolved by a third reviewer. Resultados e Conclusões: Eleven studies were included, comprising more than 100,000 patients from heterogeneous adult populations with acute myocardial infarction. Across studies, elevated RDW was consistently associated with worse outcomes, especially mortality. Admission RDW was linked to higher in-hospital and 30-day mortality, with the strongest associations observed for medium- and long-term mortality. In most adjusted analyses, high RDW remained an independent predictor of death, with adjusted hazard ratios generally ranging from approximately 1.3 to 2.8 across studies, with most studies reporting statistically significant confidence intervals. Elevated RDW was also associated with major adverse cardiovascular events, including recurrent myocardial infarction, heart failure, stroke, cardiogenic shock, arrhythmias, and stent thrombosis. Studies evaluating dynamic or pre-discharge RDW suggested that persistent elevation may identify patients at higher post-discharge risk. Composite markers, such as the RDW-to-albumin ratio, may provide additional prognostic value, although performance varied across clinical settings. Overall, evidence supports RDW as an accessible and clinically useful marker for risk stratification after AMI. These findings show that RDW is a simple, inexpensive biomarker associated with increased mortality and adverse cardiovascular outcomes in AMI. It may serve as a complementary tool in medium- and long- term risk stratification.

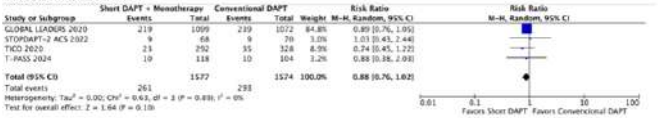
SEX DIFFERENCES IN MYOCARDIAL INJURY AFTER NON-CARDIAC SURGERY: HIGHER INCIDENCE IN MEN, OLDER AGE AT ONSET IN WOMEN, AND DIVERGENT LONG-TERM MORTALITY

LETÍCIA ZANGIROLAMI PERES1; THIAGO MOREIRA BASTOS DA SILVA2; BRUNO FERRAZ DE OLIVEIRA GOMES2; GIOVANNI POSSAMAI DUTRA2; LUAN CAVALCANTE VILAÇA LIMA1; NASSIM JOSÉ KEHDI2; HILSON AMORIM PARENTE2; DAVI DE VASCONCELLOS DIAS1; FABIANA CARDOSO DE OLIVEIRA1; LUCAS DE SOUZA MARTINS PEREIRA2; GLAUCIA MARIA MORAES DE OLIVEIRA1;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) BARRA D`OR - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Sex differences in myocardial injury after non-cardiac surgery (MINS) remain poorly characterized in Latin American populations. Objetivos: We aimed to compare the incidence, clinical profile, in-hospital complications, and short- and long-term outcomes of MINS by sex in a Brazilian tertiary surgical intensive care unit (ICU). Métodos: Historical cohort study of consecutive patients admitted to a surgical ICU following non-cardiac surgery (2011–2016), with a median follow-up of 6.7 years (maximum 10.2 years). MINS was defined as troponin elevation exceeding the 99th-percentile upper reference limit without a non-ischemic etiology. Primary outcome was long-term all-cause mortality. Secondary outcomes included 30-day and 1-year mortality and ICU complications. Odds ratios (ORs) with 95% confidence intervals (CIs) were calculated; continuous variables were compared with the Mann-Whitney U test. Resultados e Conclusões: Results: Of 2,532 patients (male 46.4%, female 53.6%), MINS incidence was significantly higher in males (15.8%) than females (9.7%) (OR 1.74, 95%CI 1.37–2.21, p<0.001). Among the 317 patients with MINS (male n=185, female n=132), women were significantly older at the time of injury (median 73 vs 69 years, p=0.022). Males had a higher prevalence of previous myocardial infarction (30.3% vs 15.9%, OR 2.29, p=0.003) and tobacco use (16.2% vs 2.3%, OR 8.32, p<0.001). ICU severity was greater in males (SOFA 3 vs 2, p=0.010), with more frequent mechanical ventilation (44.9% vs 30.3%, OR 1.87, p=0.010); females required more transfusions (46.2% vs 32.4%, p=0.014), consistent with a predominantly orthopedic surgical profile. Thirty-day (16.0% vs 14.8%, p=0.847) and 1-year (34.0% vs 28.7%, p=0.449) mortality did not differ significantly between sexes. Long-term all-cause mortality was significantly higher in males (60.6% vs 46.3%, OR 1.79, 95%CI 1.02–3.13, p=0.048). Conclusions: Although males are 74% more susceptible to MINS, women develop injury at an older age and with a distinct comorbidity and surgical profile. The similar early mortality but significantly higher long-term mortality in males points toward a CAD-driven pathway that accelerates late cardiovascular death. These findings reinforce that MINS carries sex-specific prognostic implications extending well beyond the perioperative window.

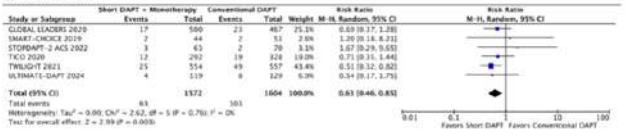
18343



SHORT DAPT FOLLOWED BY P2Y12 INHIBITOR MONOTHERAPY IN PATIENTS WITH CHRONIC KIDNEY DISEASE: REDUCED BLEEDING WITHOUT INCREASED CARDIOVASCULAR RISK — A SYSTEMATIC REVIEW AND META-ANALYSIS

MANOELA LENZI PINTO1; RAFAEL RITTER DAL PIZZOL1; IGOR HEINECK OURIQUES1; NATÁLIA CARVALHO BRATKOWSKI1; DANIEL LUÍS BERNARDI NERY1; BIANCA FULAS DENARDI1; GABRIEL FELIPI DE FONTES GUILIOTI1; ELEONORA BALZAN FLECK1; JULIANE THIBES KREISIG1; NICOLAS ENDRIUS TORRES LOPES1; MARIA PAULA RONCHI COLOMBO2; FABIO ALBAN3;

(1) UFCSPA - PORTO ALEGRE - RS - BRASIL; (2) SANTA CASA DE PORTO ALEGRE - PORTO ALEGRE - RS - BRASIL; (3) POMPÉIA ECOSSISTEMA DE SAÚDE - CAXIAS DO SUL - RS - BRASIL;



Introdução/Fundamentos: Short dual antiplatelet therapy (DAPT) followed by P2Y12 inhibitor monotherapy has emerged as an alternative to the current standard of care, prolonged DAPT, in patients with acute coronary syndrome (ACS) undergoing percutaneous coronary intervention (PCI). Patients with chronic kidney disease (CKD) represent a high-risk subgroup, with both increased ischemic and bleeding risks. However, major randomized trials comparing these strategies underrepresent this population, resulting in limited evidence regarding the safety and efficacy of P2Y12 inhibitor monotherapy in patients with CKD. Objetivos: To determine if P2Y12 inhibitors monotherapy after a short course of DAPT improves safety without losing efficacy compared to prolonged DAPT in ACS patients with CKD undergoing PCI. Métodos: This systematic review and meta-analysis of randomized clinical trials (RCT) followed the PRISMA 2020 statement, although not registered in PROSPERO. A systematic search was conducted in MEDLINE/PubMed and Embase in April 2026. Two reviewers independently screened the articles and discrepancies were resolved by a third reviewer. Eligibility criteria were RCTs comparing P2Y12 inhibitor monotherapy versus conventional DAPT in patients with ACS reporting outcomes for the CKD subgroup. The primary outcomes were cardiovascular events and bleeding, including composite endpoints. Analyses were performed using Review Manager, and risk ratios (RR) with 95% confidence intervals were calculated using a random-effects Mantel–Haenszel model. Statistical heterogeneity was assessed using the I² statistic. Resultados e Conclusões: A total of 4607 patients were included. Short dual antiplatelet therapy (DAPT) followed by P2Y12 inhibitor monotherapy was associated with a significant reduction in major bleeding compared with conventional DAPT (RR 0.63; 95% CI 0.46–0.85; p=0.003; I²=0%). A significant reduction was also observed for the broader bleeding endpoint (RR 0.65; 95% CI 0.43–0.99; p=0.04; I²=0%). No significant differences were found for cardiovascular outcomes (RR 0.89; 95% CI 0.77–1.04; p=0.15; I²=0%) or for the composite endpoint of cardiovascular events plus bleeding (RR 0.88; 95% CI 0.76–1.02; p=0.10; I²=0%). These findings suggest that short DAPT followed by P2Y12 inhibitor monotherapy reduces bleeding, including major bleeding, without increasing cardiovascular risk, supporting this strategy as a safer alternative in patients at higher bleeding risk.

Figure 1. Forest plot of cardiovascular outcomes and bleeding: short DAPT followed by P2Y12 monotherapy versus conventional DAPT

Effect estimates are presented as risk ratios (RR) with 95% confidence intervals (CI). Squares represent individual studies and horizontal lines indicate 95% CI; square size reflects study weight. The diamond represents the pooled estimate. A random-effects model was used.

Figure 2. Forest plot of clinically relevant bleeding: short DAPT followed by P2Y12 monotherapy versus conventional DAPT

Effect estimates are presented as risk ratios (RR) with 95% confidence intervals (CI). Squares represent individual studies and horizontal lines indicate 95% CI; square size reflects study weight. The diamond represents the pooled estimate. A random-effects model was used.

SPATIOTEMPORAL TRENDS IN HOSPITALIZATIONS FOR ACUTE MYOCARDIAL INFARCTION IN BRAZIL, 2008–2024.

GUILHERME GUILHERME GOMES1; ANA CÂNDIDA MARQUES NOGUEIRA COÊLHO1; FRANCISCO RAFAEL GOMES LIMA1; JOÃO EDUARDO AMORIM BASTOS MOURA1; MICAELLE MARIANA BARROSO DE SOUSA1; MARIA DE FÁTIMA PAIVA MARREIROS MARQUES1; LETÍCIA SANTOS ROCHA MARTINS SOARES1; PEDRO IGOR ARAÚJO DANTAS DA SILVA1; SABRINA HELEN BEZERRA LOPES1; LUIS FELIPE VIEIRA NUNES PORTO1; RAÍSSA VASCONCELOS GALVÃO PORTELLA NUNES1; CARLOS EDUARDO BATISTA DE LIMA1;

(1) UNIVERSIDADE FEDERAL DO PIAUI - PIAUÍ - PI - BRASIL;

Introdução/Fundamentos: Acute myocardial infarction (AMI) is a major cause of morbidity and mortality worldwide, resulting from myocardial ischemia and necrosis, usually after coronary plaque rupture and thrombosis. In Brazil, AMI remains a leading cause of death, with marked regional disparities in access to care. Evaluating spatiotemporal hospitalization trends may reveal inequalities and support public health planning. Objetivos: This study investigates temporal trends and spatial autocorrelation patterns of hospitalizations for acute myocardial infarction in Brazil from 2008 to 2024, identifying geographic clusters and regional disparities at the municipal level. Métodos: This ecological time-series study analyzed hospitalizations for Acute Myocardial Infarction (ICD-10 I21) in 5,570 Brazilian municipalities from 2008–2024 using SIH/SUS (Hospital Information System of the Unified Health System) data from DATASUS (Department of Informatics of the Brazilian Unified Health System) and population estimates from IBGE (Brazilian Institute of Geography and Statistics). Hospitalization rates per 100,000 inhabitants were calculated and smoothed using the Empirical Bayesian method. Data processing and geospatial integration were performed in Python with Pandas, NumPy, and GeoPandas. Temporal trends were assessed using Joinpoint Regression and piecewise linear regression, estimating APC and AAPC with 95% confidence intervals. Spatial autocorrelation was evaluated using Global Moran's I and Local Indicators of Spatial Association (LISA), classifying clusters as High-High, Low-Low, High-Low, and Low-High. Ethical approval was waived because only public aggregated data were used. Resultados e Conclusões: Between 2008 and 2024, 1,910,532 hospitalizations for AMI occurred in Brazil, with a significant upward temporal trend and positive APC. Men accounted for 63.5% of cases, predominantly among individuals aged 60–69 years. Urgent admissions represented 90.6% of all cases, reinforcing failures in prevention and early management. There were 199,967 in-hospital deaths, with a case fatality rate of 10.47%, without significant reduction over time. Total costs exceeded R$ 7.5 billion. The Southeast concentrated the highest number of hospitalizations, whereas the North and Northeast presented the highest mortality rates. Spatial analysis identified clusters of elevated mortality in these regions. These findings indicate persistent regional inequalities, highlighting the need to strengthen prevention and cardiovascular care.

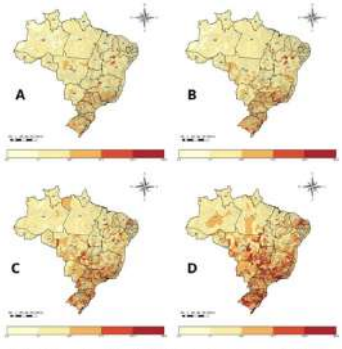

Figure 1: Spatiotemporal evolution of hospitalizations for acute myocardial infarction in Brazil, 2008–2024.

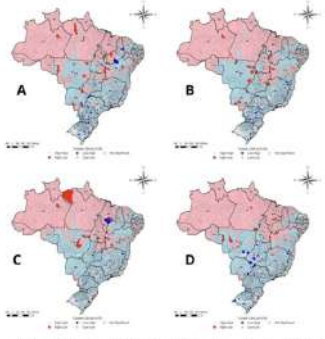

Figure 2: Local spatial clusters (LISA) of hospitalizations for acute myocardial infarction in Brazil, 2008–2024.

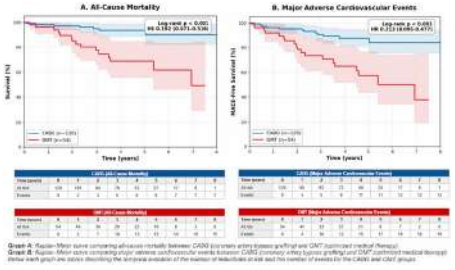
Triglycerides (mg/dL)	156.5 ± 135.4	147.1 ± 82.7	0.953
HbA1c (%)	6.9 ± 1.6	6.8 ± 1.8	0.307
Creatinine (mg/dL)	1.1 ± 0.4	1.0 ± 0.2	0.264
Hemoglobin (g/dL)	13.8 ± 1.7	13.6 ± 1.8	0.581
Glucose (mg/dL)	129.0 ± 51.9	131.8 ± 52.5	0.999
Outcomes			
Median follow-up (years)	3.2	3.6	—
All-cause mortality, n (%)	15 (27.8%)	7 (5.8%)	**<0.001**
MACE, n (%)	19 (35.2%)	12 (10.0%)	**< 0.001**



Continuous variables: mean ± SD (Welch t-test or Mann-Whitney U test, depending on the normality of the distribution). Categorical variables: n (%) (Chi-squared or Fisher exact test). Bold p-values indicate statistical significance (p<0.05). OMT = Optimized Medical Therapy; CABG = Coronary Artery Bypass Grafting; MI = myocardial infarction; LVEF = left ventricular ejection fraction; LMCA = left main coronary artery; CCS = Canadian Cardiovascular Society; MACE = major adverse cardiovascular events.

Table 2. Clinical Outcomes Stratified by LMCA Stenosis

	OMT (n=54)	CABG (n=120)	Total
LMCA stenosis			
Severe (≥70%)	8	41	49
Moderate (50 - 69%)	46	79	125
All-Cause Mortality (n=22)			
Severe (≥70%)	3	5	8
Moderate (50 - 69%)	12	4	16
MACE (n=31)			
Severe (≥70%)	3	5	8
Moderate (50 - 69%)	16	7	23

OMT = Optimized Medical Therapy; CABG = Coronary Artery Bypass Grafting; LMCA = left main coronary artery; MACE = major adverse cardiovascular events.

Introdução/Fundamentos: Left Main Coronary Artery (LMCA) disease is associated with substantial cardiovascular morbidity and mortality. Coronary Artery Bypass Grafting (CABG) is the guideline-directed revascularization strategy based on trials from the 1970s-1980s, yet no contemporary data compare CABG against current Optimized Medical Therapy (OMT) in real-world cohorts. Objetivos: To evaluate overall survival and major adverse cardiovascular events (MACE) in patients with LMCA stenosis ≥50% treated with CABG versus OMT. Métodos: Retrospective single-center cohort of patients with angiographically confirmed LMCA stenosis ≥50%. Exclusion criteria comprised chronic kidney disease, peripheral arterial disease, and prior CABG, yielding 174 patients: OMT (n=54, included from 2018) and CABG (n=120, included from 2017). Primary endpoint was all-cause mortality; secondary endpoint was MACE (death, nonfatal myocardial infarction, or stroke). Survival was estimated using Kaplan-Meier with Log-rank testing. Multivariable Cox regression adjusted for treatment, age and LMCA severity was validated by Schoenfeld residuals. Resultados e Conclusões: Median follow-up was 3.2 years (OMT) and 3.6 years (CABG). Groups were well-matched for major clinical and laboratory parameters (all p>0.05), except OMT patients were older (67.9±9.0 vs. 63.1±8.8 years; p=0.001), while CABG had more severe LMCA stenosis (≥70%:34.2% vs. 14.8%; p=0.009) and higher CCS class III-IV angina (35.8% vs. 11.1%; p<0.001), reflecting CABG selection. Primary endpoint: 22 deaths (OMT:15; CABG:7). On Kaplan-Meier analysis, median survival was 6.9 years for OMT versus not reached for CABG (Log-rank p<0.001), and Cox regression confirmed CABG as independently protective (HR 0.192; 95%CI: 0.071–0.516; p=0.001; Schoenfeld Global p=0.248). Secondary endpoint: 31 patients experienced MACE (OMT:19; CABG:12). On Kaplan-Meier analysis, MACE-free survival also favored CABG (Log-rank p<0.001), and Cox regression confirmed protection (HR 0.213; 95%CI: 0.095–0.477; p<0.001; Schoenfeld Global p=0.546). Notably, 72.7% of all deaths and 74.2% of all MACE occurred in patients with moderate LMCA stenosis; within this subgroup, 75.0% of deaths and 69.6% of MACE occurred in the OMT group. This finding challenges the perceived safety of conservative management in moderate LMCA stenosis, whose risk may be underestimated given less severe anatomy and fewer symptoms. Therefore, even in the era of contemporary pharmacotherapy, surgical revascularization remains the preferred strategy in LMCA disease.

Graph A: Kaplan-Meier curve comparing all-cause mortality between CABG (coronary artery bypass grafting) and OMT (optimized medical therapy).
Graph B: Kaplan-Meier curve comparing major adverse cardiovascular events between CABG (coronary artery bypass grafting) and OMT (optimized medical therapy). Below each graph are tables describing the number at risk and the number of events for the CABG and OMT groups.

SYSTEMIC INFLAMMATION AND MICROVASCULAR DYSFUNCTION IN INOCA: A SYSTEMATIC REVIEW ON THE ROLE OF INFLAMMATORY BIOMARKERS

MARIA FERNANDA CAMPOS NEVES DOS SANTOS1; GIOVANNI MONTEIRO MATOS1; FABRICIO BACELAR MARILHO FILHO1; MELINA CONDE MAUÉS LIMA2; ESTHER ELGRABLY DE MELO E SILVA ZATZ1; HANNAH UNGER1; FABIANA MACHADO ALVES1; GABRIELA CARVALHO DE ASSUNÇÃO1; MARIELLE DE NAZARÉ GONÇALVES DE LIMA E SILVA1;

(1) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL;

Introdução/Fundamentos: INOCA is an increasingly recognized clinical condition characterized by angina and ischemia in the absence of obstructive epicardial coronary artery disease. Despite “normal” angiographic findings, patients often present with significant symptom burden, impaired quality of life, and increased risk of adverse cardiovascular outcomes. Growing evidence indicates that coronary microvascular dysfunction and endothelial dysfunction are central mechanisms in its pathophysiology, with systemic inflammation playing a key contributory role. In this context, inflammatory biomarkers, including high-sensitivity C-reactive protein (hs-CRP), interleukin-6 (IL-6), tumor necrosis factor-alpha (TNF-α), and endothelial adhesion molecules, have been investigated as potential tools for diagnosis, risk stratification, and prognostic assessment. Objetivos: To systematically evaluate the association between inflammatory biomarkers and the presence, clinical severity, and prognosis of INOCA. Métodos: A systematic review was conducted according to PRISMA guidelines. A comprehensive literature search was performed in PubMed, Scopus, Web of Science, and Cochrane Library databases, covering studies published between 2010 and 2024. The search strategy included the terms “INOCA”, “Ischemia with Non-Obstructive Coronary Arteries” , “Inflammatory biomarkers”, “C-reactive protein”, “Interleukin-6”, and “Endothelial dysfunction”, combined using Boolean operators. Eligible studies included observational studies, cohort studies, and clinical trials involving adult patients with INOCA and assessment of inflammatory biomarkers. Case reports, narrative reviews, small-sample studies, and pediatric populations were excluded. Study selection was independently performed by two reviewers. Resultados e Conclusões: Results: Included studies demonstrated a consistent association between elevated inflammatory biomarkers and INOCA. hs-CRP showed the strongest correlation with coronary microvascular dysfunction and reduced coronary flow reserve. IL-6 and TNF-α were associated with endothelial dysfunction and impaired microvascular perfusion. Higher biomarker levels were linked to increased angina burden, recurrent hospitalizations, and higher incidence of adverse cardiovascular outcomes, with stronger associations observed in women. Conclusions: Inflammatory biomarkers are significantly associated with the presence and prognosis of INOCA, reinforcing the role of systemic inflammation in coronary microvascular dysfunction.

TEMPORAL EVOLUTION AND CLINICAL OUTCOMES OF PRIMARY ANGIOPLASTY: A 15-YEAR REGISTRY AT A REFERRAL CENTER

JOÃO PAULO BEILNER HOLZ1; GIOVANA RECH1; EDUARDA MORARI JESKE1; EDUARDO TARASCONI RUSCHEL1; JULIA BUDNY SERAFIM1; MARCIA MOURA SCHMIDT1; ALEXANDRE SCHAAN DE QUADROS1;

(1) ICFUC - PORTO ALEGRE - RS - BRASIL;

Introdução/Fundamentos: The guidelines for the treatment of patients with ST-segment elevation myocardial infarction (STEMI) are primarily based on data from randomized clinical trials, which include selected populations and may not fully reflect real-world clinical practice. Objetivos: To evaluate temporal trends in baseline and procedural characteristics and clinical outcomes, of patients with STEMI treated at a tertiary referral cardiology center. Métodos: This prospective cohort study included all consecutive patients with STEMI undergoing primary angioplasty at a referral cardiology center in southern Brazil. For temporal analysis, patients were stratified into five-year periods (2010–2014, 2015–2019, and 2020–2024). Clinical and angiographic characteristics, treatment strategies, and 12-month Kaplan Meier survival curves were compared across periods. During follow-up, outcomes were reinfarction, stroke, and cardiovascular mortality. Resultados e Conclusões: A total of 6,686 patients who underwent primary angioplasty were included. The prevalence of diabetes (24.3% vs. 27.1% vs. 29.5%; p=0.001), chronic kidney disease (2.2% vs. 2.7% vs. 4.0%; p<0.001), and heart failure (4.9% vs. 6.7% vs. 6.9%; p<0.001) increased over time, while the TIMI risk score remained stable (3.6 vs. 3.7 vs. 3.6; p=0.638). Procedural characteristics significantly differ over time, with an improvement in door-to-balloon time (70 min vs. 67 min vs. 56 min; p<0.001), increased use of the radial approach (44.1% vs. 78.7% vs. 86.3%;), drug-eluting stents (3.0% vs. 42.4% vs. 99.8%;), treatment of longer coronary lesions (18.76 ± 8.50 vs. 24.99 ± 11.54 vs. 30.18 ± 13.12), left main interventions (3.9% vs. 3.4% vs. 6.0%), and stent post-dilation (27.2% vs. 32.5% vs. 40.4%). All comparisons showed statistical significance (all p < 0.001). The mean follow-up was 304 ± 224 days, with a 10.3% loss to follow-up. Twelve-month mortality remained stable across the study periods (10.6% vs. 9.9% vs. 10.0%; p=0.56). In contrast, MACE (composite of death, myocardial infarction, and stroke) decreased progressively over time (17.6% vs. 11.3% vs. 11.0%; p<0.001). Despite increasing clinical complexity, advances in interventional techniques and improvements in in-hospital efficiency were associated with a reduction in MACE over time, while 12-month mortality remained stable.

THE REACT-ST STUDY: DISPARITIES IN STEMI CARE IN THE BRAZILIAN AMAZON — A PROSPECTIVE COHORT STUDY

PAULO VINÍCIUS BARROS PEREIRA DE SÁ1; SAMUEL DE OLIVEIRA LEITE2; RAFAELLY BELIZÁRIO DE SOUZA1; ANNE MONTEIRO DOS SANTOS1; ELLEN KATHELLEN SÁ DE SOUZA1; HUMBERTO LUIZ DE OLIVEIRA LOPES1; ELISYANE DOMINGOS NETTO DOS SANTOS2; ROBERTA LINS GONÇALVES2;

(1) UNIVERSIDADE FEDERAL DO AMAZONAS - MANAUS - AM - BRASIL; (2) UNIVERSIDADE FEDERAL DE JUIZ DE FORA - JUIZ DE FORA - MG - BRASIL;

Introdução/Fundamentos: Timely reperfusion in ST-segment elevation myocardial infarction (STEMI) is critical. The REACT-ST study aimed to investigate treatment times and clinical outcomes at the largest public emergency hospital in the Brazilian Amazon. Objetivos: To analyze reperfusion delays and their association with mortality and functional outcomes in patients with STEMI. Métodos: Methods: REACT-ST is a prospective cohort study conducted from April to December 2024, approved by the Ethics Committee (CAAE: 6939823.9.0000.5020; No. 6.732.492). We included consecutive STEMI patients and collected clinical data, reperfusion times, and outcomes. Functional capacity was assessed 3 months post-discharge using the Duke Activity Status Index (DASI). Kaplan-Meier curves and Cox regression were used for survival analysis. Resultados e Conclusões: The sample included 99 patients (62.9 ± 12.5 years; 71.7% hypertensive; 42.4% diabetic). No patient underwent primary PCI. Fibrinolytic therapy was performed in 55.6% of cases, with a mean door-to-needle time of 5.13 ± 3.23 hours. Among those who underwent subsequent PCI, the mean waiting time was 10 days. In-hospital mortality was 27.3%, and 3-month mortality reached 30.3%. Patients receiving fibrinolysis showed higher cumulative survival probabilities compared with those without reperfusion: in-hospital survival was 74.8% vs. 53.5%, and 3-month survival was 73.2% vs. 42.1%. Although adjusted Cox regression showed a trend (HR = 0.69; 95% CI: 0.29–1.63; p = 0.402), multivariate logistic regression identified non-performance of fibrinolysis as the only significant predictor of in-hospital death (OR = 12.05; p = 0.049). Regarding functional recovery, each additional day of hospitalization was associated with a reduction of 0.84 points in the DASI score (β = −0.8428; p = 0.002) at 3 months. Clinical scores (GRACE/TIMI) were robust prognostic markers (p < 0.05), while age and sex were not statistically significant in this model. Conclusion: The study reveals a critical gap in STEMI care in the Amazon, with mortality rates nearly triple the national average (6–14%). The absence of primary PCI and delayed fibrinolysis significantly compromises survival and functional capacity. These findings highlight the urgent need for a structured regional infarct network to ensure timely reperfusion and early rehabilitation in remote areas.

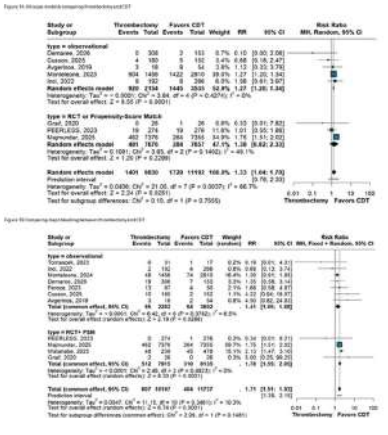
THE USE OF ARTIFICIAL INTELLIGENCE FOR IDENTIFYING ACUTE CORONARY SYNDROME ON ELECTROCARDIOGRAM: A FIVE-YEAR SYSTEMATIC REVIEW

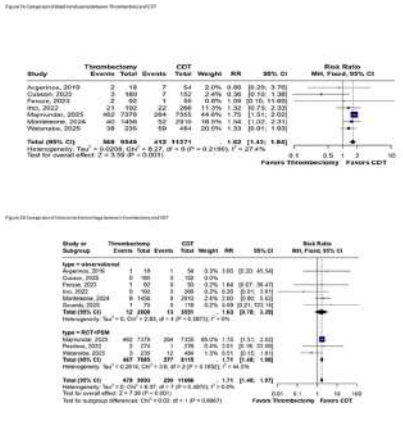
LUCAS PINHEIRO HOLANDA LIMA1; FAVIO ALEXANDRO ANDRADE DELGADO1; GUILHERME DE ANDRADE ABREU1; PEDRO PINHEIRO HOLANDA LIMA1; CARLOS MAURÍCIO RATTES1; THAIANA BEZERRA DUARTE1;

(1) AFYA - FACULDADE DE CIÊNCIAS MÉDICAS DE ITACOATIARA - ITACOATIARA - AM - BRASIL;

Introdução/Fundamentos: Cardiovascular diseases remain the leading cause of mortality worldwide, with Acute Coronary Syndrome (ACS) accounting for a significant portion of these deaths. The 12-lead electrocardiogram (ECG) is essential for initial diagnosis, although its interpretation may be limited by interobserver variability and the subtle evolution of ischemic changes. With recent advances in artificial intelligence (AI), machine learning and deep learning models have emerged as promising tools to improve ACS detection. Objetivos: To summarize recent evidence on the diagnostic performance of AI models applied to 12-lead ECGs for identifying ACS in adult patients. Métodos: This Systematic Review followed PRISMA 2020 recommendations, PROSPERO: CRD420261368150. Searches were conducted in MEDLINE/PubMed, EMBASE, and the Cochrane Library using MeSH descriptors related to ACS, artificial intelligence, and electrocardiography. Original studies involving adults (≥18 years) that applied AI for ACS/AMI detection and reported diagnostic performance metrics were included. Risk of bias was evaluated using the QUADAS-2 tool. Resultados e Conclusões: Of the 199 records identified, 5 studies met the inclusion criteria. The studies were published between 2021 and 2025 and conducted in the United States, South Korea, and the Netherlands. The analyzed models included architectures based on deep learning (60%) and traditional machine learning (40%). Reported performance metrics ranged from AUROC 0.83 to 0.939, sensitivity 0.71 to 0.977, and specificity 0.76 to 0.898. In studies comparing AI with physicians, AI demonstrated superior sensitivity and overall discriminative ability, while clinicians occasionally achieved slightly higher specificity. Heterogeneity across studies was influenced by differences in diagnostic criteria, adjudication methods, and model structures. Overall risk of bias was low, with some concerns related to patient selection and reference standards. AI applied to 12-lead ECGs shows consistently high diagnostic performance for ACS detection, surpassing clinicians in sensitivity and global discrimination in several studies. These tools have the potential to enhance early triage, particularly in emergency and prehospital settings. However, methodological limitations, lack of broad external validation, and the scarcity of clinical outcome assessments still restrict widespread clinical adoption. Future investigations should prioritize methodological standardization, real-world validation, and evaluation of clinical impact.



18046



THROMBECTOMY AS AN ALTERNATIVE TO THROMBOLYSIS IN PULMONARY EMBOLISM: A SYSTEMATIC REVIEW AND META-ANALYSIS.

RICARDO ESTEVÃO MATOS SOUTO1; MARINA VINAGRE PIRES1; VICTOR DE ARAUJO GABRIEL1; MAYANA MARQUES LISBOA1; ADRIELLE CILENA DUARTE DA COSTA1; JULIANA VITÓRIA GOMES MORAES1; VICTOR AUGUSTO DE ALENCAR MENEZES1; GLORIA ALBUQUERQUE FRANCO1; LEONARDO GOUVÊA DE OLIVEIRA1; LUANA KAORI SAKAGUCHI SAKAMOTO1; STER MARQUES DE LIMA SILVA1; REANATO GARCIA LISBOA BORGES1;

(1) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Pulmonary thromboembolism (PTE) remains the third leading cause of cardiovascular death worldwide. In patients with intermediate-high or high-risk PTE, catheter-based therapies, such as catheter-directed thrombolysis (CDT) and mechanical thrombectomy, have been widely used with evidence of improved right ventricular function and hemodynamics, but with distinct bleeding risk profiles. However, direct comparative evidence between these modalities remains conflicting regarding efficacy and safety, with divergent findings regarding ICU length of stay, mortality, and bleeding. Objetivos: To conduct a systematic review with meta-analysis to compare the efficacy and safety of mechanical thrombectomy versus CDT, evaluating critical outcomes such as mortality, bleeding complications, and parameters of hemodynamic recovery in patients with acute PE Métodos: A systematic review was conducted, with searches performed in the PubMed, Embase, Cochrane Library, and Web of Science databases (February/2026). Randomized clinical trials and cohort studies were included. In the comparison between mechanical thrombectomy and catheter-directed thrombolysis, the following outcomes were evaluated: (1) all-cause mortality; (2) major bleeding; (3) Blood Transfusions; (4) Intracranial Hemorrhage; (5) Length of stay. The meta-analysis was performed using R (v4.5.1) software, study heterogeneity was assessed using Cochran's Q test and I² statistic. Resultados e Conclusões: All-cause mortality was significantly lower in the CDT group (3,4%) as compared with Thrombectomy patients (5,8%) (RR 1.33; 95% CI 1.04-1.70; P<0.05; Fig. 1A). Major bleeding was significantly reduced in the Thrombectomy group (14.25%) as compared with CDT-treated patients (15.44%) (RR 1.71; 95% CI 1.51-1.93; P<0.0001; Fig. 1B). Blood transfusions were significantly higher in the CDT group compared with the Thrombectomy group (RR 1.62; 95% CI 1.43–1.84; P<0.001; Fig. 2A). Similarly, intracranial hemorrhage (ICH) was significantly higher in the CDT group (RR 1.71; 95% CI 1.48–1.97; P<0.001; I²=0%; Fig. 2B). Patients treated with thrombectomy presented no significant differences on LOS when compared to CDT patients (MD -0.36; 95% CI -0.78-0.05; P<0.01). Mechanical thrombectomy has better outcomes on major bleeding, blood transfusions and intracranial hemorrhage, while CDT has more satisfactory outcomes on all-cause mortality.

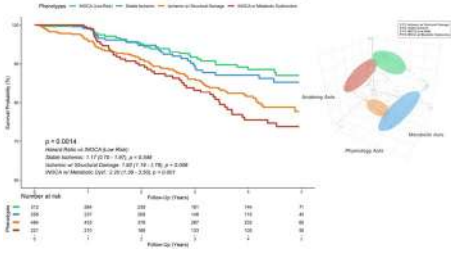
UNSUPERVISED MACHINE LEARNING AND CLUSTERING ANALYSIS FOR CLINICAL-METABOLIC PHENOTYPING IN CHRONIC CORONARY SYNDROME: HIGH-RISK INOCA DRIVEN BY METABOLIC DYSFUNCTION

ANISIO UCHOA LEITE SANTANA1; ALFREDO ROGÉRIO DIAS DALCOMUNI2; JOÃO VITOR BIANCALANA FERREIRA PERES CALIL2; VITOR BATALHA DE CAMARGO2; ARTHUR PINHEIRO SILVEIRA FREITAS2; EDUARDO MARTELLI MOREIRA1; FABIO GRUNSPUN PITTA1; EDUARDO GOMES LIMA1; FABIANA HANNA RACHED1; HENRIQUE TROMBINI PINESI1; CARLOS VICENTE SERRANO JR.1;

(1) INCOR - INSTITUTO DO CORACAO DA UNIVERSIDADE DE SAO PAULO - SAO PAULO - SP - BRASIL; (2) FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL;



Introdução/Fundamentos: Traditional classification of chronic coronary syndrome (CCS) relies heavily on anatomical obstruction. Consequently, Ischemia with No Obstructive Coronary Artery Disease (INOCA) is often deemed uniformly benign. However, INOCA encompasses a highly heterogeneous population. We hypothesized that unsupervised machine learning could uncover hidden clinical-metabolic phenotypes and challenge this assumption. Objetivos: To identify distinct clinical-metabolic phenotypes in a CCS cohort using unsupervised machine learning and to evaluate their independent impact on 5-year all-cause mortality. Métodos: An unsupervised machine learning approach, specifically clustering analysis (Partitioning Around Medoids with Gower distance), was applied to a prospective cohort of 1,276 patients with CCS. The model used 20 demographic, clinical, echocardiographic, and laboratory variables. Survival analysis was performed using Kaplan-Meier and multivariate Cox proportional hazards models. Resultados e Conclusões: The model revealed four distinct phenotypes: P1: Ischemic with Structural Damage (n=484); P2: Stable Ischemic (n=258); P3: INOCA Low Risk (n=313); and P4: INOCA with Metabolic Dysfunction (n=221).While P1 and P2 shared high anatomical burden (median 3 obstructed territories), P1 had worse structural impairment (LVEF 50% vs. 55%). Conversely, both P3 and P4 had a median of 0 obstructed territories. Despite this anatomical similarity, P4 exhibited the highest 5-year mortality (21%), contrasting sharply with P3 (9.6%). Clinically, P4 was defined by systemic inflammation, poor glycemic control (HbA1c 6.7%), and obesity (BMI 29.1 kg/m²), translating into early myocardial remodeling (worse diastolic dysfunction and higher LV mass) and functional limitation (NYHA ≥ II in 24%). In Cox regression, using the low-risk P3 as reference, the metabolic INOCA group (P4) had a 2.20-fold increased risk of death (HR 2.20, 95% CI 1.38-3.50, p<0.001), surpassing even the severe obstructive P1 group (HR 1.82, 95% CI 1.19-2.79, p=0.006), as shown in the figure. In conclusion Clustering analysis reveals that INOCA is a highly heterogeneous condition, wherein a specific metabolic-driven phenotype carries a mortality risk higher than traditional obstructive CCS, demanding aggressive systemic risk management beyond anatomical evaluation.

Table: Clinical-Metabolic-Anatomic Phenotypes

Characteristic[1]	Overall N = 1,276	P1: Ischemic w/ Structural Damage N = 484	P2: Stable Ischemic N = 258	P3: INOCA (Low Risk) N = 313	P4: INOCA w/ Metabolic Dysfunction N = 221	p-value
Age (years)	64 ± 9	64 ± 9	64 ± 9	65 ± 10	64 ± 9	0.6

ANALYSIS OF INFANT MORTALITY DUE TO UNSPECIFIED CONGENITAL HEART DISEASES IN BRAZIL: A CROSS-SECTIONAL STUDY (2018–2024)

WILLK MARIO PINTO FRANÇA LOPES1; DAVI COSTA FIGUEIREDO1; CAROLINE MOREIRA DE SOUZA1; WILKER FRAINKYLI SILVA MENDONCA1; MATHEUS GABRIEL MONTELES DA SILVA1; EVELYN BEZERRA DOS SANTOS1; JULIO DA SILVA BARROS1; □PEDRO FELIPE LEITÃO ALVES1; KENNIO ROBERTO CAMPOS RIBEIRO1; RAMON FABRÍCIO DE AMORIM NEVES E FRANÇA1; ISABELA MIRANDA MELO1; VINICIUS JOSE DA SILVA NINA1;

(1) UFMA - CAMPUS SAO LUIS - SÃO LUÍS - MA - BRASIL;

Introdução/Fundamentos: Congenital heart diseases (CHD) rank among the leading causes of infant mortality in Brazil. However, a significant proportion of these deaths are registered under code Q24.9 (unspecified congenital malformation of the heart), which compromises epidemiological surveillance, the estimation of surgical demand, and healthcare planning. The persistence of this code can be interpreted as a sentinel indicator of diagnostic fragility, reflecting failures in access to fetal and neonatal echocardiography, particularly in socially vulnerable regions. Objetivos: To analyze the magnitude, regional distribution, and factors associated with infant mortality due to unspecified CHD in Brazil, from 2018 to 2024. Métodos: This was a cross-sectional, ecological study using secondary data from the Mortality Information System (SIM/DATASUS). Infant deaths (<1 year) with the underlying cause classified between Q20–Q28, with emphasis on code Q24.9, were included. Proportions and odds ratios (OR) were estimated for deaths recorded without a specific diagnosis, adopting the Southeast region as the reference. Ninety-five percent confidence intervals (95% CI) and a significance level of 5% (p<0.05) were used. The temporal evolution of the proportion of unspecified CHDs was assessed by linear regression, with analyses performed in R software. Resultados e Conclusões: During the analyzed period, 20,888 infant deaths due to CHD were recorded, of which 8,093 (38.7%) were nonspecific. The highest proportions occurred in the Northeast (46.9%) and North (44.0%) compared to the South (28.7%), with a higher proportion of home deaths due to unspecified CHD in the North (2.58%) (Table 1). The risk of a death being recorded as nonspecific was significantly higher in the Northeast (OR=1.67; 95% CI 1.56-1.80; p<0.001) and North (OR=1.49; 95% CI 1.36-1.63; p<0.001) compared to the Southeast. The South region showed an inverse association with the outcome (OR=0.76; 95% CI 0.69-0.84; p<0.001). Temporal analysis revealed stagnation of diagnostic quality in the North and Northeast (p>0.05), in contrast to significant improvement in the South and Southeast (Table 2). While secondary mortality data entails classification biases, the high prevalence of this code itself evidences regional inequality. The elevated risk in the North/Northeast suggests structural barriers to diagnosis and care, generating epidemiological invisibility. Strengthening neonatal screening and the regionalization of cardiology services is fundamental to reducing mortality.

Table 1: Quality of Registration and Pediatric Care for Congenital Heart Diseases: Magnitude of Unspecified Causes (Q24.9) and Occurrence of Home Deaths (2018–2024)

	Total	Unspecified Causes (Q24.9)		Critical Unassistance*	
Region	Deaths (N)	N	% (Indefiniteness)	Home Deaths	%
Northeast	5,848	2,740	**46.9%**	48	1.75%
North	2,644	1,164	44.0%	30	2.58%
Central-West	2,028	776	38.3%	12	1.55%
Southeast	7,557	2,607	34.5%	25	0.96%
South	2,811	806	28.7%	6	0.74%
Brazil	**20,888**	**8,093**	**38.7%**	**121**	**1.50%**

Source: Authors' own elaboration based on SIM/DATASUS data (2018–2024).
**Critical Unassistance: Refers to the subpopulation of deaths classified as unspecified (Q24.9) that occurred at home, indicating a critical failure in the care network.*

Table 2: Integrated Analysis of Registration Quality (Q24.9): Risk Association (Odds Ratio) and Temporal Trend (2018–2024)

	Comparative Risk (vs. Southeast)		Temporal Trend (2018–2024)	
Region	OR (95% CI)	p-value	Slope (Annual Var.)	p-value
Northeast	1.67 (1.56 – 1.80)	< 0.001	-0.64 p.p.	0.152
North	1.49 (1.36 – 1.63)	< 0.001	-0.67 p.p.	0.124
Central-West	1.18 (1.06 – 1.30)	0.002	-2.37 p.p.	0.004
Southeast	*1.00 (Reference)*	–	-1.28 p.p.	0.007
South	0.76 (0.69 – 0.84)	< 0.001	-1.46 p.p.	0.002

Source: Authors' own elaboration based on SIM/DATASUS data (2018–2024).
Legend: **OR** = Odds Ratio; **CI** = Confidence Interval; **p.p.** = percentage points.
Note: OR > 1 indicates a greater chance of diagnostic error relative to the Southeast. In the trend analysis, a negative 'Slope' indicates a reduction in error; p-value > 0.05 indicates stagnation of the metric.

19930

AUTOIMMUNE CONGENITAL HEART BLOCK IN FETUSES OF ANTI-SSA/RO-POSITIVE MOTHERS: IMPACT OF HYDROXYCHLOROQUINE AND INTRAUTERINE THERAPY ON CLINICAL OUTCOMES — A SYSTEMATIC REVIEW

SOPHIA GOUVEIA DAMASCENO1; JULIANNY CARVALHO DA ROSA GUEDES2; JÚLIA AZEVEDO PARREIRA MARTINS3; ARTHUR MORAES DOS SANTOS4; LUCAS SILVA CABEÇA1; MARIA EDUARDA SOUZA MARTINS1; GIOVANNA BARCELOS FONTENELE PEREIRA3;

(1) UNIVERSIDADE FEDERAL DO PARA (UFPA) - BELÉM - PA - BRASIL; (2) CENTRO UNIVERSITARIO METROPOLITANO DA AMAZONIA - BELÉM - PA - BRASIL; (3) CENTRO UNIVERSITARIO DO ESTADO DO PARA (CESUPA) - BELÉM - PA - BRASIL; (4) UNIVERSIDADE DO ESTADO DO PARA (UEPA) - BELÉM - PA - BRASIL;

Introdução/Fundamentos: Congenital atrioventricular block is a rare condition associated with maternal anti-Ro/SSA autoantibodies, which can cross the placenta and impair the fetal cardiac conduction system, particularly through calcium channel disruption and immune-mediated injury to the atrioventricular node, resulting in bradycardia and increased risk of adverse outcomes such as hydrops fetalis and intrauterine death. Early identification and appropriate management are essential to reduce complications and guide antenatal counseling. Objetivos: To evaluate the association between autoimmune fetal atrioventricular block and clinical outcomes, with emphasis on the impact of hydroxychloroquine and other intrauterine interventions. Métodos: Systematic review of clinical trials and observational studies conducted in accordance with PRISMA recommendations. The literature search was performed in Cochrane Library, PubMed, and Scopus using the descriptors "congenital heart block", "fetal heart block", "anti-Ro", "autoimmune", and "treatment", including full-text studies published within the last 10 years in English, Spanish, and Portuguese. Outcomes analyzed were progression to asystole, fetal mortality, and need for neonatal pacemaker. Study selection was performed using Rayyan software, and risk of bias was assessed using ROBINS-I tools. Resultados e Conclusões: After screening, three studies were included. A consistent association was observed between autoimmune fetal atrioventricular block and adverse outcomes, particularly persistent bradycardia and progression of conduction abnormalities. Hydroxychloroquine demonstrated a significant reduction in recurrence of congenital heart block (7.4% vs 18%), representing a reduction greater than 50%. Neonatal electrophysiological analysis showed no correlation between drug levels and QTc prolongation (R=0.02; p=0.86), with a low incidence of QTc prolongation (>2 SD) in 11% of neonates, supporting its favorable safety profile. In contrast, therapeutic apheresis showed limited evidence of efficacy, although well tolerated (2.1% adverse events), suggesting a secondary role in selected cases. Moderate risk of bias predominated, due to lack of randomization and small sample sizes. Overall, hydroxychloroquine emerges as the intervention with the strongest supporting evidence and best risk-benefit profile; however, the absence of randomized controlled trials precludes definitive conclusions, warranting prospective studies.

BEYOND TRADITIONAL SCORES: ARTIFICIAL INTELLIGENCE IN SURGICAL PLANNING OF CONGENITAL HEART DISEASES

JOÃO WALLACE CARVALHO DE OLIVEIRA1; MARCELA ALINA JEREISSATI DE CASTRO1; MARINA MARQUES MAIA1; THAÍSSA UCHOA LIMA1; GABRIELA GADELHA RATTACASO1; LÍVIA AZEVEDO VASCONCELOS1; JOÃO CAMILO AGUILA LANDIM2; MONALISA SILVA LEAL RODRIGUES1; MILENE CAETANO DA ROCHA1; MARINA PINHEIRO UCHOA AZEVEDO1; CAIO CÉSAR OTÔNI ESPÍNDOLA ROCHA1;

(1) UNIVERSIDADE CHRISTUS - FORTALEZA - CE - BRASIL; (2) FACULDADE DE MEDICINA UNINTA - SOBRAL - CE - BRASIL;

Introdução/Fundamentos: Congenital heart diseases (CHD) are among the most common anomalies at birth and present high anatomical complexity and clinical variability, making surgical planning and outcome prediction difficult. In this context, artificial intelligence (AI) emerges as a promising tool by integrating clinical and operative data, improving risk stratification and surgical planning. Objetivos: To analyze the application of AI in the surgical planning of patients with CHD, comparing it to conventional approaches and evaluating its impacts on planning accuracy and outcomes. Métodos: This systematic review was conducted according to PRISMA guidelines, with searches in the PubMed, Scopus, Cochrane Library and Embase databases, using the descriptors “Treatment Planning”, “Surgical Procedures, Operative”, “Artificial Intelligence” and “Congenital Heart Disease”. Studies from the last 5 years, available in full text in English or Portuguese, were included, with duplicates, reviews, case reports and animal studies excluded. Selection was performed on the Rayyan® platform, resulting in 7 studies included among 12 identified. Resultados e Conclusões: AI models show high accuracy in predicting outcomes in CHD, with AUC up to 0.97 in pediatric postoperative complications and between 0.75–0.90 in adults, often outperforming traditional scores. Models such as LightGBM and XGBoost stand out in predicting adverse events, allowing identification of the occurrence and type of complication with greater precision compared to conventional approaches. The application of AI in surgical planning, through the integration of clinical and operative variables, enables more precise risk stratification, favoring early identification of high-risk patients and optimization of perioperative planning, with association in reducing complications and mortality. AI demonstrates greater accuracy in surgical planning of CHD compared to conventional approaches, with better ability to predict outcomes and risk stratification, being associated with improvement in surgical outcomes and mortality. Models such as LightGBM and XGBoost stand out for their high accuracy in identifying complications. However, its clinical application still depends on prospective validation and integration into care workflows, being configured as a promising complementary tool.

ECHOCARDIOGRAPHIC ANALYSIS AND CEREBRAL BLOOD FLOW DYNAMICS IN CHILDREN AND ADOLESCENTS WITH SICKLE CELL DISEASE: A CROSS-SECTIONAL STUDY

VICENTE CASTOR BRITO1; CATARINA RAMALHO DOS SANTOS2; SUELY ARRUDA VIDAL3; CANDYCE DE ANDRADE CARDOSO RAMALHO2; ARIANI IMPIERI SOUZA3; LÍVIA RAULINO DE OLIVEIRA CASTRO MARQUES4; FELIPE MARTINS DE LIMA2; JORGIANA ESTER DE MACEDO COSTA DA SILVA2; LARISSA BARBOSA DOS SANTOS2; PEDRO ADSON DA CUNHA MEDEIROS2; TACIANA RAULINO DE OLIVEIRA CASTRO MARQUES2;

(1) UFCG - CAMPINA GRANDE - PB - BRASIL; (2) UNIVERSIDADE FEDERAL DE CAMPINA GRANDE - UFCG - CAMPINA GRANDE - PB - BRASIL; (3) INSTITUTO DE MEDICINA INTEGRAL PROFESSOR FERNANDO FIGUEIRA - IMIP - RECIFE - PE - BRASIL; (4) UNIFACISA - CAMPINA GRANDE - PB - BRASIL;

Introdução/Fundamentos: In sickle cell disease (SCD), cerebrovascular and cardiovascular involvement share common risk factors and significantly impact morbidity and mortality. Objetivos: This study aims to analyze associations between echocardiographic parameters and cerebral blood flow dynamics in children with SCD. Métodos: This cross-sectional study included 42 patients (aged 2–18 years) with SCD who underwent transthoracic Doppler echocardiography and transcranial Doppler ultrasonography. Echocardiographic assessment focused on cardiac chamber dimensions, aortic root diameter, left ventricular global longitudinal strain, tricuspid regurgitation velocity, and pulmonary artery systolic pressure. Transcranial Doppler evaluated the time-averaged maximum mean velocity of cerebral blood flow in the internal carotid and middle cerebral arteries, based on the Stroke Prevention Trial in Sickle Cell Anemia. Resultados e Conclusões: Left atrial dilation was the most common abnormality (N=34/81%); 83.3% (N=35) had normal transcranial Doppler findings. Cerebral blood flow velocity showed a positive correlation with left ventricular global longitudinal strain (r=0.35; p=0.039) and a negative correlation with aortic root diameter (r=−0.38; p=0.012). Higher median absolute values of left ventricular global longitudinal strain and cerebral blood flow velocity were observed in patients with genotypes associated with greater disease severity (p=0.001 and p=0.055, respectively). Higher cerebral blood flow velocity was associated with smaller aortic root diameter and increased left ventricular myocardial deformation. Genotypes associated with greater severity exhibited higher median absolute values of left ventricular global longitudinal strain and cerebral blood flow velocity. These findings reinforce the need for early evaluation of multisystem involvement, enabling identification of children at risk for progression to multiorgan disease.

EFFICACY AND SAFETY OF SODIUM-GLUCOSE COTRANSPORTER 2 (SGLT2) INHIBITORS IN PEDIATRIC CARDIORENAL SYNDROME: A SYSTEMATIC REVIEW OF PRELIMINARY EVIDENCE

FELIPE GONÇALVES ROSA1; JOHAN ALMEIDA1; IGOR COGUI SANTON1; ARTHUR VENDRAMIN FÚRIO1; RAFAEL LUIS MOREIRA DOMINGOS1; CECÍLIA COUTINHO GUIMARÃES2; ANA CRISTINA SIMÕES SILVA1;

(1) HOSPITAL DAS CLINICAS DA UFMG - BELO HORIZONTE - MG - BRASIL; (2) FACULDADE DE MEDICINA UNIVERSIDADE PROFESSOR EDSON ANTONIO VELANO - UNIFENAS - BELO HORIZONTE - MG - BRASIL;

Introdução/Fundamentos: Pediatric cardiorenal syndrome (CRS), frequently associated with congenital conditions, results in high morbidity and mortality worldwide. Although the therapeutic use of SGLT2 inhibitors (SGLT2i) demonstrates consolidated cardiorenal benefits and a favorable safety profile in adults (DAPA-CKD, DAPA-HF, CREDENCE, EMPA-KIDNEY, EMPEROR-Reduced, and EMPA-REG trials), its pediatric use remains restricted to T2DM, with scarce evidence regarding the management of heart failure or kidney disease. A gap persists regarding the efficacy and safety of this class in modifying the natural history of CRS in children. Objetivos: To evaluate the clinical efficacy and safety profile of SGLT2i in modifying outcomes in pediatric patients with CRS. Métodos: A systematic review was conducted according to PRISMA 2020 guidelines. The search was performed in seven databases (PubMed, Embase, Cochrane, Web of Science, LILACS, ClinicalTrials.gov, and WHO ICTRP) and grey literature using AI tools (Open Evidence and Embase AI) until May 2026. PICO criteria were: patients <21 years with CRS (P); SGLT2i (I); placebo or standard of care (C); efficacy outcomes (GFR, UACR, LVEF, and NT-proBNP) and safety outcomes (growth and neurodevelopment) (O). Clinical trials (completed or ongoing) and cohort studies were included. Title and abstract screening was conducted by two independent blinded reviewers, with conflicts resolved by a third reviewer. Ten studies met the eligibility criteria. Resultados e Conclusões: After full-text analysis, two additional studies were excluded, and 8 studies were analyzed (n=828; 508 in completed cohorts), with a predominance of dapagliflozin use. Long-term GFR stability was observed despite an initial transient decline (month 1), along with a consistent reduction in biomarkers (BNP/NT-proBNP). There was an improvement in weight Z-score among infants. The safety profile was favorable: UTIs and transient AKIs were the most frequent events, with discontinuation rates below 12%. It is concluded that SGLT2i demonstrate a promising safety profile and preliminary evidence of clinical benefit in pediatric CRS. Future long-term and well-designed studies are needed for further knowledge regarding the clinical efficacy and safety profile of these agents in children. Given the predominantly observational nature of current data, robust ongoing clinical trials (EMPA-KIDNEY Kids and IECA-MEX trials) are essential to consolidate these therapies in pediatric practice.

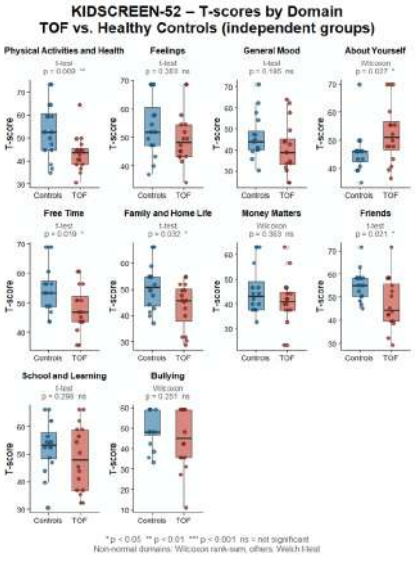
FUNCTIONAL CAPACITY IN CHILDREN AND ADOLESCENTS WITH CONGENITAL HEART DISEASE: A SYSTEMATIC REVIEW OF THE LITERATURE

ANNA BEATRIZ DE OLIVEIRA NOGUEIRA1; VICTOR MEDEIROS REBOUÇAS1; THIAGO HENRIQUE DUARTE MOREIRA1; LUCAS HORTÊNCIO RIBEIRO DE OLIVEIRA1; GERSON BARBOSA DO NASCIMENTO1;

(1) ESCOLA MULTICAMPI DE CIENCIAS MEDICAS - CAICÓ - RN - BRASIL;



Introdução/Fundamentos: Congenital heart disease (CHD) involves structural defects of the heart and great vessels. Understanding the functional capacity of children and adolescents with CHD is important for assessing the risk of morbidity and mortality, as well as for promoting quality of life in this population. Objetivos: To review the current scientific evidence regarding the impact of CHD on the functional capacity of children and adolescents. Métodos: This is a systematic review conducted in accordance with the PRISMA guidelines, based on the selection of scientific publications from the LILACS and MEDLINE databases. The Health Sciences Descriptors used were “Congenital Heart Diseases” and “Exercise.” Inclusion criteria comprised randomized clinical trials and observational studies conducted in children and adolescents aged 6 to 18 years; use of functional capacity assessment tests; and publications written in Portuguese, English, and/or Spanish between 2014 and 2025. After applying the eligibility criteria, a final sample of 10 studies was obtained. Resultados e Conclusões: In the analysis of 1,074 children and adolescents with CHD, functional capacity, physical fitness, performance in activities of daily living, and quality of life were found to be impaired compared to healthy peers. Functional capacity was assessed using the Six-Minute Walk Test, in which individuals with CHD covered shorter distances, with a positive correlation between poorer results and the need for surgical procedures. The TGlittre-P test evaluated performance in activities of daily living, and patients with CHD showed longer completion times. Physical activity level, body mass index, flexibility, and metabolic score did not differ between the CHD and control groups. Aerobic capacity was reduced (75% of predicted). Most children were physically active (75.9% of children with CHD and 84.3% of the control group). Obesity, higher disease complexity, and total cavopulmonary connection were associated with failure to meet the recommendations for average weekly physical activity. Increased physical activity was associated with improved functional capacity and quality of life, whereas reduced functional capacity was linked to a higher likelihood of future cardiovascular events. Children and adolescents with CHD have impaired functional capacity, and regular physical activity should be encouraged in this population, as it is associated with improvements in functional capacity and quality of life.

HEALTH-RELATED QUALITY OF LIFE IN BRAZILIAN CHILDREN AND ADOLESCENTS WITH REPAIRED TETRALOGY OF FALLOT: A KIDSCREEN-52 ASSESSMENT

JULIA AMARAL-PEREIRA1; MANUEL GOUVEIA1; FERNANDA PADRÃO FERNANDES2; ADRIANA M INNOCENZI2; JULIANA PÓVOA3; FLAVIA MIELE ARAÚJO3; FERNANDA TOVAR-MOLL3; PAULO MATTOS3; RENATA MOLL-BERNARDES3; MARIANA PÓVOA-CORRÊA1;

(1) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (2) INSTITUTO NACIONAL DE CARDIOLOGIA - RIO DE JANEIRO - RJ - BRASIL; (3) IDOR - RIO DE JANEIRO - RJ - BRASIL;

Introdução/Fundamentos: Advances in surgical care have markedly increased survival in Tetralogy of Fallot (TOF), the most common cyanotic congenital heart defect. This longevity has increased the burden of potential cardiac and neurodevelopmental issues that may affect quality of life. Despite advances in surgical outcomes and long-term survival in Tetralogy of Fallot in Brazil, evidence regarding quality of life remains scarce. Objetivos: To assess Health-Related Quality of Life (HRQoL) in Brazilian children and adolescents with TOF compared to healthy age- and sex-matched controls using the KIDSCREEN-52 questionnaire. Métodos: This cross-sectional study enrolled surgically repaired TOF patients aged 7–18 years who underwent surgery before three years old, referred from outpatient cardiology clinics, with healthy controls matched for sex and age. HRQoL was measured using the KIDSCREEN-52, a psychometrically validated instrument for the Brazilian population covering ten domains, with results expressed as T-scores (mean 50, SD 10). Normality of T-score distributions by domain and group was assessed with the Shapiro–Wilk test. Domains with normal distributions in both groups ($p \geq 0.05$) were compared using the independent-samples Student's t-test; otherwise, the Mann–Whitney U test was used. A two-tailed $p < 0.05$ was considered significant. Analyses were performed in R (base stats package). Resultados e Conclusões: Sixteen TOF patients and 16 controls were evaluated. Significant differences were identified in five domains. TOF patients scored lower in Physical Well-being (43.63 [38.47–45.32] vs. 52.43 [44.73–60.59]; p = 0.009), Autonomy (46.85 [43.59–52.15] vs. 53.22 [48.70–57.33]; p = 0.019), Social Support and Peers (44.34 [39.49–55.73] vs. 54.93 [50.24–58.14]; p = 0.021), and Parent Relations (45.72 [37.67–50.08] vs. 50.66 [43.70–54.65]; p = 0.032). Notably, TOF patients scored higher in Self-Perception (50.97 [46.63–56.56] vs. 46.08 [42.51–46.09]; p = 0.027). TOF patients showed impaired HRQoL across physical, social, and family domains. The higher Self-Perception scores may reflect adaptive psychological mechanisms and warrant further investigation. Multidisciplinary follow-up addressing quality of life beyond cardiac outcomes is essential in this population.

Domain	TOF — Median [IQR]	Controls — Median [IQR]	p-value

IMPACT OF PATENT DUCTUS ARTERIOSUS IN VERY AND EXTREMELY LOW BIRTH WEIGHT NEONATES: MATERNAL-FETAL RISK FACTORS AND CLINICAL OUTCOMES (2019-2023)

LUIS FELIPE DE LUCENA FABRICIO1; JOÃO GUILHERME FONTENELE GAMA1; GABRIELA MOURA MAXIMO1; LEONARDO PATRICK DE ALMEIDA PEREIRA1; MARIA EDUARDA FERNANDES ROCHA1; RAPHAELL LUCAS DE ARAUJO TEIXEIRA1; LOUISE MARIA DIAS CORTEZ BRAGA1; VITOR CHAVANTE SILVA1; GUSTAVO HENRIQUE FONTENELE GAMA2; NIVIA MARIA RODRIGUES ARRAIS1;

(1) UFRN - NATAL - RN - BRASIL; (2) UFMA - CAMPUS SAO LUIS - SÃO LUÍS - MA - BRASIL;

Introdução/Fundamentos: Patent Ductus Arteriosus (PDA) is a frequent cardiovascular complication in the neonatal period, especially in very low birth weight (VLBW) and extremely low birth weight (ELBW) infants. Failure of ductal closure is associated with hemodynamic instability and increased mortality. While prematurity is the primary factor, the role of maternal comorbidities and the impact of therapies on outcomes require further investigation. Objetivos: To analyze the prevalence of PDA in VLBW and ELBW neonates, correlating it with neonatal anthropometric profiles, maternal pathologies, and the impact of interventions on clinical outcomes. Métodos: A retrospective cohort study analyzed data from infants born between 2019 and 2023 at a quaternary center. The sample included neonates with recorded birth weight and gestational age (GA) and a confirmed diagnosis of PDA. Variable normality was tested using the Shapiro-Wilk method. Due to the observed non-parametric distribution, the Mann-Whitney U test was used for comparing means/medians, and the Chi-Square test was applied for the analysis of categorical variables (HBP, DM, treatment, and outcomes), with a significance level of p≤0,05. Resultados e Conclusões: Data from 818 neonates were analyzed, of which 152 (18,6%) were diagnosed with PDA. Neonates with PDA had significantly lower birth weight (943,8 ± 256,8g vs. 1106,2 ± 302,9g; p < 0,0001) and gestational age (193,8 ± 19,8 days vs. 207,7 ± 21,4 days; p < 0,0001). Maternal systemic hypertension (HBP) was significantly associated with PDA (p=0,0003), presenting an inverted relation, while diabetes showed no correlation (p=0,36). Within the PDA group, pharmacological treatment - ibuprofen or paracetamol - was a key determinant for survival: treated neonates had a significantly lower mortality rate (14,8%) compared to untreated ones (38,7%) (p=0,006). It is concluded that PDA prevalence is inversely proportional to weight and GA, and early pharmacological treatment is critical for reducing neonatal mortality. The absence of maternal HBP correlated with higher PDA incidence, suggesting that maternal physiological stress may paradoxically assist in ductal maturation.

Table 1: Biometric Comparison and Maternal Factor (*N* =818)

Variable	PDA Present (*n* =152)	PDA Absent (*n* =666)	*p*-value
Mean Weight (g)	943.8 ± 256	1106.1 ± 302	**< 0.0001**
Mean GA (days)	193.8 ± 19	207.7 ± 21	**< 0.0001**
Maternal HBP (%)	35.5%	52.1%	**0.0003**

Source: Created by the Author.

Table 2: Clinical Outcomes in PDA Group by Treatment

Outcome	With Medication (*n* =54)	Without Medication (*n* =98)
Survival (Disch./Transf.)	85.2%	61.3%
Death	14.8%	38.7%
Association p-value: 0.006

INFECTIVE ENDOCARDITIS AFTER TETRALOGY OF FALLOT REPAIR: A SYSTEMATIC REVIEW OF ASSOCIATED FACTORS

BEATRIZ SILVA OLIVEIRA1; GUILHERME ALVES COLAÇO1; BEATRIZ MARQUES FERREIRA1; AMANDA OLIVEIRA1; MARCO ANTONIO FERREIRA1;

(1) UNIVERSIDADE DE MOGI DAS CRUZES - MOGI DAS CRUZES - SP - BRASIL;

Introdução/Fundamentos: Tetralogy of Fallot (TOF) is the most common cyanotic congenital heart disease, characterized by ventricular septal defect, overriding aorta, right ventricular hypertrophy, and right ventricular outflow tract obstruction. Despite surgical advances, repaired patients remain at increased risk for infective endocarditis (IE), with in-hospital mortality reaching 20% and long-term survival below 50%. Objetivos: The objective of this study was to systematically evaluate the main risk factors associated with infective endocarditis following Tetralogy of Fallot repair, with emphasis on prosthetic material, residual hemodynamic abnormalities, and previous cardiac interventions. Métodos: A systematic review was conducted according to PRISMA guidelines using PubMed, SciELO, and Lilacs databases with the descriptors: “Tetralogy of Fallot” AND “endocarditis”. Original studies, systematic reviews, and meta-analyses published within the last five years, in English or Portuguese, and with free full-text access were included, resulting in 44 studies. After excluding case reports and duplicate articles, 12 studies were selected for final analysis. Resultados e Conclusões: Comparative analysis by prosthesis type demonstrated a lower incidence of IE in homografts and bioprosthetic valves compared with mechanical prostheses. The main risk factors identified included the presence of valvular prosthetic material, previous cardiac procedures, with an 8.22-fold increased risk during the first six months, adverse residual hemodynamic abnormalities, structural heart disease present in 92.5% of IE cases, residual or late cyanosis, and previous history of endocarditis. Furthermore, persistent pulmonary regurgitation, particularly when moderate to severe, was associated with increased IE occurrence. Socioeconomic factors and limited access to specialized healthcare were also related to higher risk, contributing to delayed correction and inadequate follow-up. Overall, patients with repaired Tetralogy of Fallot remain at significant risk for infective endocarditis, especially in the presence of prosthetic valvular material, residual hemodynamic abnormalities, and prior cardiac interventions. Therefore, antibiotic prophylaxis, continuous clinical surveillance, and early diagnosis remain essential to reduce morbidity and mortality.

LEFT VENTRICULAR GLOBAL LONGITUDINAL STRAIN ALTERATIONS IN CHILDREN WITH SICKLE CELL DISEASE

VICENTE CASTOR BRITO1; SUELY ARRUDA VIDAL2; CANDYCE DE ANDRADE CARDOSO RAMALHO1; ARIANI IMPIERI SOUZA2; LÍVIA RAULINO DE OLIVEIRA CASTRO MARQUES3; FELIPE MARTINS DE LIMA1; CATARINA RAMALHO DOS SANTOS1; JORGIANA ESTER DE MACEDO COSTA DA SILVA1; LARISSA BARBOSA DOS SANTOS1; PEDRO ADSON DA CUNHA MEDEIROS1; TACIANA RAULINO DE OLIVEIRA CASTRO MARQUES1;

(1) UNIVERSIDADE FEDERAL DE CAMPINA GRANDE - UFCG - CAMPINA GRANDE - PB - BRASIL; (2) INSTITUTO DE MEDICINA INTEGRAL PROFESSOR FERNANDO FIGUEIRA - IMIP - RECIFE - PE - BRASIL; (3) UNIFACISA - CAMPINA GRANDE - PB - BRASIL;

Introdução/Fundamentos: Cardiopulmonary impairment in sickle cell disease (SCD) progresses silently and represents a leading cause of mortality in adults with the disease. Objetivos: This study aimed to describe and analyze the echocardiographic parameters of patients with SCD. Métodos: A cross-sectional study with an analytical component involving patients with SCD. Inclusion criteria considered participants aged between 2 and 18 years, without other systemic diseases causing pulmonary hypertension, who were treated at a high-complexity public healthcare service in Northeastern Brazil. Transthoracic Doppler echocardiography assessed myocardial function, including the left ventricular global longitudinal strain (LVGLS) by speckle tracking. Fisher’s exact test, Mood’s median test, the Benjamini-Hochberg method, and Pearson’s correlation coefficient were applied to explore associations between variables. Statistical significance was defined as p<0.05. Resultados e Conclusões: Among the 42 patients evaluated, the median age was 10 years (interquartile range [IQR]: 7-13), with a predominance of the HbSS genotype. The most common findings included left atrial and left ventricular (LV) dilation. LVGLS was impaired in two patients (4.7%) and was significantly associated with the genotype, with greater absolute values in SS/Sß0 genotypes (p=0.001). Tricuspid annular plane systolic excursion presented high median values in the HbSC genotype group (p=0.033). Tricuspid regurgitation velocity was increased in three patients (7.2%), with positive correlations observed for leukocyte count (r=0.39; p=0.044) and lactate dehydrogenase (LDH) (r=0.45; p=0.034). The LV deformation observed in this population suggests early-stage cardiac dysfunction in SCD. The associations between LVGLS and genotype, and between tricuspid regurgitation and laboratory parameters, support the need for individualized risk stratification and early intervention in these patients.

LVEF = left ventricular ejection fraction; TRV = tricuspid regurgitation velocity; LDH = lactate dehydrogenase.

MATERNAL DISTRESS — GUILT, DEPRESSION, AND ANXIETY AMONG MOTHERS OF CHILDREN WITH AND WITHOUT CONGENITAL HEART DISEASE

EDUARDA MORARI JESKE1; RAFAELA CAMPOS PERUCHI1; DANIELA DA ROSA VIEIRA1; ALICE PEIXOTO MARTINS1; MARCIA MOURA SCHMIDT1;

(1) INSTITUTO DE CARDIOLOGIA / FUNDAÇÃO UNIVERSITARIA DE CARDIOLOGIA - PORTO ALEGRE - RS - BRASIL;

Introdução/Fundamentos: Depressive and anxiety symptoms are common among caregivers and are often linked to guilt, a multidimensional construct shaped by moral, social, and relational factors. Women, especially mothers, tend to report higher and more diverse sources of guilt, particularly in family and interpersonal contexts. In chronic pediatric conditions such as congenital heart disease (CHD), hospitalization and caregiving demands may intensify maternal distress and guilt. Excessive guilt is associated with poorer psychological well-being and may impair caregiving and family functioning. Despite its relevance, maternal guilt remains understudied in this setting, especially in low- and middle-income countries, where research has focused mainly on anxiety and depression. Moreover, comparisons between mothers of children with and without CHD are limited, restricting understanding of how caregiving contexts influence guilt. Objetivos: To investigate guilt prevalence and its association with depressive and anxiety symptoms in mothers of children with congenital heart disease (CHD) hospitalized in a referral cardiology hospital, compared with mothers of children without CHD. Métodos: This cross-sectional comparativestudy included 123 mothers of children with CHD and 123 mothers of children without CHD. Participants completed the Beck Depression Inventory-II (BDI-II), the Beck Anxiety Inventory (BAI), and the Multifactorial Guilt Scale (MGS). Crude and adjusted associations between independent variables and the presence of guilt were estimated using Poisson regression with robust variance to calculate prevalence ratios (PRs). Resultados e Conclusões: Guilt was highly prevalent, affecting 78% of the total sample. Mothers of children with CHD reported lower levels of guilt but higher levels of anxiety compared with mothers of children without CHD, while depressive symptom levels were similar between groups. Mothers of children without CHD were 35% more likely to experience guilt. The presence of depressive symptoms—mild, moderate, or severe—increased the likelihood of guilt by 21% to 29%. Anxiety was not significantly associated with guilt. Maternal guilt was frequent and strongly associated with depressive symptoms, regardless of the child's clinical condition. Differences between groups suggest that contextual and caregiving factors may influence emotional experiences. These findings highlight the need for psychological interventions tailored to the specific profiles and support needs of each group of mothers.

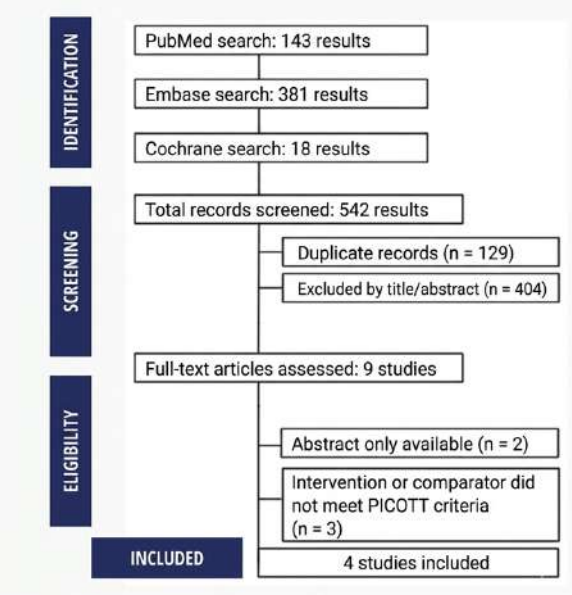
MICRORNAS AS DIAGNOSTIC AND PROGNOSTIC BIOMARKERS IN PEDIATRIC MYOCARDITIS: A SYSTEMATIC REVIEW

MAYARA LEITE DUTRA1; LAURA NERES FARIAS1; EMANUELLY ALINE GOMES CAVALCANTE1; LAURA BEATRIZ DANTAS TORRES2; ADRIANA SANTOS CUNHA CALADO3;

(1) UNIVERSIDADE DE MACEIO UNIMA - MACEIÓ - AL - BRASIL; (2) UNIVERSIDADE FEDERAL DE ALAGOAS - MACEIÓ - AL - BRASIL; (3) CENTRO UNIVERSITARIO CESMAC - MACEIO - AL - BRASIL;

Introdução/Fundamentos: Pediatric myocarditis is a potentially severe inflammatory condition and an important cause of acute heart failure in children, with diagnosis often challenging due to nonspecific clinical presentation and limitations of conventional diagnostic methods. Its clinical course is highly variable, ranging from mild symptoms to fulminant disease, making early identification essential to improve outcomes. In this context, microRNAs have emerged as promising biomarkers owing to their stability in biological fluids and their role in inflammatory and myocardial remodeling pathways. Objetivos: To evaluate the diagnostic and prognostic value of microRNAs in pediatric myocarditis. Métodos: A systematic review was conducted in accordance with PRISMA guidelines, using a PICOT-based strategy, without restrictions on language or publication period. Searches were performed in PubMed and Embase using the terms "microRNAs", "Myocarditis", and "Child", combined with "Biomarkers", "Diagnosis", and "Prognosis". Observational clinical studies involving pediatric patients with myocarditis and assessment of microRNA expression were included, while studies in adults, experimental models, case reports, and reviews were excluded. After screening and full-text assessment, four studies were included, comprising 506 participants (259 with myocarditis and 247 controls). Risk of bias was assessed using the Newcastle-Ottawa Scale. Resultados e Conclusões: Across the included studies, significant alterations in microRNA expression were consistently associated with the presence of myocarditis. In fulminant cases, increased levels of exosomal microRNAs were reported, particularly hsa-miR-146a-5p, which demonstrated strong diagnostic performance and correlation with markers of myocardial injury. In non-fulminant viral myocarditis, decreased levels of miR-425-3p were associated with both diagnosis and worse clinical outcomes. Additionally, miR-146b and hsa-miR-21 were significantly elevated and correlated with disease severity, ventricular dysfunction, and adverse outcomes. MicroRNAs show considerable potential as diagnostic and prognostic biomarkers in pediatric myocarditis and may contribute to future strategies for early diagnosis and risk stratification. However, methodological heterogeneity and the limited number of studies restrict the generalizability of these findings, highlighting the need for prospective, multicenter validation, and may complement current diagnostic tools in clinical practice.

AUTHOR (YEAR)	TYPE OF MYOCARDITIS	MICRORNA	MAIN FINDING
Zhang et al., 2023	Pediatric fulminant	hsa-miR-146a-5p	Exosomal increase; high diagnostic performance
Cao et al., 2024	Pediatric viral	miR-425-3p	Serum reduction; independent predictor of prognosis
Yan et al., 2021	Pediatric viral	miR-146b	Increased levels associated with disease severity and ventricular dysfunction
Wang et al., 2025	Pediatric fulminant	hsa-miR-21	Increased expression associated with adverse outcomes



16414

MUSCLE STRENGTH AND FUNCTIONAL CAPACITY IN CHILDREN WITH PULMONARY ARTERIAL HYPERTENSION: A SYSTEMATIC REVIEW

CAROLINA SILVA FERNANDES1; LUÍSA ROHR SCHAFER1; ARTHUR SIMAS HEISSER1; GONÇALO ZARDIN CHECHI ZARDIN CHECHI1; KAREN ISABEL KLEIN1; AMANDA BENDO PEREIRA1; CLARA FIGUEIREDO DOS SANTOS1; JULIA LARSEN DORCINIO1; JULIANA ROSSET DOS SANTOS1; EDUARDA PAIVA BORSA1; HENRIQUE SILVA LOVERA1; ROGERIO EDUARDO GOMES SARMENTO SARMENTO-LEITE2;

(1) UFCSPA - PORTO ALEGRE - RS - BRASIL; (2) INSTITUTO DE CARDIOLOGIA / FUNDAÇÃO UNIVERSITARIA DE CARDIOLOGIA - PORTO ALEGRE - RS - BRASIL;

Introdução/Fundamentos: Pulmonary arterial hypertension (PAH) in children and adolescents is a rare and severe condition associated with progressive functional limitation. In addition to cardiovascular dysfunction, these patients often present reduced lean mass and muscle strength due to chronic hypoxemia, systemic inflammation, and reduced physical activity. Objective assessment of muscle strength and functional capacity, through tests such as handgrip strength, isometric contraction, and the six-minute walk test (6MWT), allows evaluation of the systemic impact of PAH and its relationship with clinical markers such as NT-proBNP. Objetivos: This study aimed to review the available evidence on muscle strength and functional capacity in children and adolescents with PAH, highlighting their main correlations and clinical implications. Métodos: Systematic review conducted according to PRISMA guidelines. PubMed, Embase, and Cochrane databases were searched without time restrictions using the descriptors “Pulmonary Arterial Hypertension”, “Child”, and “Muscle Strength”. A total of 413 studies were identified. Screening, selection, and data extraction were performed by two independent reviewers based on predefined criteria, resulting in 4 included studies. Resultados e Conclusões: Four studies published between 2021 and 2024 were included, totaling 75 pediatric patients with PAH. All studies consistently demonstrated reduced muscle strength and lean mass, with direct impact on functional capacity. Kavgaç et al. (2024) found a positive correlation between handgrip strength and 6MWT ($r = 0.586$; $p = 0.022$), and a negative correlation with pro-BNP ($r = −0.565$; $p = 0.023$). Peppinkhuijzen et al. (2023) reported mean handgrip strength of 16 ± 9 kg ($z = −2.4 \pm 1.2$; $p < 0.001$) and total MVIC $z = −2.9 \pm 1.2$ ($p < 0.001$). Avitabile et al. (2022; 2021) showed lean mass deficits (LLMZ up to $−1.40 \pm 1.12$) and a positive association between LLMZ and 6MWT performance ($R^2 = 0.39$; $p = 0.03$). Children with PAH show reduced muscle strength and lean mass across different assessments. These impairments are directly related to clinical parameters such as NT-proBNP levels and 6MWT performance, suggesting that muscle evaluation may serve as an additional prognostic marker to support clinical decision-making.

17144

NEURODEVELOPMENT AFTER THE FONTAN CIRCULATION: RISK FACTORS AND MID- TO LONG-TERM OUTCOMES IN CHILDREN

MARIAH GEOVANNA SOARES SOUZA1; SABRINA BRASILEIRO DA COSTA1; LUCIANA CRISTINA MARTINS RAMOS2; ARTHUR VILAR DE OLIVEIRA MALHEIROS3;

(1) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (2) IDOMED/ESTACIO - RIO DE JANEIRO - RJ - BRASIL; (3) UNIVERSIDADE DE SANTO AMARO - SÃO PAULO - SP - BRASIL;

Introdução/Fundamentos: The Fontan circulation represents the final palliative strategy for single-ventricle congenital heart disease; however, it is associated with neurodevelopmental risks due to chronic hypoxia, systemic inflammation, and perioperative surgical complications. Cognitive, motor, and executive deficits affect up to 50% of children, impacting quality of life and social adaptation in the mid-term (1–5 years) and long term (>5 years). Objetivos: To synthesize evidence from PubMed and SciELO, using PRISMA methodology, on risk factors and neuropsychological outcomes after the Fontan procedure in children, with the aim of informing neurodevelopmental interventions. Métodos: A PRISMA-guided systematic review was conducted in PubMed and SciELO (up to April 2026) using the search terms “Fontan AND (neurodevelopment OR neurodesenvolvimento) AND children.” Inclusion criteria were studies with ≥10 pediatric patients, follow-up ≥1 year, and assessment of neurocognitive domains. Case reports were excluded. The search identified 1,247 records; after removal of 156 duplicates, 842 were screened, 28 assessed for eligibility, and 12 included. Risk of bias was assessed using the Newcastle–Ottawa Scale. Resultados e Conclusões: RESULTS: Preoperative hypoxia (O□ <85%; OR 2.5 for IQ <85), prolonged cardiopulmonary bypass (>120 min), and postoperative factors (arrhythmias in 17% at 10 years; venous hypertension) were associated with worse outcomes. Mid-term findings included motor delay (40%), cognitive deficits, and reduced self-image. Long-term, up to 60% showed impairments in lexical fluency, working memory, and cognitive flexibility, with a 20–30% reduction in quality of life. Overall, neurodevelopmental impairments persist chronically after Fontan circulation, including cognitive deficits (IQ <85 in 30–50%), motor delay (40%), and executive dysfunction (up to 60%), impacting academic performance and social adaptation. CONCLUSION: Routine neuropsychological screening is recommended 12–24 months postoperatively using validated tools (Bayley-III <3y; WPPSI-IV 3–7y; WISC-V >7y), with biennial follow-up through adolescence in a multidisciplinary approach. Future protocols should prioritize neuroprotection, including NIRS monitoring, reduction of bypass time (<120 min), anti-inflammatory strategies, and optimized nutritional support.

22056

PRENATAL EXPOSURE TO ENDOCRINE-DISRUPTING CHEMICALS AND THE RISK OF STRUCTURAL CONGENITAL HEART DEFECTS: A SYSTEMATIC REVIEW

THAINA MACHADO MOTA1; VITOR PAIVA DA SILVA1; SOFIA MASSA VALLE1; SOFIA FRAGNAN SILVA1; RAFAEL MESQUITA BERNARDES1; MANOELA MASSA MOURA2; TAYNAH DE SOUZA DA CUNHA3; ALEXANDRA OLIVEIRA DE MESQUITA4;

(1) UNICEUB - BRASÍLIA - DF - BRASIL; (2) UNIVERSIDADE DE BRASILIA - BRASÍLIA - DF - BRASIL; (3) UNICEPLAC - BRASILIA - DF - BRASIL; (4) HOSPITAL DE BASE DO DISTRITO FEDERAL - BRASÍLIA - DF - BRASIL;

Introdução/Fundamentos: Congenital heart disease is the most common structural malformation and a major cause of neonatal mortality. Its multifactorial etiology includes environmental influences during cardiac morphogenesis, with endocrine-disrupting chemicals potentially affecting hormonal and embryonic pathways. Although recent meta-analyses link maternal EDC exposure to CHDs, none has formally compared biomonitoring with indirect exposure assessment as a source of heterogeneity or applied GRADE across exposure classes and cardiac subtypes, limiting interpretation and prevention strategies. Objetivos: To assess the association between maternal prenatal exposure to endocrine-disrupting chemicals and structural congenital heart defects (CHDs) in offspring. Métodos: A systematic review was conducted according to PRISMA 2020, with PROSPERO registration. Observational studies evaluating maternal prenatal or periconceptional exposure to endocrine-disrupting chemicals and structural CHDs were included. Searches were performed in PubMed/MEDLINE, Embase, Web of Science, CENTRAL and Scopus, with no date restriction. Two reviewers independently conducted study selection, data extraction and risk-of-bias assessment using the Newcastle-Ottawa Scale. Evidence was qualitatively synthesized according to exposure class, exposure assessment method, cardiac subtype and study quality, prioritizing adjusted estimates and biomonitoring-based studies. Certainty of evidence was evaluated using GRADE. Resultados e Conclusões: Following screening of over 2,700 records, 59 studies comprising more than 1.3 million participants were included. Biomonitoring-based studies consistently demonstrated positive associations between maternal exposure to endocrine-disrupting chemicals and structural CHDs, particularly for heavy metals, polycyclic aromatic hydrocarbons and PFAS. Studies based on indirect exposure assessment showed more heterogeneous and less consistent findings. Subtype-specific associations were identified, with heavy metals predominantly linked to septal defects and Polycyclic Aromatic Hydrocarbons to conotruncal defects. These findings support precautionary exposure-reduction strategies during periconception and pregnancy and prospective studies with standardized biomonitoring, confounder control, and phenotype-stratified outcomes.

20158

REAL-WORLD CLINICAL PRACTICE VERSUS ESC/AHA GUIDELINE RECOMMENDATIONS IN PEDIATRIC AND ADULT CONGENITAL HEART DISEASE-ASSOCIATED PULMONARY HYPERTENSION: A POPULATION-BASED STUDY FROM SOUTHERN BRAZIL

LUCAS CESAR PERIN-GUIMARÃES1; BETÂNIA ZULIAN DE LIMA1; ISABELA COLELLA LEPREVOST1; SILVIA MEYER CARDOSO2;

(1) UNIVERSIDADE FEDERAL DO PARANÁ - CURITIBA - PR - BRASIL; (2) UNIVERSIDADE FEDERAL DE SANTA CATARINA - FLORIANÓPOLIS - SC - BRASIL;

Introdução/Fundamentos: Pulmonary hypertension associated with congenital heart disease (PH-CHD) requires targeted pharmacological strategies. Current guidelines from the European Society of Cardiology (ESC) and American Heart Association (AHA) recommend early combination therapy, particularly in intermediate- to high-risk patients. However, real-world adherence remains uncertain, especially in middle-income settings. Objetivos: To describe pharmacological treatment patterns in PH-CHD and assess their alignment with guideline recommendations, comparing pediatric and adult populations. Métodos: This population-based, cross-sectional study included 134 patients with PH-CHD (ICD I27.8) from a regional database in Southern Brazil. Therapies were categorized into phosphodiesterase-5 inhibitors (PDE5), endothelin receptor antagonists (ERA), and prostacyclin analogues. Comparisons were performed using chi-square tests ($p<0.05$). Resultados e Conclusões: The sample was distributed between pediatric and adult patients (n=67 each). The mean age was 10.8 ± 3.6 years in the pediatric group and 38.9 ± 18.3 years in the adult group. Females comprised 46.3% of pediatric and 73.1% of adult patients. Pediatric population had higher monotherapy rates (59.7% vs. 49.3%), while adults more frequently received dual therapy (46.3% vs. 32.8%); triple therapy was similar (4.5% in both), and quadruple therapy occurred only in pediatrics (3%). No significant difference was observed in overall treatment intensity ($\chi^2=4.20$; $p=0.24$). PDE5 inhibitors were more frequently used in pediatrics (85.1% vs. 67.2%; $\chi^2=6.0$; $p=0.014$), whereas ERA use was higher in adults (59.7% vs. 41.8%; $\chi^2=4.3$; $p=0.038$). Prostacyclin analogue use was low and similar between groups ($\chi^2=0.4$; $p=0.52$). Combination therapy, particularly PDE5 plus ERA, was more common in adults. Real-world management was partially aligned with ESC/AHA recommendations regarding drug classes. However, the predominance of monotherapy and low prostacyclin use suggest a gap in implementing guideline-recommended combination strategies. These findings likely reflect structural limitations, as the studied healthcare service does not provide access to key therapies such as macitentan, riociguat, and selexipag. This highlights important barriers to optimal care and underscores the need to expand access and improve adherence to evidence-based therapies in PH-CHD.

DEMOGRAPHIC CHARACTERISTICS BY AGE GROUP

Variable	<18 years	≥ 18 years
N	67	67
Female (%)	31 (46.3)	49 (73.1%)
Male (%)	36 (53.7%)	18 (26.9%)
Age (mean ± SD)	10.8 ± 3.6 years	38.9 ± 18.3 years

Abbreviations: N, sample; SD, standard deviation.

PHARMACOLOGICAL CLASSES AND THERAPY COMPLEXITY BY AGE GROUP

Variable	< 18 years (n = 67)	≥ 18 years (n = 67)
PDE5 inhibitors	57 (85.1%)	45 (67.2%)
ERA	28 (41.8%)	40 (59.7%)
Prostacyclin analogues	6 (9.0%)	4 (6.0%)
Monotherapy	40 (59.7%)	33 (49.3%)
Dual therapy	22 (32.8%)	31 (46.3%)
Triple therapy	3 (4.5%)	3 (4.5%)
Quadruple therapy	2 (3.0%)	0 (0.0%)

Abbreviations: PDE5, phosphodiesterase-5 inhibitors; ERA, endothelin receptor antagonists

RISK FACTORS ASSOCIATED WITH ADVERSE OUTCOMES IN PEDIATRIC PATIENTS WITH CONGENITAL HEART DISEASE IN A REFERRAL HOSPITAL

ALICE PETROLA BEZERRA SAYÃO1; BRUNA MAIA FURTADO DE FIGUEIREDO1; CECÍLIA GABRIELA DANTAS DE SOUZA1; RAFAELA RIOS SABINO1; LORENA GURGEL LEITE VIANA1; MARIANA STORARI MARÃO PAZ1; MARIA CLARA RODRIGUES DE CARVALHO1; ANA LUIZA TORQUATO DE AQUINO2; CAMYLLA SANTOS DE SOUZA2; ANDREA CONSUELO DE OLIVEIRA TELES2; CANDICE TORRES DE MELO BEZERRA CAVALCANTE2; KLEBIA MAGALHÃES PEREIRA CASTELLO BRANCO2;

(1) UNIVERSIDADE DE FORTALEZA - UNIFOR - FORTALEZA - CE - BRASIL; (2) HOSPITAL DE MESSEJANA - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Mortality in pediatric cardiac surgery has declined in recent decades but remains a major challenge, especially in children under two years of age. Identifying risk factors is essential for risk stratification, surgical planning, and perioperative management. Variables such as low body weight, younger age, and higher surgical complexity are associated with worse outcomes, reflecting the vulnerability of this population. Objetivos: To identify clinical and surgical factors associated with in-hospital mortality in children under two years undergoing cardiac surgery at a tertiary referral center in Brazil. Métodos: This retrospective observational study included children under 2 years of age who underwent congenital heart surgery between 2018 and 2024 at a tertiary referral hospital in Brazil. Demographic variables (age, weight) and surgical variables (RACHS-1 score, cardiopulmonary bypass time) were analyzed to identify factors associated with in-hospital mortality, which was defined as the primary outcome. Continuous variables were expressed as mean ± standard deviation or median (interquartile range), and categorical variables as percentages. Comparisons were performed between survivors and non-survivors. A multivariable logistic regression model was constructed including RACHS-1 score, weight, and cardiopulmonary bypass time. Results were expressed as odds ratios (OR) with 95% confidence intervals (CI), and model discrimination was assessed using the area under the receiver operating characteristic (ROC) curve. Resultados e Conclusões: A total of 1,234 patients were included. Non-survivors had lower weight (3.81±1.73kg vs. 5.48±2.58kg), younger age (median 36vs.120 days), longer cardiopulmonary bypass (CPB) time (73.7±55 vs. 60.5±49.2 minutes), and higher RACHS-1 score (3.46±1.1 vs. 2.69±0.99) compared to survivors. In multivariable analysis, RACHS-1 score (OR 1.50; 95% CI 1.24–1.82; p <0.001) and weight (OR 0.72; 95% CI 0.63–0.81; p <0.001) were independent predictors of mortality, while CPB time did not remain significant after adjustment (p=0.25). The model demonstrated good discriminatory capacity (AUC=0.74). In conclusion, lower operative weight and higher surgical complexity are independent predictors of mortality, highlighting the critical role of patient-related factors in surgical outcomes and supporting the need for early risk stratification and preoperative optimization.

SGLT2 INHIBITORS IN PEDIATRIC HEART FAILURE: A SYSTEMATIC REVIEW AND SINGLE-ARM META-ANALYSIS

YAN ROBERTH DELMIRO SILVA1; GIOVANA CRUZ MACIEL1; ETVALDO RODRIGUES DA SILVA FILHO2; GUILHERME MATHEUS SANTOS MARQUES CAVALCANTE1; LUCAS MACIEL DE ALMEIDA CORRÊA3; MANUELLA SOARES COSTA1; TAIANA ALVES DE ALCANTARA ANDRADE4;

(1) UNIVERSIDADE FEDERAL DE ALAGOAS - ARAPIRACA - AL - BRASIL; (2) COMPLEXO HOSPITALAR MANOEL ANDRÉ - ARAPIRACA - AL - BRASIL; (3) FACULDADE DE MEDICINA DE SÃO JOSÉ DO RIO PRETO - SÃO JOSÉ DO RIO PRETO - SP - BRASIL; (4) PRONTO SOCORRO CARDIOLOGICO DE PERNAMBUCO - PROCAPE - RECIFE - PE - BRASIL;

Introdução/Fundamentos: Pediatric heart failure (PHF) remains a significant clinical burden characterized by substantial patient morbidity. While SGLT2 inhibitors have established themselves as a cornerstone of adult therapy, their application in pediatric populations is not yet well-defined. Objetivos: To synthesize the evidence regarding the structural, functional, biochemical effects, and safety profile of SGLT2 inhibitors in pediatric patients with diagnosis of Heart failure (HF). Métodos: Adhering to PRISMA guidelines, a systematic review and single-arm meta-analysis were conducted. Cochrane Library, Embase, PubMed, and Web of Science were searched in September 2025. Inclusion criteria were: HF patients aged younger than 21 years, SGLT2 inhibitor therapy, availability of pre- and post-intervention data, and studies with 2 or more patients. Exclusion criteria comprised single-patient case reports and the concurrent unstable initiation of other pharmacological agents. The analyzed variables were Systemic Ventricular Ejection Fraction (SVEF), NYHA functional class, BNP, NT-proBNP, and adverse events. Risk of bias was evaluated using the Joanna Briggs Institute and Newcastle-Ottawa Scale tools. Quantitative synthesis utilized random-effects models, with outcomes expressed as mean differences (MD) or standardized mean differences (SMD) alongside 95% confidence intervals (CI). Resultados e Conclusões: A total of seven studies involving 473 patients were included; six studies (407 patients) were suitable for quantitative analysis. Structural and functional outcomes showed non-significant favorable trends, affected by high heterogeneity: SVEF increased (MD 6.52%; 95% CI: -0.39 to 13.44) and NYHA class improved (MD -0.69; 95% CI: -1.38 to 0.01). Biochemically, NT-proBNP reduced significantly (SMD -0.52; 95% CI: -0.81 to -0.23; p=0.01), reflecting decreased cardiac filling pressures. BNP reduction was not significant (MD -104.82 pg/mL; 95% CI: -304.05 to 94.42). The safety profile was favorable; the most frequent adverse events were urinary tract infections (pooled proportion 8.7%; 95% CI: 4.0% to 17.9%) and acute kidney injury (6.2%; 95% CI: 3.3% to 11.5%), with no cases of metabolic ketoacidosis. Despite limitations such as retrospective designs, small samples, and high heterogeneity, SGLT2 inhibitors may offer promising echocardiographic, functional, and biomarker benefits with acceptable tolerability. Large-scale randomized trials are needed prior to routine clinical recommendation.

SURGERY OR BALLOON ANGIOPLASTY FOR NATIVE AORTIC COARCTATION IN INFANTS: A COMPARISON OF CLINICAL OUTCOMES THROUGH A SYSTEMATIC REVIEW.

LUÍS FELIPE CARVALHO PEREIRA1; CAIO DANTAS VERAS LUCIO1; CARLA VIDA FAÇANHA QUEZADO1; JOSENIAS MAGALHÃES DE SOUSA FILHO1; CARLOS EMANUEL NUNES MARTINS1; ANA LUISA COSTA ALENCAR1; ISAURA ELAINE GONÇALVES MOREIRA ROCHA1;

(1) UNIVERSIDADE FEDERAL DO CARIRI - BARBALHA - CE - BRASIL;

Introdução/Fundamentos: Native aortic coarctation (CoA) is a congenital cardiovascular malformation defined by a stenosis of the descending thoracic aorta, being one of the most severe heart diseases in the neonatal period and in infants. The main therapeutic options include surgical correction or balloon angioplasty. However, the preferred modality in this age group remains controversial in the literature, with no first-line treatment choice. Objetivos: To compare the clinical outcomes of surgical approach and balloon angioplasty in the treatment of native CoA in patients under 1 year old. Métodos: A systematic review of studies published between 2016 and 2026 in the PubMed, Scopus, and BVS databases was conducted, using DeCS/MeSH descriptors according to PRISMA guidelines. Comparative studies of patients under 1 year old with native CoA who underwent surgery or balloon angioplasty were included. The primary evaluation was for reintervention and secondarily for mortality, length of stay, and complications. The risk of bias was assessed using the Newcastle-Ottawa scale. Due to the clinical and methodological heterogeneity of the studies, a meta-analysis was not conducted. Resultados e Conclusões: Three studies were included, totaling 299 patients. Heterogeneity was observed between the groups, with a predominance of critical neonates in the subgroup undergoing angioplasty, which was predominantly employed as a palliative strategy. The mortality was low in both groups, with no statistically significant difference. Regarding the outcomes, a significantly higher reintervention rate ($p<0.01$) was observed in angioplasty in one study, while surgery showed a higher event-free survival rate in another ($p=0.028$). On the other hand, in another article, angioplasty was associated with a shorter hospital stay (mean=6.7 days; $p<0.05$), a lower need for intensive post-procedure support, and a lower incidence of systemic complications, predominantly restricted to minor vascular events. In this field, data suggest that surgery may be associated with greater durability of results, while angioplasty showed lower immediate morbidity and faster clinical recovery. However, the heterogeneity between the groups limits comparability and may overestimate the reintervention rate associated with angioplasty. The scarcity of controlled prospective studies and randomized trials reflects clinical challenges and reinforces the need for individualized management, especially in critical neonates.

19038

THE EFFECTIVENESS OF IVABRADINE USE IN THE MANAGEMENT OF PEDIATRIC TACHYARRHYTHMIAS.

ANA LUÍSA FERREIRA DIAZ1; MARINA NEVES VIEIRA1; LIVIA VELLO BITTENCOURT1; AMANDA NUNES MARQUES FIRME1; KARLA LOUREIRO LOSS2;

(1) ESCOLA SUPERIOR DE CIENCIAS DA SANTA CASA DE MISERICORDIA DE VITORIA - VITÓRIA - ES - BRASIL; (2) MCMASTER UNIVERSITY - CANADA;

Introdução/Fundamentos: Tachyarrhythmias are cardiac rhythm disorders that are difficult to manage clinically, especially in the pediatric population, since current therapies have limited effectiveness. In this context, the use of Ivabradine stands out, as it selectively inhibits the “funny” current. Thus, it is pertinent to investigate its application in this scenario, given that its use as a potential alternative or in association with conventional therapies has not yet been consolidated. Objetivos: To evaluate the effectiveness of Ivabradine in the management of pediatric tachyarrhythmias. Métodos: Systematic review conducted with articles from the PubMed and Virtual Health Library databases, obtained using the search strategy (pediatrics OR child) AND (arrhythmias OR tachyarrhythmia) AND ivabradine, totaling 50 articles. Texts in English, Portuguese, and Spanish, published between 2016 and 2026, were included. Duplicate articles, reviews or meta-analyses, incomplete and/or paid articles were excluded. After full reading, studies that did not correspond to the research proposal were excluded. Resultados e Conclusões: After applying the criteria, 14 studies were included, with a total of 246 patients evaluated. Among the selected studies, Ivabradine was analyzed regarding heart rate (HR) control, reversion to sinus rhythm, improvement of hemodynamic parameters and ventricular function, as well as its safety in pediatric patients with supraventricular tachyarrhythmias and junctional ectopic tachycardia. It demonstrated similar results to amiodarone in the reversion of sinus rhythm, with a mean difference in treatment effect of 2.3% (95% confidence interval: -6.7% to 11.5%), showing therapeutic success and significant efficacy in cases refractory to conventional interventions, both in monotherapy and combination therapy. A reduction in heart rate, improved cardiac output, tissue perfusion, and ventricular function were observed, including recovery of ejection fraction in cases of tachycardia-induced cardiomyopathy. The main adverse effect was bradycardia, which is manageable with dose adjustment. Furthermore, it was highlighted that its early use was associated with better clinical outcomes, less need for invasive therapies, and more effective control of arrhythmias Therefore, it is concluded that Ivabradine shows promising results in restoring sinus rhythm in children, especially in difficult-to-manage cases, being an alternative to traditional antiarrhythmics.

THE USE OF SGLT2 INHIBITORS IN PEDIATRIC PATIENTS WITH HEART FAILURE: A SINGLE-ARM META-ANALYSIS

MARINA DE ASSIS BEZERRA CAVALCANTI LEITE1; LUCAS GRANGEIRO PEQUENO1; ANA CAROLINA LEMANSKI2; TAYENNE DO VALE CABRAL3; RUY TAMOYO VENDAS RODRIGUES NETO4; MICHELLE MUSSI5; RENATA SILVA DUARTE DOS SANTOS6; CAROLINA BASTOS MESQUITA7; JÉSSICA LAUREANO MARTINS1;

(1) UNIVERSIDADE FEDERAL DA PARAIBA - JOÃO PESSOA - PB - BRASIL; (2) CENTRO UNIVERSITARIO DE VARZEA GRANDE - UNIVAG - CUIABÁ - MT - BRASIL; (3) HOSPITAL ISRAELITA ALBERT EINSTEIN - SAO PAULO - SP - BRASIL; (4) UNIVERSIDADE FEDERAL DO RIO DE JANEIRO - RIO DE JANEIRO - RJ - BRASIL; (5) HOSPITAL EVANGÉLICO DE LONDRINA - LONDRINA - PR - BRASIL; (6) UNISINOS - SÃO LEOPOLDO - RS - BRASIL; (7) UNIVERSIDADE DE MOGI DAS CRUZES - MOGI DAS CRUZES - SP - BRASIL;

Introdução/Fundamentos: Sodium-glucose cotransporter-2 inhibitors (SGLT2i), such as dapagliflozin and empagliflozin, have demonstrated significant clinical efficacy in adult cohorts with heart failure (HF). Although emerging evidence suggests that SGLT2i maintain a favorable safety and tolerability profile in younger patients, primary research evaluating their efficacy in pediatric HF is currently limited. Objetivos: This study aims to provide pooled estimates of clinical outcomes in pediatric HF patients following SGLT2i administration. Métodos: We conducted a systematic review and single-arm meta-analysis of observational and randomized clinical trial (RCT) data in accordance with PRISMA guidelines. PubMed, Embase and Cochrane databases were searched for studies that described the use of dapagliflozin or empagliflozin in pediatric patients with HF and reported the outcomes of (1) left ventricular ejection fraction (LVEF); (2) estimated glomerular filtration rate (eGFR); and (3) NT-proBNP levels. Heterogeneity was examined with I² statistics. Statistical synthesis was performed using a random-effects model with raw means as the summary measure. All analyses were conducted using R software (version 2026.1.2.418). Resultados e Conclusões: Five studies involving 411 pediatric patients were included. Across the cohorts, the mean age ranged from 4.09 to 14.73 years, and dilated cardiomyopathy was the predominant etiology of HF. At baseline, the mean LVEF ranged from 25.74% to 38.92%, eGFR from 80.53 to 116.66 mL/min/1.73 m², and NT-proBNP levels from 2476.71 to 2911.90 pg/mL. Following SGLT2i administration, the pooled mean LVEF was 41.90% (95% CI: 38.13–45.67%; I² = 51.8%), and the pooled mean NT-proBNP level was 777.66 pg/mL (95% CI: 469.57–1085.75; I² = 36%). The pooled mean eGFR was 95.96 mL/min/1.73 m² (95% CI: 79.13–112.80), though substantial heterogeneity was noted across the studies (I² = 95.1%). Notably, post-treatment values showed higher LVEF and lower NT-proBNP levels compared to baseline. While the pooled eGFR suggests well-preserved renal function, the high heterogeneity in this outcome warrants a cautious interpretation of the renal data. Despite these encouraging observations, the single-arm design and lack of a control group preclude definitive conclusions regarding the direct therapeutic impact of SGLT2i. Further RCTs are essential to establish conclusive evidence regarding the therapeutic role of SGLT2i in pediatric heart failure management.

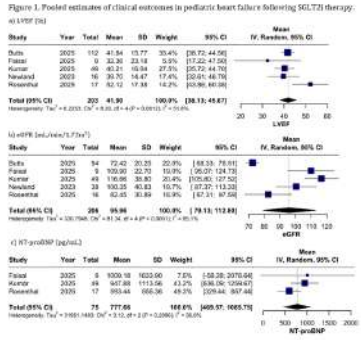

Table 1. Baseline characteristics of included studies

TIMING OF EXTRACORPOREAL MEMBRANE OXYGENATION INITIATION AFTER CONGENITAL HEART SURGERY IN CHILDREN: A SYSTEMATIC REVIEW OF CARDIAC OUTCOMES

FERNANDO MARQUES MAIA1; RYAN CEZÁRIO DOS SANTOS1; LÍVIA KAROLINE BARRETO WERNCKE SILVA2; CARLOS EDUARDO PIMENTA DIAS2; HEITOR RODRIGUES VAZ1; LUIS AUGUSTO AIRES FREIRE PERUZZO3; MARCUS DE FRANÇA BARROS FILHO4; MARIA BÁRBARA DE HOLANDA CAVALCANTE UBALDO MONTEIRO BARBOSA5; PAULO HENRIQUE DA SILVA MARQUES2; DAVI SEVERO SILVA6; RICKY NATHAN PASSARIN1; VINICIUS MAIA DE OLIVEIRA7;

(1) AFYA FACULDADE DE CIENCIAS MEDICAS DE PALMAS - PALMAS - TO - BRASIL; (2) INSTITUTO TOCANTINENSE PRESIDENTE ANTONIO CARLOS - CAMPUS PORTO NACIONAL - TO - PORTO NACIONAL - TO - BRASIL; (3) INSTITUTO TOCANTINENSE PRESIDENTE ANTONIO CARLOS PORTO - ITPAC PORTO - PORTO NACIONAL - TO - BRASIL; (4) UNINOVAFAPI - TERESINA - PI - BRASIL; (5) ITPAC - PORTO NACIONAL - PORTO NACIONAL - TO - BRASIL; (6) UNIVERSIDADE TOCANTINENSE PRESIDENTE ANTONIO CARLOS - ARAGUAÍNA - TO - BRASIL; (7) CENTRO UNIVERSITARIO UNICESUMAR - MARINGA - PR - BRASIL;

Introdução/Fundamentos: Survival after pediatric cardiac surgery has significantly improved, yet high-risk patients often face refractory low cardiac output syndrome (LCOS) or cardiac arrest. Extracorporeal membrane oxygenation (ECMO) provides cardiorespiratory support for those failing to wean from cardiopulmonary bypass or experiencing cardiovascular collapse. Despite being life-saving, postoperative ECMO requirement is a strong independent risk factor for early mortality. Objetivos: To systematically review evidence regarding the timing of ECMO initiation post-congenital heart surgery and its correlation with cardiac outcomes and survival. Métodos: This systematic review was conducted in accordance with the PRISMA guidelines. A structured search was performed in PubMed and Scopus in April 2026, including studies published between 2020 and 2026. The search strategy combined controlled vocabulary terms (Descriptors in Health Sciences - DeCS), such as “Extracorporeal Membrane Oxygenation”, “congenital heart disease”, “pediatric”, “timing” and “cardiac outcomes”, with free-text keywords, using Boolean operators. Studies were independently selected based on predefined eligibility criteria. Study selection and data extraction were independently performed by two reviewers. A total of 68 records were identified, of which 13 were included in the final analysis. Resultados e Conclusões: Conclusão: Results: Included studies showed that early ECMO initiation, frequently within 5 hours post-surgery, is associated with survival benefits when perfusion markers like pH and serum lactate improve rapidly. Hospital survival varied between 30% and 58.3%. Specific strategies, such as shunt occlusion or PDA ligation, were vital to prevent systemic underperfusion. In complex cases like the Norwood procedure, delayed initiation or prolonged support was linked to higher mortality and neurological morbidity. Conclusion: Timing of ECMO initiation is a pivotal determinant of recovery. While early support serves as a “beacon of hope,” the need for ECMO remains a potent predictor of mortality. Standardized protocols focusing on early triggers are essential to optimize functional outcomes.

20689

WINDOW IN TETRALOGY OF FALLOT REPAIR IN BRAZIL: A REAL-WORLD EVIDENCE ANALYSIS (2008–2025)

MARIA EUGÊNIA RODRIGUES PAIVA1; GIOVANNA VILA REAL MARQUES BARRA DE GOUVEIA TREVISAN1; GABRIEL APARECIDO RODRIGUES1; CAROLAINE BRENDA RIDOLFI1; LARISSA DUARTE MELO1; SOFIA ANTONIA COHEN COUTO1; LAIANE RODRIGUES MACEDO1; LETICIA RODRIGUES SIMON1; FLÁVIA BEATRIZ DO CARMO MOREIRA1; BEATRIZ LIMA VITÓRIO FERREIRA2; VALESKA TAVARES SCAVARDA1;

(1) UNIVERSIDADE NOVE DE JULHO - SÃO PAULO - SP - BRASIL; (2) UNIFACISA - CAMPINA GRANDE - PB - BRASIL;

Introdução/Fundamentos: Background: Timely surgical repair of Tetralogy of Fallot (ToF) is the primary determinant of long-term survival and reduced morbidity. However, structural inequities within the Brazilian Public Health System (SUS) may impose critical therapeutic delays. Given the scarcity of contemporary population-based data, this study evaluates the impact of macro-regional disparities on surgical timing and hospital lethality nationwide. Objetivos: Objectives: To analyze the correlation between regional inequities, age at intervention, and hospital lethality rates for total ToF repair in Brazil between 2008 and 2025. Métodos: Methods: A population-based, analytical, ecological study was conducted using data from the Hospital Information System (SIH/SUS). All hospitalizations for total ToF repair during the period were included. Surgical timing was stratified into: early (0–3 years) and late (>= 4 years). Comparative analysis cross-referenced age stratification with the macro-region of residence and lethality rates, employing the latter as a metric for healthcare resolutivity. Resultados e Conclusões: Results: Among the 6,058 procedures identified, 77.1% (n=4,671) were performed early and 22.9% (n=1,387) were late interventions. Surgical volume was concentrated in the Southeast (41.3%) and Northeast (27.3%). A profound asymmetry in the therapeutic window was evidenced: the Northeast presented the highest prevalence of late repairs (30.1%), followed by the North (24.2%) and Center-West (23.9%) regions, while the South recorded the lowest rate (13.3%). The national mean hospital lethality was 10.02%. The Center-West recorded the highest mortality (18.56%), a rate 2.3 times higher than the Southeast (7.87%), which showed the best institutional performance. Conclusions: This real-world evidence analysis exposes critical gaps in the pediatric cardiology line of care. The high prevalence of late interventions in the Northeast and the alarming lethality in the Center-West reflect structural failures in screening and referral flows. Although the administrative nature of the data limits adjustment by clinical risk scores (such as RACHS-1), the interregional mortality discrepancy confirms the urgent need for decentralization policies and technological support to ensure timely surgical treatment and reduce preventable deaths.

ARTIFICIAL INTELLIGENCE-ENABLED ELECTROCARDIOGRAPHY FOR THE PREDICTION OF MALIGNANT VENTRICULAR ARRHYTHMIAS AND SUDDEN CARDIAC DEATH

ICARO HEICKMEN MELO1; LUCAS QUEIROZ MENEZES1; TIAGO NOGUES ALMEIDA1; ANDRE NOGUES ALMEIDA1; ANISIO UCHOA SANTANA2; DEBORA QUEIROZ MENEZES3; ITALO TAVEIRA MELO4; RENATO MAX FARIA1;

(1) UFRN - NATAL - RN - BRASIL; (2) UNIVERSIDADE DE SAO PAULO - SÃO PAULO - SP - BRASIL; (3) FACULDADE DE MEDICINA DE OLINDA - OLINDA - PE - BRASIL; (4) UNIVERSIDADE FEDERAL DO RECONCAVO DA BAHIA - SANTO ANTONIO DE JESUS - BA - BRASIL;

Introdução/Fundamentos: Malignant ventricular arrhythmias (MVAs) and sudden cardiac death (SCD) remain leading causes of global mortality. Conventional electrocardiography (ECG) has limited sensitivity for early risk stratification. Artificial intelligence (AI)-enabled ECG has emerged as a promising tool for identifying high-risk individuals. We aimed to systematically evaluate the diagnostic accuracy of AI-based ECG models for predicting MVAs and/or SCD. Objetivos: To synthesize the diagnostic accuracy of artificial intelligence (AI)-enabled electrocardiography (ECG) for the prediction and early detection of malignant ventricular arrhythmias (MVAs) and sudden cardiac death (SCD). Métodos: This systematic review and meta-analysis followed PRISMA-DTA guidelines. PubMed, Embase, and Web of Science were searched through January 2026 for studies evaluating AI algorithms applied to 12-lead or wearable ECGs for prediction of MVAs and/or SCD. Study quality was assessed using QUADAS-2. Pooled sensitivity, specificity, likelihood ratios, and diagnostic odds ratio (DOR) were calculated using bivariate random-effects models. Heterogeneity was assessed using I^2, with subgroup analyses by ECG modality. Resultados e Conclusões: Fifteen studies (12,500 patients; 2,100 events) were included. Pooled sensitivity was 0.88 (95% CI: 0.85–0.91) and specificity 0.82 (95% CI: 0.79–0.85). The area under the curve was 0.91 (95% CI: 0.89–0.93). The DOR was 35.0 (95% CI: 28.5–43.0). Substantial heterogeneity was observed (I^2 > 75%). Higher accuracy was found in 12-lead ECG studies. AI-enabled ECG shows promising diagnostic performance for predicting malignant ventricular arrhythmias and sudden cardiac death. However, heterogeneity and potential overfitting require caution, and prospective external validation is needed before clinical implementation.

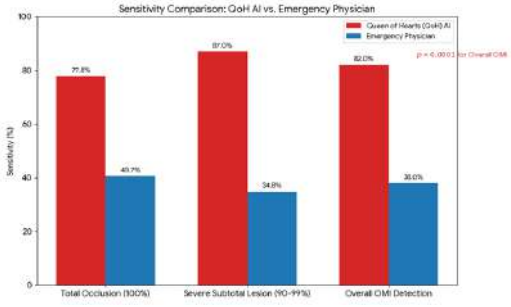
AI-GUIDED CARDIAC SIGNAL SCREENING INCREASES DETECTION OF PREVIOUSLY UNDIAGNOSED LEFT VENTRICULAR SYSTOLIC DYSFUNCTION: A META-ANALYSIS OF RANDOMIZED TRIALS

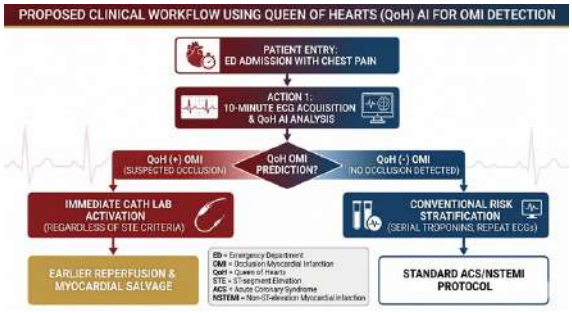
JOÃO ÍTALO PEREIRA CAVALCANTE1; PEDRO GONÇALVES NOGUEIRA NETO1; LETÍCIA NUNES BENEVIDES1; CAMILA VIVIANE RIBERA CHAGAS1; ALÉXIA ALBUQUERQUE PAIVA DAMASCENO1; MARIANA LOPES SOARES1; LUCAS BITU SALVIANO1; MARCELO YASSUO DE ALMEIDA HISATUGO1; FABRICIA CARDOSO MARQUES1; HANIEL FELIPE DE OLIVEIRA SAMPAIO1; FILIPE LEITÃO DE CARVALHO1; LEO NUNES BENEVIDES2;

(1) UNIVERSIDADE FEDERAL DO CEARA - FORTALEZA - CE - BRASIL; (2) HOSPITAL UNIVERSITARIO WALTER CANTIDIO - FORTALEZA - CE - BRASIL;

Introdução/Fundamentos: Left ventricular systolic dysfunction (LVSD) frequently remains underdiagnosed until advanced stages of disease and is associated with substantial morbidity and mortality. Artificial intelligence (AI)-guided analysis of cardiac signals, including electrocardiography and digital auscultation, has emerged as a scalable strategy for earlier identification of previously unrecognized LVSD in real-world clinical settings. However, randomized evidence evaluating its clinical implementation remains limited. Objetivos: To evaluate the effect of AI-guided cardiac signal screening strategies on the detection of newly diagnosed LVSD compared with standard care through a systematic review and meta-analysis of randomized controlled trials. Métodos: Following PRISMA guidelines, we performed a systematic review and meta-analysis of randomized controlled trials identified through PubMed, Embase, and Cochrane CENTRAL comparing AI-guided cardiac signal screening strategies with standard care for the detection of previously undiagnosed LVSD. Eligible studies included adult patients without prior heart failure or LVSD and evaluated AI-based analysis of cardiac signals, including 12-lead electrocardiography and digital stethoscope platforms. The primary outcome was newly diagnosed LVSD during study follow-up. Pooled risk ratios (RRs) and 95% confidence intervals (CIs) were estimated using a random-effects model with restricted maximum likelihood estimation and Hartung-Knapp adjustment. Statistical heterogeneity was assessed using the I^2 statistic. Resultados e Conclusões: Three randomized controlled trials comprising 37,467 participants were included. AI-guided cardiac signal screening was associated with a higher likelihood of newly diagnosed LVSD compared with standard care (RR 1.36, 95% CI 1.00–1.85; I^2 = 0%). The direction of effect consistently favored AI-guided screening across studies despite differences in clinical settings and screening modalities. These findings suggest that AI-guided cardiac signal analysis may improve identification of previously unrecognized LVSD in real-world practice. Larger randomized trials are warranted to confirm these findings and determine their impact on downstream clinical outcomes.



18906



ANGIOGRAPHIC VALIDATION OF THE QUEEN OF HEARTS AI FOR DETECTION OF OCCLUSION MYOCARDIAL INFARCTION

FRANCISCO TSHIH TEH POON1; FERNANDO MARTINO1; PAULO HENRIQUE MAIA VILELA1; ISABELLA ARAUJO ZAPPAROLLI1; ANA CAROLINA MONARO BARBOZA1; JOSE AUGUSTO MANTOVANI RESENDE1; MARIA EDUARDA STACCIARINI BORGES1; BRUNO MAEDA FUZISSIMA1;

(1) UNIVERSIDADE FEDERAL DO TRIANGULO MINEIRO - UBERABA - MG - BRASIL;

Introdução/Fundamentos: The traditional STEMI/NSTEMI framework has important limitations, failing to identify a substantial proportion of acute coronary occlusions at presentation. The Occlusion Myocardial Infarction (OMI) paradigm has emerged to address this gap by emphasizing electrocardiographic (ECG) features associated with acute coronary occlusion. The Queen of Hearts (QoH) is an artificial intelligence tool designed to detect subtle ECG patterns suggestive of OMI, potentially improving early diagnosis. Objetivos: To evaluate the diagnostic performance of QoH in identifying OMI in a cohort of emergency department patients, using coronary angiography as the reference standard. Métodos: This cross-sectional study included 100 patients presenting with suspected non-ST-segment elevation acute coronary syndrome (NSTEMI) and referred for an invasive strategy. Admission ECGs were analyzed using QoH and compared with the interpretation of attending physicians, both blinded to angiographic results. OMI was defined as angiographic evidence of acute coronary occlusion (TIMI 0–2 flow) or high-grade culprit lesions (≥ 90%) consistent with an occlusive mechanism. Resultados e Conclusões: The prevalence of OMI was 50% in this cohort. QoH demonstrated significantly higher sensitivity compared with physician interpretation (82.0% vs. 38.0%; p < 0.0001). Among patients with total occlusion (n=27), sensitivity was 77.8% for QoH and 40.7% for physicians. In severe subtotal lesions (90–99%; n=23), QoH sensitivity was 87.0% versus 34.8%. Specificity was lower for QoH (9.8%) compared with physicians (84.3%), reflecting a high-sensitivity detection profile optimized for emergency screening. Mean admission troponin I was 5.85 ng/mL in the OMI group. In this cohort, QoH significantly improved the sensitivity for detecting angiographically confirmed coronary occlusions compared with standard ECG interpretation. While associated with reduced specificity, this high-sensitivity profile is valuable in the emergency setting for identifying patients at risk of missed occlusion who require immediate reperfusion. These findings support the potential role of AI-assisted ECG interpretation as a vital complementary tool in the evaluation of suspected acute coronary syndromes.

ARRHYTHMIA AND CARDIAC ISCHEMIA DETECTION ACCURACY WITH ECG-CAPABLE SMARTWATCHES: COMPARATIVE STUDY

GIOVANNE LUCAS BARRETO PINHEIRO SOUZA PINTO1; SAMUEL BARRETO PINHEIRO SOUZA PINTO2; MARIA CAROLINA BEZERRA DI MEDEIROS LEAL1; LUZITANO BRANDÃO FERREIRA1;

(1) UNICEPLAC - BRASILIA - DF - BRASIL; (2) UNIVERSIDADE FEDERAL DE MATO GROSSO DO SUL - CAMPO GRANDE - MS - BRASIL;

Introdução/Fundamentos: Electrocardiogram (ECG) capable smartwatches arose as promising tools in arrhythmia detection. Systematic reviews report high sensitivity and specificity of such gadgets for detecting arrhythmias such as atrial fibrillation. However, their reliability in emergency situations remains poorly documented in literature. Objetivos: To evaluate the diagnostic accuracy of four smartwatches against a Philips TC30 reference ECG standard for detecting varied signals, including reduced R-wave amplitude, broad heart rate (HR) ranges, and ST-segment deviations. Métodos: Captured signals from each device and the reference were loaded and followed an uniform pipeline: noise removal and standardization to a 10-second timeframe. Data was sourced from the PhysioNet ECG Smartwatch Validation Database, using signals injected by a METRON PS-440 patient simulator; acquisition complied with IEC 60601-2-25:2011 standards for electrocardiographic device accuracy and calibration. As this study utilized non-human cardiac simulated signals, institutional review board approval was not required. The following metrics were computed: (1) HR; (2) R-wave amplitude in µV; (3) ST-segment deviation; and (4) waveform root mean square error (RMSE) in mV. For each test condition, five independent replicates were analyzed. HR and ST-segment errors were calculated relative to the TC30 measurements. Resultados e Conclusões: Out of 720 wearable ECG records, 719 were successfully processed and included in the analysis. Apple Watch Series 9 demonstrated optimal balance (HR error 16.2%; ST 27.6%). Samsung Galaxy Watch 6 excelled in tachycardia (99.9%) but degraded in bradycardia (72.3%), yielding mean HR/ST errors of 20.9%/17.1%. Conversely, Withings ScanWatch exhibited lowest waveform RMSE yet critical ST detection failure (57.5%) and high HR error (46.2%). Fitbit Sense 2 recorded highest errors (HR 49.5%; ST 69.9%), though data inconsistencies limited definitive assessment. Smartwatches exhibit variable accuracy. The Apple Watch Series 9 demonstrated superior overall reliability, while the Samsung Galaxy Watch 6 excelled in tachyarrhythmia detection. Notably, the Withings ScanWatch failed to detect ischemic ST-segment deviations despite the lowest waveform RMSE. Ultimately, no device matched hospital-grade 12-lead ECG accuracy. Thus, smartwatches should remain adjunctive screening tools, requiring confirmatory standard ECG for suspected ischemia or significant arrhythmias.

ARTIFICIAL INTELLIGENCE AND ELECTROCARDIOGRAM: A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE PREDICTIVE CAPACITY FOR HEART FAILURE

JOÃO PEDRO VASCONCELOS DOS ANJOS CORREIA1; LEONARDO MACHADO MARTINS1; JOÃO VICTOR SANTOS GOMES1; JOÃO GABRIEL SANTANA TRINDADE1; HANNA VITÓRIA DA CRUZ CORREIA2; MARIANA SILVA SANTANA1; EULLER GALILLLEU MARTINS MENEZES1; GABRIEL DO CARMO ARAÚJO1; VITOR LIMA NASCIMENTO1; THIAGO DA SILVA MENDES1; DIEGO SANTOS DE SOUZA1;

(1) UNIVERSIDADE FEDERAL DE SERGIPE - ARACAJU - SE - BRASIL; (2) UNIVERSIDADE TIRADENTES (UNIT) - ARACAJU - SE - BRASIL;

Introdução/Fundamentos: Heart failure (HF) affects over 64 million people globally, causing high mortality and economic burden on healthcare systems. Early identification of high-risk individuals improves life expectancy and effectively changes disease trajectory. Traditional predictive strategies, based on clinical scores and invasive biomarkers, face major implementation challenges and high costs in resource-limited settings. Artificial intelligence-enabled electrocardiogram (AI-ECG) analysis offers a promising non-invasive and cost-effective alternative. Objetivos: This systematic reviews and meta-analysis aims to evaluate the performance of AI-ECG models in predicting HF by analyzing their discriminatory capability. Métodos: A systematic review was conducted by searching Pubmed/Medline, Scopus, Embase, Cochrane, IEEE Xplore and Scielo databases using DeCS/MeSH validated descriptors: Heart Failure; Electrocardiogram; Prediction; Artificial Intelligence. The review followed the PRISMA guidelines, and 11 retrospective cohort studies were selected (Figure 1). Duplicates were excluded. Exclusion criteria included: papers with objectives divergent from predicting HF, specific subgroups, such as patients with atrial fibrillation, wrong publication type (conference abstracts, systematic reviews and letters). Resultados e Conclusões: The sample totaled 883,002 participants, with a mean age ranging from 54.1 to 62.2 years, women accounted for approximately 43% of the total population. The artificial intelligence architectures evaluated comprised Convolutional Neural Networks (CNN), Graph Convolutional Networks (GCNs), and hybrid models (including integrations with Gradient Boosting). Global random-effects meta-analysis showed robust performance in event prediction, with a pooled Area Under the Curve (AUC) of 0.85 [95% CI: 0.81–0.90; I² = 100%; p < 0.0001]. Subgroup analysis revealed a statistically significant difference between model architectures (p < 0.0001). The AUC was 0.84 (95% CI: 0.79–0.88) for CNN models, 0.86 (95% CI: 0.86–0.86) for ECG2HF, and 0.83 (95% CI: 0.70–0.95) for hybrid models. The AI-ECG analysis exhibits high discriminatory accuracy in predicting HF, establishing themselves as promising, cost-effective tools for large-scale population screening, with Convolutional Neural Networks (CNN) demonstrating superior results. Despite high heterogeneity, findings suggest AI-ECG integration in practice may optimize earlier interventions.

Introdução/Fundamentos: Heart failure (HF) is a leading cause of hospitalization and mortality worldwide. Artificial intelligence (AI) and machine learning (ML) may improve outcome prediction in HF, but heterogeneity in algorithms, populations, and outcome definitions limits quantitative synthesis. Objetivos: To systematically review AI and ML models for predicting mortality and hospital readmission in adults with HF, synthesizing evidence on model types, performance, predictors, validation, and methodological quality. Métodos: We conducted a PRISMA 2020-compliant systematic review of MEDLINE, Embase, CENTRAL, Web of Science, and IEEE Xplore from January 2018 to March 2026, without language restrictions. Eligible studies developed or validated AI/ML models for mortality and/or readmission in adults with HF and reported quantitative performance metrics. Two reviewers independently screened studies, extracted data, and assessed risk of bias with PROBAST. Owing to heterogeneity in ML algorithms, heart failure populations, outcome definitions, and reported performance metrics, findings were synthesized narratively. Resultados e Conclusões: Of 3,847 records, 64 studies including 943,941 patients from 18 countries were analyzed. Most used retrospective electronic health record cohorts, and only 17% performed external validation. Ensemble methods, especially Random Forest and XGBoost, were most common, whereas deep learning was less frequent. Mortality prediction showed moderate-to-good discrimination, with AUCs of 0.71-0.91 across time horizons; readmission prediction was lower and more variable, with AUCs of 0.60-0.81. Multimodal models outperformed single-source approaches. Important predictors included age, left ventricular ejection fraction, creatinine, natriuretic peptides, sodium, hemoglobin, systolic blood pressure, functional class, and comorbidity burden. Compared with traditional risk scores, ML models usually showed better discrimination. 78% of studies had high risk of bias in at least one PROBAST domain, mainly because of limited external validation, inadequate handling of missing data, poor calibration reporting, and overfitting concerns. Overall, AI-driven prediction in HF is promising, particularly for mortality risk stratification, but clinical translation remains limited by heterogeneity, restricted generalizability, and methodological weaknesses. Future research should prioritize external and prospective validation, standardized outcomes and reporting, fairness assessment, and evaluation of clinical utility.

Introdução/Fundamentos: General-purpose artificial intelligence (AI) models are increasingly used in routine daily activities, including health-related decision support. However, their reliability for echocardiographic interpretation remains uncertain. Objetivos: To evaluate diagnostic agreement between AI-generated and medical reports in echocardiography. Métodos: This retrospective comparative study evaluated six general-purpose AI models for echocardiographic interpretation: ChatGPT 5.2 Instant, ChatGPT 5.2 Thinking (GPT5.2t), ChatGPT 5.3 Instant, ChatGPT 5.4 Thinking, Gemini 3 Fast (G3f), and Gemini 3 Thinking (G3t). 120 echocardiograms were independently analyzed twice by each model and compared with the corresponding medical reports used as the reference standard with minor adaptations. Analyses evaluated four domains: normal versus abnormal classification, view identification, main finding recognition, and need for additional medical support. Diagnostic performance metrics included accuracy, sensitivity, specificity, positive predictive value, and negative predictive value. Cohen's Kappa was used to assess reproducibility between repeated analyses, and Generalized Estimating Equations (GEE) were used to compare model performance while accounting for repeated analyses. Resultados e Conclusões: Analysis of 120 echocardiograms yielded 1,440 interpretations. G3t achieved the highest diagnostic accuracy (85.8%), followed by G3f (83.3%), both with high sensitivity (100.0% and 98.0%, respectively). GPT models showed lower accuracies (28.3%-35.0%). GPT5.2t demonstrated the highest specificity among GPT models (94.4%). In GEE analysis, all GPT models showed significantly lower odds of correct interpretation compared with G3t (OR 0.060–0.097; 95% CI 0.028–0.196; all p<0.001). G3f showed similar performance to G3t (OR 0.938; 95% CI 0.859–1.024; p=0.153). Subxiphoid views were associated with lower diagnostic performance (OR 0.631; 95% CI 0.411–0.969; p=0.035). Reproducibility was highest for G3f (κ=0.937; p<0.001) and G3t (κ=0.935; p<0.001), whereas GPT models demonstrated lower agreement (κ=0.429–0.628). General-purpose AI models demonstrated variable performance in echocardiographic interpretation. Gemini models achieved higher diagnostic agreement and reproducibility, whereas GPT models showed limited reliability, particularly in complex interpretative tasks. These findings highlight important limitations of current general-purpose AI systems for advanced cardiac imaging interpretation.

Introdução/Fundamentos: Structural heart diseases (SHD) are frequently underdiagnosed in primary care due to the low sensitivity of standard human auscultation. Artificial intelligence (AI)-enabled digital stethoscopes offer a novel point-of-care screening solution, improving the early detection of reduced ejection fraction and valvular diseases. This meta-analysis evaluates the diagnostic accuracy and clinical efficacy of AI-augmented auscultation versus standard clinical care. Objetivos: To evaluate the diagnostic accuracy and clinical efficacy of AI-enabled digital stethoscopes compared with standard clinical auscultation for the point-of-care detection of SHD (specifically reduced ejection fraction and moderate-to-severe valvular heart disease) in adults. Métodos: A systematic review and meta-analysis was conducted, searching PubMed and Embase for studies up to March 2026. Trials evaluating adults undergoing routine cardiovascular screening or triage were included. The intervention involved point-of-care AI-enabled digital stethoscopes compared with standard acoustic auscultation. Clinical outcomes included prospective SHD detection rates and predictive performance. Analyses used the meta package in R. DerSimonian-Laird random-effects models pooled diagnostic accuracy (Sensitivity, Specificity, and Negative Predictive Value), and the Mantel-Haenszel method calculated Odds Ratios (ORs) with 95% confidence intervals to evaluate comparative detection efficacy. Resultados e Conclusões: Four studies comprising 1,555,777 patients were included. AI-enabled digital stethoscopes significantly increased the probability of detecting SHD compared with standard clinical auscultation. The intervention demonstrated superior diagnostic efficacy, with a pooled Odds Ratio of 1.94 (95% CI: 1.53 – 2.46; I^2=0%), evidencing nearly twice the chance of prospective disease identification. Pooled predictive performance yielded a sensitivity of 65.24% (95% CI: 36.01–94.47%) and specificity of 83.73% (95% CI: 74.44–93.01%). The technology demonstrated an exceptional pooled Negative Predictive Value (NPV) of 97.86% (95% CI: 94.88–100.00%). In conclusion, AI-augmented auscultation significantly outperforms the conventional standard of care in ambulatory screening. Its consistently high NPV consolidates it as a reliable point-of-care rule-out tool, capable of optimizing referral pathways and reducing the echocardiography burden on healthcare systems.
